Postmaster: Send address changes to *Journal of Dairy Science*, Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043.

Customer Service (orders, claims, back volumes, online access, change of address): Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043. Telephone: 800.654.2452 (US and Canada), 314.447.8871 (outside US and Canada); fax: 314.447.8029; e-mail: journalscustomerservice-usa@elsevier.com (for print support) or journalsonlinesupport-usa@elsevier.com (for online support). Allow 4 to 6 weeks for the change of address to be implemented.

Institutional Subscription Rates: For institutions in the United States and possessions: $1020 for print. For institutions in all other countries (prices include airspeed delivery): $1150 for print. Current prices are in effect for back volumes and back issues. Electronic access is additional. Please contact customer service for pricing.

ADSA Membership Rates: For individual membership, contact the ADSA office (adsa@assochq.org) to pay dues and obtain access to the journal. For professional members: $110 per year, graduate student membership: $10, undergraduate student affiliate membership: $5. Membership includes electronic version of the journal; additional $65.00 for paper copy in US, and additional $95.00 for paper copy in all other countries). Membership in the ADSA is on a calendar year basis from January through December.

Advertising Information: For display advertising orders and inquiries please contact Ken Senerth at 609.577.0916; by fax at 212.633.3980; or by e-mail at kensenerth@gmail.com. For non-recruitment classified advertising orders and inquiries please contact Rob Issler at 321.400.8279; by fax at 407.814.7516; or by e-mail at robisslerjr@gmail.com.

Author Inquiries: For inquiries relating to the submission of articles, complete Instructions for Authors can be found online at http://www.journalofdairyscience.org. Manuscripts submitted for consideration should be submitted electronically at http://mc.manuscriptcentral.com/jds in accordance with the Instructions for Authors. Need help? Contact shaunam@assochq.org.
Offprints. Authors may place orders for offprints when proof corrections are sent to the editorial office (before the journal is sent for printing). For queries about offprints or order status, e-mail vickip@assochq.org; fax 217.378.4083.
Reprints. To order author reprints after the issue has been printed, e-mail authorsupport@elsevier.com. To order 100 or more reprints for educational, commercial, or promotional use, contact the Commercial Reprints Department, Elsevier Inc., 360 Park Avenue South, New York, NY 10010-1710; fax: 212.633.3820; e-mail: reprints@elsevier.com. Access to single articles available online may be obtained by purchasing Pay-Per-View access on the journal website (http://www.journalofdairyscience.org).

Application for membership in the American Society of Animal Science (ASAS) is invited from persons with interest in animal science and livestock production. In 2014, annual dues including access to the electronic version of the Journal of Animal Science are $135 in the United States, Canada, and Mexico and in other countries. For those in the United States, Canada, or Mexico who wish to receive a paper copy of the journal, the additional fee is $400. Student affiliate membership is granted to those who are certified by a professional member as a regularly enrolled college student who does not hold a full-time position at the time of application for, or annual renewal of, membership. Graduate student memberships ($20 annually) and undergraduate student memberships (free) include access to the electronic version of the Journal of Animal Science. Postdoctoral fellows' membership dues are $65. An institutional subscription ($695 annually) entitles an institution Internet access to e-JAS within appropriate IP addresses. For an additional $400 fee, institutions within the United States, Canada, and Mexico will receive a paper copy of the journal. For corporate subscriptions, please contact the ASAS office for pricing. Individual sustaining membership, $375 per year. Applications for membership with remittance should be mailed to the ASAS Business Office.

ASAS Business Office, PO Box 7410, Champaign, IL 61826
Telephone: 217-356-9050; Fax: 217-568-6070; E-mail: asas@asas.org Office hours: 8:00 a.m.–5:00 p.m.

Calendar of American Society of Animal Science Upcoming Meetings

Innovate	September 14–16, 2016	Brainerd, MN

Manuscript Submission. Information about manuscript submission is given in *Style and Form* published on the journal website (http://www.animalsciencepublications.org/publications/jas). All manuscripts submitted to the *Journal of Animal Science* must be accompanied by the JAS manuscript submission form certifying that any research that involves animals has followed established standards for the humane care and use of animals. Manuscripts should be submitted online via http://mc.manuscriptcentral.com/jas.

Address Change and Missing Copies. Notice of change in address should be received by the ASAS Business Office 60 days in advance of change.

Claims for missing copies should be received within three months (USA) or six months (international) of printing to be replaced without charge. ASAS will attempt to send one replacement for the issue requested if in the time period indicated. After free replacement period, missing back issues are available for $65.00 per issue.

Journal of Animal Science (ISSN 0021-8812) is published 12 times per year (monthly) by the American Society of Animal Science. Periodicals postage paid at 201 W. Springfield, Ste 1202, Champaign, IL 61820 and at additional mailing offices. Form 3579 to be returned to the ASAS Business Office. Postmaster: Send change of address to American Society of Animal Science, PO Box 7410, Champaign, IL 61826.

0001 Effects of maternal nutritional status on nutrient transporter expression in bovine utero-placental tissue on days 16 to 50 of gestation. M. S. Crouse*[1], K. J. McLean[1], M. R. Crosswhite[2], N. Negrin Pereira[1], A. K. Ward[1], L. P. Reynolds[1], C. R. Dahlen[1], B. W. Neville[3], P. P. Borowicz[1], and J. S. Caton[1], *[1]Department of Animal Sciences, North Dakota State University, Fargo, [2]North Dakota State University, Fargo, [3]North Dakota State University, Streeter.*

We hypothesized that maternal nutrition and day of gestation would impact mRNA expression of nutrient transporters *GLUT1*, *CAT-1*, *CAT-2*, and *CAT-3* in beef heifers. Crossbred Angus heifers (n = 49) were synchronized, bred via AI, assigned to nutritional treatment (CON = 100% of requirements for 0.45 kg/d gain and RES = 60% of CON) and ovariohysterectomized on d 16, 34, or 50 of gestation (n = 6 to 9/d); nonpregnant (NP) controls were not bred and ovariohysterectomized on d 16 of the synchronized estrous cycle (n = 6). The resulting arrangement of treatments was a 2 × 3 factorial + 1. Caruncle (CAR), intercaruncular endometrium (ICAR), and fetal membranes (FM), were obtained from the pregnant uterine horn immediately following ovariohysterectomy. For NP controls, only CAR and ICAR were obtained. Relative expression of the glucose transporter *GLUT1* and cationic amino acid transporters *CAT-1*, *CAT-2*, and *CAT-3* was determined for each tissue utilizing NP-CAR and NP-ICAR tissue as the baseline. For FM, NP endometrium served as the baseline. There was no interaction of day and treatment in FM for any genes ($P \geq 0.05$). Expression of *GLUT1* and *CAT-1* both showed a day effect, being greater ($P < 0.05$) in FM on d 34 and 50, compared with d 16. In CAR there was no day × treatment interaction and *CAT-3* expression tended ($P = 0.06$) to be greater in CON vs. RES heifers. Additionally, expression of *GLUT1*, *CAT-1*, and *CAT-2* in CAR were greater ($P < 0.01$) on d 16 compared with d 34 and 50, d 34 compared with d 50, and d 16 and 34 compared with d 50, respectively. In ICAR, *CAT-2* showed a day × treatment interaction, being greater ($P = 0.01$) on d 50 CON compared with all other groups. Transporter *CAT-3* tended ($P = 0.09$) to be greater in day × treatment in ICAR on d 16 CON compared with all other days and treatments. The expression of *GLUT1* was greater ($P < 0.01$) in ICAR on d 16 than all other days. Arginine transporter *CAT-1* was greater ($P < 0.01$) in ICAR on d 34 and 50 compared with d 16. These results partially support our hypothesis and indicate that day was a more influential factor for mRNA expression of utero-placental glucose and cationic amino acid transporters than maternal nutritional status in heifers during early pregnancy.

Key Words: arginine, gestation, glucose, maternal nutrition, transporters

0002 Effects of dried distiller's grains and lasalocid on feedlot lamb growth, carcass traits, nutrient digestibility, ruminal fluid volatile fatty acid concentrations, and ruminal hydrogen sulfide concentration. A. R. Crane*[1,2], R. R. Redden[3], K. C. Swanson[2], B. M. Howard[2], T. J. Frick[2], K. R. Maddock-Carlin[4], and C. S. Schauer[1], *[1]Hettinger Research Extension Center, Hettinger, ND, [2]Department of Animal Sciences, North Dakota State University, Fargo, [3]Texas A&M AgriLife Research and Extension Center, San Angelo, TX, [4]North Dakota State University, Fargo.*

Our hypothesis was increasing the inclusion level of dried distiller's grains with solubles (DDG) to feedlot lambs would increase growth, while the inclusion of lasalocid (LAS; Bovatec, Alpharma, LLC, Bridgewater, NJ) would increase ADG and G:F while not affecting digestibility, ruminal VFA concentration, and pH in the rumen fluid. Furthermore, we hypothesized that rations including LAS and higher levels of DDG would cause increased ruminal hydrogen sulfide gas (H_2S) concentrations. To test this hypothesis, 240 crossbred (Suffolk × Rambouillet) lambs (31.9 ± 5.87 kg BW; approximately 90 d of age) were allocated to six treatments in a completely random design with a 3 × 2 factorial arrangement of treatments. Lambs were placed into 24 feedlot pens (four pens/treatment; 10 lambs/pen) for a 111-d finishing study. Main effects included concentration of DDG (0, 15, or 30% DM basis) and inclusion of LAS (0 or 20 g/t LAS) resulting in treatments of (1) 0% DDG without LAS (0DDG-NL), (2) 0% DDG with LAS (0DDG-L), (3) 15% DDG without LAS (15DDG-NL), (4) 15% DDG with LAS (15DDG-L), (5) 30% DDG without LAS (30DDG-NL), and (6) 30% DDG with LAS (30DDG-L). Two-day weights were taken at the beginning and end of the trial. Two hundred and eighteen lambs (63.7 ± 8.78 kg) were harvested on d 112 at a commercial abattoir and carcass data collected after a 24 h chill. The inclusion of LAS increased ($P \leq 0.02$) final BW, ADG, G:F, and HCW. As DDG in the ration increased to 30%, DMI decreased linearly ($P = 0.03$) while G:F increased linearly ($P = 0.03$). A second study was conducted utilizing the same treatments to evaluate N and S balance, ruminal VFA and H_2S concentration, and ruminal pH in 24 crossbred wethers (Suffolk × Rambouillet; 41.2 ± 12.23 kg BW). Daily urinary sulfur excretion and H_2S production were linearly increased ($P < 0.001$) as DDG increased in the ration. Total ruminal VFA concentration linearly decreased ($P = 0.002$) as DDG increased in the ration. The inclusion of LAS increased ($P = 0.02$) ruminal pH. The results confirm our hypothesis that LAS increased overall growth and increasing DDG increased ruminal H_2S concentration, however, DDG

inclusion did not increase growth. Additionally, we reject the hypothesis that the combined effects of LAS and DDG would have no effect on rumen pH and VFA concentrations.

Key Words: dried distiller's grains with solubles, ionophores, lambs

0003 Impacts of stocking density on growth and puberty attainment of replacement beef heifers. K. M. Schubach[*1], R. F. Cooke[1], A. P. Brandao[1,2], K. Lippolis[1], R. Marques[1], M. T. Hinchliff[1], D. W. Bohnert[1], *[1]Oregon State University- EOARC Burns, Burns, OR, [2]UNESP-FMVZ, Botucatu, Brazil.*

Sixty Angus × Hereford heifers were ranked by age and BW (210 ± 2 d and 220 ± 2 kg, respectively) on d 0, and assigned to: (A) 1 of 3 drylot pens (10 × 14 m pens; 10 heifers/pen) resulting in a stocking density of 14 m^2/heifer (HIDENS), or (B) 1 of 3 pastures (1-ha pastures; 10 heifers/pasture), resulting in a stocking density of 1000 m^2/heifer (LOWDENS). Before the beginning of the experiment, pastures were harvested for hay, leaving no forage available for grazing for LOWDENS heifers. All heifers received the same diet consisting of (as-fed basis) 5 kg alfalfa hay and 3.5 kg of corn per heifer/d. On d 0, heifers were fitted with a pedometer (HJ-321; Omron Healthcare, Inc., Bannockburn, IL). Each week for the duration of the experiment (d 0 to d 161), pedometer results were recorded, heifer BW was measured, and blood samples were collected. Heifer shrunk BW (after 16 h of water and feed deprivation) was also collected on d –5 and 162 of the experiment. Puberty onset was determined according to plasma progesterone concentration. Heifers were considered pubertal when plasma progesterone concentration was >1.0 ng/mL for two consecutive weeks. A treatment × day interaction was detected ($P < 0.01$) for BW, considering HIDENS heifers were, on average, 10 ± 4 kg heavier than LOWDENS heifers beginning on d 28. This difference in body weight can be attributed to increased physical activity of LOWDENS heifers, as they exhibited more ($P < 0.01$) steps compared with HIDENS heifers. However, ADG using shrunk BW values did not differ ($P = 0.49$) among treatments. Treatment × day interactions were detected for plasma cortisol ($P < 0.01$) and IGF-1 ($P < 0.01$), given that concentration of these hormones were greater for LOWDENS compared with HIDENS heifers on d 84 ($P < 0.01$) and d 140 ($P \leq 0.04$). A treatment × day interaction was also detected ($P < 0.01$) for puberty attainment, considering a greater proportion of LOWDENS heifers reached puberty compared with HIDENS cohorts during the experiment (54.6 vs. 3.4% of heifers pubertal by d 161, respectively; $P < 0.01$, SEM = 5.3). In conclusion, heifers reared in a low-stocking density exhibited hastened puberty attainment, despite the observed decrease in heifer BW attributed to increased physical activity, compared with heifers reared in high stocking density.

Key Words: beef heifers, growth, puberty, stocking density

0004 Physiologic, health and production responses of dairy cows supplemented with an immunomodulatory feed ingredient during the transition period. A. P. Brandao[*1,2], R. F. Cooke[1], F. N. Correa[3], M. B. Piccolo[2], R. Gennari[4], T. Leiva[2], and J. L. M. Vasconcelos[5], *[1]Oregon State University–EOARC Burns, Burns, [2]UNESP- FMVZ, Botucatu, Brazil, [3]Department of Animal Sciences, University of Florida, Gainesville, [4]UNESP- FMVZ, Botucatu, FL, [5]Sao Paulo State University, Botucatu, Brazil.*

This study compared physiological, health, and productive parameters in dairy cows supplemented or not with Omnigen-AF® (OMN) during the transition period. Thirty-eight nonlactating, multiparous, pregnant Holstein × Gir cows were ranked by BW and BCS, and assigned to receive ($n = 19$) or not (CON; $n = 19$) OMN at 56 g/cow daily (as-fed basis) beginning 35 d before calving. Before calving, cows had ad libitum access to corn silage, and received (as-fed basis) 3 kg/cow daily of concentrate. After calving, cows were milked twice daily, offered (as-fed basis) 35 kg/cow daily of corn silage, and individually received a concentrate formulated to meet their nutritional requirements. Cows received OMN individually as top-dressing into the morning concentrate feeding. Before calving, cow BW and BCS were recorded weekly and blood samples collected every 5 d beginning on d –35 relative to calving. After calving and until 46 d in milk (DIM), BW and BCS were recorded weekly, individual milk production was recorded, and milk samples were collected daily. Blood was sampled daily from 0 to 7 DIM, every other day from 9 to 21 DIM, and every 5 d from 26 to 46 DIM. On 30 and 46 DIM, cows were evaluated for endometritis via cytobrush technique, based on percentage of polymorphonuclear (PMN) cells in 100 total cell count (PMN + endometrial cells). On 48.7 ± 1.6 DIM, nine cows/treatment received a lipopolysaccharide (LPS) injection (0.25 μg/kg of BW), and blood was sampled hourly from –2 to 8 h, at 12-h intervals from 12 to 72 h, and at 24-h intervals form 96 to 120 h relative to LPS administration. No treatment differences were detected on BW, BCS, and serum concentrations of cortisol, NEFA, insulin, glucose, haptoglobin, cortisol, and IGF-I ($P \geq 0.15$). Cows receiving OMN had greater ($P \leq 0.04$) milk yield (30.3 vs. 27.1 kg/d; SEM = 0.9) and percentage of PMN cells in endometrial cell population (12.2 vs. 3.9%; SEM = 2.9) compared with CON cows. After LPS administration, cows receiving OMN had greater ($P \leq 0.04$) mean serum haptoglobin (212 vs. 94 μg/mL; SEM = 38) and serum concentration of tumor necrosis factor α at 1, 2, and 3 h relative to LPS injection compared with CON cows. In conclusion, OMN supplementation during the transition period enhanced innate immunity parameters and increased milk production in dairy cows.

Key Words: inflammation, milk production, Omnigen-AF, transition cows

0005 Bioavailability of supplemental ruminally-protected leucine in sheep. J. G. Castro*, J. B. Alford, K. E. Quinn, F. A. Lopez, S. L. Pillmore, E. J. Scholljegerdes, and C. A. Loest, *New Mexico State University, Las Cruces*.

The objective of this study was to evaluate the effects of rumen-protected L-Leu on plasma branched-chain AA concentrations and rumen fermentation characteristics of lambs. Four ruminally-cannulated wether lambs (34 ± 2.4 kg BW) were used in a 4 × 4 Latin square. Each period consisted of 7 d: 5 d for adaptation, 1 d for collections, and 1 d of rest. Lambs were fed a basal diet (corn grain and alfalfa hay; 0.6 kg/d DM) and supplements (0.1 kg/d DM) containing no added leucine (CON), 6 g/d of unprotected L-Leu (UP-LEU), and 18 g/d ruminally-protected L-Leu (RP-LEU), or postruminally infused with 6 g/d of L-Leu (INF-LEU). Blood and rumen fluid samples were collected on d 6 of each period at 0, 3, 6, and 9 h after feeding. The statistical model included period, sheep, treatment, hour, and treatment × hour. Lambs receiving INF-LEU had plasma Leu concentrations that were greater at 3 and 6 h, but not different at 9 h compared with CON, UP-LEU, and RP-LEU (treatment × h; $P < 0.01$). Plasma Ile concentrations were lower for RP-LEU than CON, UP-LEU, and INF-LEU at 0 h, lower for INF-LEU than CON, UP-LEU, RP-LEU and at 3 h, not different among treatments at 6 h, and lower for RP-LEU and INF-LEU than CON and UP-LEU at 9 h (treatment × h, $P = 0.02$). Rumen fluid acetate (mol/100 mol) tended to be lower for RP-LEU than CON, UP-LEU, and INF-LEU at 0 h, lower for UP-LEU than CON, RP-LEU, and INF-LEU at 3 h, not different among treatments at 6 h, and greater for UP-LEU than CON, RP-LEU, but not INF-LEU, at 9 h (treatment × h, $P < 0.01$). Rumen isovalerate (mol/100 mol) was greatest for RP-LEU, intermediate for UP-LEU, and lowest for INF-LEU and CON ($P < 0.01$). Rumen fluid pH, NH_3, total VFA, and molar proportions of propionate, isobutyrate, butyrate, valerate, and acetate:propionate ratio were not altered by treatments ($P \geq 0.01$). Although supplementation of RP-LEU was unable to elevate plasma Leu concentrations, decreases in plasma Ile concentrations are likely due to the antagonistic effects of postabsorptive L-Leu on plasma Ile concentrations. This data implies that the ruminally-protected Leu was absorbed by the gastrointestinal tract of lambs. Altered rumen fermentation also demonstrated that the ruminally-protected L-Leu source was not entirely protected from rumen microorganisms.

Key Words: leucine, rumen-protected, sheep

0006 Key metabolic pathways associated with differences in weight maintenance and gain in mature cow skeletal and adipose tissue. *H. C. Cunningham*[*1], K. J. Austin[1], K. M. Cammack[1], H. C. Freetly[2], A. K. Lindholm-Perry[2], [1]Department of Animal Science, University of Wyoming, Laramie, [2]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

During the production year of a cow, the majority of nutrients are used to support maintenance. Differences in feedstuff utilization and metabolism can impact the ability of the cow to meet maintenance requirements. Tissue specific metabolism is critical to energy homeostasis of the animal, and therefore, regulation of metabolism is critical to understand. The objective of this research was to determine whether cows that differ in efficiency of weight maintenance and weight gain differ in the relative abundance of transcripts associated with protein and lipid turnover of skeletal muscle and adipose tissue, respectively. Crossbred cows ($n = 121$) were feed restricted for 112 d followed by an ad libitum feeding period for 98 d. Individual feed intake was monitored and body weights were collected to estimate ADG. Adipose and muscle biopsies were collected at d 105 of restricted feeding and at d 49 of ad libitum feeding. Total RNA was extracted from these tissues of the cows with the highest ($n = 6$) and the lowest ($n = 6$) ADG during the ad libitum period. The Affymetrix GeneAtlas microarray system was used to determine relative transcript abundance differences between ADG classes within feeding periods and tissue type. Subsequent analyses using the Database for Annotation, Visualization, and Integrated Discovery (DAVID) and Ingenuity Pathway Analysis (IPA) programs identified key gene clusters and pathways associated with differential gene expression, largely including pathways associated with lipid and carbohydrate metabolism, cell-cell signaling and interaction, and cellular function and maintenance. These data suggest key metabolic pathways may be critical to differences in weight maintenance and gain.

Key Words: adipose tissue, metabolism, skeletal muscle

0007 Effects of grazing intensity and advancing season on chemical composition and in vitro organic matter disappearance in steers grazing mixed-grass prairie. K. E. Chilcoat*, *Animal Sciences Dep., North Dakota State University, Fargo.*

A study was conducted to evaluate the influence of advancing season and grazing intensity on dietary chemical composition and in vitro organic matter disappearance (IVOMD) in beef steers grazing mixed-grass prairie in the Missouri Coteau of south central North Dakota. Five sampling periods were conducted from mid-May to early September 2015. Twelve ruminal cannulated crossbred steers were used to collect diets while 188 crossbred steers were used to maintain specific

grazing intensities on 12 pastures. Treatments were light (LT), moderate (MOD), heavy (HVY), and extreme (EXT) grazing intensities. Each treatment was assigned to 3 pastures. Grazing treatment × sampling period interactions were not present ($P \geq 0.29$) for all variables measured except IVOMD ($P < 0.01$). There were no main effects of grazing treatment for NDF, ADF, total N, soluble N (SN), insoluble N (IN), and ADIN. Responses to grazing season were evaluated with linear, quadratic, and cubic contrasts. Neutral detergent fiber increased linearly ($P < 0.01$) and cubically ($P = 0.01$), while ADF tended ($P = 0.17$) to increase linearly with advancing season. Dietary N decreased linearly ($P < 0.01$), quadratically ($P = 0.01$), and cubically ($P = 0.01$). Soluble N and IN expressed a linear ($P < 0.001$) and quadratic ($P = 0.03$) decrease across advancing season, while IN also showed a cubic response ($P < 0.001$). Acid detergent insoluble N did not change as season advanced ($P > 0.14$). In vitro OM digestibility decreased from May to September ($P < 0.01$) in all sampling periods, but did not show any trends across treatments ($P = 0.82$). However, IVOMD did show a treatment × period interaction ($P < 0.01$). In summary, these data indicate increases ($P < 0.001$) in dietary NDF and decreases ($P < 0.001$) in N, SN, IN, and IVOMD with advancing season. These data suggest seasonal factors are a more important driver of grazed masticate forage nutrient composition than the grazing intensities evaluated in this study.

Key Words: dietary nutrient composition, grazing intensity, season

---

0008 Altering the time of vaccination against respiratory pathogens to enhance vaccine efficacy, health, and performance of feedlot cattle.

K. Lippolis*[1], R. F. Cooke[1], K. M. Schubach[1], A. P. Brandao[1,2], R. Marques[1], M. T. Hinchliff[1], and D. W. Bohnert[1], *[1]Oregon State University–EOARC Burns, Burns, [2]UNESP- FMVZ, Botucatu, Brazil.*

Ninety Angus × Hereford calves were ranked by gender, BW, and age, and assigned to 1 of 3 vaccination schemes against respiratory pathogens: (1) vaccination at weaning (d 0) and at feedlot entry (d 30; CON, $n = 30$), (2) vaccination 15 d before weaning (d –15) and 15 d before feedlot entry (d 15; EARLY, $n = 30$), and (3) vaccination 15 d after weaning (d 15) and 15 d after feedlot entry (d 45; DELAYED, $n = 30$). From d –15 to 6, calves were maintained on pasture. On d 7, calves were placed according to treatments into 1 of 18 drylot pens (6 pens/treatment; 5 calves/pen), and fed a forage-based preconditioning diet. On d 30, calves were transported 1440 km in a livestock trailer and returned to different drylot pens for a 45-d receiving period. Calves were fed a forage + concentrate diet during the receiving period. Blood samples and BW were collected on d –15, 0, 15, 30, 45, 60, and 75. Additional BW was collected on the day after blood sampling so two consecutive BW were recorded and averaged. There were no treatment effects on BW preweaning, weaning, or during the preconditioning and receiving periods ($P \geq 0.59$). The EARLY calves had less ($P \leq 0.05$) ADG preweaning, however had greater ($P \leq 0.04$) ADG during feedlot receiving compared with the other treatments. During preconditioning, CON had greater ($P = 0.05$) DMI compared with EARLY and DELAYED calves, but there were treatment effects ($P \geq 0.20$) on DMI during the feedlot receiving. There were no treatment effects ($P \geq 0.16$) on G:F, morbidity, or mortality. By 15-d after initial vaccination, DELAYED calves had the greatest ($P < 0.01$) antibody titers against *Mannheimia haemolytica,* and EARLY calves had the lowest ($P \leq 0.05$) antibody titer against this pathogen. By revaccination, there was no difference ($P = 0.82$) between DELAYED or CON for antibody titers against *M. haemolytica* titers, while EARLY titers remained the lowest ($P < 0.01$). However, by 45-d after initial vaccination, EARLY calves had the greatest antibody titers ($P \leq 0.05$) against *M. haemolytica*, which remained the greatest until 60-d after initial vaccination. These data suggest that while preweaning ADG may be inhibited by vaccination before weaning, vaccination before weaning and revaccination before feedlot receiving can improve overall antibody titer to *M. haemolytica* and ADG during feedlot receiving.

Key Words: feeder cattle, health, performance, vaccination

0009 Evaluation of genetic structure across five U.S. climate zones using prominent AI sires of two British *Bos taurus* breeds.

B. C. Krehbiel*[1,2], M. G. Thomas[1], H. D. Blackburn[2], S. E. Speidel[1], R. M. Enns[1], and L. Keenan[3], *[1]Department of Animal Sciences, Colorado State University, Fort Collins, [2]National Animal Germplasm Program ARS-USDA, Fort Collins, CO, [3]Red Angus Association of America, Denton, TX.*

Cattle performance in diverse climates can be problematic if they cannot adapt to climate variability. Previous research showed Hereford cattle to have genetic substructure associated with U.S. climates: cool arid (CA), cool humid (CH), transition zone (TZ), warm arid (WA), and warm humid (WH). Allele frequencies of 66 SNP from BovineSNP50 (Illumina BeadChip) were associated with the following traits: mature cow body weight, heat stress, milk yield, heifer conception rate, and early embryonic survival. Knowledge of these genotype to phenotype associations were queried from CattleQTLdb. The GENALEX (6.501) software was used to estimate population genetic results. To characterize the diversity in another British *Bos taurus* breed, population genetic characteristics were estimated in Red Angus bulls ($n = 175$) that were included in the 2000 Bull Project. Similar software, climate zone regions, and SNP were used in the analyses. The number of sires in the climates zones of CA, CH, TZ, WA, and WH were 126, 32, 11, 5, and 1, respectively. We hypothesized

Red Angus bulls would possess genetic substructure across the five climatic zones as observed in Hereford bulls. ARLEQUIN (3.5.2.2) software was used to estimate Hardy-Weinberg Equilibrium (HWE) and conduct an analysis of molecular variance for genotype to phenotype associations. The number of significant ($P < 0.05$) SNP for the traits of milk yield, early embryonic survival, and mature cow body weight were 4, 1, and 1, respectively. Based on the results and genotypes from the bulls studied in the 2000 Bull Project, we reject our hypothesis that Red Angus bulls possess genetic substructure similar to Hereford bulls across five U.S. climate zones. These results provide evidence to suggest that Red Angus cattle in the United States appear to be preferred in beef production systems in cooler climate zones, whereas Hereford cattle populate these regions as well as drier climate zones.

Key Words: *Bos taurus*, genetic diversity management, molecular markers

0010 Effect of processing of supplemental corn on metabolizable protein of beef cows grazing winter wheat pasture. C. S. Hebbert*[1], M. A. Lopez-Baca[2], L. Avendaño-Reyes[2], U. Macias-Cruz[2], and S. A. Soto-Navarro[1], *[1]New Mexico State University, Las Cruces, [2]Instituto de Ciencias Agricolas, Universidad Autonoma de Baja California, Ejido Nuevo Leon, Baja California, Mexico.*

Eight ruminally and duodenally cannulated, Angus-crossbred cows (587 ± 49.0 kg) grazing winter wheat pasture (WWP) were used in a completely randomized design with the objective of evaluating effects of processing of supplemental corn (ground vs. steam-flaked) on forage intake and metabolizable protein. The experiment was conducted from 23 Mar. through 6 Apr. 2015. Cows grazed a single WWP with ground corn (GC) or steam-flaked corn (SFC) offered individually at 0.4% of BW, once daily at 0700 h. Forage DM intake and total DM intake were greater ($P = 0.01$) for SFC than for GC supplementation. Forage OM, CP, and NDF intake was greater ($P = 0.01$) for SFC than for GC supplementation. Total OM, CP, and NDF intake was greater ($P < 0.02$) for SFC than for GC supplementation. Although feed CP flow to the small intestine was not affected ($P = 0.97$) by corn processing method, microbial CP synthesis was greater ($P = 0.01$) for SFC than for GC supplementation. Therefore, total CP flow to the small intestine (metabolizable protein) was greater ($P = 0.03$) for SFC than for GC supplementation. Total tract digestibility of OM, CP, and NDF (expressed as g/d) were greater ($P < 0.02$) for SFC than for GC supplementation. In conclusion, forage intake, microbial protein synthesis, and metabolizable protein improved by steam-flaking as compared with grinding supplemental corn for cattle grazing WWP. Steam flaking, as compared with grinding supplemental corn, may improve performance of cattle grazing WWP by improving forage intake and microbial CP synthesis.

Key Words: grain processing, metabolizable protein, winter wheat pasture

0011 Does adaptive grazing management influence dietary quality of yearlings during the grazing season on western Great Plains rangelands? T. R. Plechaty*[1], J. D. Scasta[1], J. D. Derner[2], *[1]University of Wyoming, Laramie, [2]USDA–Agricultural Research Service, Cheyenne, WY.*

Grazing management decisions, such as timing of herd movements, can have a direct impact on the diet quality and nutritional plane of cattle. The variation in diet quality relative to adaptive versus continuous grazing strategies can lead to differences in cattle weight gains which directly impacts the profit margin for livestock producers. Near Infrared Reflectance Spectroscopy (NIRS) was used on fecal samples collected weekly from yearlings during the 2015 grazing season (May through October) to evaluate if differences occurred in measurements of dietary quality (crude protein and digestible organic matter) between adaptive grazing and continuous, season-long grazing in two rangeland ecosystems of the western Great Plains: shortgrass steppe and northern mixed-grass prairie. Yearling cattle under traditional grazing management at a moderate stocking rate had a 1.2 to 2.4% higher dietary crude protein ($P < 0.003$, $P < 0.001$) and a 0.5 to 1.4% higher digestible organic matter ($P < 0.1$, $P < 0.001$) than yearling cattle under adaptive grazing management across the season at HPGRS and CPER, respectively, with maximum differences for both protein and digestibility exceeding 5% at times. At CPER, adaptive grazing management caused a two- to greater-than-fourfold steeper decline in digestibility between rotations compared with traditional grazing management.

Key Words: beef cattle, diet quality, grazing management

0012 Long-term progesterone influence on feed efficiency, body composition, nonesterified fatty acids, and metabolic hormones in mature Rambouillet ewes. M. R. Herrygers*, J. M. Thomson, K. A. Perz, P. J. Merta, M. Knerr, K. Metcalf, K. B. Herrygers, and J. G. Berardinelli, *Montana State University, Bozeman.*

The objectives of this study were to evaluate the effects of long-term progesterone (P4) treatment on changes in feed efficiency, BW, body composition, NEFA and metabolic hormones in mature Rambouillet ewes. Thirty multiparous 5- and 6-yr-old Rambouillet ewes were stratified by age and metabolic BW and assigned randomly to receive long-term P4 administration using a sequential replacement of either a P4-containing controlled internal drug release device (CIDR) or non-P4-containing CIDR (CIDRX). Initially, ewes were

synchronized for estrus using a 7 d CIDR and $PGF_{2\alpha}$ protocol. All ewes exhibited estrus within 72 h after $PGF_{2\alpha}$. Twelve days after estrus (d = 0), each ewe received either a CIDR (n = 15) or a CIDRX (n = 15). Every 14 d thereafter, the CIDR or CIDRX was removed from each ewe and replaced with a new CIDR or CIDRX for 126 d. Jugular venous blood samples were collected from each ewe at the time of CIDR or CIDRX replacement. Serum samples were assayed for P4, NEFA, insulin (INS), triiodothyronine (T3), and thyroxine (T4). Individual feed intake was recorded using GrowSafe units, beginning at d 0 following a 3-wk adaptation period. Ewes were fed a mixed grass hay diet ad libitum that met the nutrient requirements for maintenance. BW for each ewe was collected every 14 d when CIDR or CIDRX were replaced. Back fat (BF) and rib-eye area (REA) were measured for each ewe every 28 d using ultrasonography. BW, residual feed intake, BF and REA did not differ ($P > 0.10$) between CIDR- and CIDRX-treated ewes. Calculated estimates of body composition did not differ ($P > 0.10$) between CIDR- and CIDRX-treated ewes. NEFA, T3, and T4 concentrations did not differ ($P > 0.10$) between CIDR- and CIDRX-treated ewes. However, INS concentrations did differ ($P < 0.05$) between CIDR- and CIDRX-treated ewes. In conclusion, long-term P4 treatment did not appear to alter feed efficiency and partitioning of nutrients. However, maintaining P4 may alter the homeostatic relationship between INS and carbohydrate metabolism in ewes.

Key Words: carcass traits, ewe, metabolism, progesterone, residual feed intake

0013 Health evaluation of immune-stimulated and hay-supplemented feedlot receiving calves as assessed by blood gas analysis.

E. R. Oosthuysen*[1], M. Hubbert[2], K. L. Samuelson[1], E. J. Scholljegerdes[1], G. C. Duff[1], and C. A. Loest[1], *[1]New Mexico State University, Las Cruces, [2]Clayton Livestock Research Center, New Mexico State University, Clayton.*

This study evaluated blood parameters, health, and performance of immune-stimulated and hay-supplemented feedlot receiving calves. Heifers (n = 705; 179 ± 0.58 kg BW) were blocked by six truckloads and assigned to 48 pens and four treatments in a randomized complete block design. Treatments were a factorial arrangement of hay (+HAY vs. –HAY) and immunostimulation (+IMMUN vs. –IMMUN). Pens assigned +HAY received supplemental alfalfa hay to the receiving ration for the first 14 d. Calves assigned +IMMUN received a DNA immunostimulant on d 0. On d 0, 14, and 28, BW, rectal temperatures, and venous blood were collected. Health was recorded throughout the 56-d study, and pen weights on d 56. No HAY × IMMUN interactions occurred ($P \geq 0.18$). During the first 14 d, calf ADG was greater ($P < 0.01$) for +HAY than-HAY, but d 14 to 28 ADG was lower ($P < 0.01$) for +HAY than-HAY. Calf ADG was lower ($P \leq 0.01$) for +IMMUN than –IMMUN from d 28 to 56 and from d 0 to 56. Total DMI was greater ($P < 0.01$) for +HAY than –HAY from d 0 to 14, but lower ($P \leq 0.04$) from d 14 to 28 and from d 28 to 56. Gain efficiency of +HAY calves was greater (less negative; $P < 0.01$) from d 0 to 14, but lower ($P < 0.01$) from d 14 to 28 when compared with –HAY. Gain efficiency was lower ($P \leq 0.02$) for +IMMUN than –IMMUN calves from d 28 to 56 and d 0 to 56. Calf morbidity, mortality, and blood parameters (pH, glucose, lactate, hemoglobin saturated with oxygen [sO_2]) were not affected ($P \geq 0.18$) by treatments. Blood sO_2 was lower ($P < 0.01$) on d 0 than d 14 and 28, and glucose was greater ($P < 0.01$) on d 28 than d 0 and 14. Blood sO_2 correlated ($P < 0.05$) with glucose (R^2 = 0.09), lactate (R^2 = –0.12), and mortality (R^2 = 0.08). Glucose correlated with lactate (R^2 = 0.61), and first (R^2 = –0.22) and second (R^2 = –0.13) medical treatment. Lactate correlated ($P < 0.05$) with first medical treatment (R^2 = –0.12) and mortality (R^2 = –0.12). In conclusion, hay supplementation and immune stimulation did not affect calf health, performance, or blood gas parameters. Changes in calf health can be observed in measures of blood parameters.

Key Words: calves, hay, immunostimulant

0014 Effect of postweaning heifer development system on average daily gain, pregnancy rates, and subsequent feed efficiency as a pregnant heifer.

S. A. Springman*, H. R. Nielson, T. L. Meyer, and R. N. Funston, *University of Nebraska, West Central Research and Extension Center, North Platte.*

A 4-yr study was conducted using Angus-based, spring born heifers. In yr 1, weaned heifers grazed corn residue (CR, n = 50) or were fed in a drylot (DLHI, n = 50). In yr 2, 3, and 4, heifers grazed CR (n = 75), upland range (RANGE, n = 75), or were fed diets differing in energy, high (DLHI, n = 75) or low (DLLO, n = 75), in a drylot. Percentage of mature BW before the breeding season was greater (P = 0.01) for DLHI (67%) compared with Range (59%), CR (60%), and DLLO (63%). Pregnancy rates to AI were similar (P = 0.39) among treatments (67, 63, 61, 49 ± 7.2%; RANGE, CR, DLHI, DLLO), and final pregnancy rates were also similar (84, 90, 91, 91 ± 5.4%; Range, CR, DLHI, DLLO; P = 0.59). A subset of AI pregnant heifers from each treatment was placed in a Calan gate system. Heifers were allowed a 20 d acclimation period before beginning the 90 d trial at approximately gestational d 170. Heifers were offered ad libitum hay; amount offered was recorded daily and orts collected weekly. Initial BW was not different (P = 0.35) among treatments (451, 457, 472, 464 ± 10 kg; RANGE, CR, DLHI, DLLO). Body weight at the end of the trial was also similar (P = 0.24; 488, 497, 511, 502 ± 14 kg; RANGE, CR, DLHI, DLLO). Intake was similar, either as DMI (P = 0.27; 9.74, 9.97, 10.18, 10.00 ± 0.76 kg; RANGE, CR, DLHI, DLLO) or residual feed intake (P = 0.61; 0.094, 0.091, –0.056, –0.0743 ± 0.160 kg; RANGE, CR, DLHI, DLLO). There was no difference in ADG (P = 0.36; 0.38, 0.45, 0.43, 0.41 ± 0.17 kg/d; RANGE, CR, DLHI, DLLO)

among treatments. Although the development cost was not different among treatments ($P = 0.41$; \$166, 141, 160, 171 ± 12, RANGE, CR, DLHI, DLLO), there was a \$30 numerical difference between the most (DLHI) and least (CR) expensive treatment. Developing heifers to a greater prebreeding BW did not influence subsequent AI or overall pregnancy rates or feed efficiency as a pregnant heifer.

Key Words: beef heifers, feed conversion, heifer development

0015 Comparison of timed insemination vs. modified estrus detection protocol in beef heifers.

B. T. Tibbitts[*1], T. L. Meyer[2], D. J. Kelly[3], and R. N. Funston[2], *[1]University of Nebraska-Lincoln, Lincoln, [2]University of Nebraska, West Central Research and Extension Center, North Platte, [3]Kelly Ranches, Sutherland.*

Angus-based, crossbred heifers (n = 972, 346 kg ± 14 kg) were assigned to either a fixed-time AI (FTAI) protocol or modified estrus detection with fixed-time AI (MTAI) to evaluate synchronization, conception, and pregnancy rates. During the prebreeding development period, heifers were fed to achieve a target of 60 ± 5% mature BW at breeding. Heifers were synchronized via melengestrol acetate-prostaglandin $F_{2\alpha}$ (MGA-PG) protocol and received an estrus detection aid (patch) at PG administration. A patch score was recorded for each heifer at AI to reflect what percentage of rub-off coating had been removed. Heifers in the FTAI treatment received 2 mL GnRH injection and were AI 72 ± 2 h following PG. Heifers in MTAI treatment were observed for estrus at 58 ± 2 and 70 ± 2 h after PG. Approximately 72 ± 2 h after $PGF_{2\alpha}$, heifers in MTAI were AI in the following order: heifers in estrus at 58 h post-PG, heifers in estrus at 70 h post-PG, and heifers not expressing estrus at either estrus observation. Heifers not expressing estrus received GnRH at AI. Pregnancy was determined via transrectal ultrasonography. Heifers exhibiting estrus had greater ($P < 0.01$; 71 and 66 ± 5% for FTAI vs. MTAI, respectively) AI conception rates than heifers not expressing estrus in both FTAI and MTAI treatments vs. 47 and 53 ± 9% AI conception rates in nonestrus heifers for FTAI and MTAI, respectively. However, overall AI conception rate (62 ± 5%, $P = 0.49$) and final pregnancy rates were similar ($P = 0.98$; 96 and 97 ± 3% for FTAI vs. MTAI, respectively). Similar AI conception rates were achieved without estrus detection.

Key Words: beef heifers, estrus synchronization, timed artificial insemination

0016 Growth and reproductive performance of yearling beef heifers implanted with Revalor G in the Nebraska Sandhills.

B. T. Tibbitts[*1], H. R. Nielson[2], K. C. Ramsay[3], and R. N. Funston[2], *[1]University of Nebraska-Lincoln, Lincoln, [2]University of Nebraska, West Central Research and Extension Center, North Platte, [3]Rex Ranches, Ashby, NE.*

Crossbred beef heifers (n = 3242), approximately 12 mo of age, were managed at three locations in the Nebraska Sandhills and randomly assigned to be implanted with Revalor G (40 mg of trenbolone acetate and 8 mg estradiol, IMP), while the control group (CON) did not receive an implant. Heifers (238 ± 2 kg) grazed native Sandhills range for the duration of the trial (164 ± 4 d). Eighty-two ± 2 d following trial initiation, heifers were synchronized for estrus and AI followed with clean-up bulls as part of a 25 d breeding season. Body weight was measured at the beginning and end of trial. Pregnancy detection occurred 45 d following bull removal at the conclusion of the summer grazing period. Implanted heifers gained more and were heavier ($P < 0.05$; 0.68 vs. 0.64 ± 0.01 kg/d and 347 vs. 340 ± 3 kg, IMP vs. CON, respectively) at the end of the trial. However, pregnancy rate was greater ($P < 0.01$) for CON vs. IMP (64 vs. 46 ± 3%, respectively). Implanted heifers also had a lower pregnancy rate in their second breeding season ($P = 0.02$; 93 vs. 96 ± 2%, IMP vs. CON, respectively). Implanting beef heifers with Revalor G at approximately 12 mo of age increased ADG and summer BW gain; however, it decreased initial and subsequent pregnancy rate compared with heifers not implanted.

Key Words: beef heifers, fertility, growth implants

0017 Performance and net energy in high and low RFI beef cattle.

K. C. Dykier[*] and R. D. Sainz, *University of California, Davis.*

The objective of this study was to relate feed efficiency to performance and net energy in beef cattle. To identify animals with greater or lesser feed efficiency, 98 weaned Angus cross beef calves (71 steers and 27 heifers) were fed individually for 56 d. Feed offered and refused were measured daily, body weights were taken at 14 d intervals, and ultrasound measures (longissimus muscle area and subcutaneous fat over the 12th to 13th ribs) were taken at the beginning, middle and end of the trial. Feed was delivered twice a day, on an ad libitum basis. Residual feed intake (RFI) was determined as the residual of the regression of DMI on mid-test $BW^{0.75}$ and ADG. High and low RFI groups were defined as >0.5 SD above or below zero, respectively, with intermediate animals classified as medium RFI. As expected, RFI groups had similar initial and final BW and ADG, and different DMI, gain:feed and RFI ($P < 0.001$). Fat gain, protein gain, and recovered energy (RE) were not different between RFI groups, although subcutaneous fat over the 12th and 13th rib was 0.19 cm higher in high RFI than low RFI cattle ($P = 0.012$). Heat energy (HE),

Table 0017.

Table 2. Performance, body composition, and net energy in RFI groups and sex after 56 days *ad libitum* feeding.

	RFI			Sex			P-value		
Trait	High	Medium	Low	H	S	SD	RFI	Sex	Sex x RFI
Initial BW, kg	279.3	272.3	277.2	261.3	291.2	30.2	0.67	< 0.001	0.53
Final BW, kg	382.6	370.1	382.4	346.7	410.0	35.9	0.33	< 0.001	0.32
ADG, kg/d	1.844	1.747	1.878	1.524	2.122	0.238	0.11	< 0 .001	0.32
DMI, kg/d	9.06	8.17	7.84	7.63	9.08	0.866	< 0.001	< 0.001	0.16

Protein gain, kg/d	0.22	0.21	0.23	0.179	0.258	0.05	0.26	< 0.001	0.62
Fat:protein	3.02	2.81	2.73	2.892	2.817	0.67	0.29	0.62	0.06
RE, Mcal/d	7.25	6.89	7.00	5.860	8.231	1.78	0.63	< 0.001	0.19
RE, Mcal $kg^{0.75}$	0.102	0.099	0.098	0.089	0.112	0.02	0.77	< 0.001	0.28
HE, Mcal/d	19.40	17.14	16.08	16.58	18.50	2.69	< 0.001	< 0.001	0.40
HE, Mcal $kg^{0.75}$	0.274	0.248	0.228	0.250	0.250	0.03	< 0.001	0.91	0.55
NEm, Mcal/$kg^{0.75}$	0.103	0.087	0.077	0.098	0.081	0.03	0.001	0.002	0.75

defined as the difference between metabolizable energy intake (MEI) and RE was lower in low RFI cattle ($P < 0.001$). Estimated NE_m requirement (Mcal/$kg^{0.75}$) was lower in low than in high RFI cattle ($P = 0.001$). Overall heifers gained less than steers; however, there were no sex × RFI class interactions. Low RFI cattle have similar weights and weight gains, but lower intakes and higher feed efficiencies as high RFI cattle. This may be partially due to decreased maintenance requirement and heat production.

Key Words: efficiency, net energy, residual feed intake

0018 Impact of maternal protein restriction in first-calf heifers during mid- to late- gestation on gene expression, feedlot performance, and carcass characteristics of progeny.

J. J. Kincheloe*[1], M. J. Webb[2], R. N. Funston[3], K. R. Underwood[2], M. G. Gonda[2], A. D. Blair[1], and K. C. Olson[1], *[1]South Dakota State University, Rapid City, [2]South Dakota State University, Brookings, [3]University of Nebraska, West Central Research and Extension Center, North Platte.*

Maternal nutrient restriction in beef cows impacts developmental processes in the fetus that may influence postnatal performance. This study investigated impacts of MP restriction in mid- and late-gestation on the transcriptome of neonatal muscle tissue and subsequent feedlot performance and carcass characteristics of progeny. One hundred eight Angus × Simmental heifers were blocked by BW and method of conception (AI or natural service, based on fetal age at ultrasound) and allocated to 12 pens in a randomized complete block design with a 2 × 2 factorial treatment structure including two stages of gestation (mid- and late-) and two levels of dietary protein (control [CON]; approximately 102% of MP requirements and restricted [R]; approximately 80% of MP requirements). Pens were randomly assigned to CON or R treatments within blocks during mid- and/or late-gestation. Heifers were removed from treatments after calving and managed as a common group. Within 48 h of birth, LM biopsy samples were collected from a subset of three male AI calves from each treatment combination for analysis of gene expression using RNA-Seq technology. Following weaning, calves were backgrounded for 2 wk then finished in a GrowSafe feeding system on a common finishing diet. Individual carcass measurements were recorded. Genes found in pathways associated with muscle tissue development were up-regulated ($P \leq 0.02$) in calves born to dams on the CON treatment throughout mid- and late- gestation. Genes involved in adipogenesis were up-regulated in calves born to dams on the R-R treatment ($P = 0.05$). No differences were observed for calf BW, DMI, ADG, G:F, or residual feed intake (RFI) due to maternal nutritional treatments across the entire feeding period ($P > 0.10$). Hot carcass weight, adjusted 12th rib fat thickness, KPH, marbling score, and proportion of carcasses in each USDA quality grade were not influenced ($P > 0.10$) by maternal diet during gestation. Progeny of dams on the R treatment in late gestation had greater LM area ($P = 0.05$) vs. progeny from CON dams. There was a tendency ($P = 0.06$) for a mid- by late-gestation treatment interaction for

yield grade, with lower yield grades in progeny from dams on CON-R or R-CON treatments vs. CON-CON. Differences in gene expression, animal performance, and carcass characteristics indicate MP restriction during mid- and late-gestation may impact developmental programming.

Key Words: beef cattle, MP restriction, gene expression

ASAS WESTERN SECTION UNDERGRADUATE STUDENT POSTER COMPETITION

0019 Development of an immunohistochemical technique to determine presence and localization of glucose transporter GLUT3 in bovine utero-placental tissues from days 16 to 50 of gestation.

J. Osei*, M. S. Crouse, K. J. McLean, J. A. Flaten, P. P. Borowicz, L. P. Reynolds, J. S. Caton, and C. R. Dahlen, *Department of Animal Sciences, North Dakota State University, Fargo.*

Before the establishment of transplacental exchange, nutrients must be transported to the embryo via nutrient transporters. Glucose transporter *GLUT3* is known as a higher affinity, facilitated diffusion glucose transporter found in high glucose demanding tissues such as the brain, placenta, sperm, pre-implantation embryos, and some cancers. The objectives of our current study were (1) develop an immunohistochemistry technique to localize *GLUT3* in bovine utero-placental tissues, and (2) confirm the presence and location of *GLUT3* in bovine utero-placental tissues. We hypothesized that *GLUT3* would be present in utero-placental tissues from d 16 to 50 of gestation. To test this hypothesis, crossbred Angus heifers (n = 49), were synchronized, bred via AI, randomly assigned to nutritional treatment beginning at AI (CON; heifers receiving 100% of requirements to gain 0.45 kg daily) or (RES; 60% of CON), then ovariohysterectomized on d 16, 34, or 50 of gestation (n = 6 to 7/d/treatment), or were not bred and ovariohysterectomized on d 16 of a synchronized estrous cycle (n = 6) to serve as nonpregnant (NP) controls. Uterine cross-sections were obtained from the pregnant horn, fixed in neutral buffered formalin, and embedded in paraffin for histology. Rabbit primary antibody for *GLUT3* (Abcam) followed by fluorescently labeled, goat nonrabbit secondary antibody (Alexa Fluor 633; Abcam) was used to localize *GLUT3* transporter. A DAPI stain was used to counterstain cell nuclei. Photomicrographs were taken with a Zeiss Imager.M2 epifluorescence microscope using a 10× objective and AxioCam HR camera with a Zeiss piezo automated stage. To describe localization of *GLUT3*, the mosaic image of a large tissue area covering the whole cross-section of the uterus with fetal membranes (12 × 3 pictures) on the slide was taken using the MosaiX module of Zeiss AxioVision software. We localized *GLUT3* in fetal membrane [chorioallantois], uterine endometrium [caruncles and intercaruncular endometrium] interglandular (stromal) tissue, superficial glands, deep glands, as well as myometrium in NP, CON, and RES tissues on d 16, 34, and 50. These results accomplished our objectives and clearly supported our hypothesis that *GLUT3* is present in uterine tissues from d 16 to 50 of gestation. Further research and more detailed measurements using fluorescence intensity in utero-placental tissues across day and treatments is needed to determine impacts of maternal nutrition status and day of early gestation on localization as well as concentration of the *GLUT3* transporter within utero-placental tissues.

Key Words: bovine, glucose, immunohistochemistry, utero-placental tissue

0020 Do ewes born with a male co-twin have greater longevity with lambing over time?

D. N. Grogan*[1], J. A. Brown[1], and J. B. Taylor[2], *[1]Wingate University, Wingate, NC, [2]USDA, ARS, Rangeland Sheep Production Efficiency Research, Dubois, ID.*

Based on a recent analysis of historical records, ewes born co-twin to a ram had greater lifetime reproductive performance than ewes born co-twin to an ewe. We are interested in determining what component(s) of lifetime reproductive performance may be associated with a ewe's co-twin sex. As an initial indicator of longevity in the flock, we hypothesized that co-twin sex will affect the age at which ewes consistently appear in the lambing records (i.e., recorded as having lambed). Therefore, the objective was to determine the percentage of ewes, born with a female or male co-twin, that appear in the lambing records at ages 1 to 7 yr. Using the USDA–ARS, U.S. Sheep Experiment Station database, lambing records from 1994 to 1997 were queried for ewes that were either born with a male or female co-twin. A total of 4442 ewes were identified, and breeds included Columbia (n = 417), Polypay (n = 627), Rambouillet (n = 446), and Targhee (n = 427). For each age class, Chi square analysis was used to compare the expected percentage of ewes lambing that were either born to a female or male co-twin. Of ewes born as a twin and subsequently recorded as having lambed, we expected that, within each age class (1 to 7 yr), 50% of the ewes were originally born as a co-twin to a female (FF) and 50% born as a co-twin to a male (FM). The observed percentage of FF (52.7%) or FM (47.3%) ewes did not differ, regardless of age or breed; $P > 0.10$). Within breed, no differences between percentages were observed in Columbia (FF = 53.8% and FM = 46.2%; $P > 0.10$), Rambouillet (FF = 55.2% and FM = 44.8; $P > 0.60$), and Targhee (FF = 46.3% and FM = 53.7%; $P > 0.30$) ewes regardless of age. However, in 2-yr-old Polypay ewes, there were more FF ewes recorded as having lambed compared with FM ewes (FF = 55% and FM = 45%; $P < 0.01$), but no differences were found at any other age. We suggest that the percentage of ewes having a female or male co-twin did not vary from the expected percentage, thus ewes having a male

co-twin did not have greater longevity with lambing compared with ewes with a female co-twin.

Key Words: co-twin, longevity, lambing

0021 Effect of postweaning brewers grain supplementation on growth and reproductive performance of angus and red angus heifers.

S. E. Butterfield*, J. M. Wisniewski, D. A. Daley, S. P. Doyle, and K. L. DeAtley, *California State University, Chico.*

Objectives of this study were to determine the effects of supplemental brewers grain on growth performance and reproductive characteristics of Angus and Red Angus heifers in a 3-yr study. A total of 85 spring-born, weaned heifers were randomized via gate cut and placed on an 84 d supplementation trial. Treatment groups were either control (CON; $n = 43$; initial BW = 311.90 ± 8.57 kg) or wet brewers grain (WBG; $n = 42$; initial BW = 309.43 ± 8.57 kg) groups. Heifers were housed on adjacent improved pastures (TDN, 56.5%; CP, 11.19%; NDF, 64.8%) and supplemented once daily at 1800 with either the control (CON, alfalfa hay + corn silage; TDN, 52.4%, CP, 8.2%, NDF, 65.6%) or WBG (Alfalfa hay + corn silage + wet brewers grain; TDN, 53.6%, CP: 9.8%, NDF, 66.2%) ration. Diets were balanced to target 0.68 kg ADG/head and were offered on an ad libitum basis. Fifteen days after supplementation period, heifers were synchronized using the 14 d controlled internal drug release-PG + heat detection + timed AI protocol. Traits collected were: BW at d 0, 28, 56, and 84; total gain; ADG; response to synchronization protocols; and ultrasound pregnancy rate. During yr 2, weekly blood serum samples were collected via jugular venipuncture for determination of serum progesterone concentration. Age at puberty was defined as heifer age in days on date of second consecutive progesterone values > 1 ng/mL. Growth performance measures were analyzed as a completely randomized block design (block = year of study) and age at puberty was analyzed as a completely randomized design. No difference ($P > 0.05$) was detected between the control and treatment groups for heifer BW on d 28 (325.97 ± 8.88 vs. 324.86 ± 8.88 kg), d 56 (341.54 ± 8.57 vs. 341.84 ± 8.57 kg), d 84 (361.42 ± 8.21 vs. 360.38 ± 8.21 kg), and ADG (0.14 ± 0.01 vs. 0.14 ± 0.01 kg). Age of puberty did not differ ($P > 0.05$) between treatment groups. Results indicate that heifers supplemented with brewer's grain showed no deviation in development compared with heifers fed the control ration. Cumulative results suggest that WBG could be used as part of a heifer development ration to help offset costs associated with diet ingredients; however, economic analyses of ration and development costs need to be investigated further.

Key Words: heifer development, growth, supplementation

0022 Growth performance and feed efficiency of commercial and half-blood lowline-angus steers in backgrounding and finishing phases.

G. E. Woodmansee*, S. P. Doyle, J. M. Wisniewski, D. A. Daley, and K. L. DeAtley, *California State University, Chico.*

Objectives of this study were to measure growth performance and feed efficiency of commercial ($n = 20$) and half-blood Lowline-Angus ($n = 20$) steers during the backgrounding and finishing growth phases. A total of 40, spring-born steers were delivered to the CSU, Chico cattle feeding facility 30 d postweaning and randomly assigned to three 7 × 18 m pens equipped with GrowSafe feed intake system for a 28 d adaption period. Commercial ($n = 20$) and half-blood Lowline-Angus ($n = 20$) steers were fed a forage-based backgrounding ration (CP, 15.6%; TDN, 56.22%; NDF, 52%, DM basis) for 58 d and allowed ad libitum access to feed and water. Cattle were transitioned to the finishing ration (CP, 11.9%; TDN, 72.58%; NDF, 20.21%, DM basis) over a 16 d period. Finishing phase trial was 72 d and weights were taken on d 0, 1, 35, 71, and 72. Data were analyzed as a randomized block design (block = pen). Breed × pen effect was not significant ($P > 0.05$). In the backgrounding phase, dry matter intake tended ($P = 0.06$) to be greater for commercial steers (DMI; 9.16 ± 0.36 kg) compared with half-blood Lowline-Angus (DMI; 8.17 ± 0.36 kg) steers. ADG, metabolic mid-weight, residual feed intake and feed conversion ratio were not different ($P > 0.05$) between breed groups in the backgrounding phase. In the finishing phase, commercial and half-blood Lowline-Angus steers had different ($P < 0.05$) ADG (1.82 ± 0.05 kg vs. 1.53 ± 0.05 kg), metabolic mid-weight (MMWT; 72.30 ± 1.18 kg vs. 68.16 ± 1.18 kg), DMI (10.12 ± 0.20 kg vs. 8.65 ± 0.20 kg), residual feed intake (RFI; 0.24 ± 0.13 kg vs. –0.22 ± 0.13 kg) and end weight (464.41 ± 9.28 kg vs. 423.16 ± 9.25 kg). Results indicate that backgrounding phase performance may not be an accurate predictor for finishing phase performance. Lack of significance in the backgrounding phase between breed groups may be a function of half-blood steers being F1 generation. Further research should be conducted to assess feed efficiency performance during the backgrounding phase in commercial and half-blood Lowline-Angus steers.

Key Words: GrowSafe, growth performance, steer

0023 Utilization of wet brewers grain as a winter feed supplement for beef cows grazing native annual grasslands. K. N. Bohn*[1], S. P. Doyle[1], J. Davy[2], D. K. Flavell[3], N. Schweitzer[3], K. L. DeAtley[1], *[1]California State University, Chico, [2]University of California, Cooperative Extension Service, Red Bluff, [3]University of California, Cooperative Extension Service, Browns Valley.*

Objectives of this study were to determine the effects of wet brewers grain (WBG) as a winter supplement on cow and calf performance while grazing native annual grasslands. The study was conducted at the Sierra Foothill Research and Extension Center (Browns Valley, CA) during 2014–2015 and 2015–2016 winter grazing seasons (i.e., November through January). A total of 92, fall-calving Angus × Hereford cows grazing native annual pastures (12.12 ha/pair for 84 d; 3.56% CP, 39.3% TDN, 75.3% NDF) were supplemented with either molasses low moisture protein block, available ad libitum (CON; n = 28; CP, 26%) or WBG (fed 3 times/wk; formulated to offer 0.68 kg CP head/d on DM basis; CP, 26%). Treatment groups were housed in adjacent pastures during the 84 d supplementation period and weights were taken in 28 d intervals. Dependent variables included: cow and calf BW and cow BCS. Data were analyzed as a randomized block design where block = year of study. Treatment × block interaction was not significant ($P > 0.05$). Calves were born before beginning of study each year and calf date of birth was fit as a covariate. Brewers grain supplemented cows were heavier on d 56 compared with CON cows (560.63 vs. 529.86 ± 13.99 kg; $P = 0.03$). Similarly, WBG calves were also heavier on d 56 compared with CON calves (117.97 vs. 110.06 ± 3.72 kg; $P = 0.03$). Calves born to WBG supplemented cows tended ($P < 0.10$) to be heavier than those of CON supplemented cows on d 0 (57.96 vs. 58.81 ± 2.73 kg) and d 86 (141.64 vs. 152.03 ± 3.74 kg). Results indicate that cows and calves supplemented with WBG recovered weight more quickly than those consuming liquid protein supplement. Therefore, WBG may have considerable potential as a winter protein supplement on California grasslands; however, economic analyses need further investigation.

Key Words: annual grasslands, feed supplementation, wet brewers grain

0024 Derivation of economic values for feedlot performance traits in commercial and lowline-influenced angus steers. L. C. Huffaker*, K. L. DeAtley, J. N. Brimlow, and S. P. Doyle, *California State University, Chico.*

Feed costs and market volatility make identifying cattle biological types and performance traits with significant economic impact at the feedlot imperative. Thus, the objective of this study was to determine the economic values of feedlot performance traits in commercial Angus (n = 20), half-blood Lowline-influenced Angus (n = 20), and full-blood Lowline Angus (n = 8) steers. Steers were fed for 72-d after a 28-d adjustment period at the CSU, Chico Agricultural Teaching and Research Center's beef cattle feeding facility. Upon delivery, steers were randomly assigned to three, 7 × 18 m pens, each fitted with two GrowSafe feed nodes and allowed ad libitum access to water and finishing ration (CP = 11.9%, TDN = 72.58%, NDF = 20.20%). After the 72-d GrowSafe trial, steers continued in their assigned GrowSafe pens until slaughter. Feedlot performance traits with significant economic impact were identified using stepwise, multiple-trait linear regression of net revenue onto residual feed intake (RFI), ADG, DMI, slaughter weight, and dummy variables representing breed type. Net revenue was defined as gross revenue minus feed costs. Gross revenue for each steer was determined by multiplying each animal's slaughter weight by market price at the time of sale ($3.26/kg). Costs included yardage ($.50/hd/d), billed daily feed consumption, and average feeder price ($3.68/kg) multiplied by delivery weight. Average net revenue (±SD, USD) for the commercial Angus, half-blood Lowline-influenced and full-blood Lowline Angus steers were $10.13 ± 86.97, $–44.30 ± 69.98, and $–105.05 ± 86.97, respectively. Multiple linear regression results identified slaughter weight, DMI, and ADG as significant predictors of feedlot net revenue ($R^2 = 0.41$; $P < 0.05$). Coefficients representing economic values for slaughter weight, DMI and ADG were $0.66, $–32.92, and $71.30, respectively. Results suggest that slaughter weight, DMI, and ADG are key predictors of feedlot net revenue, and deserve consideration in the development of breeding objectives with the goal of improving feedlot profitability.

Key Words: economic values, feedlot cattle, performance

ASAS WESTERN SECTION YOUNG SCHOLARS

0025 Effects of organic or inorganic Co, Cu, Mn, and Zn supplementation to late-gestating beef cows on productive and physiological responses of the offspring. R. Marques*[1], R. F. Cooke[1], M. C. Rodrigues[1], B. I. Cappellozza[1], R. R. Mills[2], C. K. Larson[3], P. Moriel[4], and D. W. Bohnert[1], *[1]Oregon State University–EOARC Burns, Burns, [2]Oregon State University Extension Service, Pendleton, [3]Zinpro Corporation, Eden Prairie, MN, [4]UF/IFAS Range Cattle Research and Education Center, Ona, FL.*

Eighty-four multiparous, nonlactating, pregnant Angus × Hereford cows were ranked by pregnancy type (AI = 56, natural service = 28), BW, and BCS, and allocated to 21 drylot

pens at the end of their second trimester of gestation (d 0). Pens were assigned to receive forage-based diets containing: (1) sulfate sources of Cu, Co, Mn, and Zn (INR), (2) an organic complexed source of Cu, Mn, Co, and Zn (AAC; Availa®4; Zinpro Corporation, Eden Prairie, MN), or (3) no supplemental Cu, Co, Mn, and Zn (CON). Diets were offered from d 0 until calving, and formulated to meet requirements for energy, protein, macrominerals, Se, I, and vitamins. The INR and AAC diets provided the same daily amount of Cu, Co, Mn, and Zn. Cow BW and BCS were recorded, and liver samples were collected on d –10 and 2 wk (d 75) before the calving season. Within 3 h after calving, calf BW was recorded, liver samples were collected, and the expelled placenta was retrieved (n = 47 placentas). Calves were weaned on d 283 of the experiment, preconditioned for 45 d (d 283 to 328), transferred to a growing lot on d 328, and moved to a finishing lot on d 440 where they remained until slaughter. Liver Co, Cu, and Zn concentrations on d 75 were greater ($P \leq 0.05$) for INR and AAC compared with CON cows, whereas INR had reduced ($P = 0.04$) liver Co but greater ($P = 0.03$) liver Cu compared with AAC cows. In placental cotyledons, Co concentrations were greater ($P \leq 0.05$) in AAC and INR compared with CON cows, whereas Cu concentrations were only increased ($P = 0.05$) in AAC compared with CON cows. Calves from INR and AAC had greater ($P < 0.01$) liver Co concentrations at birth compared with calves from CON cows. Liver Cu and Zn concentrations at birth were greater ($P \leq 0.05$) in calves from AAC compared with cohorts from CON cows. Weaning BW was greater ($P \leq 0.05$) in calves from AAC compared with cohorts from CON cows, and this difference was maintained until slaughter. In the growing lot, calves from AAC cows had reduced ($P < 0.01$) incidence of bovine respiratory disease compared with CON and INR cohorts. Collectively, these results suggest that feeding the AAC diet to late-gestating beef cows stimulated programming effects on postnatal offspring growth and health compared with the CON diet. Therefore, supplementing late-gestating beef cows with an organic complexed source of Co, Cu, Zn, and Mn instead of no supplementation appears to optimize offspring productivity in beef production systems.

Key Words: trace mineral, beef cow, supplementation

0026 Altered rumen microbial populations in response to high sulfate water in lambs.

A. N. Abrams*[1], C. J. Clarkson[1], K. J. Austin[1], M. Ellison[1], H. C. Cunningham[1], G. C. Conant[2], W. R. Lamberson[2], T. M. Taxis[2], and K. M. Cammack[1], [1]*Department of Animal Science, University of Wyoming, Laramie,* [2] *University of Missouri, Columbia.*

Water is involved directly or indirectly in essentially every bodily process. Therefore, access to quality water sources is critical for livestock wellbeing. In the western United States, however, high sulfate (SO_4^{2-}) water sources are frequently encountered. High SO_4^{2-} water can cause overproduction of ruminal H_2S and result in compromised health and performance of the host. An initial trial (Trial 1) was conducted to determine the impact of high SO_4^{2-} drinking water on the rumen microbiome of growing lambs. A follow-up trial (Trial 2) then sought to confirm rumen microbial species involved in the response to high SO_4^{2-} drinking water and additionally identify species that adapt to SO_4^{2-} challenges. Each trial consisted of individually penned Hampshire-cross lambs (n = 43 in Trial 1; n = 16 in Trial 2) which had access to ad libitum feed and high SO_4^{2-} water (3000 mg SO_4^{2-}/L) for a 28 d period. Trial 2 also included a 7 d posttreatment period to obtain recovery data for later analysis. DNA was extracted and sequenced from d 0, 7, and 28 rumen samples and then compared with known 16S rDNA reads for microbial identification. Operational taxonomic units (OTU) were defined as sequence clusters with ≥97% identity and analyzed for the fixed effect of sampling day using the GENMOD procedure of SAS. Trial 1 resulted in a total of 145 OTU found in at least one of the 24 sequenced samples (eight lambs; three sampling dates); eight OTU were affected ($P \leq 0.05$) by sampling day. Trial 2 resulted in 287 OTU identified in at least one of the 24 sequenced samples (eight lambs; three sampling dates), with sampling day affecting ($P \leq 0.05$) 38 of those OTU. Collectively, these results indicate a shift in rumen microbe relative abundance in response to high SO_4^{2-} water. Abundance variation may confer differences in host animal ability to tolerate and adapt to high SO_4^{2-} water. Similarities in microbial abundance changes across the two trials suggest that particular species are especially reactive to high ruminal SO_4^{2-} and are likely important to host response. Furthermore, certain microbial species demonstrated greater potential to adapt over time to a high SO_4^{2-} environment. Greater understanding of the rumen microbes involved in the response to high SO_4^{2-} drinking water is necessary for development of effective treatment and prevention strategies for ruminant livestock maintained in high SO_4^{2-} water regions.

Key Words: DNA sequencing, microbes, rumen, sheep, sulfate

0027 Immunological implications of pregnancy: A focus on inflammatory cytokines.

S. Z. Prosser*, K. E. Quinn, and R. L. Ashley, *New Mexico State University, Las Cruces.*

The present studies aim to (1) determine expression of (C-X-C motif) Ligand 12 (CXCL12), CXCR4, and inflammatory cytokines in corpus luteum (CL) and fetal-maternal interface during early pregnancy and when CXCR4 signaling is inhibited in ewes, and (2) determine alterations in CL cytokine expression using an in vivo model with hCG-stimulated P4 levels. Several human studies highlight CXCL12-CXCR4 signaling in regulating cytokine production, but whether similar mechanisms occur in livestock is uncertain. Our laboratory

reported activation of CXCL12-CXCR4 signaling axis at the fetal-maternal interface in sheep but whether this axis is involved in modifying reproductive tissue or peripheral blood inflammatory responses is uncertain. We hypothesized CXCL12-CXCR4 signaling acts as a potentiator during early pregnancy in ewes by altering cytokine populations at the fetal-maternal interface and the luteal microenvironment. To test this hypothesis, CL tissue was collected from NP (d 10 of estrous cycle) and pregnant ewes on d 20 and 25. In a separate study, we utilized AMD3100, a potent CXCR4 antagonist, to disrupt CXCR4 signaling to determine inhibition effects on fetal-maternal cytokines. Mini-osmotic pumps were surgically installed on d 12 of gestation and delivered AMD3100 or PBS into the uterine lumen ipsilateral to CL for 7 d. Endometrium (caruncular and intercaruncular) and fetal membrane tissues were collected on d 23 of gestation. Gene expression of inflammatory cytokines were investigated using real time PCR. During gestation, proinflammatory cytokines increased ($P < 0.05$) in CL from pregnant compared with NP ewes. Similarly, CXCL12 and CXCR4 increased ($P < 0.05$) on d 20 of gestation in pregnant compared with NP ewes. Under hCG stimulation, interferon γ (IFNG) decreased ($P < 0.01$) on d 25 in CL tissue compared with control ewes. In AMD3100-treated ewes, transcripts for tumor necrosis factor (TNF; $P < 0.05$) and interleukin 12 (IL12A; $P < 0.01$) increased in caruncle, while transforming growth factor β 1 (TGFB1) and IL12A tended ($P = 0.2$) to increase in intercaruncular endometrium compared with control. Interleukin 10 (IL10) transcript from treated ewe fetal membrane tended ($P = 0.1$) to increase compared with control. Using immunofluorescence, IL10 protein was localized to uterine luminal and glandular epithelium, and TNF to uterine glandular epithelium and stroma. Using flow cytometry, we established peripheral blood T lymphocytes are CXCR4-positive. Our results highlight the role CXCL12-CXCR4 signaling may play in regulating localized inflammation at the fetal-maternal interface and immune cell trafficking in peripheral blood, contributing to pregnancy maintenance.

Key Words: chemokine receptor 4, cytokines, inflammation

MEETING TODAY'S ANIMAL CARE STANDARDS: ARE YOU READY?

0028 New *Ag Guide*—What should we expect?

A. B. Webster*, *Department of Poultry Science, The University of Georgia, Athens.*

The first edition of the *Ag Guide* was published in 1988 to define standards of care for agricultural animals used in agricultural research and teaching. These standards were to accomplish two important objectives. One was to ensure that the agricultural animals used for research and teaching are fit subjects so as not to compromise outcomes by having poor condition. The other objective was to give regard to and preserve the wellbeing of these animals based on our growing recognition that they, by their nature, ought to be in the realm of human moral concern. The second edition of the *Ag Guide* came out in 1999, with an expanded authorship and chapters devoted to specific types of agricultural animals. The current third edition (2010) has 62 authors and additional chapters covering institutional policies and principles related to health care, husbandry, environmental enrichment, and handling and transport. The title of the third edition was changed to *Guide for the Care and Use of Agricultural Animals in Research and Teaching*, on the principle that the standards therein are applicable to agricultural animals in all research and teaching situations, not just those seen as strictly agricultural. The *Ag Guide* has become the reference document for agricultural animals by IACUC's nationwide, and has been adopted by AAALAC as a primary standard to evaluate animal care and use programs. At the last meeting of the FASS Scientific Advisory Committee on Animal Care (SACAC) in May 2015, it was decided to revise the *Ag Guide* to produce a fourth edition. Items were identified for each chapter and a tentative timeline was developed. The sale of ASAS and PSA interests in FASS to ADSA in 2015 provided for transfer of ownership of the *Ag Guide* to ADSA, ASAS, and PSA and dissolved the SACAC, temporarily suspending action on the *Ag Guide*. As of the writing of this abstract, the revision process has been initiated, but a determinable timeline for publication has not been established. The three societies recognize the vital importance of an up-to-date *Ag Guide* and intend to jointly publish a revised fourth edition.

Key Words: *Ag Guide*

0029 How ag research and teaching differs from "rodent" studies in AAALAC international accreditation.

J. J. McGlone*, *Texas Tech University, Lubbock.*

Ethical care of farm animals is required for conduct of farm animal research and teaching, journal article submission, and production on commercial farms. The highest standard of animal care is provided when an agricultural research and teaching institution becomes accredited by AAALAC International. Some people in animal agriculture are leery of AAALAC accreditation because they have experienced laboratory animal ethics applied to farm animal research and teaching. Here I argue that the fundamental ethical principles underlying farm animal care are often different than those that underpin laboratory animal care. The laboratory animal community lean heavily on the 3 R's (reduce, replace, and refine). I argue that these are not appropriate for farm animals as they are for laboratory animals. Agricultural research doesn't reduce the sample size, it optimizes the sample size. Agricultural animal researchers don't often replace animal models with a "lower" model species (say using a mouse rather than a chimp for a

human disease), they use the actual target species (say using a pig for pig research). Sample size is often optimized, not set at the lowest numbers possible. Field studies may use the building or barn as the experimental unit which greatly increases numbers of animals in an appropriate manner. Retailers and consumers may set ethical requirements on the entire market or niche markets that require certain production practices. Finally, animals used in teaching have entirely different ethical standards depending on if the learning is meant to be a demonstration or if the student is expected to be proficient at an animal procedure. In addition to budgetary pressures for university farms, animal science programs must determine if they can justify model animal farms for teaching purposes. In conclusion, laboratory animal ethical principles are different in some ways than the standards for agricultural animals used in farm animal research or teaching. Using laboratory animal standards like the 3 R's may not help and may harm farm animal welfare. AAALAC International utilizes the *Ag Guide* as its guiding document for farm animals in teaching and research. As long as overseeing bodies use the appropriate ethical framework, farm animal care will be protected in both farm animal research and teaching.

Key Words: animal care, accreditation, ethics

0030 Getting along with your IACUC and helping them understand agricultural species research.
J. Salak-Johnson*, *University of Illinois, Urbana.*

The Institutional Animal Care and Use Committee (IACUC) is responsible for ensuring the humane use and care of farm animals in research and teaching at Universities. Despite, the challenges IACUCs face in oversight of farm animals used in research in terms of the diverse animal facilities or farm or production settings, this does not change the acceptable guidelines for ensuring animal farm well-being. Farm animal care and use in research and teaching requires the same science-based practices that are outlined and supported by the *Guide for Care and Use of Agricultural Animals in Research and Teaching* (*Ag Guide*, 2010). It is necessary for IACUCs to have expertise on their committees that understand how to best apply these standards specifically to species in question in a particular setting. An IACUC that is adequately informed to consider species-specific issues within the context of the specific research being conducted can better ensure proper animal care while maximizing farm animal welfare. But, this can only be achieved if an IACUC has explicit knowledge of each species for which it has oversight which can be accomplish only if there is knowledgeable representation on the committee. The past few years, IACUCs have been faced with challenges from the public and other committee members that lack knowledge and understanding of the importance of the *Ag Guide* and animal unit specific standard operating procedures (SOPs) for farm animals. The objective is to give an overview of the importance of a good working relationship between IACUCs and animal scientists to ensure successful research programs that use agricultural species in research and teaching by emphasizing importance of *Ag Guide*, development of species-specific SOPs derived from science-based data and approved by IACUC, and when issues need to be addressed that a subcommittee of experts are part of the decision making process. Animal scientists and IACUCs must work together to ensure the best care for farm animals used in research and teaching at their respective universities.

Key Words: animal care, research, welfare

0031 Applying AAALAC international's peer review program to support agricultural research programs.
J. Bradfield*, *AAALAC International, Frederick, MD.*

Agricultural animal research is arguably more important today than ever before. The challenge of providing food for the world's population in a sustainable, ethical manner is no small task. Public awareness regarding animal production is increasingly focused on humane treatment and methods, while at the same time there is a significant lack of understanding about production animals, their needs, and the best practices to rear and care for them. Institutions that engage in animal research and production must ensure that high standards of animal care and use are used both to meet expectations of society and to be ethical stewards of the animals with which we work. AAALAC International provides a third party, peer review of all facets of the animal care and use program that has proven to be an effective mechanism to ensure institutions meet the standards of the *Ag Guide*, undergo continuous improvement, and demonstrate institutional commitment to high standards of animal care and use. Data from 671 AAALAC site visits highlight the common challenges faced by animal care and use programs and provide information to aid those engaged in research animal program management. Findings data in each of the six main areas of the animal program will be provided: institutional commitment and resources, personnel expertise and training, husbandry and veterinary care, occupational health and safety, facilities, and effective oversight by the institutional animal care and use committee. An AAALAC review by peers who are experienced in agricultural animal research is collegial, confidential, and outcome-based. It is designed to help identify strengths and weaknesses of the program, with the aim of ensuring high quality scientific outcomes and a high level of animal welfare.

Key Words: AAALAC, review, welfare

0032 AAALAC international agricultural animal research program accreditation at Purdue University: "The good, the bad, and the ugly." J. S. Radcliffe*, *Purdue University, West Lafayette, IN.*

Admittedly, most production animal researchers at Purdue where scared when Purdue decided to move forward with AAALAC International Agricultural Animal Research Program accreditation. Two main concerns dominated: (1) How would AAALAC deal with the unique issues of animals in a production setting versus a laboratory setting? And (2) Would AAALAC accreditation interfere with our research? Particular emphasis was placed on cost of accreditation in terms of making or keeping programs compliant, facility maintenance, enhanced workload on researchers, and the possibility of excessive or "unnecessary" oversight. As we navigated through the accreditation process, we found that expense was manageable and, that if the program was well run, already it easily fit within the AAALAC guidelines and, if improvements were needed, it helped to have the need for accreditation as the reason to force the necessary improvements. We also found that AAALAC itself was willing to have open discussions about issues specific to production animal research and work with Purdue to create solutions to any issues. Today, AAALAC accreditation and maintenance of our accreditation status allows Purdue to promote and advertise our high standards for research and animal care across all species, demonstrate our commitment to public accountability, lobby the university for continuous improvement, and market our accreditation to federal and industry funding sources.

Key Words: AAALAC accreditation, Purdue, welfare

ADSA PRODUCTION DIVISION SYMPOSIUM: ROBOTIC DAIRYING: ADAPTING FARM AND BUSINESS MANAGEMENT

0033 Changes in dairy farm management strategies with the adoption of robotic milking. J. Rodenburg*, *DairyLogix, Woodstock, ON, Canada.*

Adoption of robotic milking on dairies of up to 250 cows is improving the lifestyle of dairy families, and it is an effective way to reduce labor in herds of all sizes. Since milking is voluntary, and feed delivered during milking is the main enticer for attendance, feeding strategies that offer palatable pelleted concentrate in the milking stations, combined with low starch mixed feeds or forage at the feed fence, improve milking frequency and production. Barn layouts that encourage low-stress access by providing adequate open space near the milking stations and escape routes for waiting cows also improve milking frequency and reduce the number of cows requiring fetching. Lame cows present themselves less often for milking and produce less milk. Preventing lameness with comfortable stalls, clean alley floors, and effective foot bathing and treatment protocols is given greater emphasis on robotic dairies. Variable milking times create challenges for foot bathing, sorting and handling, and dealing with special-needs cows. These challenges must be addressed with appropriate cow routing and separation options at the milking stations, if the expected labor savings are to be realized. With less work, all protocols and the layout and gating of the barn should make it possible to complete handling tasks alone. Unattended milking demands reliance on sensors to monitor health and performance; but this, along with computer control of milking intervals and feeding levels, creates new opportunities to manage cows individually. Much of the potential to improve the productivity, health, and longevity of dairy cows, and to decrease feed costs through combining the use of sensor data with individual feeding and milking, is as yet unrealized. Free traffic and guided traffic systems have been adopted, and results are similar when excellent management is applied. In less-ideal circumstances, guided traffic and the use of commitment pens results in long standing times and stress, particularly for lower-ranking cows, while poor management with free traffic results in more labor for fetching nonattending cows. Robotic dairies require a smaller labor force than conventional dairies, but function best with skilled workers than can perform a variety of tasks.

Key Words: automatic milking, robotic milking

0034 Opportunities and challenges for herd health and reproduction with robotic milking. S. J. LeBlanc*, *Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

There has been a rapid increase in the number of herds with automatic milking systems (AMS). This technology is a well-established means to harvest milk from cows. Robotic milking offers potential advantages in labor per cow, increased milking frequency, and integration of sensors and data collection that assist with estrus detection, and might help with detection of health problems or lameness. Activity monitoring (AM) systems (in AMS or parlor-milked freestall barns) have been shown to produce, on average, comparable herd pregnancy rates to alternative approaches to reproductive management. However, AM requires supplemental interventions for timely AI for approximately 20% of inseminations. AMS provide streams of a variety of data on activity, milking frequency and timing, quarter-level milk yield, and conductivity, and the daily cow-level variation in these metrics. The systematic collection of these data offers the promise of detection of some health problems earlier and with less variation. However, selection of valid, actionable indicators of health from

AMS data remains a work in progress, and a balancing act of adequate detection and false alerts. As with conventional systems, the associations of AMS with cow health, welfare, and performance are confounded by their human managers. There is little data on measures of health with AMS. More research is needed on the predictive value of indicators of mastitis from AMS. Research on approaches to and outcomes of treatment of mastitis with AMS-based detection is lacking. Reports indicate a similar prevalence of lameness to non-AMS freestall barns, with similar stall- and bedding-related factors associated with lameness, injuries, and lying time. Processing of multiple data inputs, mostly related to cow activity and milking performance, has been shown to have reasonable accuracy for detection of lameness, which if successfully implemented, would likely be earlier and more thorough. Preliminary data indicate a higher prevalence of ketosis in herds with AMS. Feeding behavior is generally driven by feed delivery as in non-AMS barns, such that feeding space requirements are similar. Timely detection of metabolic disease such as ketosis may be aided but not replaced by AMS-derived data, and detection of reproductive disease still requires daily observation of the cows by skilled people; pen design and cow handling equipment are needed to facilitate interactions with the cows.

Key Words: health, disease detection, precision technology

0035 Nutritional approaches in robotic herds.

A. Bach[*1,2], M. Vidal[2], and V. Cabrera[3], *[1]ICREA, Barcelona, Spain, [2]IRTA, Caldes de Montbui, Spain, [3]University of Wisconsin-Madison, Madison.*

Cows in herds equipped with conventional milking parlor systems follow a structured, consistent, and social milking and feeding routine. Furthermore, in most cases, cows in these systems receive all their nutrients from a TMR, whereas in herds equipped with robotic or automatic milking systems (AMS), cows receive a fraction of their nutrients during milking, mainly as a means to attract them to the milking system. In this regards, the AMS presents both a challenge and an opportunity for feeding cows. The main challenge resides in maintaining a minimum and relatively constant milking frequency in AMS. Hover, milking frequency is dependent on many factors, including the social structure of the herd, the farm layout design, the type of traffic imposed to cows, the type of flooring, the health status of the cow (especially lameness, but also mastitis, metritis, etc.), the stage of lactation, the parity, and the type of ration fed at the feed bunk and the concentrate offered in the AMS. Uneven milk frequency has been associated with milk losses and increased risk of mastitis, but most importantly, with a lost opportunity for milking the cow. On the other hand, the opportunity from AMS resides in the possibility of milking more frequently, and feeding cows more precisely or closely to their nutrient needs (in an individual basis), potentially resulting in a more profitable production system. However, feeding cows in the parlor or AMS has many challenges by itself. On one side, feeding starchy, high-palatable ingredients, may upset rumen fermentation or alter feeding behavior after milking, and feeding high-fiber concentrates may compromise total energy intake and ultimately milking performance. Nevertheless, AMS (and some milking parlors, especially rotary ones) offer the possibility of feeding the cows to their estimated individual nutrient needs with the aim of maximizing profits (rather than milk yield). This approach requires that not only the amount of feed offered, but also the composition of the feed for each individual cow need to change according to the nutrient needs. The change in composition can be achieved by combining several feed ingredients or concentrates on real-time as the cow enter the AMS (or the milking parlor). This review discusses the opportunities and pitfalls of milking and feeding cows in an AMS and summarizes different feeding strategies to maximize profits by managing the nutrition of the cows individually.

Key Words: modeling, precision feeding, optimization

0036 Finances and returns for robotic dairies.

J. A. Salfer[*1], M. I. Endres[2], W. Lazarus[2], and K. Minegishi[2], *[1]University of Minnesota, St. Cloud, [2]University of Minnesota, St. Paul.*

Automatic or robotic milking systems (AMS) are being adopted by dairy producers at a relatively fast rate. Previous studies of the economic returns of AMS compared with parlor milking systems (PMS) are scarce and offer mixed results mostly because of the assumptions used by the researchers. The key parameters that affected these results pertained to the costs and economic life of AMS, and the prospect of the AMS to increase milk production and decrease labor. Another key factor affecting profitability of AMS is milk production per AMS milking unit. Increasing average milk flow rate and reducing milking preparation time, along with increasing the percentage of milking box occupation time, has been shown to increase milk production per AMS unit. The nonfinancial lifestyle improvement factor is another consideration that influences the decision to install an AMS. We developed a simulation model to compare the economics of alternative milking systems under current Minnesota conditions. As an example, for a 120-cow operation currently switch milking in a tiestall barn, the most profitable alternative is to build a new freestall barn and install a retrofit PMS (double 8) in the old building. A new PMS is slightly less profitable because of the higher cost of investment. Another factor affecting profitability in our model is how much money is spent on the freestall barn. Many AMS freestall barns constructed in cold climates are warm barns and have expensive manure handling systems (slatted floors or automatic scrapers). An AMS is less profitable than a PMS under those circumstances, if milking and chore labor is valued at $15/h. It would require a labor rate of around $50/hour to make the AMS and PMS equally profitable. Including inflation in labor rate also increases the

profitability of AMS systems compared with PMS because of the labor saved. If the barn is equipped more like a typical parlor operation, an AMS may be similar to a PMS in profitability. Those results assume a labor reduction and a milk production increase with the AMS compared with the PMS. Surveys have shown that most farmers are happy with the decision to install AMS. Much of the satisfaction is not based on economic returns, but on improved lifestyle. Maximizing milk per robot by optimizing cow numbers and milking speed, along with improved labor efficiency and increased milk production per cow, will maximize dairy farm returns.

Key Words: automatic milking systems, profitability

ADSA-SAD (STUDENT AFFILIATE DIVISION) UNDERGRADUATE STUDENT ORAL COMPETITION: DAIRY FOODS

0037 Milk is milk, isn't it? J. M. Madigan* and S. P. Washburn, *North Carolina State University, Raleigh.*

This paper examines the differences in beverages from almonds or soybeans compared with milk from cows. There are some people that argue plant-based beverages hold the same nutritional aspects as milk and are overall better for the consumer. Through examination of multiple research papers on cow-based milk and plant-based "milk" products, discussion and analysis of potential benefits and limitations of each product is examined. One key point of analysis is that soymilk was shown to reduce cholesterol (Meyer et al., 2004), but in another study showed no effect even with increased isoflavone in samples taken (Onuegbu et al., 2011). Almond milk seemed to cause hyperoxaluria and genitourinary disorders in children due to richness in oxalate, though showed to be a good option for lactose intolerant individuals (Ellis and Lieb, 2015). Though almond based beverages can be an alternative for lactose intolerant people, NC State University's Department of Food, Bioprocessing, and Nutrition discovered that the use of *Lactobacillus acidophilus* bacteria can help make milk acceptable to lactose intolerant individuals (Sanders and Klaenhammer, 2001). A study also showed that people who consumed cow milk more than once a day had a lower likelihood to have type 2 diabetes (Morcillo et al., 2012). A key nutrient, protein, was shown to be lacking in almond milk, which has less than 1 g per cup vs. 2% milk with 8 g per cup (USDA). Milk is also a better source for essential fatty acids than either soymilk or almond milk (USDA, nutritiondata.self.com). From the data collected over multiple studies and databases, a conclusion is reached that, though plant based "milk" products such as beverages made from almonds and soybeans have some nutritional promise, they have a difficult time replacing milk from a cow.

0038 Health benefits of *Lactobacillus helveticus* in dairy foods. C. Kenny*, *Louisiana State University, Baton Rouge.*

Lactic acid bacteria (LAB) are often used as a starter culture in the production of cheeses. These LAB produce biopeptides by breaking down proteins in milk that have positive effects on the functions of the body. One specific LAB, *Lactobacillus helveticus,* which is used in the production of many Italian cheeses such as Swiss, Provolone, Mozzarella, and Parmesan, has many extremely valuable health benefits. *Lactobacillus helveticus* is able to survive after being eaten, and adheres to epithelial cells in the gastrointestinal tract. Because of this, *L. helveticus* can stimulate the digestive tract and reduce lactose intolerance, and inhibit the absorption of some pathogens while also increasing the absorption of certain nutrients. However, the two most valuable benefits of *L. helveticus* are its nontumorogenic and nonhypertensive properties. *Lactobacillus helveticus* has been shown in research studies to inhibit the growth of colon cancer cells and breast cancer cells in vivo. Because of these studies, *L. helveticus* is being considered to be a potential anticancer treatment. Further, *L. helveticus* is an angiotensin converting enzyme (ACE) Inhibitor, meaning that it prevents the release of Angiotensin II, which constricts blood vessels. This keeps blood vessels and the heart healthy, which prevents high blood pressure. From all angles of human health, *L. helveticus* has many benefits when consumed.

Key Words: lactic acid bacteria, cheese, health benefits

0039 A2 milk marketing and human health. J. Nystrom* and D. R. Winston, *Virginia Tech, Blacksburg.*

Although butter and cheese sales have been increasing over recent years, fluid milk sales have been declining in the United States since 1970. With declines in per capita milk consumption, and changes in the export market, the dairy industry has to be creative in developing products to increase milk sales. Recent products like Fairlife® ultra-filtered milk is an example of an innovative fluid milk product that demonstrates adaptability of the dairy industry to consumer preferences. In the U.K., Australia, New Zealand, and recently, California, A2 milk has been introduced as a functional dairy food. A2 milk contains a homozygous A2 β-casein protein, whereas conventional milk contains a heterozygous combination of A1 and A2 β-casein proteins. While A2 milk has been available in U.K. since 2012 and previously in New Zealand and Australia, it has just recently made its way to the U.S. markets. Research on digestibility of A2 milk is ongoing; however, the A2 Milk Company is a processor that only sells 100% A2 milk in New Zealand and also exports to the U.K., China, the United States, and Australia. In the first human trial of A2 versus A1 milk digestion, conducted by Ho et al., A2 and A1 milk was significantly higher in digestibility than A1 milk. Almost all cows have the A2 gene, but the majority have an A1/A2 combination. The

Guernsey breed naturally produces a higher percentage of A2 milk, which may create a new niche market and therefore increase demand for Guernseys nationwide. In conclusion, A2 β-casein milk is a new way to use genetics to create a niche market, potentially increasing sales of fluid milk nationwide.

Key Words: A2 milk

0040 Ultrasonic separation of milk to select for fat globule size distribution. S. P. Itle* and D. R. Olver, *Pennsylvania State University, University Park.*

The size of fat globules is important in manufacturing dairy products such as cheese and butter. Smaller fat globules result in a smooth texture and mouthfeel in cheese, while butter production better utilizes larger globule sizes. Although the cream separator is most commonly used in dairy processing operations to separate cream from milk, centrifugal technology is not commonly used for selecting for a specific fat globule size distribution. This is due to the complexity and nearly-perfect timing needed to control g-forces. Some artisan cheese producers have opted to utilize gravity separation to isolate smaller fat globules, but this process can take many hours while imposing a food safety risk. A new technology, ultrasonic separation, promises faster separation of fat globule fractions than gravity separation. This method utilizes sound waves that can rapidly separate the fat components of milk with a high specificity in globule sizes. In a recent Australian study, ultrasonic separation by dual transducers operating at 2 MHz achieved appreciable fractionation after 20 min and resulted in a 0.9 μm decrease in fat globule size.

0041 Gene therapy and the prevention of mastitis in dairy cattle. K. Boudreaux*, *Louisiana State University, Baton Rouge.*

Mastitis in dairy cattle is an inflammation of the mammary gland and surrounding udder tissue, often an immune response to a pathogen invading the teat canal. It can also be a result of chemical, mechanical, or thermal injury to the udder. Mastitis can present clinically or subclinically, so routine testing and examinations are done to prevent the spread of infection. This infection is most often treated with antibiotics, but during antibiotic treatment, the cow's milk is not able to consumed or sold, because it contains antibiotic residues. It is an ongoing epidemic in the dairy industry, and monetary losses are accrued from the milk that must be disposed of due to antibiotic usage, reduction in milk yields due to permanent damage to the udder as a result of infection, labor costs to tend to infected cows, veterinary and medicinal costs, and in extreme cases, premature culling costs. Studies are being conducted to show that gene therapy may be a possible solution to prevent mastitis. Research has been done in an attempt to transfect the udders of dairy cattle with cercropin B, a lytic peptide found in Cercropia moths, that has broad spectrum bactericidal properties. This technology has been applied to other species through different experimental procedures and has yielded favorable outcomes and a decrease in targeted infectious diseases. The research with dairy cattle has not yet yielded favorable results, but with some experimental modifications, could be proven effective in preventing mastitis. This practice, once perfected, could be incorporated in routine dairy farm procedures, such as vaccine administration, and could reduce or eliminate antibiotic treatment of mastitis and reduce the losses of milk unable to be sold because of residual antibiotic contamination.

Key Words: gene therapy, mastitis, dairy cattle

0042 The importance of mastitis management practices in maintaining milk quality in the United States. K. Bochantin* and J. M. Bewley, *University of Kentucky, Lexington.*

Dairy producers strive to achieve optimal milk quality in an effort to provide the highest quality product possible to consumers. Milk quality is highly influenced by management practices used on farms. Poor milk quality may lead to decreased cheese yield and reduced shelf life for all dairy products. Measurements of milk quality include somatic cell count (SCC), bulk tank bacterial counts, antibiotic residues, and nutrient values. Lowered milk quality in certain regions of the United States within the past few years has caused some concerns within the industry, leading to renewed efforts toward improving milk quality. Such changes are centered on key management practices, including mastitis treatment and prevention. Mastitis is one of the most prevalent and costly diseases within the dairy industry, impacting both cows' health and milk quality. Awareness of the disease and its economic impact can increase motivations for change. Prevention of mastitis is key to management of the disease. Management of the environment (including housing and routine procedures) and cleanliness of the parlor can reduce the spread of mastitis-causing pathogens and decrease the risk of contamination. Housing and bedding should be kept clean and dry. In-parlor milking procedures, which include pre- and post-teat dip with proper germicides, can help remove existing bacteria from the udder and lower the risk of mastitis. Heifers are also at risk for mastitis and infection can lead to reduced milk yield during lactation. Prevention strategies include proper management, nutrition, and attention to prepartum udder health. Dry cows have a higher risk of mastitis infections than lactating cows.

Prevention of mastitis for dry cows at drying off includes treating all quarters with antibiotic products designed specifically for dry cow therapy. Vaccinations are also available to prevent against certain strains of mastitis-causing bacteria. Detection and awareness of mastitis is important for proper, timely treatment. Treatment methods can vary based on the severity of the case and can influence milk yield, quality, and overall cow health and performance. Dairy Herd Information Association (DHIA) records can help with somatic cell count management. Culturing of milk to determine bacteriological causes of mastitis can be useful for designing pathogen-specific prevention and treatment strategies.

Key Words: mastitis management, milk quality, United States

0043 The impact of amount and quality of colostrum and subsequent transition milk on calf health and growth. J. Hardy*[1], K. M. Daniels[2], and D. R. Winston[1], [1]*Virginia Tech, Blacksburg,* [2]*Virginia Polytechnic Institute and State University, Blacksburg.*

In the United States, the current "gold standard" is to deliver colostrum to newborn calves at 10% of BW within the first 2 h of life. In practice, many farmers simply offer calves 1.89 L of colostrum within 12 h of birth. For a 43 kg calf, this is about 4.5% of the calf's weight—not even half of the recommended amount. Colostrum ingestion is critical for passive transfer of immunity in the form of immunoglobulins (Ig). Researchers in Ireland examined the effects of feeding different volumes of colostrum (7, 8.5, or 10% of BW within 2 h of birth) and subsequent feedings (0, 2, or 4) of transition milk on serum IgG and health status. Ninety-nine calves were enrolled. They found that calves fed 8.5% of BW within 2 h of birth achieved the highest levels of IgG transfer. Following the initial feeding of colostrum, offering transition milk to calves appears to have positive impacts on calf health. Calves fed two or four subsequent feedings of transition milk seemed to have a lower risk of getting assigned poor nasal and eye scores (Conneely et al., 2014). The researchers were right to focus on measurement of serum IgG concentration in their project calves, as serum IgG is a major indicator of calf health because calves are born agammaglobulinemic. Therefore, when calf Ig measurements are obtained after consumption of colostrum, they reflect Ig content of colostrum and absorptive ability of the calf's small intestine. Colostral Ig absorption is highest in the first 24h of life and declines sharply; this has to do with permeability of the calf's small intestine to large molecules such as Ig. This process is termed passive transfer of immunity and it is key in protecting the calf against pathogens that the dam was previously exposed to, before the calf's own immune system maturing and becoming more functional (Godden, 2008). In conclusion, if colostrum quality is sufficient and calves are managed properly, calves seem to excel at 8.5% of their body weight at birth and when offered a few feedings of transition milk will have improved health and be less prone to disease in the first three to 4 wk of life (Conneely et al., 2014). For a 43 kg Holstein calf, this equates to 3.66 L of colostrum.

Key Words: dairy calf, immunoglobulin

0044 A future for genomics in animal health through the Bovine Respiratory Disease Complex: Coordinated Agricultural Project. S. J. Thomsen* and J. F. Bohlen, *University of Georgia, Athens.*

Whether through animal welfare and antibiotic residual concerns from the public, or the Veterinary Feed Directive, antibiotic use in animal agriculture is increasingly scrutinized and restricted. As such, it is essential for the future of the dairy industry to consider options to reduce the prevalence of disease on farm with new technology while decreasing their dependence on antibiotics. The 5-yr Bovine Respiratory Disease Complex: Coordinated Agricultural Project (BRD:-CAP) funded by the USDA and formed with the help of several universities, scientists and agriculturalists is searching to find new methods of addressing Bovine Respiratory Disease (BRD). Once determining that BRD has moderate heritability at 0.21, the goal of the BRDC:CAP is to utilize new genetic technology and the bovine genome to determine genetic markers for the susceptibility and resistance of Bovine Respiratory Disease and consider the financial impact of BRD genetic selection. Despite increased knowledge regarding BRD and progress in vaccine and preventative technology, BRD continues to be a financial liability of over $692 million dollars to the industry and contributes to 46% of the deaths among weaned calves, while having long-term influences of animal performance and health for affected individuals. Understanding the science behind BRDC:CAP will provide a gateway to analyzing the practicality of such genetic research on the farm. This may provide for its inclusion as a single selection criterion or as part of an index, such as Net Merit, for a sire proof. With this genetic selection for reduction in BRD incidence rates, the average dairy producer could see reduction in financial costs from treatment, calf mortality, and the resulting implications poor heifer development will have on future lactation performance. Continued work is necessary to ascertain the reliability and usefulness of genomics with regards to infectious diseases such as BRD. Increased farm profitability may be realized with proven ability to practically apply this information to the dairy industry.

Key Words: genomics, bovine respiratory disease, farm profitability

0045 Breeding for strength may create frail cows.
A. N. Gabel* and C. D. Decho, *The Pennsylvania State University, University Park.*

The Purebred Dairy Cattle Association Dairy Cow Unified Scorecard assigns 25% of weight to the dairy strength category, which is described as "a combination of dairyness and strength that supports sustained production and longevity." Stronger cattle are assumed by many breeders to have longer herd-life, but data from several studies suggest otherwise. In a 2003 study, relative culling risks (RCR) were assigned based on strength scores (1 = weak to 50 = strong) from 268,008 Jersey cows. A score of 25 equated to a RCR of 1.00. RCR values below or above 1.00 indicated low or high culling risks, respectively. Scores from 11 to 20 were optimal, whereas cows with a score of 41 to 45 were at most risk of being culled (RCR = 1.30). A similar analysis was performed in a study of 891,524 Holstein cows (Caraviello et. al., 2003; 2004), and strength scores higher than 25 were associated with significantly elevated RCR. These two studies indicate that "stronger" cattle have greater culling risk, which may partially be attributed to unfavorable associations with disease. Genetic correlations of strength with displaced abomasum, ketosis, mastitis, and cystic ovaries indicated that selection for strength would elevate disease risks (Zwald et. al., 2004). A 2015 analysis (Dechow) compared chest width and body condition score (BCS) in Canadian Holstein genetic evaluations with the Canadian dairy strength trait and U.S. productive life (PL) and daughter pregnancy rate (DPR). In this study, 527 bulls with Canadian and U.S. daughters were divided into groups based on chest width and BCS. Sires that transmitted wide chests and low BCS had the highest dairy strength scores (+9.5), followed by wide chest and average BCS sires (+6.5). These groups had the lowest PL (–2.5 and –1.6 mo, respectively) and DPR (–2.75% and –1.6%, respectively). In contrast, sires that transmitted narrow chests and high BCS scored lowest for dairy strength (–5.5), highest for PL (+1.1 mo), and highest for DPR (+0.4%). Therefore, high scores for strength suggest decreased longevity and reproductive efficiency. This counterintuitive relationship of dairy strength with health and survival may result from poorly defined measures of strength in linear scoring programs; cows with extremely low BCS have minimal muscle mass but are still considered to have high dairy strength if they have a wide skeletal system. Dairy producers should take caution when breeding for strength.

Key Words: strength, longevity, genetics

0046 The links between uterine infection and infertility.
N. Walker*, *University of Florida, Gainesville.*

The objective of this presentation is to explain the impact that uterine infections have on female reproductive fertility and dairy production. Uterine infections such as metritis and endometritis are prevalent among Holsteins primarily after parturition. Anatomical barriers act as a natural defense against bacterial pathogens, but during parturition these barriers are compromised. While these infections can be treated, they pose lasting negative effects on fertility. *Escherichia coli* and *Trueperella pyogenes* are the most common pathogens that cause uterine infections. These pathogens initiate an inflammatory response in the endocrine signaling system, the endometrium, and the ovaries. The inflammatory responses in these organs, coupled with innate immunity, can overload the female reproductive tract and lead to infertility. It is not known why reproductive fertility is compromised even after the uterine infection is treated. Further research is needed to better understand the exact mechanisms that lead to infertility. When those mechanisms are discovered, there is a potential to intervene before fertility is compromised. There are also current developments for metritis vaccines to prevent uterine infections. Until further advancements are made in those areas, implementing good management practices such as nutrition and hygiene during partition are feasible solutions.

Key Words: cow, immunity, fertility, infection, uterus

0047 Comparison of calving data among Jersey, Jersey × Holstein crosses, and Norwegian Red × Holstein × Jersey crosses.
S. M. Royal*, K. A. E. Mullen, and S. P. Washburn, *North Carolina State University, Raleigh.*

The dairy at the Center for Environmental Farming Systems (CEFS) has been a pasture-based herd of Holstein (H), Jersey (J), and crosses of those breeds, but now is transitioning into three breed groups: Group A includes pure J and mostly J being bred to become pure Jerseys; Group B includes a two-way criss-cross of H and J breeds by alternating sire breeds each generation; whereas Group C is a three-way rotational cross with Norwegian Red (NR) introduced as the third breed in 2014. The objective of the study is to examine differences in calving characteristics among breed groups across two calving years. Groups included: A (83 calves, J sires), Bh (48 calves, H sires), Bj (60 calves, J sires), and C (94 calves, NR sires), respectively. Breed group ($P < 0.05$), interaction of parity × calving year ($P < 0.01$), and the three-way interaction (breed group × parity × year; $P < 0.05$) significantly affected gestation length. Least squares means for birth weight for groups A, Bj, Bh, and C, respectively were: 26.8 kg ± 0.5 kg, 27.7 kg ± 0.7 kg, 32.9 kg ± 0.7 kg, and 34.5 kg ± 0.5 kg. Parity ($P < 0.001$), breed group ($P < 0.001$), and calf gender ($P < 0.001$) all affected birth weight. Multiparous cows had heavier calves than first parity cows ($P < 0.001$). Group C calves were heavier

than Group Bj ($P < 0.001$) and Group A ($P < 0.001$) calves. Group Bh calves were also heavier than Group A calves. Male calves weighed more than female calves ($P < 0.001$). Breed group was associated with calving difficulty ($P < 0.05$). Cows delivering NR crossbred calves had more difficulty than cows having Group Bj calves ($P < 0.05$). Based on current data and earlier studies, use of either NR or H sires results in heavier birth weights and potentially more challenges at calving.

Key Words: crossbreeding, gestation, calving

0048 Effects of a low moisture block supplement on cow distribution and time budget. A. J. DiGennaro*, A. R. Lee, B. A. Wadsworth, J. D. Clark, and J. M. Bewley, *University of Kentucky, Lexington.*

The objective of this study was to compare the visitation effects of cows between a low moisture block supplement barrel (LMB; Buffer-lyx®, Ridley Block Operations, Flemingsburg, KY) and an empty control barrel (ECB). The study was conducted in two freestall pens ($n = 40$ and $n = 43$) at the University of Kentucky Coldstream Dairy from January 21, 2015 to February 25, 2015. Both LMB and ECB were placed in low traffic areas in the pens. All cows were exposed to a 7 d acclimation period with an ECB, an initial 14 d period with either LMB or ECB (P1), a 7 d washout period with ECB, and a second 14 d period of the opposite treatment (P2). Cows receiving LMB followed by ECB were characterized as treatment control (TC) and cows receiving ECB followed by LMB were characterized as control treatment (CT). Time spent around the barrels was measured using SmartBow (MKW Electronics, Jutogasse, Austria), an eartag based real-time location system. Smartbow recorded per second XY coordinate data to calculate cow location within the housing facility in h/d. When a cow entered or exited the 3 m radius around either barrel, a start or stop time was recorded. All collected data was analyzed using a mixed linear model performed with the MIXED procedure of SAS 9.3 (SAS Institute, Inc., Cary, NC). Cows spent more time around the LMB than the ECB (16.49 ± 1.57 and 4.98 ± 1.62 min, $P < 0.01$). Period (P1: 15.68 ± 1.62 and P2: 5.78 ± 1.57 min, $P < 0.01$) and sequence (TC: 19.79 ± 1.84 and CT: 1.67 ± 1.82 min, $P < 0.01$) effects were also observed. Period and sequence effects may be attributed to inclement weather during P2 or cows becoming conditioned to expect the ECB. Strategic placement of LMB appears to modify dairy cattle movement and behavior in a freestall setting. Dairy farmers may consider the use of LMB to entice cows toward an automated milking system.

Key Words: low moisture block, real-time location system

0049 The influence of age and weaning on the structure of the gastrointestinal epithelium in Holstein bull calves. S. I. Pletts*, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

The objective of this study was to characterize how age and weaning influence structural adaptations of the gastrointestinal tract (GIT) in calves. Tissues from the GIT were taken from 21 Holstein bull calves that were randomly assigned to 1 of 3 treatments: preweaned calves sampled at d 16 (PRE; $n = 7$); weaned calves sampled at d 42 (WN; $n = 7$); and control calves sampled at d 42 (CON; $n = 7$). A step down weaning approach was used (from d 35 to d 42 of life), while CON calves were not weaned. Histological analysis was performed on the rumen, duodenum, jejunum, ileum, proximal and distal colon, and the cecum. Tissues were processed and fully imaged under 40×, and minimum of 10 images under 100×. Measurements were taken of rumen sloughing, papillae dimensions, crypt depth throughout the small intestines, mucosal width in the hindgut, and goblet cell counts in all intestinal compartments. Treatments were compared using the mixed procedure in the statistical analysis system. Weaning effects were most notable in the rumen and duodenum: rumen sloughing scores were highest ($P < 0.01$) in WN (2.64 ± 0.25) relative to CON (1.50 ± 0.25) and PRE (1.51 ± 0.25); duodenal villi length was longer ($P = 0.02$) in CON (356.5μm ± 32.67) than in WN (218.9μm ± 32.67). Crypt depths were consistently deeper ($P < 0.01$) for duodenum, jejunum, proximal, and distal colon of PRE calves compared with CON and WN. Mucosa thickness in the hindgut compartments was greater ($P < 0.01$) in the PRE group. There were no treatment differences on goblet cell count except in the proximal colon, with PRE (0.08 ± 0.01) having less ($P < 0.01$) goblet cells in 100μm^2 than WN (0.15 ± 0.01) and CON (0.15 ± 0.01). These data suggest that during weaning there is significant structural alteration in the rumen and intestine. The most notable differences were detected in the rumen and the beginning of the small and large intestine. Future research is needed to assess the functional adaptation of the entire GIT, and how these adaptations may relate to calf health and performance.

Key Words: GIT, weaning, histology

0050 Effects of supplementing a commercial blend of anaerobic probiotic bacteria, MBiotix Calf, on the growth and health of preweaned and immediately postweaned Holstein calves. R. E. Hudson*, Y. Liang, T. L. Harris, K. P. Sharon, and M. A. Ballou, *Texas Tech University, Lubbock, TX.*

The objectives of these studies were to determine the effects of supplementing a blend of anaerobic bacteria on the growth and health of preweaned and immediately postweaned Holstein calves. Holstein calves within 1 d of birth were randomly

assigned to 1 of 2 dietary treatments ($N = 35$). Treatments included a negative Control and MBiotix Calf (BTX) treatment, which was administered in the milk replacer and top-dressed on the starter during the preweaned and immediately postweaned periods, respectively. The BTX treatment dose was 2×10^9 CFU/d of a proprietary blend of *Lactobacillus casei* and *Enterococcus faecium* strains; however, during the first 3 d of the study, the BTX calves were given a 10× dose. The study was conducted in 3 periods ($n = 20$ Control and $n = 15$ BTX). Calves were individually housed and fed between 250 and 350 g depending on the period of a 22% CP and 20% fat milk replacer twice daily at 0730 and 1630. Calves had ad libitum access to a calf starter and water. Calves were individually housed until they were weaned at 56 d when they were grouped by treatment for an additional 28 d. Peripheral blood samples were collected on d 0, 7, 21, 56, 70, and 84, and analyzed for hematology. Data were analyzed as a repeated measures ANOVA with treatment, time, and treatment × time as the fixed effects and period as a random effect. Calf nested within treatment was the subject of the repeated statement. Data are reported as Control vs. BTX, respectively. There was a treatment × time interaction ($P = 0.001$) on calf starter intake during the preweaned period, whereas BTX calves began to consume more starter during the fourth week of life, and the difference in starter intake was different ($P \leq 0.05$) during the sixth to eighth week of life. BTX calves were consuming more starter at weaning (1.065 vs. 1.305 ± 0.141 kg/d; $P = 0.025$). Further, the BTX calves had greater ADG during the 84 d observation period (0.701 vs. 0.883 ± 0.079 kg/d; $P = 0.016$). There were no treatment or treatment × time effects on hematocrit percentage (34.3 vs. 35.9 ± 1.98%; $P \geq 0.235$). Further, there were no treatment or treatment × time effects ($P \geq 0.178$) on any hematological variable. These data indicated that supplementing MBiotix Calf improved calf starter intake and average daily gain during the preweaned and immediate postweaned periods.

Key Words: calf, health, nutrition, probiotic

0051 Assessing the correlation between teat end scores and presence of mastitis in lactating Holstein cows. K. J. Alward*, J. F. Bohlen, L. O. Ely, and S. C. Nickerson, *University of Georgia, Athens.*

Mastitis is an inflammation of the mammary gland caused by bacteria that affects one in every three cows, and costs the producer an average of $180/cow/year. Penetration of bacteria into the teat canal causing mastitic infections may be enhanced by hyperkeratosis, a thickening of the teat canal keratin, which provides a breeding ground for bacteria. The objective of this project was to determine if a correlation exists between elevated teat end scores (degree of hyperkeratosis) and presence of mastitis as indicated by elevated somatic cell counts (SCC). Purebred Holstein cows ($n = 30$) were assessed and sampled between 30 and 100 d in milk. Each animal was given a teat end score (TES) at sampling on a scale of 1 (smooth) to 4 (rough ring) according to level of severity, and teat canal swabs as well as milk samples were collected aseptically from each quarter for microbiological examination to determine infection status and, if infected, the pathogen(s) present. All milk samples were further evaluated for SCC using a DeLaval Cell Counter. The association of TES, infection status, and SCC was analyzed using the CORR procedure of SAS. A strong positive correlation was seen between level of infection and SCC for each quarter ($P = 0.001$) and for TES and age of the cow ($P = 0.001$). The average TES for uninfected quarters was 2.00, while the average TES for infected quarters was 2.42. However, there was no correlation between presence of infection and TES ($P = 0.444$) or SCC and TES ($P = 0.439$). When infected quarters were compared for pathogen and average TES, the following observations were made: CNS (TES = 1.9), *Streptococcus* (TES = 2.), *Prototheca* (TES = 2.0), *S. aureus* (TES = 2.6), mold (TES = 3.0) and *E. coli* (TES = 3.0). While no correlation was found for the presence of infection and teat end scores, the observation regarding the presence of specific mastitis causing bacteria and elevated teat end scores is an area for future investigation. This observation also suggests that teat end hyperkeratosis is associated with presence of mastitis caused by certain pathogens and that management practices should be in place to promote healthy teat ends for decreased mastitis incidence rates.

Key Words: hyperkeratosis, somatic cell count, mastitis pathogens

---

0052 Evaluating the effects of heat stress on rumen pH and temperature. L. Beckett*, R. R. White, and M. D. Hanigan, *Virginia Tech, Blacksburg.*

As the climate changes, heat stress is becoming an increasing concern for heavily utilized agriculture assets like dairy cattle. The goal of this study is to evaluate the effects of ambient temperature change on ruminal pH and temperature. The study was conducted using eight Holstein heifers (250 kg) housed in climate-controlled rooms (four heifers per room). Heifers were housed at a thermoneutral (20°C) temperature for 2 wk after which room temperature was raised to 30°C. Measurements were taken with a ruminal pH and temperature bolus that was manually inserted into the reticulum through a rumen cannula. Each bolus wirelessly transmitted ruminal pH and temperature every 10 min for the duration of the study. Response variables included: hourly mean, minimum, and maximum pH; proportion of hourly time spent below 5.5 or 5.75; and mean, minimum, and maximum rumen temperature. Data was used from 2 d prior and 2 d after changing the ambient temperature to specifically assess this temperature transition. A mixed-effect model was used to evaluate the data with fixed effects for group (heat stress; HS; or thermoneutral; TN), period (thermoneutral, P1; stressed, P2), and group by period interaction and a random effect for cow. The results

Table 0052.

Table 1. Mean and significance of differences between group and periods

Response[1]	Group 1		Group 2		*P*-Values		
	P1 (20 °C)	P2 (30 °C)	P1 (20 °C)	P2 (20 °C)	Group	Period	Group x Period
Time Below 5.5, h/h	0.06	0.01	0.13	<0.01	0.662	0.067	0.418
Time Below 5.75, h/h	0.25	0.07	0.29	0.16	0.560	0.074	0.778
Min. pH	6.16	6.09	6.25	6.23	0.010	0.055	0.266
Mean pH	6.28	6.20	6.36	6.34	0.077	0.004	0.053
Max. pH	6.40	6.30	6.47	6.45	0.060	<0.001	0.005
Max. T, °C	39.7	39.7	39.5	39.4	0.019	0.044	0.165
Mean T, °C	39.5	39.4	39.3	39.2	0.101	0.010	0.310
Min. T, °C	39.2	39.1	39.1	38.9	0.384	0.057	0.241

[1]Response variables included minimum (min.), mean, and maximum (max.) pH and temperature (T; °C), proportion of time pH was below 5.5 and 5.75 (hour/hour).

are summarized in Table 1. The significance of the group by period interaction for mean ($P = 0.053$) and maximum ($P = 0.005$) pH demonstrates that that heat stress lowers average rumen pH by reducing the height of pH peaks occurring in between digestion events. However, this pH shift is not associated with decreases in minimum pH or a change in time spent below cutoff pH values ($P > 0.05$). Further work must be conducted to evaluate what effects this pH shift has on rumen fermentation kinetics during heat stress.

Key Words: heat stress, rumen pH, rumen temperature

ADSA-SAD (STUDENT AFFILIATE DIVISION) UNDERGRADUATE STUDENT POSTER COMPETITION

0053 Validation of a commercially available β-hydroxybutyrate meter for assessing rumen development in dairy calves. M. A. Richard*[1], C. C. Williams[2], R. M. Orellana[1], S. J. Blair[1], and A. H. Dolejsiova[2], [1]*Louisiana State University, Baton Rouge,* [2]*Louisiana State University AgCenter, Baton Rouge.*

Previous research has shown that glucometers used for testing blood glucose levels in humans are accurate for testing blood glucose in dairy calves and cows. Ketone monitors have been developed for assessment of ketoacidosis in human diabetics. Both acetoacetatic acid and β-hydroxybutyric acid (BHBA) are classified as ketones, but BHBA is the metabolite of interest when assessing rumen development. The Abbot Precision Xtra meter measures BHBA in whole blood. Thus, this instrument would be beneficial from both a basic and applied standpoint in dairy calf nutrition and management. The objective of this experiment was to validate the use of a commercially available hand held β-hydroxybutyrate meter for assessing rumen development in young dairy calves. Blood was collected from 24 Holstein calves at the LSU Dairy Farm via jugular venipuncture during weeks 2, 4, 6, 8, 10, and 12 for analysis of BHBA. Blood was immediately tested for BHBA concentrations using the Abbot Precision Xtra meter. The remainder of each sample was separated and frozen until analyzed for BHBA using a commercial spectrophotometric kit. The BHBA concentrations obtained with the Abbot Precision Xtra meter were strongly correlated with overall plasma BHBA concentrations. Correlations were good when monitoring BHBA concentrations in different age groups. The meter values were not accurate when compared with plasma BHBA concentrations. Beta-hydroxybutyrate meters can be useful tools for monitoring changes in blood ketone concentrations but are not accurate for use in research data collection.

Key Words: β-hydroxybutyrate, dairy calves, ketone monitors

0054 The effect of the liquid nitrogen level on the temperature in a semen storage tank. A. Hale*[1], A. Ahmadzadeh[1], B. Shafii[1], and J. Dalton[2], [1]*University of Idaho, Moscow,* [2]*University of Idaho, Caldwell.*

The temperature in semen storage tanks is critical to maintain the viability of semen stored within the tanks. The objective was to investigate the effect of liquid N level on the temperature in a semen storage tank. Using an electronic thermometer, semen tank temperature was measured at three locations: (a) 2 cm below the top of the neck, (b) 7 cm below the top of the neck (below the frost line), and (c) 2 cm above the level of liquid N. Liquid N volume in the tank was incrementally decreased from 45 to 19 L. The experiment was repeated twice, and temperatures at each location and N level were recorded four times. The data on the effects of N level, location, and two-way interaction on the tank's temperature were analyzed using a general linear mixed model and procedure GLIMMIX in SAS. There was an effect of location and volume by location interaction on tank temperature ($P < 0.01$). Mean tank temperature was greater ($P < 0.01$) 2 cm below the top of the neck as compared with 7 cm below the top of the neck (below the frost line; 6.3 ± 0.1°C vs. –38.4 ± 0.3°C). Results showed that the

effect of liquid N volume on tank temperature was not consistent across locations. As N levels decreased, the temperature gradient remained above 0°C and did not change at 2 cm below the top of the neck. However, as liquid N level decreased, the temperature gradient increased ($P < 0.05$; from –41 ± 1 to –36 ± 1°C) at 7 cm below the top of the neck (below the frost line). Similarly, as N levels decreased, the temperature gradient increased ($P < 0.05$; –187 ± 0.3 to –185 ± 0.3°C) at 2 cm above the level of liquid N. Based on covariance parameters estimated, the temperature gradient below the frost line in the neck of the tank demonstrated the most variability. Data provide evidence of an increase in temperature gradient at 7 cm below the top of the neck (below the frost line) as the liquid N level decreases over time. Therefore, as liquid N level in the tank decreases, removal of semen straws should be done efficiently, to preserve semen viability via minimization of semen exposure to increased temperatures in the neck of the tank.

Key Words: semen storage tank, nitrogen level, temperature gradient

0055 Evaluating the effects of a sodium hypochlorite post milking teat disinfectant on teat condition using a split udder trial. N. Lind*, *University of Kentucky, Lexington.*

The objective of this study was to compare the effects of sodium hypochlorite, DX 648, (GEA Farm Technologies, Naperville, Illinois) and 1% iodine postmilking teat disinfectants on teat condition. Sixty-two primiparous and multiparous lactating Holstein cows averaging 209.63 ± 128.12 d in milk, from the University of Kentucky Coldstream Dairy Farm, were included in an 8-wk study from 27 Nov. 2015 to 21 Jan. 2016. A split udder trial was used to control for cow effects and maximize the number of experimental units. The teats on the left side of the udder were dipped in DX 648 while the teats on the right side were dipped in iodine. All teats were dipped using nonreturn dip cups. Teat end condition and teat skin condition were scored weekly after milking. Teat end condition was scored on a scale of 1 to 4 (1 = no ring, 2 = smooth or slightly rough ring, 3 = rough ring, and 4 = very rough ring). Teat skin condition was scored on a scale of 1 to 3 (1 = normal, 2 = dry, and 3 = rough). The MIXED procedure of SAS 9.4 was used to evaluate the fixed effects of week and teat dip on teat end and teat skin condition. Data was repeated by week with teat within cow as subject using a compound symmetry covariance structure. Teat skin condition scores were not significantly different ($P = 0.98$) between teats dipped with sodium hypochlorite (1.04 ± 0.01) and iodine (1.04 ± 0.01). Teat end condition scores were not significantly different ($P = 0.40$) between teats dipped with sodium hypochlorite (2.45 ± 0.05) and iodine (2.45 ± 0.05). The DX 648 teat dip performed similarly to iodine regarding teat end and teat skin condition, indicating that this dip may be used without adverse effects.

Key Words: postmilking teat dip, sodium hypochlorite, teat condition

0056 The effect of ergothioneine-containing mushroom powder (MP) on sensory acceptability and probiotic survivability in yogurt. B. Blain, C. Boothroyd*, D. R. Roberts, and E. Furumoto, *The Pennsylvania State University, University Park.*

L-ergothioneine, produced by certain fungi and bacteria, is known to have protective effects for both microorganisms and humans due to nonoxidative capabilities. Commercial preparations of L-ergothioneine are derived from mushrooms and can also serve as a source of vitamin D. The objective of this work was to determine if addition of commercial mushroom powder (ErgoD2) could be used as a natural source of vitamin D and antioxidant in yogurt. To test this hypothesis, control and treatment probiotic-containing yogurts (composition: 12% milk solids nonfat, 0.5% milk fat, 3% sucrose) were produced in the Food Science Pilot plant. Mixes were homogenized at 2000 psi and pasteurized at 85°C for 30 min. Mushroom powder (2.5 mg/g ergothioneine) was added at 0.02% by weight to the treatment sample before pasteurization. The pH was monitored throughout fermentation and viable counts of *Streptococcus thermophilus*, *Lactobacillus delbrueckii* subsp. *bulgaricus*, and the probiotic *Bifidobacterium animalis* ssp. *lactis* Bb-12 were monitored at the beginning and end of fermentation. The pH of yogurt and probiotic survival were also monitored weekly for 5 wk. Hedonic liking and preference tests were conducted on both control and treatment products with 106 participants. Yogurt containing mushroom powder fermented at a similar rate to the control. Addition of mushroom powder did not affect growth of Bb-12, *S. thermophilus*, or *L. delbrueckii* subsp. *bulgaricus*. Although counts of Bb-12 decreased during storage, the rate of decline was similar in control and treatment yogurts throughout the 5 wk storage period. No significant differences were observed in acceptability between control and treatment products. Results suggest mushroom powder containing L-ergothonine and vitamin D could be used successfully in yogurt.

Key Words: ergothioneine, yogurt, probiotic

STRATEGIES FOR MANAGING HEIFERS IN THE SOUTHEAST

0057 Influences of feeding and housing practices on the behavior and performance of dairy calves.
E. K. Miller-Cushon*[1] and T. J. DeVries[2], [1]*Department of Animal Sciences, University of Florida, Gainesville,* [2]*Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada.*

Approaches to rearing replacement dairy heifers vary widely between farms across the Southeast, and the behavior and performance of the calf early in life is highly subject to management practices. There is also increasing evidence that early life environment and experiences can have longer-term effects on the performance and health of the growing heifer and mature cow. This presentation will review the current understanding of the short and longer-term behavioral and performance implications of early life management factors that may vary on-farm, including milk feeding method, solid feed provision, and social housing. First, on-farm milk-feeding levels typically range between conventional restricted feeding programs to free-access feeding. From a behavioral standpoint, milk feeding level influences milk meal frequency and diurnal patterns of feeding time before weaning. Early rate of weight gain is dependent on milk feeding level, and there is evidence that differences in performance may be maintained postweaning and have later benefits in life. A main goal of rearing replacement heifers is to wean them successfully from milk to solid feed, and early solid feed intake is critical for this transition. Solid feed types and presentation directly affect intake and feeding patterns, and there is evidence that feed experiences during the milk-feeding stage may have a longer-term influence on feeding behavior of weaned dairy calves. For example, postweaning feed sorting behavior appears to depend on feed preferences, which are formed by prior feed experiences, as well as an early opportunity to perform this behavior, as provided by access to a mixed diet. Finally, the housing environment can be highly influential in the social development of the calf and may also interact with feeding methods, having both immediate and longer-term effects on performance and behavior. Social contact has been demonstrated to be beneficial in encouraging early solid feed intake and supporting weight gain through weaning. Further, early social environment influences social development, and may have longer-term effects on the behavior of the calf. Group-housing facilities introduce the possibility of competition for feed access, and this may also influence the development of social and feeding behavior. The extent to which all of these early rearing factors may influence long-term behavioral development and performance into lactation remains largely unknown and requires further investigation.

Key Words: behavior, dairy calf, feeding

0058 Developing replacement heifers that get pregnant and maintain pregnancy.
K. G. Pohler*[1], M. H. Pereira[2], S. Reese[1], and J. L. M. Vasconcelos[3]. [1]*The University of Tennessee, Knoxville,* [2]*UNESP-FMVZ, Botucatu, Brazil,* [3]*Sao Paulo State University, Botucatu, Brazil.*

Reproductive failure is one of the most substantial barriers to profitability in dairy herds. Management issues, cow infertility, bull infertility, heat stress, embryonic mortality (EM), and poor heifer development are all contributing factors to reproductive inefficiency. Developing heifers that successfully establish and maintain a pregnancy, give birth to live offspring, and stay in the herd for a number of years is critical. In addition to proper selection of these heifers, minimizing reproductive inefficiency, specifically EM, is vital. Embryonic mortality is generally considered to be the primary factor limiting conception rates in cattle and occurs early (<d 25) or late (≥d 25) during gestation (d 0 = estrus). In cattle, the incidence of early EM is approximately 25% and the incidence of late EM is varied, approximately 3.2 to 42.7%. However, in heifers, these numbers are thought to be decreased but are still a major issue. Significant effort has been directed toward understanding the mechanisms resulting in early EM; however, relatively little is known about the causes or mechanisms associated with late EM, most of which occurs around the time of placentation. Mechanisms associated with reproductive loss around the time of placentation may be associated with inadequate placental development or function. Binucleate trophoblast cells constitute 15 to 20% of the ruminant placenta trophoblast population, appear around d 19 to 20 of gestation in cattle, and secrete pregnancy associated glycoproteins (PAGs), along with other products. Bovine PAGs are commonly used to diagnose pregnancy success in cattle and have recently been reported to be a potential marker of late EM in dairy cattle (Pohler et al., 2015). Based on positive and negative predicative value analysis, we have identified circulating concentrations of PAG that are 95% accurate in predicting EM at d 28 of gestation. This talk will highlight some of the work our group, as well as others, are focusing on with regard to selecting high fertility heifers, as well as management strategies to decrease reproductive loss in those heifers using PAG testing. In summary, based on the experiments and relevant literature, PAGs seem to be a good marker for predicting EM, but also may provide a useful tool for selection of high fertility heifers. Advancements in our understanding of the mechanisms associated with EM may lead to development of strategies to overcome these reproductive losses.

Key Words: cattle, pregnancy, placenta, embryonic mortality

0059 Benefits of fly control in dairy heifers.
S. C. Nickerson*, *University of Georgia, Athens.*

This presentation discusses the role of the horn fly (*Haematobia irritans*) in the initiation and spread of staphylococcal mastitis among dairy heifers, how this insect vector can be managed, and the benefits of control for animal health and well-being, as well as producer profits. The horn fly is an irritant to livestock, and in response to the incessant painful biting, blood sucking, and stress, cattle expend a great deal of energy in defensive behavior, resulting in elevated heart and respiratory rates, reduced grazing time, decreased feeding efficiency and rate of gain, and reduced milk production. Additionally, the horn fly can serve as a disease vector, such as in the initiation and spread of mastitis in dairy heifers. As such, it is one of the most economically important pests of cattle worldwide. In the United States, $700 M to $1 B in losses are attributed to the horn fly each year, while additional $60 M is spent annually on parasite control. Herd surveys have revealed that the prevalence of mastitis in heifers is markedly lower in dairy herds using some form of fly control compared with herds without a pest control program. The horn fly has a demonstrated role in the development of teat lesions on heifers that develop into chronic *Staphylococcus aureus* mastitis, which is then spread among heifers by these same insect vectors. Such infections, if left untreated, negatively affect the development of milk-producing tissues in the udder, resulting in less than optimal yield and quality during the first and subsequent lactations. The implementation of horn fly control measures such as aerosols, bait, strips, foggers, dust bags, traps, oilers, ear tags, pour-ons, natural predators, and insect growth regulators is instrumental in reducing the new infection rate, while existing mastitis cases can be eliminated with antibiotic therapy. Such management practices will promote animal health and well-being, as well as ensure that heifers calve with low SCC and the potential for maximum milk yield, thereby enhancing producer profits.

Key Words: horn fly, dairy heifer, staph mastitis

0060 Economic trade-offs between replacement rates and improved genetics.
A. De Vries*, *Department of Animal Sciences, University of Florida, Gainesville.*

Genetic progress in sires used for AI is rapidly increasing. This means that replacement heifers are increasingly much better genetically than cows. Economically, this should lead to increased voluntary culling and thereby decrease cow longevity. On the other hand, lower culling rates are often viewed favorably because the costs and environmental impact to maintain herd size are generally lower. Thus, there is an economic trade-off between genetic progress and longevity in dairy cattle. Objective was to investigate these trade-offs. USDA results show that the annual increase in average predicted transmitting ability (PTA) of Net Merit dollars of Holstein sires is accelerating from $20/yr when the sire entered AI in 2000 to 2004, to $52/yr in 2005 to 2009, to $86/yr in 2010 to 2014. We expect that heifers born in 2015 are about $50 more profitable per lactation than heifers born in 2014. An elegant but older study is from Allaire (1981). He found that the economically optimal cull rates were in the range of 25 to 27%, compared with the lowest possible cull rate of 20%. There was only a small effect of using the best surviving dams to generate the replacement heifer calves. Genetic progress from sires also had little effect. Using a spreadsheet model to determine genetic lag in Net Merit PTA between service sires and dams shows that increased cow cull rates reduce the genetic lag only marginally. The ratio of annual genetic trend in sires' PTA for Net Merit and genetic lag was 6.6, 7.7, 8.7, and 9.4% for the annual cull rates of 20, 30, 40, and 50%, independent of the magnitude in sire genetic trend. These results confirm the findings of Allaire (1981) that cow depreciation costs overwhelm the value of the genetic superiority of the replacement heifers. Van Arendonk (1985) showed that the effect of changes in genetic improvement in milk revenue minus feed cost on herd longevity was relatively small. Reduced involuntary cull rates improved profitability, but also increased optimal voluntary culling. Finally, an economic optimal culling model with prices from 2015 confirmed that optimal annual cull rates were insensitive to heifer prices and therefore insensitive to superior genetics in heifers. In conclusion, economic cow longevity depends more on the difference between heifer raising costs and cow cull prices than on genetic progress. This is confirmed by old and new studies.

Key Words: genetics, longevity, economics

ANIMAL BEHAVIOR AND WELL-BEING

0061 Utility of an online learning module for teaching disbudding in dairy calves, including cornual nerve block application.
C. B. Winder*[1], S. J. LeBlanc[2], D. B. Haley[2], K. D. Lissemore[1], M. A. Godkin[3], and T. F. Duffield[2], *[1]University of Guelph, Guelph, ON, Canada, [2]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, [3]Ontario Ministry of Agriculture, Food and Rural Affairs, Guelph, ON, Canada.*

Although disbudding or dehorning dairy heifers is necessary for the safety of humans and other cattle, it has been identified as a key animal welfare issue when done without appropriate analgesia. Three-quarters of disbudding or dehorning is done by dairy producers or on-farm staff, the remainder is done by a veterinarian or veterinary technician. Reported use of pain control by dairy producers ranges from 15 to 60%. Cautery disbudding is the most commonly used method; best practices

include administration of a nonsteroidal noninflammatory drug (NSAID) and local anesthetic given as a cornual nerve block (CNB), which requires technical training. Teaching methods may involve one-on-one training with a veterinarian. As well, online training videos exist. To our knowledge, none of these methods have been studied for efficacy. Our objective was to determine if an interactive, online module could teach CNB application and cautery disbudding, as compared with hands-on training. Thirty-four student participants were assigned to either hands-on training or to self-directed online training. Assessments were performed by a blinded evaluator who examined knowledge, handling, CNB technique, disbudding technique, time taken, and self-confidence. Success of CNB was defined as a lack of pain-related behaviors during the first 5 s of disbudding iron application. The hands-on training group had no CNB failures, while online training had 25% CNB failures ($P = 0.13$). Online learners were significantly less confident ($P < 0.01$); had poorer handling ($P = 0.02$), CNB ($P = 0.05$), and disbudding ($P = 0.05$) technical skills; and took more time to perform all tasks ($P = 0.03$). Although online learning alone was surprisingly effective for a psychomotor skill, best practices should include hands-on training. Online learning alone may be appropriate for hard-to-reach populations, or as a preliminary step to hands-on training.

Key Words: calf, dehorn, pain control

0062 WS Grazing behavior and production characteristics among cows differing in residual feed intake while grazing late season Idaho rangeland. J. E. Sprinkle*[1,2], J. B. Taylor[3], P. E. Clark[4], M. C. Roberts-Lew[1], and J. B. Hall[1,2], *[1]University of Idaho Nancy M. Cummings Research, Extension Education Center, Carmen, [2]Department of Animal & Veterinary Sciences, University of Idaho, Moscow, [3]USDA, ARS, U.S. Sheep Experiment Station, Dubois, ID, [4]USDA, ARS, Northwest Watershed Management Research Unit, Boise, ID.*

The objectives were to determine if cows classified as either low- or high-residual feed intake (LRFI or HRFI) differed in BW, BCS, and winter grazing activity over time. Thirty Hereford × Angus (LRFI = 16; HRFI = 14) 2-yr-old cows grazed sagebrush-steppe for 78 d beginning 29 Sept. 2016. Body weight and BCS were collected before and after grazing. Five cows of each RFI classification were fitted with global-positioning-system (GPS) collars on 16 Nov. 2015, with data collection commencing 3 d later and continuing for 25 d in a 323 ha pasture. The GPS units collected location coordinates every 2 min, from which total daily travel was calculated. Visual counts for bite rate were obtained from collared cows over 8 d. Coordinate data, daily bite rate, BW, and BCS were analyzed as repeated measures using a mixed model, which included RFI group, day, and RFI group × day as fixed effects, and cow within RFI group as the random effect. Change in BW and BCS were analyzed by ANOVA, with RFI group as the main effect. Cow BCS and BW differed for both day ($P < 0.0001$) and day × RFI ($P < 0.05$). Body condition was less in LRFI cows at the beginning (5.8 ± 0.13 vs. 6.2 ± 0.14 BCS), but similar to HRFI at the end of the study (4.6 ± 0.13 vs. 4.6 ± 0.14). Body weight for the different RFI cows did not differ ($P = 0.1974$) before going to range. However, BW-change and BCS-change differed ($P = 0.05$) among RFI groups. Not only did the LRFI cows lose less BW (–50.0 ± 5.41 kg vs. –66.6 ± 5.78 kg) over the trial, they also were less variable with respect to BW loss. Cows did not differ ($P > 0.21$) by RFI for distance traveled or bite rate, but day was significant ($P < 0.0001$) with cows increasing bite rate as the season of year progressed (55.2 ± 5.63 bites/min for d 4 vs. 84.8 ± 5.32 bites/min for d 21) and increasing distance traveled as snow storms occurred. Although LRFI cows were leaner than HRFI cows at the commencement of the project, they loss less BW and functioned competitively in a late season rangeland environment.

Key Words: beef cattle, grazing behavior, rangeland, residual feed intake

---

0063 Variability in feeding behavior between individual dairy cows fed under different levels of competition. R. E. Crossley*, A. Harlander, and T. J. DeVries. *Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to investigate the effects of differing levels of competition for feed access on group-housed dairy cows and on the variation in feeding behavior between individuals within the group. We hypothesized that, as competition increases, (1) cows will consume feed faster and in larger meals, and (2) individuals within the group will experience greater variability in feed consumption patterns. Eighteen lactating Holstein dairy cows with average DIM of 77 ± 20 d and production of 46 ± 7 kg/d at the start of the trial, were divided into groups of three, and fed three times per day. Groups were exposed to each of three competition levels: high (3 cows: 1 feed bin), moderate (3 cows: 2 feed bins), and low (3 cows: 3 feed bins). Treatments were assigned in random order according to a modified Latin Square design and applied for 10 d. DMI and feeding behavior (feeding time, feeding rate, and meal patterns) for each cow were recorded using an automated feed intake system on d 6 to 10 of each period. Data were summarized by group and treatment period, and analyzed in a general linear mixed model. DMI (29.1 kg/d) was found to be similar ($P = 0.63$) across treatments. Increased competition resulted in a reduction in feeding time (low = 202.6, moderate = 194.9, high = 83.6 min/d; SED = 4.49; $P = 0.015$), especially following fresh feed delivery and milking. Rate of feed intake increased with greater competition (low = 0.16; moderate = 0.18; high = 0.20 kg DM/min; SED = 0.01; $P = 0.01$). Meal frequency (8 meals/d) and size (4.0 kg DM/meal) were unaffected by treatment ($P > 0.40$), while meal length increased

Table 0064.

Table 1. Probabilities of being lame for variables measured by precision dairy farming technologies.

Variable	Odds ratio	Standard Error	*P* - value
Lying time (increase by one hour)[1]	1.56	0.14	0.01
Rumination time (decrease by 30 minutes)[2]	1.25	0.04	0.02
Neck activity (decrease by 150 units)[3]	3.87	1.35	0.01
Reticulorumen temperature (increase by one degree)[4]	1.00	0.00	0.01
Milk yield (decrease by five kg)[5]	0.88	0.08	0.16

[1]Lying time was measured by an IceQube (IceRobotics, Edinburgh, Scotland)
[2]Rumination time was measured by an HR tag (SCR Engineers ltd., Netanya, Israel)
[3]Neck activity was measured by an HR tag (SCR Engineers ltd., Netanya, Israel)
[4]Reticulorumen temperature was measured by a DVM bolus (DVM Systems, LLC Boulder, CO)
[5]Milk yield was recorded by the Milkline Milpro P4C (Gariga di Podenzano, Italy) milking system

under high competition (low = 37.0; moderate = 36.6; high = 47.3 min/meal; SED = 3.7; $P = 0.046$). This was due to greater within-meal nonfeeding time, which at the high competition level, was approximately double that of the other treatment levels (low = 10.0; moderate = 10.8; high = 20.3 min/meal; SED = 2.3; $P = 0.008$). Analysis of individual within group variability, calculated as the daily SD of each group averaged across d 6 to 10, revealed treatment differences in variability of meal length (low = 12.0; moderate = 13.9; high = 29.0 min/meal; SED = 5.56; $P = 0.04$) and within-meal nonfeeding time (low = 6.4; moderate = 8.3; high = 21.5 min/meal; SED = 4.57; $P = 0.03$). These results suggest that at elevated competition levels, cows modify their feeding behavior to consume more feed in a shorter period of time and devote a large portion of their meal time toward waiting to gain feed access. Further, there is greater variability in meal patterns within groups at higher levels of competition for feed access.

Key Words: dairy cow, feeding behavior, competition, meal patterns

0064 Identification of lameness using lying time, rumination time, neck activity, reticulorumen temperature, and milk yield. B. A. Wadsworth*, A. Stone, J. D. Clark, and J. M. Bewley, *University of Kentucky, Lexington.*

Early identification and treatment of lameness can reduce pain and negative performance related to the disease. However, producers frequently misidentify lame cows; therefore, automatic identification of lame cows is needed. The objective of this study was to identify lame cows using precision dairy monitoring technologies. Cows ($n = 98$) were housed at the University of Kentucky Coldstream Dairy from 11 Jan. 2012 to 3 May 2013. Cows were equipped with an IceQube (IceRobotics, Edinburgh, Scotland) on their left rear leg, which measured daily lying time (LT), an HR tag (SCR Engineers ltd., Netanya, Israel) around their neck, which recorded daily rumination time (RUM) and neck activity (ACT), and a DVM bolus (DVM Systems, LLC Boulder, CO) that measured reticulorumen temperature (RETT). Milkline Milpro P4C (Gariga di Podenzano, Italy) milking system recorded daily milk yield (MY). Seasons were categorized as Season 1 (December, January, and February), Season 2 (March, April, and May), Season 3 (June, July, and August), and Season 4 (September, October, and November). Cow gait was assessed weekly using a one (sound cow) to five (severely lame cow) scale. General symmetry, tracking, spine curvature, head bob, speed, and abduction/adduction were scored individually. Final gait score was calculated as a weighted average of general symmetry (24.92%), tracking (20.38%), spine curvature (19.81%), head bob (13.77%), speed (13.12%), and abduction/adduction (8%). Cows that scored ≥ 2 overall were classified as lame. A generalized linear model using the GENMOD procedure in SAS (SAS Institute, Inc., Cary, NC) was used to evaluate the effects of parity, season, LT, RUM, ACT, RETT, and MY on overall gait scores and their two-way interactions. Stepwise backward elimination was used to remove nonsignificant interactions ($P \geq 0.05$). Variables associated with a probability of being lame were an increase in LT by 1 h, a decrease in RUM by 30 min, a

decrease in ACT by 150 units, and an increase in RETT by one degree (Table 1). Milk yield was not associated with a probability of being lame (Table 1). When identifying lameness, using precision dairy monitoring technologies that determine LT, RUM, ACT, or RETT may be useful.

0065 Management and dimensions of footbaths on California dairies. M. Pineda* and N. Silva-del-Rio, *Veterinary Medicine and Research Center, University of California, Tulare.*

Lameness is a common disease found on dairies with important economic and animal welfare implications. Digital dermatitis is one of most common infectious causes of lameness. Footbaths (FB) are commonly used on California dairies to prevent infectious foot diseases. The objective of this study was to describe footbath dimensions and management practices on California. Twenty dairies located in the San Joaquin Valley of California were enrolled in the study. Herds ranged in size from 800 to 10,000 cows. The length, width, and depth of FB was measured. Information on the chemical composition of FB solutions and the frequency that fresh FB solutions were added was obtained through interviews with hoof trimmers and dairy managers. Data collected was entered into spreadsheets for data analysis (Microsoft Office Excel; 2010). Dairies had 1 to 4 FB per dairy (total 39). One dairy applied disinfectant FB solution with front and rear jets. On four dairies, prebaths were placed <30 cm from the FB. No information on frequency of FB use was obtained from one dairy. The frequency of new FB solution application was seven (n = 2), five (n = 6), four (n = 4), three (n = 5), or two (n = 1) days a week. Cows walked through the FB once (n = 12), twice (n = 6), or thrice (n = 1) a day. One dairy walked dry cows through a FB once a week. The maximum FB length was <1.5 (15%), 1.5 to <2.5 m (57%), 2.5 to <3 m (18%), or >3 m (10%). Width measures were <1 m (39%), 1 to <2 m (20%), and ≥2 m (41%). FB solution depth averaged 10 cm (range: 5.4 to 15 cm). Volume of chemical solution in FB averaged 339 L (range: 109 to 1095 L). Most FB (66%) contained between 150 and 500 L of solution. Disinfectant chemical solutions used on dairies were $CuSO_4$ (n = 3), $ZnSO_4$ (n = 2), or formaldehyde (n = 3). However, some dairies combined $CuSO_4$ and formaldehyde (n = 9), $CuSO_4$ and chlorine (n = 1), or $CuSO_4$ and glutaraldehyde (n = 1). On average, 921 cows (range: 185 to 2000 cows) walked through a FB solution before adding fresh solution. Across dairies there was a wide variation on design, dimensions, and management of FB. Further research is needed to establish the implications of various management practices and FB designs on hoof health.

Key Words: lameness, footbath, dairy cow

0066 History of management procedures and hierarchy in dairy cows. A. Butterworth[*1] and L. van Dijk[2], *[1]University of Bristol, Bristol, United Kingdom, [2]HAS Institute, Amsterdam, Amsterdam, the Netherlands.*

This study assessed social interactions between cows in a 186 lactating cow herd, split into high milk yield (<35 wk into milking) and a low milk yield (>35 wk into milking) groups. The shifting hierarchical behaviors of the cows over 20 d was observed through analysis of video. The objective was to determine whether cows with a higher history of management procedures associated with treatment for common mastitis, lameness, and dystokia, would be lower in rank in the social hierarchy, and show more fluctuation in rank, than cows with a low management procedure history. A still-image photo library of the cows in the herd was compiled so that every cow could be identified from video recordings. Cows were identified as being in a high management history group (HMG) or a low management history group (LMG) based on their electronic farm management record. For blind analysis, the categorization into low and high management groups was made after the video analysis had been completed. Cows were filmed at the feed barrier using 1080 p 50 fps GoProHero 4 cameras, each camera supported to give a stable image along the feed barrier. Activity and time budget analysis of individual cow interactions from the video images allowed dominant (+) and submissive (–) interactions between cows to be noted. No significant difference was found in the "average hierarchical rank" between cows in the HMG and the LMG (P = 0.330). Heifers did rank significantly lower than cows, for example, when comparing heifers to cows in their third lactation (P = 0.004). The LMG showed a higher variability (deviation in means score) in rank than the HMG. This pilot study may aid understanding of possible long-term effects of common dairy management procedures. With further development, this method could (a) inform steps to reduce long-term impacts of common procedures, and (b) utilize altered hierarchical behavior as a detection tool for cattle showing long-term deleterious effects of previous management procedures. Cows that had a higher history of management for common dairy cow conditions (lameness, mastitis, or dystokia) did not experience long-term effects on hierarchical behaviors during feeding. However, significant behavioral differences in groups based on age were detected.

Key Words: dairy cows, management, disease, hierarchical, behavior

0067 Behavioral analysis and performance response of feedlot steers on concrete slats versus rubber slats. D. Wagner*, *Colorado State University, Fort Collins.*

Concrete slats as a flooring substrate pose welfare concerns for feedlot cattle. An alternative system includes overlying rubber mats that fit existing slats. In this series of trials, three

sets of 16 steers were housed on either concrete slats (CONC) or rubber-covered concrete slats (RUBBER) during their finishing period. Each trial had four pens of four steers each, with two pens per treatment. Animals were fed a finishing diet once per day, the room was held at 18.3°C with continuous illumination. Cattle DMI, ADG, G:F, weight, and carpus circumference were tracked for the duration of the finishing period, up to 128 d. Lying and standing duration behavior was also measured on each treatment. Cattle also had their blood sampled at regular intervals for complete blood count analysis. After slaughter, carcass characteristics and front limbs were collected for soft tissue and histological examination. For growth measurements and CBC panel data, with pen as the experimental unit, there were no treatment differences ($P > 0.05$). Carpal circumference was larger on CONC than on RUBBER as each trial progressed, and in particular, the left carpus increased at a faster rate on CONC. Lying and standing behavior differed between treatment groups: on CONC, cattle consistently had fewer lying bouts per day than steers on RUBBER; in Trial 1, the average number per day was 21.2 ± 1.3 on CONC and 25.1 ± 1.3 on RUBBER ($P = 0.0039$). In Trial 2, lying and standing duration behavior did not differ between treatments. The average number of lying bouts per 24 h period was 33.1 ± 2.2 and 39.2 ± 2.2 on CONC and RUBBER, respectively ($P = 0.0068$). In Trial 3, average number of lying bouts per 24 h period was 14.6 ± 1.4 on CONC and 21.3 ± 1.4 on RUBBER ($P < 0.0001$).The behavioral results in conjunction with the joint circumference results, indicate that cattle were experiencing a greater amount of discomfort in lying and standing transition phases. It is concluded that steers on RUBBER have a higher standard of welfare than cattle on CONC.

Key Words: cattle, joint, rubber, lying

0068 Effect of corral modification for humane livestock handling on cattle behavior and cortisol release.

M. L. P. Lima*[1], J. A. Negrao[2], C. C. P. Paz[3,4], and T. Grandin[5], *[1]Instituto de Zootecnia, Sertãozinho, Brazil, [2]Faculdade de Zootecnia e Engenharia de Alimentos, FZEA, USP, Pirassununga, Brazil, [3]Universidade de Sao Paulo, Faculdade de Medicina de Ribeirao Preto- Departamento de Genetica (USP/FMRP), Ribeirao Preto-SP, Brazil, [4]SAA/APTA/Instituto de Zootecnia-Centro de Bovinos de Corte, Sertaozinho-SP, Brazil, [5]Colorado State University, Fort Collins.*

Most traditional corral facilities are designed and built without the use of animal welfare principles, and can cause stress and fear reactions. This experiment was conducted to evaluate the influence of modifications to transform traditional corral into humane livestock handling system in cattle behavior and serum cortisol. The corral modifications consisted of blocking vision when the worker stands inside the animal's flight zone, eliminating contrast of light and dark or shadows, and keeping the workers calm, not allowing them to scream or hit the animals during handling. Electric cattle prods were not permitted. A total of 382 Nellore steers, from 12 to 20 mo of age, from five different ranches were studied. First, the behavior of the animals in a traditional corral was evaluated. After corral modification and changing for calm handling procedures, the same animals returned (6 d later) for a second behavioral assessment. During restraining, before and after corral modifications, blood samples were collected from the jugular vein for analysis of serum cortisol. The cattle were evaluated using visual scores. Entry behavior (EB) into the restraint device was evaluated by observing whether the bovines walked, trotted, or ran. Chute temperament (CT) was assessed by considering whether the animal was very calm, calm, agitated, very agitated, or struggling to escape; and exit gait (EX) by observing whether the animal walked, trotted, or ran. After corral modification, cattle exhibited lower EB ($P < 0.0001$) and EX ($P < 0.0001$) and a higher proportion of animals was calm (CT-P < 0.0001) during restraining. The proportion of cattle that walked, trotted or ran was, respectively, 61.9, 30.4, and 7.7% for EB and 47.9, 36.9, and 13.4% for EX before corral modification, and 79.3, 16.8, and 3.9% for EB and 74.0, 19.7, and 6.3% for EX after corral modification. For CT, the proportion of very calm, calm, agitated, very agitated, and struggling to escape animals was 26.8, 36.6, 23.4, 12.1, and 4.2% before corral modification, and 48.1, 32.1, 15.1, 3.6, and 1.1% after corral modification, respectively. Serum cortisol levels were significantly lower ($P < 0.0001$) after corral modification. Mean serum cortisol was 47.87 mg/dL before corral modification and 32.49 mg/dL after corral modification. Good handling practices, corral reconstruction, blocking vision in specifics areas, and respecting the natural movement can reduce stress in cattle.

Key Words: cattle stress, good practice, welfare

0069 A preliminary examination of swine caretakers' perspectives for euthanasia technology and training.

M. McGee*[1], R. L. Parsons[1], A. M. O'Connor[1], A. K. Johnson[2], R. Anthony[3], A. Ramirez[1], and S. T. Millman[1,4], *[1]Department of Veterinary Diagnostic & Production Animal Medicine, Iowa State University, Ames, [2]Iowa State University, Ames, [3]Department of Philosophy, University of Alaska Anchorage, Anchorage, [4]Department of Biomedical Sciences, Iowa State University, Ames.*

An observational study was performed to better understand swine caretaker attitudes and opinions about euthanasia methods in swine production. A questionnaire was developed for swine caretakers to document the following: (1) psychosocial aspects, such as moral stress and job satisfaction associated with euthanasia, (2) current use of euthanasia techniques, and (3) views on animal welfare. To gain insight on caretakers'

perspectives on the issues listed above, caretakers were asked to rank their personal opinions on these topics. A total of 2104 surveys were mailed between December 2014 and June 2015 to caretakers associated with four swine production companies in eight states. The return rate was 8.3% (n = 175), with 168 completed surveys used for analysis. Respondents included 115 male and 53 female caretakers, whose work experiences with pigs ranged from <1 to 55 yr. Sixty-seven percent of caretakers worked in swine breeding units, while the remainder worked in farrowing, nursery, grow finish units, or a combination of production cycle units. Odds ratio analyses were performed to examine the effects of gender on caretaker opinion and acceptance regarding euthanasia techniques. There were no differences between male and female caretakers regarding the acceptance of different euthanasia methods in suckling pigs ($P > 0.05$). A large percentage of caretakers agreed that it is important to have good skills for euthanasia, that they knew how to euthanize humanely, and that it is more humane to euthanize terminally ill pigs than to let them die (93, 95, and 95%, respectively). Male and female caretakers did not differ in their personal opinions about euthanizing pigs, speaking publicly about their job, or euthanasia preferences ($P > 0.05$). Forty-nine percent of caretakers were trained in euthanasia techniques within the last year, and 30% reported that they would like more training. Caretakers preferred to be trained on-farm, followed by the use of video, classroom setting with a trainer, and reading materials. Caretakers rated carbon dioxide more acceptable than the use of blunt force trauma for suckling pigs (70% and 37%, respectively). The current study suggests that swine caretakers agree that proper euthanasia techniques are important and male and female caretakers do not differ in perspectives concerning euthanasia technology and training.

Key Words: swine caretakers, caretaker attitudes, euthanasia, animal welfare

0070 Slow doesn't win the race: Reduced energy diets did not improve sow articular cartilage.

N. M. Chapel[*1], R. L. Dennis[2], J. N. Marchant-Forde[3], B. T. Richert[1], and D. C. Lay Jr.[3], *[1]Purdue University, West Lafayette, IN, [2]University of Maryland, College Park, [3]USDA-ARS Livestock Behavior Research Unit, West Lafayette, IN.*

Sow lameness accounts for approximately 15% of culling, resulting in a decrease in productivity and welfare. Previous research in our laboratory has shown a high incidence of osteochondritic lesions in young sows. We hypothesized that decreasing the growth rate of sows would allow for proper formation of articular cartilage. The objectives of this study were to (1) quantify behavioral changes associated with the diet, and (2) prevent the development of osteochondritic lesions. Therefore, 70-d old gilts were placed on either a control diet (CON; n = 23) or a low energy diet (LOW; n = 24). The CON diet contained 3427 Kcal/kg ME. The LOW diet utilized wheat middling and soy hulls, and contained 2643 Kcal/kg ME, targeting 65 to 70% of growth. Both diets were available ad libitum from d 70 to 182. Gilts were fed LOW or CON diets in four 28 d phases, and were weighed at diet changes to calculate ADG and ADFI, which were 0.80 and 0.92 kg, respectively, for CON gilts and 0.61 and 1.06 kg, respectively, for LOW gilts. A G:F of 1.15 resulted for CON and 1.73 for LOW gilts. Behavioral observations were recorded monthly and included posture, activity, agonistic behavior, and vices. Joint samples were taken (CON = 9; LOW = 10) between d 182 to 361 and analyzed for damage. Joints were evaluated for number of lesions, lesion size, and received an articular cartilage score from 0 to 4, with 0 representing healthy cartilage and 4 representing severely lesioned cartilage. The LOW gilts spent more time standing ($P < 0.01$), sitting ($P < 0.01$), and feeding ($P < 0.01$). Overall, diet did not alter sham chewing ($P = 0.76$), nosing ($P = 0.11$), or tail biting ($P = 0.36$). Both LOW and CON gilts did not differ in the number of fights ($P = 0.67$); however, CON gilts spent less time fighting than LOW gilts ($P < 0.01$). Energy restricted feed did not decrease the lesion size or prevalence of lesions ($P > 0.10$). Older gilts had larger lesions on the proximal humerus ($P < 0.01$) and femur ($P < 0.01$) and the distal humerus ($P < 0.03$) and femur ($P < 0.04$) than younger gilts. An energy restricted diet is not a suitable solution to decrease fighting or to improve joint health in young sows.

Key Words: articular cartilage, energy restriction, sow longevity

0071 WS Use of a human triaxial pedometer for measurement of sheep activity.

K. A. Perz*, J. G. Berardinelli, R. A. Shevitski II, J. White, and J. M. Thomson, *Montana State University, Bozeman.*

The accuracy of a simple, human triaxial pedometer at measuring sheep steps at a walk was investigated. Adult ewes (n = 10) were subjected to a three week halter-training program, with the end result of ewes being able to walk for 100 m next to a handler with little or no resistant behavior. A triaxial pedometer was attached to the left hind leg. Ewes were led for 100 m and the number of steps reported by the pedometer was recorded. A handheld video camera was used to record each trip, and the visual step count of the ewe was determined from the video recording. Each ewe was led through this pattern twice, and the average of the pedometer and visual step count at 80 m was used for statistical analysis. A Wilcoxon signed rank test was used to compare the means of the pedometer and visual step counts, and a Pearson correlation was drawn. The means of the pedometer and visual step counts were statistically different ($P < 0.001$) and the correlation was negligible ($r = 0.03$). The simple triaxial pedometers overestimated the amount of steps each ewe made, and therefore, cannot be considered accurate at measuring sheep activity.

Key Words: sheep, activity, triaxial pedometer

0072 Cooling cows with soakers: Spray duration affects heat loss in dairy cattle. G. Tresoldi[*1], K. E. Schütz[2], C. B. Tucker[1], [1]*University of California, Davis,* [2]*AgResearch, Hamilton, New Zealand.*

Soakers reduce heat load in cattle. Determining appropriate spraying strategies (e.g., time on and off) may improve the efficiency of heat loss and water use. Our objective was to evaluate the effects of a single cycle of spray on evaporation time, the surrounding air temperature, and heat load responses in dairy cows. In a crossover design, five spray durations (0, 0.5, 1.5, 3, and 13 min; flow rate = 4.9 L/min) were tested in 15 Holstein cows (milk yield 38 ± 3 kg/d) and replicated on 3 d/treatment (15 d total/cow) when air temperature, humidity, and the combined index averaged 31 ± 3°C, 27 ± 10%, and 76 ± 2, respectively. Cows were restrained in shaded head gates at the feed bunk for up to 1.75 h. Respiration rate (RR), skin temperature on the shoulder (received direct spray) and upper leg (remained dry), and the air temperature surrounding the leg were measured immediately before and after the spray application (water temperature 30 ± 3°C), and every 3 min until their coat was dry (a proxy for evaporation time), as measured by water sensitive paper applied to the coat. Data were analyzed with mixed models using SAS. In contrast to 0 min, all treatments reduced skin temperature on the shoulder (range of mean ± SE: –1.1 to –4.4 ± 0.2°C; $P < 0.01$), whereas treatments ≥1.5 min reduced RR (range: –7 to –24 ± 2 breaths/min; $P \leq 0.04$), and the surrounding air temperature (range: –0.3 to –1.8 ± 0.0°C; $P < 0.01$). Only spraying for ≥3 min reduced the upper leg temperature (range: –0.1 to –0.6 ± 0.0°C; $P < 0.01$). In general, the magnitude of the changes described above increased as the longer spray was on ($P < 0.05$). The coat took slightly longer to dry when cows were sprayed for 13 min compared with ≤3 min (mean ± SE = 16 ± 0.6 vs. 14 ± 0.5 min, respectively; $P < 0.01$). Within this period, RR increased by 5 breaths/min regardless of treatment ($P = 0.75$). Cooling benefits, as well as changes in air temperature surrounding the leg, were more pronounced when water was sprayed for longer. Spray duration had a little effect on evaporation time, and no additional cooling was observed in this phase.

Key Words: sprinklers, heat stress, spray length

0073 Association between rumination behavior, milk yield, and milk composition in dairy cows kept on commercial farms. T. Miedema and T. J. DeVries*, *Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada.*

Automatic sensors are able to give an accurate indication of the duration of time that dairy cows spend ruminating, allowing for collection of rumination data on cows kept in commercial environments. The objective of this study was to associate rumination behavior with milk yield and milk composition for lactating dairy cows kept in commercial operations. In this study, 8 commercial dairy farms in Eastern Ontario, Canada, were recruited for participation. Selection criteria included: free-stall housing, parlor milking, >90 lactating cows in the herd, primarily have Holstein-Friesian genetics, participated in a DHI program, and fed a TMR. Chosen farms had a mean herd size of 187 cows (range: 95 to 419 cows), mean adjusted 305-d milk yield of 11,228 kg (range: 9787 to 13,006 kg), and a geometric mean annual bulk milk SCC of 162,000 cells/mL (range: 145,000 to 172,000 cells/mL). Rumination time for 30 cows/herd was monitored using an automated rumination monitoring system. In total, the rumination activity of 240 lactating Holstein cows (57 ± 29 DIM) was monitored for 6 d and associated, in a multivariable general linear mixed model, with their production data (as measured by the closest in time DHI test, on average ± 3.5 d from the day of rumination sensor placement), controlling for farm, parity, DIM, body condition score, and dietary (TMR) characteristics (nutrient content and particle size). Across cows, rumination time averaged 506 ± 85 min/d (mean ± SD), milk yield averaged 44.7 ± 10.2 kg/d, milk fat averaged 3.69 ± 0.54%, and milk protein averaged 2.97 ± 0.24%. Rumination time increased with cow parity ($P < 0.001$) and tended ($P = 0.09$) to be positively associated with the percentage of long particles (>19 mm) in the TMR fed to the cows (+10.0 ± 5.5 min/d rumination time per 5% increase in long particles). Milk yield increased with cow parity ($P < 0.001$), milking 3× vs. 2× (+4.5 ± 2.3 kg/d; $P = 0.05$), and was positively associated with rumination time (+0.2 ± 0.07 kg milk per 10 min increase in rumination time per d; $P = 0.01$). Rumination activity was not associated with milk fat content, and tended ($P = 0.08$) to be quadratically associated with milk protein content. In summary, the results of this study demonstrate that rumination time, as measured on lactating cows on commercial dairy farms, could indicative of milk yield; however, it showed less consistent association with milk components.

Key Words: rumination, behavior, dairy cow

0074 Lameness, productivity and cow behavior in dairy herds with automated milking systems. M. T. King[*1], E. A. Pajor[2], S. J. LeBlanc[3], and T. J. DeVries[1], [1]*Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada,* [2]*University of Calgary, Calgary, AB, Canada,* [3]*Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to evaluate how herd management, barn design, and lameness relate to productivity and cow behavior in herds with automated milking systems (AMS). We visited 41 AMS farms in Canada (Ontario: $n = 26$; Alberta: $n = 15$), averaging 105 ± 56 (mean ± SE) lactating cows and 2.2 ± 1.3 AMS units. Details of barn design, stocking density, and herd management were collected. At each farm, 40 cows

were gait scored (or 30% for herds > 130 cows) using a five-point numerical rating system (NRS; 1 = sound to 5 = lame). Cows were defined as clinically lame with NRS $\geq$ 3 (26.2 ± 13.0%) and severely lame with NRS $\geq$ 4 (2.2 ± 3.1%). For 6 d periods, we collected milking data from AMS units and lying data from electronic data loggers. Data were analyzed in multivariable mixed-effect linear regression models. At the herd level, an increase of 1 percentage point (p.p.) in the prevalence of severe lameness was associated with production losses of 0.6 kg of milk produced/cow/d ($P = 0.05$) and 32 kg milk harvested/AMS/d ($P = 0.03$), while each 10 p.p. increase in clinical lameness prevalence was associated with 0.1 fewer milkings/cow/d ($P = 0.05$). One additional cow/AMS unit was associated with 32 kg more milk harvested/AMS/d ($P < 0.001$), but also decreased milking frequency (–0.2 milkings/cow/d for each 10 additional cows/AMS; $P < 0.001$). Daily lying time was positively associated with the frequency of feed push-ups (+3 min/cow/d/push-up; $P = 0.05$) and negatively associated with the placement of neck rails from the rear curb of lying stalls, such that cows lied down less as neck rails were placed farther forward (–23 min/cow/d/10 cm; $P = 0.03$). Lying bouts (min/bout) were 12 min longer in deep-bedded stalls vs. mattresses ($P = 0.003$), and 5 min longer with each 10 p.p. increase in the prevalence of clinical lameness ($P = 0.001$). In a cow-level comparison (30 cows/farm) of lame (NRS $\geq$ 3: $n = 353$) and sound cows (NRS < 3: $n = 865$), lame cows were fetched more often ($P = 0.002$), produced 1.6 kg/d less milk ($P = 0.002$) in 0.3 fewer milkings/d ($P < 0.001$), and spent more time lying down (+38 min/d; $P < 0.001$) in longer bouts (+3.5 min/bout, $P = 0.03$). In conclusion, lameness is especially problematic for AMS herds, reducing productivity at the cow and herd level. Although few cows in our study were severely lame, producers need to identify and reduce clinical lameness. Widening lying stalls, providing deep-bedded stalls, and scraping alleys more frequently were factors associated with reduced lameness prevalence and are potential ways to optimize productivity in AMS herds.

Key Words: automated milking, dairy cow behavior, lameness

0075 Assessment of biomarkers of pain and daily activity patterns in lactating dairy cows diagnosed with clinical metritis.

A. A. Barragan[1], S. Bas[*1], J. M. Piñeiro[1], G. M. Schuenemann[1], P. Rajala-Schultz[1], and D. Sanders[2], *[1]Department of Veterinary Preventive Medicine, The Ohio State University, Columbus, [2]Vaca Resources, Urbana, OH.*

Postpartum uterine diseases such as clinical metritis (MET) are associated with substantial economic losses due to reduced milk yield, delayed time to conception, treatment costs, and increased culling and death rates. Furthermore, MET has been characterized by bovine veterinarians as a painful event and can be regarded as a welfare concern since it can be associated with systemic signs, such as fever, depression, loss of appetite, and visceral pain. The objectives of this study were to: (1) assess the circulating concentrations of substance P, and (2) daily activity patterns (i.e., lying and standing time) in lactating dairy cows diagnosed with MET. Lactating dairy cows ($n = 200$) from two commercial dairy herds were enrolled in the present study. Cows diagnosed with MET ($n = 100$) at 7 ± 3 d in milk (DIM) were matched according to parity and DIM to cows without MET (noMET; $n = 100$). On study d 1, MET was diagnosed (using a metricheck device) by the presence of watery, reddish, or brownish foul-smelling vaginal discharge; blood samples were collected for assessment of circulating concentration of substance P. In addition, on study d 1 activity monitors were placed on the hind leg of cows (MET; $n = 56$; noMET; $n = 56$) and were kept until study d 7. Cows showing any other signs of disease were not included in the study. Data were analyzed using the MIXED procedure of SAS. Cows with MET had higher ($P = 0.0004$) plasmatic concentrations of substance P when compared with noMET cows (MET = 72.44 pg/mL; noMET = 55.73 pg/mL). Furthermore, cows with MET tended to spend more time lying ($P = 0.06$; MET = 635.60 min/d; noMET = 603.02 min/d) and less time standing ($P = 0.06$; MET = 804.08 min/d; noMET = 837.25 min/d) than noMET cows. These findings provide evidence that circulating concentrations of substance P are increased, and activity is affected in lactating dairy cows diagnosed with MET.

Key Words: metritis, substance P, activity

0076 Effect of social feeding environment on the feeding behavior of dairy cows and their willingness to consume a novel feed.

G. Mainardes and T. J. DeVries*, *Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada.*

Social contact may improve the willingness of dairy cattle to consume a novel feed. To test the impact of social contact while feeding and the reaction of mature cows toward a novel feed, we compared (1) animals fed individually (Single) and (2) cows fed in side-by-side in social pairs (Pairs). It was hypothesized that animals feeding beside each other would show similar behavioral patterns to each other, and a greater willingness to consume a novel feed product compared with those fed individually. Twelve Holstein cows (parity = 3.3 ± 1.3; mean ± SD) were assigned to four groups of three animals (each with two cows fed beside each other in adjacent feed bins and 1 fed alone on her own feed bin). Two feed types were offered separately: a familiar food made up of a total mixed ration (TMR) and an unfamiliar 5 kg of chopped carrots topped with 6 kg of TMR (as-fed). Each group was observed for 10 d, each consisting of 3 periods: (1) 4 d of adaptation (only TMR); (2) d 5 to 7 the carrots were introduced to the Single cow and to 1 of the 2 cows eating in Pairs; and (3) from d 8 to 10, all three cows were fed carrots and TMR. Dry matter intake (DMI), feeding behavior, rumination time, and sorting activity were

monitored for each animal. Cow behavior was observed for an hour after each feed delivery. Data were summarized by cow and period and analyzed in a repeated measures general linear mixed model. No differences in DMI of TMR (27.1 kg/d) or carrots (0.09 kg/d) and feeding time (193.9 min/d) were found between any animal eating as a Single or in Pairs. However, the DMI of carrots increased from Period 2 to Period 3 (0.04 to 0.12 kg/d; $P = 0.03$). In Period 2, Paired animals (typically heifers or younger animals feeding socially) ate faster than the other cows (0.19 vs. 0.13 and 0.12 kg DM/min; $P = 0.05$). In period 2, Paired cows tended to select more for medium particles (106 vs. 102% of predicted intake; $P = 0.08$) and sorted to a greater extent against short (97 vs. 99%; $P = 0.02$) and fine fractions (89 vs. 97 and 96%; $P = 0.05$). Overall, the intake of carrots was very low in all treatments; however, animals consumed more carrots in the third period. These results suggest that the acceptance of novel food might increase with the length of exposure. It is also concluded that animals showed similar feeding behavioral patterns regardless of feeding situation.

Key Words: novel feed, dairy cow, social feeding

0077 Effects of acute and chronic heat stress on feed sorting behavior of lactating dairy cows.

A. Dayton[1], A. P. A. Monteiro[2], X. Weng[2], S. Tao[2], and E. K. Miller-Cushon*[3], *[1]University of Florida, Gainesville, [2]University of Georgia, Tifton, [3]Department of Animal Sciences, University of Florida, Gainesville.*

The objectives of this study were to assess the effects of acute and chronic exposure to heat stress on feed sorting of dairy cows. Lactating Holstein dairy cows ($n = 32$; parity = 2.8 ± 1.2; mean ± SD) were group-housed in a free stall barn and milked three times per day. Cows were fed individually using Calan gates and offered ad libitum access (target 20% orts) to TMR (containing on DM basis: 3.3% ryegrass hay, 16.5% ryegrass baleage, 24.7% corn silage, 11.1% brewers grains, 19.7% ground corn, 19.8% concentrate, and 4.9% protein/mineral supplement), provided once per day. Cows were divided into two groups (balanced by days in milk and parity) and, beginning at 186 ± 60 DIM, were exposed to either heat stress (HT; $n = 15$) conditions (average temperature-humidity index in barn: 77.6), or evaporative cooling (CL; $n = 17$), consisting of misters and fans over the freestall and feed bunks to alleviate heat stress. Data were collected during a 4 d baseline period (starting 18 d before treatment), and two 4 d experimental periods: starting at 10 d after implementing treatments (during acute heat stress for HT cows), and at 62 d after implementing treatments (chronic heat stress for HT cows). Fresh TMR and orts samples were collected daily from individual cows for particle size analysis. The particle size separator had three screens (19, 8, and 1.18 mm) and a bottom pan, resulting in four fractions (long, medium, short, fine). Sorting was calculated as the actual intake of each particle size fraction expressed as a percentage of the predicted intake of that fraction. Data were analyzed using a repeated measures general linear mixed model, with sorting during the baseline period included as a covariate. During both acute and chronic heat stress, HT cows sorted in favor of the long particle fraction to a greater extent than CL cows (105.0 vs. 100.6%; SE = 1.09, $P = 0.001$). Sorting of medium and short particles were subject to treatment by period interactions ($P < 0.006$): in the period of acute heat stress, HT cows sorted to a greater extent than CL cows against medium (86.5 vs. 93.0%; SE = 0.36; $P = 0.006$) and short particles (94.1 vs. 97.5; SE = 0.64; $P = 0.002$), whereas in the period of chronic heat stress, sorting of HT cows did not differ from CL cows ($P > 0.9$). These results suggest that exposure to heat stress influences feed sorting and that feed sorting may increase in response to acute heat stress.

Key Words: feed sorting, heat stress, lactating dairy cow

0078 In utero exposure to heat stress during late gestation has prolonged negative effects on activity patterns of dairy calves.

E. K. Miller-Cushon*, K. C. Horvath, G. E. Dahl, and J. Laporta, *Department of Animal Sciences, University of Florida, Gainesville.*

Exposure to heat stress (HS) during the dry period not only negatively affects cow performance, but it also exerts carryover effects on postnatal performance of the calf. The objective of this experiment was to evaluate the health, responsiveness, and activity of heifer calves born to cows exposed to HS (provided only shade, $n = 13$) or cooling (CL, fans, soakers, and shade, $n = 9$) environmental conditions during the entire dry period (~56 d). On the day of calving, calves were fed 3.8 L of maternal (HS or CL) colostrum. Within 2.8 ± 2.6 h of birth, we scored suckling reflex (1–3; 1 = no suckling response, 3 = strong suckling response) and movement (1–3; 1 = not able to stand when prompted, 3 = stands promptly). Calves were housed in individual pens and provided pasteurized milk (6 L/d) and ad libitum access to grain and water, until weaning at 49 d. Activity was assessed during the first week of life (week 1), weaning (week 7), and the first week postweaning (week 8) using electronic data loggers (HOBO Pendant G data Logger, Onset computer corp., Pocasset, MA) attached to the left rear leg of the calf. Heifer health was monitored weekly from birth to weaning (heath score 1–5). Data were analyzed by time period in a general linear mixed model, with day as a repeated measure for activity data. All heifers were healthy through the duration of the experiment. At birth, the suckling reflex (1.8 vs. 2.1; SE = 0.24; $P = 0.33$) and movement score (2.42 vs. 2.33; SE = 0.18; $P = 0.69$) were similar for CL and HS calves, respectively. However, CL calves spent more time standing in the first week of life (303.6 vs. 254.3 min/d; SE = 9.6; $P < 0.001$) as a result of longer standing bouts (14.2 vs. 12.2 min/bout; SE = 0.55; $P = 0.006$). In weeks 7 and 8,

CL calves maintained greater total daily standing time (442.6 vs. 406.8 min/d; SE = 10.7; $P < 0.019$) and spent more time standing/bout (30.7 vs. 24.3 min/bout; SE = 1.2; $P < 0.001$). However, CL calves had less frequent standing bouts than HS calves (15.4 vs. 17.7 bouts/d; SE = 0.6; $P < 0.01$). These results suggest that in utero HS during late gestation can have prolonged negative effects on activity patterns of dairy calves.

Key Words: heat stress, calves, behavior

0079 Factors associated with the occurrence of stillborn calves. M. I. Chavez[*1], M. A. Mellado[2], E. Carrillo[3], and J. E. Garcia[2], *[1]Universidad Autonoma Agraria Antonio Narro, TORREON, Mexico, [2]Universidad Autonoma Agraria Antonio Narro, Saltillo, Mexico, [3]Instituto Tecnologico de Torreon, Torreon, Mexico.*

The aim of this study was to determine the prevalence of stillborns calves in nulliparous and pluriparous cows in the Laguna region, as well as the effect of the type of delivery, duration of pregnancy, occurrence of dystocia, use of sexed semen and sex of calf on the occurrence of stillborns calves. The study was conducted in a large dairy operation in Laguna region (26° N). A data set of both pluriparous and nulliparous Holstein cows (2010–2014) were collected, with a total of 22,996 births. The data were statistically analyzed with descriptive methods for determining the percentage of stillborns. Odds ratios were calculated using logistic regressions (PROC LOGISTIC of SAS) for risk factors that affect the occurrence of stillborns. The results showed that gestations > 279 d decreased the occurrence of stillborns (odd ratio = 0.07, CI = 0.5–0.8; $P < 0.004$). Male calves were six times more likely (95%CI = 4.6–7.9; $P < 0.001$) to be stillborn than females. Calves with birth weight at calving ≥39 kg were less likely to be stillborn (odd ratio = 0.02, 95% CI = 0.1 to 0.2; $P < 0.001$) than lighter calves at birth. Calves derived from sexed semen breedings were twice as likely to be stillborn (95% CI = 1.6–2.7; $P < 0.001$) than calves from conventional semen. Calves coming from dystocic parturition were twice as likely (95% CI = 1.4–2.9; $P < 0.001$) to be stillborn than calves coming from normal deliveries. It was concluded that all variables studied importantly influence the occurrence of stillborns, particularly, sex of the offspring.

Key Words: stillbirth, calves, dystocia

0080 Reducing heat stress in calf hutches using reflective covers: Optical properties and implications. T. H. Friend[*1] and L. Y. Carrillo[2], *[1]Texas A&M University, College Station, [2]NASA Johnson Space Center, Houston, TX.*

Previous research found that reflective hutch covers reduced ceiling, black globe, and air temperatures within polyethylene hutches, reduced panting, and tended to improve weight gain and calf health. This engineering study reports on the optical properties of materials that can be used to improve the comfort of calves housed in polyethylene calf hutches. The opaque materials were tested in the infrared and solar ranges to determine the efficiency of the surface to absorb radiation at the NASA Johnson Space Center's Thermal Design Branch, Materials Laboratory, in Houston, TX (NASA-JSC). A model was also developed by NASA-JSC to assess the relative impact of each material in terms of British Thermal Unit (BTU)/h. The price and longevity in on-farm testing indicated that a custom aluminized low-density 3-mil thick white and black polyethylene (LDPE) was the most promising material for optical testing. Samples were tested in triplicate (unless the first two tests were identical), and the results were averaged. The high absorptivity (83.8%) of solar radiation of the hutch (Table 1) indicates reflective coverings could be very useful in keeping calves cooler. The aluminized side of the white aluminized LDPE had a low solar absorptivity (16.3%), indicating it reflects 83.7% of the incident solar energy. The aluminized black LDPE has characteristics that indicate its potential to be useful during winter, with the aluminized side turned toward the calf. The NASA-JSC model found that the bare hutch absorbed 1959 BTU/h/m^2 while the aluminized white LDPE absorbed 893 BTU/h/m^2 at its surface, indicating its potential to reduce solar heating of the hutch. The black side of the aluminized black LDPE absorbed 5037 BTU/h/m^2, indicating potential to warm hutches during sunny days in the winter. The optical properties of the aluminized polyethylene helps explain the findings from prior hot weather trials and supports further research on its winter applications.

Table 0080.

Table 1. Mean percent absorptivity (range) in the infrared and solar spectrums for the materials tested.

Material tested	Infrared	Solar
Commonly used calf hutch	50.4 (0.6)	83.8 (1.3)
Aluminized side white LDPE	9.3 (2.8)	16.3 (0.8)
White side of Al LDPE	60.1 (3.8)	38.6 (0.9)
Aluminized side black LDPE	9.7 (0.6)	19.8 (0.4)
Black side of Al LDPE	85.5 (1.5)	94.3 (0.0)

Key Words: calf, hutch, heat stress

0081 Sprinkler system in a holding pen: Behavioral responses of dairy cows during the subsequent grazing. S. V. Matarazzo[*1], D. S. Mello[1], L. M. de Toledo[2], I. Arcaro Júnior[2], and S. A. D. A. Fernandes[3], *[1]State University of Santa Cruz, Ilhéus, BA, Brazil, [2]Animal Science Institute, Nova Odessa, SP, Brazil, [3]State University of Southwestern Bahia, Itapetinga, BA, Brazil.*

Our objective was to evaluate the effects of cooling systems in a holding pen and its effects on the behavioral responses of pasture-based dairy cow. The experiment was performed

during February and March, 2014. Thirty-six black and white Holstein cows (BW = 527 ± 49 kg) were used in a crossover design (6 × 3). The cows were divided into groups of two animals (n = 18 groups) and each group was acclimated for 3 d following 6 d of data collection (2 d/treatment). The treatments used were: (1) control: no cooling, (2) sprinkler with media flow (MF): 0.08 L of water/nozzle/min, and (3) Sprinkler with high flow (HF): 1.00 L of water/nozzle/min. The sprinkler cycle included 30 s of water spraying and 60 s turned off. Cows were milked twice daily (0630 h and 1430 h) and treatments were applied during 20 min before each milking. After the milking routine, dairy cows were allowed to graze as a single herd. Environmental variables air temperature (AT), relative humidity (RH), black globe temperature (BGT), temperature humidity index (THI), and heat load (HLI) were recorded in a holding pen, in a pastured area and under the natural shade present at the grazed area. The dairy behavior (posture, location, and activity) was monitored from 0800 to 1230 h and from 1530 to 1800 h every 10 min. Panting score (PS) was evaluated each 15 min. The difference in water flow used in sprinkler systems reduced (P < 0.01) HLI and THI in a holding pen. However, sprinkler systems did not change behavioral patterns of dairy cows on pasture. The lowest PS average occurred at 0800 h (0.04) and highest at 15 h (0.75). PS was positively correlated (ρ = 0.94) with the THI under the shade, and it was negatively associated with the time spend on the paddock (ρ = –0.63). Cows were observed 50% of the time in rest activity, followed by grazing activity (25%), rumination (14%), other activities (9%), and drinking water (2%). The HLI was negatively correlated (ρ = –0.82) with the percentage of time spent on grazing. Cows spent 89% under natural shade during the hottest hours. The results demonstrate which evaporative cooling system used in a holding pen has immediate and short-term effect on dairy cows.

Key Words: welfare, evaporative cooling, pasture-based system

0082 Evaluation of alternative flooring surfaces for dairy goats. M. A. Sutherland*, G. L. Lowe, C. M. Ross, D. Rapp, and G. A. Zobel, *AgResearch, Hamilton, New Zealand.*

In New Zealand, dairy goats are predominantly housed on sawdust; however, previous studies suggest that goats may prefer alternative surfaces. Therefore, the aim of this study was to evaluate the effect of four different flooring types on goat behavior and cleanliness. At 6 mo of age, 32 female Saanan cross does (45.4 ± 6.10 kg) were restricted to one of four different flooring types for 10 d, then restricted to the other three surfaces (10 d per surface) using a Latin square design consisting of eight replicates (n = 4 goats per replicate). The four flooring types included sawdust (SW), metal slats/grating (MT), plastic slats (PL), and rubber matting (RB). Goats were then given free access to all four flooring types simultaneously for 48 h. Lying behavior and position in the pen were recorded for 24 h at the end of the free access period using camcorders and accelerometers. To assess goat cleanliness, swab samples were collected from the udder of two goats per replicate over the restriction period, and *Escherichia coli* counts were analyzed by the most probable number method. Data were analyzed by ANOVA and results are presented as least square means ± SE. At the end of the study, when given free access to all flooring types simultaneously, goats spent more (P < 0.005) time lying on RB (50 ± 4.5%) than PL (31 ± 4.5%), MT (8.6 ± 4.5%), or SW (9.7 ± 4.5%), and more (P < 0.005) time on PL than MT or SW. The same preference was shown for the standing surface (P < 0.05). The number of *E. coli* recovered from the udder was highest (P < 0.001) after goats were restricted on SW (median: 0.5 Log per cm^2; range: 0.1–1.0 Log per cm^2) than MT (median: 0.1 Log per cm^2; range: 0–1.0 Log), PL (median: 0 per cm^2; range: 0–0.2 Log per cm^2) or RB (median: 0 per cm^2; range: 0–2.1 Log per cm^2). These results suggest that goats had a preference for lying on RB and least preferred lying on MT and SW. In addition, RB appeared to be cleaner than SW. Therefore, it may be advantageous to provide dairy goats with RB lying surfaces, but further investigation into implementing this into commercial dairy goat housing facilities is needed.

Key Words: bacteriology, behavior, welfare

0083 Risk factors associated with lameness severity in feedlot cattle. S. Marti[1,2], E. D. Janzen[1], K. Orsel[1], M. J. Jelinski[3], L. C. Dorin[3], E. Pajor[1], J. K. Shearer[4], S. T. Millman[5], J. F. Coetzee[6], D. U. Thomson[7], and K. S. Schwartzkopf-Genswein*[2], *[1]University of Calgary, Calgary, AB, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [3]Veterinary Agri-Health Services, Airdrie, AB, Canada, [4]Iowa State University, Ames, [5]Department of Veterinary Diagnostic & Production Animal Medicine, Iowa State University, Ames, [6]Pharmacology Analytical Support Team, Iowa State University College of Veterinary Medicine, Ames, [7]Department of Diagnostic Medicine/Pathobiology, Kansas State University, Manhattan.*

Lameness is of significant health, welfare, and economic concern in feedlot cattle. However, few studies have identified the risk factors associated with becoming lame or the severity of lameness. The objective of this study was to determine the relationship between animal, feedlot management, and environmental risk factors associated with lameness severity in feedlot cattle. Between 2013 and 2015, data on lame cattle was collected weekly from two large feedlots (>10,000 head) in Southern Alberta. Animal variables included sex, breed, days on feed (DOF), type of cattle, source, number of implants/vaccination, body weight (BW), body condition score (BCS),

rectal temperature, hide mud score, location of affected limb, salivary cortisol, and lameness diagnosis. Feedlot management variables included diet composition, frequency and time of feeding, pen and bunk space, group size, and location of the water. Finally, environmental variables included weather (minimum, maximum, average temperature, and temperature differential; relative humidity; THI, and precipitation), pen condition, pen mud depth, and season. Lameness severity was assessed in 1128 cattle using a five-point gait score: (1) Sound; (2) Mild: slightly abnormal gait and arches back when walking; (3) Moderate: stands and walks with arched back, head bob with short strides (4) Severe: (as described for score 3) with the addition of reduced weight bearing on affected limb and slow movement with frequent stops 5) Highly Severe: reluctant to move, bears no weight on affected limb. Animal, management and environmental risk factors were tested for collinearity and data were analyzed using a stepwise multiple logistic regression separately for each group of risk factors. Significant variables remaining in each model were combined and analyzed as described above. The F-to enter and F-to remove were set at 0.15 and 0.10, respectively. Animals lame in the fore limbs had greater ($P = 0.03$) lameness severity than those with hind limb lameness. Lameness severity increased ($P < 0.01$) by 0.4% for every 1 d increase in DOF. In addition, lameness severity increased ($P = 0.001$) with number of implants/vaccinations administered. Finally, cattle housed in pens with a mud depth greater than 5 cm had double ($P < 0.01$) the risk of becoming severely lame as those cattle housed in pens with a mud depth < 5 cm. To successfully reduce lameness in feedlots, interventions should be focused on reducing DOF, handling frequency and pen mud depth.

Key Words: lameness, beef, risk factors

0084 Assessment of acute pain during and after knife and band castration following a single dose of Meloxicam in 1-wk-old beef calves.

D. M. Melendez[1,2], S. Marti[1,2], E. D. Janzen[1], D. Moya[1,2], D. R. Soares[1,2], E. A. Pajor[1], and K. S. Schwartzkopf-Genswein[*2], *[1]University of Calgary, Calgary, AB, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Beef producers are often advised to castrate calves as early as possible to reduce pain associated with tissue damage. However, there has been no research to determine if 1-wk-old calves do not feel pain at the time of castration. The aim of this study was to assess the effects of a single dose of s.c. meloxicam (Metacam®, 0.5 mg/kg BW) immediately before castration on pain mitigation during and after castration in 1-wk-old beef calves. Seventy-two 1-wk-old Angus bull calves were randomly assigned to one of 6 treatments ($n = 12$): control (C), band (B), or surgical castration (S) without meloxicam; and control (CM), band (BM) or surgical castration (SM) with meloxicam. Data were collected on d –1 before castration, immediately before castration, 60, 90, 120 min and 1, 2, 3, and 7 d after castration, except for the visual analog score only obtained during castration. Physiological measures included salivary cortisol (SC), haptoglobin (HP), substance P (SP) and scrotal area temperature (SAT). Behavioral measures consisted of a visual analog score (VAS), hind limb stride length (SL) and daily lying and standing durations. None of the physiological or behavioral parameters assessed differed between calves castrated with or without pain medication. A time × treatment interaction ($P = 0.02$) was observed for SC, S and B calves had greater SC concentrations 60 min after castration compared with C calves, while B calves had greater concentrations compared with C calves 90 min after castration. A time × treatment interaction ($P = 0.01$) for SAT was observed; S calves had lower scrotal temperatures compared with C calves 60 min after castration, while S had lower temperatures compared with B, and S and B had lower temperatures compared with C 90 and 120 min after castration. A time × treatment interaction ($P < 0.01$) was also found where B calves had lower temperatures compared with C and S 1, 2, 3, and 7 d after castration. The VAS was greater ($P < 0.001$) in S than B calves, and in S and B compared with C calves. As expected, knife and band castrated calves exhibited more signs of acute pain compared with noncastrated controls; however, results suggest that subcutaneous Meloxicam administered immediately before band or knife castration did not eliminate behavioral or physiological indicators of acute pain or discomfort in 1-wk-old calves.

Key Words: castration, acute pain, beef, calf, cortisol, behavior

0085 Effect of castration method and analgesia on inflammation and behavior in feedlot cattle.

S. L. Roberts[*1], H. D. Hughes[1], J. G. Powell[2], and J. T. Richeson[1], *[1]Department of Agricultural Sciences, West Texas A&M University, Canyon, [2]Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville.*

There is little agreement on the best castration method in feedlot cattle; a recent USDA survey reported 52.3 and 41.1% of bulls are surgically and band castrated, respectively, and analgesia may mitigate inflammatory pain associated with either method. Our objective was to determine the effect of castration timing (birth vs. feedlot entry), method (surgical vs. banding) and use of the analgesic meloxicam (MEL) on behavior and inflammation in feedlot cattle. This study was a randomized complete block design conducted over a 3-yr period. Single-source Angus × Hereford steer ($n = 42$) and bull ($n = 152$) calves were randomized at birth to one of five treatments arranged as a 2 × 2 + 1 factorial: (1) steers castrated near birth (CON), (2) bulls surgically castrated without MEL (SUR), (3) bulls surgically castrated with MEL (SUR+MEL), (4) bulls band castrated without MEL (BAN), and (5) bulls

band castrated with MEL (BAN+MEL). Upon feedlot arrival (d –10), animals were blocked by initial BW (224 ± 4.5 kg) and assigned randomly to treatment pens (n = 6). Oral MEL was administered at 1 mg/kg BW concurrent with castration on d 0. Blood samples were collected from a subset of animals (n = 5 animals/pen) on d 0, 0.25, 1, 4, 7, and 14 to determine haptoglobin (Hp) concentration, as a proxy for inflammation. On d –10, accelerometers were placed on the same subset of cattle to determine baseline and postcastration changes in behavior indicative of pain; activity variables (standing, steps, lying bouts, motion index) were continuously logged and averaged by d. There was a treatment × day interaction (P = 0.04), with SUR animals having the greatest (P < 0.01) concentration of Hp on d 1 and 4. Meloxicam administered during surgical castration reduced (P = 0.01) Hp concentration relative to SUR on d 1. Method of castration had contrasting effects on specific behavior variables. Relative to baseline, standing duration for surgical castration increased 113 min (P < 0.01), while banding caused 6.7 more lying bouts (P < 0.01) immediately following castration on d 0. Steps were increased on d 0 for banded (2723), intermediate for CON (2216), and least (1801 steps) for surgical (P < 0.01). Results suggest that MEL mitigated the more pronounced inflammation observed for surgical castration; whereas, behavior was differentially altered for castration method indicative of a divergent pain response.

Key Words: analgesia, beef cattle, castration

0086 A systematic review-meta-analysis of castration and welfare indicators in beef cattle.

M. E. A. Canozzi[1], A. Mederos[2], D. Zago[1], G. R. Pereira[1], and J. O. Barcellos[*1], *[1]NESPRO/UFRGS- Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [2]National Research Institute for Agriculture, Tacuarembo, Uruguay.*

To quantify the effects of castration in male beef cattle on welfare indicators based on cortisol concentration, average daily gain (ADG) and vocalization, a systematic review and meta-analysis were performed. We searched on five electronic databases (CAB Abstracts, ISI Web of Science, PubMed, Agricola, and Scopus) from January 1900 to May 2015 and included conference proceedings and electronically contacted experts, and also checked references of relevant review papers. Inclusion criteria were complete studies using beef cattle until 1 yr of age undergoing castration that analyzed cortisol level, ADG, or vocalization. Data were extracted using predefined protocols. The included documents were written in English, Spanish, Portuguese, or Italian. Random effect meta-analyses were conducted for each indicator separately with the mean of control and treated group. Possible influences of study characteristics and quality were assessed in meta-regression analyses. A total of 18 prospective publications reporting 23 studies and 156 trials were included in the MA involving 1617 animals. Significant between studies heterogeneity was observed for MA results when analyzing cortisol and ADG. Regardless the control group and the castration technique, the comparison analyses showed no changes ($P \geq 0.05$) changes on cortisol levels when castration was performed without drug administration. We found no evidence ($P \geq 0.05$) for multimodal therapy in decrease cortisol concentration 30 min after surgical procedure. Anesthesia tended to decrease cortisol level (MD = 0.411 nmol/L; P = 0.077; 95% CI: –0.868, 0.045) 120 min after surgical castration compared with castrated group without drug administration. Random-effect meta-analysis suggested an increase in ADG in surgical (MD = 0.231 g/d; P = 0.010; 95% CI: 0.056, 0.405) and nonsurgical castration (MD = 0.883 g/d; P < 0.001; 95% CI: 0.313, 1.453) with no pain mitigation in comparison to uncastrated cattle. Publication bias was observed when cortisol was studied as an outcome, indicating that small size studies reporting nonsignificant effect were less likely to be published than similar studies with significant effect. In a meta-regression, only publication type contributed to the total variation (18.52%) when the outcome evaluated was ADG. The vocalization score presented data in a manner that was not suitable to MA. Our MA study demonstrates an inconclusive result to draw recommendations on preferred castration practices to minimize pain in beef cattle.

0087 Blocking the steer's view of people during restraint in a squeeze chute results in calmer behavior.

M. L. P. Lima[*1], R. Woiwode[2], C. C. P. Paz[3,4], and T. Grandin[2], *[1]Instituto de Zootecnia, Sertãozinho, Brazil, [2]Colorado State University, Fort Collins, [3]Universidade de Sao Paulo, Faculdade de Medicina de Ribeirao Preto-Departamento de Genetica (USP/FMRP), Ribeirao Preto-SP, Brazil, [4]SAA/APTA/Instituto de Zootecnia-Centro de Bovinos de Corte, Sertaozinho-SP, Brazil.*

The aim of this study was to evaluate if facility design influences cattle behavior. Two types of systems were compared: open sides (OP) or solid wall (SW). To meet the objectives of this study, cattle were assessed at nine feedyards, according to the BQA Feedyard Assessment (FA) guidelines for cattle handling in commercial feedlots. Each bovine was observed once during and after vaccination processing. Four-hundred steers, from five feedyards were observed in the OP design, and 380 steers, from four feedyards were observed in SW. The variables recorded were vocalization, miscaught (MH), exit gait (run, trot, or walk) and exit behavior (jump, stumble, and fall). The statistics model for analyses included two factors: facility design (SWxOP), and feedyard. The SW design reduced vocalization (P = 0.0003) and had no effect for MH (P = 0.3158). From observed animals, respectively for OP and SW, 41.5% and 26.3% vocalized and 1.6% and 2.5% MH. There was effect on exit gait (P < 0.001) and on exit behavior

($P = 0.0008$). Steers processed in OP conditions exited faster than steers observed in the SW design, with 56.2 and 36.2% running and trotting for OP, and 23.2 and 66.9% running and trotting for SW, respectively. In conclusion, if the view of cattle is restricted during restraint, the frequency of vocalization will decrease, and exit speed will be reduced.

Key Words: cattle behavior, corral, feedyard

0088 Effect of different hydraulic squeeze chute and cattle breed on behavior of steer during restraining in feedyard facilities.

M. L. P. Lima[*1], R. Woiwode[2], C. C. P. Paz[3,4], and T. Grandin[2], *[1]Instituto de Zootecnia, Sertãozinho, Brazil, [2]Colorado State University, Fort Collins, [3]Universidade de Sao Paulo, Faculdade de Medicina de Ribeirao Preto-Departamento de Genetica (USP/FMRP), Ribeirao Preto-SP, Brazil, [4]SAA/APTA/Instituto de Zootecnia-Centro de Bovinos de Corte, Sertaozinho-SP, Brazil.*

The objective of this study was to investigate the relationship between hydraulic squeeze chute brand, breed of steers, and their behavior during processing in feedyard facilities. Two brands of hydraulic squeeze chute (A and B) and three breeds of cattle (Angus, Hereford and Continental cross) were compared. The assessments were made in 11 feedyards, totaling 1083 steers, using the BQA Feedyard Assessment (FA) guidelines for cattle handling in commercial feedlots. Each steer was observed once during and after the vaccination processing. Six feedyards had hydraulic squeeze chute (HSC) brand A (A) and eight feedyards had HSC brand B (B). The behavior variables of interest were vocalization, miscaught (MH), exit gait (run, trot or walk) and exit behavior (jump, stumble and fall). An effect of HSC brand on vocalization ($P < 0.0001$), exit gait ($P < 0.0001$) and exit behavior ($P < 0.0001$) was observed, but no effect on MH ($P = 0.52$) was observed. There was an effect of breed on vocalization ($P < 0.0001$), exit gait ($P < 0.001$) and exit behavior ($P < 0.0001$). The results for vocalization, run, trot, and jump were 25.8, 53.9, 40.4, and 14.4% for HSC A and 63.7, 42.5, 48.7, and 37.6% for HSC B, respectively. The results for vocalization, run, trot and jump were 15.1, 44.4, 47.5, and 29.4% for Angus; 2.7, 66.7, 28.8, and 17.8% for Hereford; and 22.2, 40.8, 50.7, and 31.8% for Continental cross, respectively. Brand of hydraulic squeeze chute and breed of cattle can influence the behavior of steers during and after restraining in feedyard facilities.

Key Words: breed, cattle behavior, feedyard, squeeze

0089 Movement and spatial proximity patterns of rangeland-raised Raramuri Criollo cow-calf pairs.

S. Nyamurekung'e[1], A. Cibils[1], R. Estell[*2], A. Gonzalez[2], O. Roacho-Estrada[3], and F. A. Rodríguez-Almeida[3], *[1]New Mexico State University, Las Cruces, [2]Jornada Experimental Range, Las Cruces, NM, [3]Universidad Autónoma de Chihuahua, Chihuahua, Mexico.*

The objective of this study was to compare movement patterns of nursing vs. nonnursing mature cows and to characterize cow-calf proximity patterns in two herds of Raramuri Criollo cattle. Herds grazed rangeland pastures in southern New Mexico (4355 ha) and west-central Chihuahua, Mexico (633 ha). At each site, five nursing and four nonnursing adult cows weighing approximately 325 kg were fitted with Lotek 3300 LR GPS collars which recorded animal position at 10-min intervals for 25 d during March to April 2015. Nursing cows and their calves were also fitted with Sirtrack proximity loggers that recorded number and length of dam-calf contact events ($\leq$3m distance). All calves were $\leq$2 wk old at the onset of the study. Collared animals grazed with a herd of 30 and 68 adult cows at the NM and Chihuahua sites, respectively. Distance traveled and path sinuosity of cows and time spent by calves within 3 m of their dam and number of dam-calf contact events during day and nighttime hours were calculated. Movement data were subjected to ANOVA to determine effect of cow state (nursing vs. nonnursing) on distance traveled and path sinuosity. ANOVA was also used to determine if calves spent similar amounts of time within 3 m of their dam during day vs. nighttime hours. PROC MIXED (SAS 9.3) with a randomized complete block design was used for statistical analyses. No differences were detected in distance traveled by nursing and nonnursing cows over a 24-h period (8.43 vs. 8. 56 ± 0.29 km; $P = 0.67$), daytime (5.47 km vs. 5.75 ± 0.24 km; $P = 0.24$), or nighttime hours (2.96 vs. 2.80 ± 0.15 km; $P = 0.32$). However, nighttime/daytime ratio of distance traveled was greater for nursing cows (0.62 vs. 0.55 ± 0.08; $P = 0.05$). Nursing cows exhibited more sinuous 24 h travel trajectories compared with nonnursing counterparts (0.13 vs. 0.18 ± 0.05 km; $P < 0.01$). Calves spent on average 66.9 ± 3.41 min/d within 3 m of their dam, distributed over 86.4 ± 3.7 proximity events/d. Minutes spent by calves within 3 m of their dam were not different for day vs. nighttime periods ($P = 0.07$); however, more contact events occurred during daytime hours (predawn = 13.8; AM = 26.1; PM = 22.0; postsunset = 24.5 ± 2.02 contact events). Physiological state of Criollo cows affected their movement patterns in large rangeland pastures.

Key Words: Raramuri Criollo, beef cattle, maternal behavior

0090 Effects of predation on cortisol and progesterone levels in gestating ewes. M. Ward*[1], A. F. Summers[2], S. Roscano[1], J. Beard[1], S. A. Soto-Navarro[1], and D. M. Hallford[2], *[1]New Mexico State University, Las Cruces, [2]Animal and Range Science Dep., New Mexico State University, Las Cruces.*

Production losses due to predation in range livestock are typically quantified by death loss. However, little is understood concerning the long term impacts chronic exposure to predation may have on surviving animals. Pregnant Dorper and Suffolk × Hampshire ewes (n = 40) located on the main sheep unit of the NMSU campus farm were attacked by two dogs in February 2015. During the attack, four ewes were killed or had to be euthanized and five died later based on complications from injury. Over 75% of the remaining flock sustained injury. To better understand the impacts of predation on surviving animals, blood was collected via jugular venipuncture at 4, 24, 48, and 72 h post attack. Furthermore, a subset of ewes located at the west sheep unit, not exposed to the attack, were only bled at 4 h (CON). Ewes were classified based on injury status and location into three treatments; CON = no exposure, E = exposed to dog attack with no visible injuries, and EI = exposed to dog attack with visible injury. At 4 h, EI had greater cortisol levels than both CON and E ($P < 0.01$). At 24 h, both E and EI had greater circulating cortisol than CON ($P < 0.01$). At 72 h, EI was still greater than CON ($P < 0.01$); however, CON and E cortisol levels were similar ($P > 0.05$). The attack had no effect ($P > 0.05$) on circulating progesterone across treatments. These data demonstrate increased circulating concentrations of cortisol in ewes receiving injury 4 h after attack, whereas blood cortisol concentrations were not greater than CON in the E group until the 24 h sampling. Although dog attack occurred approximately 2 wk before lambing, there was no difference in proportion of ewes experiencing dystocia (P = 0.27) or the level of dystocia (P = 0.15) based on a 3-point scale (0 = no complications, 1 = some complications, 2 = severe complications) for EI and E ewes. These data indicate exposure to predation impacts stress responses at similar levels as those injured. Additional information is needed to determine the length of time cortisol remains elevated within the two treatment groups and at which stage of gestation predation would negatively impact lambing success.

Key Words: sheep, livestock, cortisol

0091 Feeding and watering behavior of Nellore bulls fed with or without calcium, phosphorus and trace minerals supplemental sources. D. Zanetti*[1], L. A. Godoi[2], M. M. Estrada[2], F. A. S. Silva[3], L. F. Prados[2], T. E. Engle[4], and S. C. Valadares Filho[5], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Brazil, [3]Universidade Federal de Vicosa, Vicosa, Brazil, [4]Colorado State University, Fort Collins, [5]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil.*

Forty-two Nellore beef bulls were utilized to investigate the impact of roughage source and mineral supplementation on feed and water intake. Basal diets were formulated with feeds commonly utilized in Brazilian feedlot diets, with or without

Table 0091.

[1] Diet composed by sugarcane and concentrate based in soybean hulls, with supplementation of Ca, P and TM. [2]Diet composed by sugarcane and concentrate based in soybean hulls, without supplementation of Ca, P and TM. [3] Diet composed by sugarcane and concentrate based in soybean meal and grounded corn, with supplementation of Ca, P and TM. [4] Diet composed by sugarcane and concentrate based in soybean meal and grounded corn, without supplementation of Ca, P and TM. [5] Diet composed by corn silage and concentrate based in soybean meal and grounded corn, with supplementation of Ca, P and TM. [6] Diet composed by corn silage and concentrate based in soybean meal and grounded corn, without supplementation of Ca, P and TM. [7] A = SH100 versus SH0. [8] B = SC100 versus SC0. [9] C = CS100 versus CS0. [10] D = (SH100, SC100 and CS100) versus (SH0, SC0 and CS0).

supplemental Ca, P, and trace minerals. Dietary treatments consisted of: (1) Sugarcane as the roughage source and a concentrate that consisted of soybean hulls with (SH100) and without (SH0) Ca, P, and TM supplementation; (2) Sugarcane as the roughage source and a concentrate base that contained soybean meal and ground corn with (SC100) and without (SC0) Ca, P, and TM supplementation; and (3) corn silage as the roughage source and a concentrate that contained soybean meal and ground corn with (CS100) and without (CS0) Ca, P, and TM supplementation. Supplemental minerals were formulated to meet or exceed the BR Corte (2010) requirements for Nellore bulls. Cattle were housed in a group pen for 125 d. The pen contained electronic feeders and waterers that allowed for individual animal consumption data to be collected. Comparisons between treatment means were made using orthogonal contrasts. The contrasts evaluated were: (A) SH100 vs. SH0; (B) SC100 vs. SC0; (C) CS100 vs. CS0; and (D) (SH100, SC100, and CS100) vs. (SH0, SC0 and CS0). Total DMI and time spent consuming feed (kg/min) were not affected by supplemental Ca, P, and TM. Cattle receiving supplemental minerals tended ($P < 0.08$) to have less visits to the feeder per day when compared with cattle not supplemented with minerals. Cattle consuming sugarcane based diets had more ($P < 0.05$) visits to the feeder per day than cattle consuming corn silage based diets, but DMI was similar across treatments. Cattle receiving diets containing soybean hulls with supplemental minerals consumed more water (total and liters/d) and liters per minute and per visit when compared with cattle receiving diets containing soybean hulls with no supplemental minerals. We concluded that, with absence of Ca, P, and TM in diet, the number of feeding times increased without affecting DMI, and water intake was reduced.

Key Words: corn silage, feeding rate, sugarcane

0092 Effects of ventilation and water misting on the physiological response of pigs kept in a stationary trailer before unloading.

T. Pereira[1], N. Devillers[2], R. Sommavilla[3], R. Friendship[4], F. Guay[5], F. Dalla Costa[6], E. A. Titto[7], L. Faucitano[*8], *[1]University of Sao Paulo, Pirassununga, Brazil, [2]Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, [3]Agriculture & Agrifood Canada, Sherbrooke, QC, Canada, [4]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, [5]Universite Laval, Quebec City, QC, Canada, [6]Universida Estadual Paulista, Jaboticabal, Brazil, [7]University of São Paulo, School of Animal Science and Food Engineering, Pirassununga, Brazil, [8]Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.*

This study aimed at evaluating the effects of ventilation combined with water-misting on the physiological response of pigs kept in the truck during the waiting time before unloading at the slaughter plant. In the summer 2015 (19.7 ± 4.0°C, ranging from 16.5 to 28.1°C), a total of 2674 pigs were transported from a farm to a slaughter plant (2 h trip) using two pot-belly trailers (seven loads of 191 pigs/trailer). On arrival at the plant, the two trailers were kept stationary during a 30 min waiting period before unloading. During this time, one of the two trailers was exposed to external forced ventilation and misting for 30 and 10 min, respectively, using a fan-mister bank located near the unloading dock, while the other trailer (control) was not exposed to any cooling procedure. A total of 168 pigs (24 per trailer) were equipped with a gastro-intestinal tract temperature (GTT) monitor (High Resolution Thermochron iButton) for real-time recording of GTT data. Blood was collected from these pigs at exsanguination for the analysis of cortisol, lactate and creatine kinase concentrations, and hematocrit. Data were analyzed using the mixed model procedure of SAS. A probability level of $P \leq 0.05$ was chosen as the limit for statistical significance in all tests. A delta GTT (ΔGTT) was calculated as the difference between the measured GTT at a determined event and the GTT measured at rest. Except for the blood hematocrit level that was lower ($P < 0.05$) in pigs being exposed to the cooling procedure while waiting in the trailer, the cooling treatment had no effect on any blood parameter. At the end of the wait period and at unloading, the decrease of GTT was greater (higher-ΔGTT value; $P < 0.05$) in control pigs than in those exposed to the cooling treatment. This result may be explained by the greater heat loss of control pigs due to heat stress. Based on these results, the cooling method applied in this study appears to improve the thermal comfort and reduce dehydration in pigs kept in a stationary truck before unloading at the slaughter plant.

Key Words: pigs, transport, thermal comfort

0093 Increased intake of tannin-rich sainfoin (*Onobrychis viciifolia*) pellets by parasitized and nonparasitized sheep after a period of conditioning.

M. Costes-Thiré[*1], J. J. Villalba[2], H. Hoste[3], and C. Ginane[4], *[1]INRA Clermont-Ferrand/Theix, St Genès-Champanelle, France, [2]USU- Utah State University, Logan, [3]UMR 1225 INRA DGER, 23 Chemin des Capelles, Toulouse, France, [4]Institut National de la Recherche Agronomique (INRA), St-Genès-Champanelle, France.*

Individuals alter their behavior and phenotypic traits in response to environmental challenges. Recent studies suggest that parasitized herbivores are able to select tannin-containing plants with anthelminthic activity. The objective of this study was to determine whether parasitized sheep learn to prefer tannin-rich sainfoin pellets. Forty lambs (4 mo old) were randomly assigned to two groups ($n = 20$). The parasitized group (PG) was infected with 3000 L3 stage larvae of *Haemonchus contortus*, and the other group (nonparasitized; NP) was not infected. Animals were submitted to preference tests by

offering a free choice between sainfoin pellets with high (T+; 4%) or low (T–; 2%) concentration of condensed tannins during three periods of 4 d each: Initial (Test 1), after the group PG developed an infection (Test 2), and after conditioning, when all animals consumed just T+ for 21 d so that parasitized animals experienced the benefits of therapeutic doses of condensed tannins (Test 3). Preference ([intake of T+ or T–] × 100/[total intake]) and fecal egg counts (FEC) were analyzed as a repeated measures design with animals nested within group. The group PG showed a clear increase in FEC after infection (from 0 to 3512 ± 446.34 eggs per gram; $P < 0.05$), but no further increase was observed after animals received T+ during conditioning (3145 ± 401.44 eggs per gram; $P > 0.05$). During Tests 1 and 2 animals preferred T- (Test 1: PG = 71.0 ± 3.9%; NP = 71.2 ± 4.3%; Test 2: PG = 73.9 ± 2.8% NP = 74.7 ± 2.7%; $P < 0.05$). However, preference reversed after conditioning (Test 3): Both groups, PG and NP, preferred T+ (PG = 61.0 ± 3.9%; NP = 62.6 ± 3.4%; $P < 0.05$). These results stand in contrast with previous studies using other types of antiparasitic condensed tannins (e.g., tannins extracted from the quebracho tree) with antinutritional properties. In such studies, only parasitized animals increase preference for a quebracho tannin-containing food relative to nonparasitized individuals. When condensed tannins do not exert negative postingestive effects on consumers, or even provide postingestive benefits (i.e., improved nitrogen utilization) like those observed in sainfoin, both parasitized and nonparasitized animals may display similar levels of acceptability to the tannin-rich feed. These results are consistent with a feed-forward mechanism in which endoparasitic loads are controlled by the frequent ingestion of safe bioactive-containing feeds which are typically preferred by consumers.

0094 Mitigation of variability in feeding patterns between competitively-fed dairy cows through increased feed delivery frequency.

ANIMAL BEHAVIOR AND WELL-BEING SYMPOSIUM: METRICS FOR ON-FARM ANIMAL WELFARE ASSESSMENT—CURRENT STATE AND FUTURE NEEDS

0095 Poultry welfare assessments: Where do we go from here. R. Blatchford*, *University of California, Davis.*

Recent attention has been given to developing welfare assessment tools for research purposes and for use directly on poultry farms. Historically, most of these tools have relied on resource- and management-based measures, but it is unclear how well they correlate with outcomes indicative of positive animal welfare. The subjective nature of many of these tools also makes it difficult to generalize across studies and farms without extensive training. More recently, the European Union Welfare Quality® project set out to design assessment tools that were scientifically based and combined resource- and management-based measures with animal-based measures. Adding these measures was especially important for farm-level comparisons where farms may be utilizing different housing systems with inherent differences affecting the utility of resource- and management-based measures. The Welfare Quality® Assessment protocol for poultry offers researchers a tool that has been validated, tested for repeatability, and standardized across farms. This tool has been used in the United States and Canada both at the experimental and farm levels. However, assessment tools were only developed for layer-type hens and broiler chickens. There is a vast need for the development of assessment tools for other poultry species such as ducks, turkeys, quail, and game birds. Tools are continuing to be developed, but many have measures that need validation and benchmarking and creating tools that can be used by producers without needing training to use successfully is important on a go-forward basis. Tools must be designed for North American commercial production with a better understanding of the appropriate sample size, as well as their utility for use in alternative and extensive housing systems. These tools show promise in helping to understand the influence of genetics, housing design, and management factors on the welfare of poultry.

Key Words: assessment tools, poultry, welfare

0096 Metrics for beef cattle welfare. D. Griffin*, *Great Plains Veterinary Educational Center, Clay Center, NE.*

The "Five Freedoms" of livestock is an important concept in the stewardship of beef cattle. These are the backdrop for evaluating the beef cattle welfare husbandry guidelines. The beef cattle care, husbandry, and welfare guidelines for cow-calf, pastured stocker cattle and feeder cattle developed by the National Cattlemen's Beef Association (NCBA) are reviewed. The Canadian and Australian feeder cattle care and welfare guidelines will also be reviewed and compared with the NCBA guidelines. A U.S. packer currently has developed and implemented a Feedlot Cattle Audit. Their audit will be reviewed and the unique items not included on other beef cattle welfare assessments will be discussed. Important differences between site assessments and site audits are listed, and the utility of each approach to improving beef cattle care and husbandry. The major areas included are development of SOPs for; safety of employees and cattle, employee training, living space design and management, feeding and feed stuff selection management (including water), cattle handling, heath

management and pain mitigation, medication management including withdrawal times, timely attention to individual cattle needs such as injury and euthanasia, and transportation.

Key Words: beef, husbandry, welfare, management

0097 Optimizing outcome measures of welfare in dairy cattle assessment. E. Vasseur*, *McGill University, Ste-Anne-de-Bellevue, QC, Canada.*

In most countries producing milk, industry-, government- and/or other stakeholder-driven initiatives are in place to improve welfare and dairy farming sustainability, for example, by enhancing profitability and reducing environmental impact. Those initiatives typically include a system of verification of reaching targets and tracking progress over time. Reliable indicators of welfare are required to provide public assurance and allow improvement on farms. Assessing dairy cattle welfare through outcome measures is done today through visual evaluations, including lameness, injuries, hygiene, and body condition. Numerical scoring charts have been validated, together with the development of training programs, to achieve high repeatability of assessors. Sampling strategies have been validated to determine how many animals and how many days are required to obtain reliable estimates of prevalence. However, visual evaluations require a long period of data collection and multiple visits to farms, along with follow-up checks of assessors to maintain repeatability over time, and in turn, are costly to implement. An attractive alternative is relying on automated measures collected from activity monitors that are becoming common on commercial farms; among those, lying time has gotten the most attention. The use of herd lying time in both free-stall and tie-stall situations has been validated. Current research is looking at relationships between lying time and other outcome measures of welfare, as well as lying time and risk factors for welfare in the environment (e.g., poor stall configuration or hoof trimming routine). We are not yet ready to rely solely on lying time to assess welfare; however, activity monitoring could certainly contribute to early detection of health and welfare issues (e.g., frequency of visits to the robotic milking system or feeders). Another interesting avenue is the development of early outcome measures of welfare and, possibly, remote indicators; for example, performance data (milk production, reproductive success, longevity) collected routinely in DHI databases. The rationale being that a herd with good health and high longevity should be at lower risk of poor welfare. Research is needed to identify predictors and their conditions of use, allowing to discriminate good vs. poor welfare status, both at the individual and herd level. Finally, milk samples are already collected in routine to check quality and safety. It would be extremely convenient to be able to predict cow welfare status directly in the milk using biomarkers; but again, we are not there yet.

Key Words: dairy cattle, welfare, outcome measure

0098 The Common Swine Industry Audit: Future steps to assure positive on-farm animal welfare utilizing validated, repeatable, and feasible animal-based measures. M. Pairis-Garcia[1] and C. J. Rademacher*[2], *[1]The Ohio State University, Columbus, [2]Swine Medicine Education Center, Department of Vet Diagnostic & Production Animal Medicine, Ames, IA.*

The Common Swine Industry Audit (CSIA) was developed in collaboration with pork producers, packers and processors to provide stakeholders with a consistent, reliable and verifiable system to assure on-farm swine welfare and food safety. This audit tool was built from the framework of Pork Quality Assurance®Plus program to develop a single, common audit platform for the U.S. Pork industry. The audit can be broken down into 27 key aspects that cover swine care, husbandry, and preharvest food safety. Of these key areas, animal based measures represent approximately 50% of the total points achievable for the audit and encompass all critical criteria including willful acts of abuse and timely euthanasia. As this tool is designed to provide an objective, science-based platform to facilitate continuous improvement in animal care, the use of validated, repeatable, and feasible animal-based measures is critical. Recognizing this, the CSIA task force and researchers within this field are focusing on the future needs and expectations of the audit by evaluating three questions. (1) How do we determine thresholds for animal based measures? Within the CSIA, each animal based measured has a threshold for what is considered acceptable or unacceptable. For example, farms will receive 10 points if 1% or less of the pigs observed have a body condition score of 1 or 0 points if prevalence is $\geq$2%. Although thresholds provide a more objective manner to validate welfare on farm, these thresholds may often be arbitrary and based more on experience than science. (2) How do we identify, interpret and provide value to animal based measures assessed in the audit? For any assessment and audit, the data we collect must directly relate back to the welfare status of the pigs on the farm. Identifying animal-based measures that cover a broad range of potential welfare problems to provide direct interpretation and value of individual pig welfare is critical. (3) What do these values mean to the U.S. swine industry as a whole? As the goal of the audit it to provide useful feedback for continuous improvement on farm, we must as an industry be committed to utilizing the information attained through on-farm audits to develop the educational tools, resources and support to advance on-farm swine welfare.

Key Words: audit, swine, welfare

ANIMAL HEALTH

0099 In silico identification of natural product inhibitors of *Brucella abortus* threonyl-tRNA synthetase. M. Li[1,2], N. Zheng[1,2,3], F. Wen[1,2], Y. Zhang[1,2], S. Li[1,2], S. Zhao[1,2], and J. Wang[*1,2,3], *[1]Ministry of Agriculture Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Ministry of Agriculture–Milk and Dairy Product Inspection Center (Beijing), Beijing, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Bovine brucellosis is mainly caused by the bacterium *Brucella abortus*, and represents a major problem to livestock industry development worldwide and is also a threat to human health in many developing and underdeveloped countries. Aminoacyl-tRNA synthetases (aaRSs), the central enzymes in protein translation, catalyze the covalent attachment of correct amino acids to their cognate tRNAs, yielding the aminoacyl tRNAs (aa-tRNA or charged tRNA) used for protein synthesis. Due to the pivotal role in protein synthesis, aaRSs have been considered as some of the most promising targets for antibiotics development in pathogenic species. In this study, a three-dimensional structural model of *Brucella abortus* threonyl-tRNA synthetase (BaThrRS) was constructed using computer-aided molecular modeling technique taking *Escherichia coli* threonyl-tRNA synthetase (EThrRS, PDB ID: 1QF6) as template. The ZINC natural product database including 11247 compounds was subjected for virtual screening based on molecular docking against the ATP binding site of the target using Autodock Vina program. Considering the mode of binding and affinities, seven leads, ZINC67910544 (–12.4 kcal/mol), ZINC72320615 (–12.3 kcal/mol), ZINC72320626 (–12.2 kcal/mol), ZINC27215482 (–12.6 kcal/mol), ZINC35270978 (–12.1 kcal/mol), ZINC35458951 (–12.1 kcal/mol), and ZINC42805205 (–12.4 kcal/mol) were selected on basis of binding energies in comparison to the selective inhibitor borrelidin (free energy of binding: –9.3 kcal/mol). Among them, ZINC27215482 (–12.6 kcal/mol) was best lead because of its highest inhibitory activity. The binding site of ZINC27215482 on BaThrRS was a pocket consisting of 22 residues: TYR316, ASN319, MET341, ASN342, CYS343, GLN374, MET383, ARG384, VAL385, PHE388, GLN390, ASP392, HIS394, TYR476, LYS479, GLN493, GLN498, THR496, GLN498, HIS525, SER531, and ARG534. Therefore, through a high throughput virtual screen we identified seven novel BaThrRS inhibitors that are used against bovine brucellosis with great potential for further development.

Key Words: *Brucella abortus*, threonyl-tRNA synthetase, virtual screening

0100 Evaluation of immune function markers in OmniGen-AF® supplemented steers. S. A. Armstrong[*1,2], D. J. McLean[2], T. H. Schell[1,2], G. Bobe[1], and M. Bionaz[1], *[1]Department of Animal and Rangeland Sciences, Oregon State University, Corvallis, [2]Phibro Animal Health Corporation, Quincy, IL.*

The effect of OmniGen-AF® (OG) supplementation on the expression of immune function markers in circulating whole blood cells was investigated in the first 28 d of feeding healthy Angus steers. Steers were randomly assigned to control (n = 4/group) or OG (n = 5/group; supplemented daily with 56 g/head OG), and fed a diet including grass hay, alfalfa, and ground corn. Steers were housed in a freestall barn and fed via Calan Broadbent system. Blood was collected via jugular puncture before the study (–4 d) and on d 14, 21, and 28 of supplementation. Genes evaluated included *CXCR2*, *CD80*, *CD62L*, *IL10RA*, *IL10RB*, *MAPK8*, *NOD2*, and *TLR1*. Data were analyzed using LinReg software to account for efficiency of amplification and normalized by three internal control genes (*RPL19*, *RPS9*, and *TBP*) and corrected to d –4. The qRT-PCR data were log-transformed and the data points with Studentized residuals $t > 2$ removed (i.e., outliers). The final data set was subjected to ANOVA analysis with treatment, time, and treatment × time as main effect and animal as random effect using Proc GLIMMIX of SAS. Time, treatment, and time × treatment did not have an impact on *CD62L* gene expression. The expression of *CD80*, *CXCR2*, *IL10RA*, *IL10RB*, *MAPK8*, and *NOD2* was different through time ($P < 0.05$), and time had a tendency to influence *TLR1* gene expression ($0.05 < P < 0.10$). Compared with controls, OG supplementation down-regulated *CD80* and *IL10RB* gene expression ($P < 0.05$); OG supplementation had a tendency to down-regulate *CXCR2* and *MAPK8* expression compared with controls ($0.05 < P < 0.10$). A treatment × time effect was detected for *CXCR2* gene expression ($P < 0.05$) with control steers displaying higher *CXCR2* expression by the conclusion of the supplementation period compared with OG supplemented cattle. These results, when considered with previous data on immune function markers and OG supplementation, suggest OG may be regulating antigen presentation and signal transduction. Future studies may also consider using *CD80*, *CXCR2*, *IL10RB*, and *MAPK8* as markers of OG efficacy within the first 28 d of supplementation.

Key Words: OmniGen-AF®, immunity, beef steers

0101 Influence of dietary supplementation with a *Saccharomyces cerevisiae* fermentation product prototype on the pathophysiological response to a combined intranasal bovine herpesvirus-1 and intratracheal *Mannheimia haemolytica* challenge in Holstein steers. K. P. Sharon[*1], Y. Liang[1], R. E. Hudson[1], I. Yoon[2], M. F. Scott[2], N. C. Burdick Sanchez[3], P. R. Broadway[3], J. A. Carroll[3], and M. A. Ballou[1], *[1]Texas Tech University, Lubbock, TX, [2]Diamond V, Cedar Rapids, IA, [3]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objective of this study was to determine the effects of supplementing a *Saccharomyces cerevisiae* fermentation product prototype (Prototype) on the pathophysiological response during a combined viral-bacterial respiratory challenge. Holstein steer calves (126.5 ± 6.11kg; $N = 16$) were completely randomized to treatments including 0 (CON) or 20 g/head/d of Prototype ($n = 8$). Calves were housed in open, dry lot corrals with four calves per pen (2 pens/treatment). Calves were offered ad libitum access to a 50:50 total mixed ration of a commercially available 16% CP pelleted calf grower and 18% CP chopped alfalfa hay. Treatments were top dressed for 30 d. Orts were measured daily and the quantity of feed was adjusted for approximately 10% orts. Calves were moved to individual stanchions (2.13 × 0.76 cm) in an enclosed barn, fitted with rectal temperature monitoring devices, and allowed 24 h adaptation before initiating the respiratory challenge. All calves were challenged with 1.5×10^8 PFU·mL^{-1}·nostril^{-1} of bovine herpesvirus-1 cooper strain at –72 h using a mucosal atomizer and with 10^6 CFU of *M. haemolytica* (MH) intratracheal at 0 h. Blood samples were collected via jugular venipuncture at –96, –72, –48, –24, 0, 6, 24, 48, 72, 120, 168, and 240 h relative to the MH challenge. Total leukocytes counts tended ($P = 0.063$) to be greater at 24 h among CON steers. Neutrophil:lymphocyte also tended to be greater ($P \leq 0.095$) at 24 and 72 h among CON steers. Monocyte phagocytosis of an environmental *Escherichia coli* tended ($P = 0.056$) to be greater in steers fed the Prototype at 24 h. Neutrophil oxidative burst to an environmental *Escherichia coli* tended ($P = 0.071$) to be greater at 6 h and was greater ($P = 0.011$) at 168 h among steers fed the Prototype. However, monocyte oxidative burst tended ($P = 0.052$) to be greater among CON at 72h. Neutrophil L-selectin did not differ between treatments ($P = 0.515$). Neither serum haptoglobin concentrations ($P = 0.773$) nor rectal temperature ($P = 0.985$) differed between treatments. These data demonstrate that the *Saccharomyces cerevisiae* fermentation product prototype may influence some acute leukocyte responses during a viral-bacterial respiratory challenge, but did not have strong influences on measures of inflammation or disease.

Key Words: health, respiratory, *Saccharomyces cerevisiae* fermentation product

0102 Dose response effect of *Saccharomyces cerevisiae* fermentation product prototype on leukocyte functionality and ex vivo cytokine production during a dexamethasone challenge in Holsteins steer calves. K. P. Sharon[*1], Y. Liang[1], R. E. Hudson[1], I. Yoon[2], M. F. Scott[2], N. C. Burdick Sanchez[3], P. R. Broadway[3], J. A. Carroll[3], and M. A. Ballou[1], *[1]Texas Tech University, Lubbock, [2]Diamond V, Cedar Rapids, IA, [3]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objective of this study was to determine the dose response effects of supplementing *Saccharomyces cerevisiae* fermentation product prototype on leukocyte functionality and ex vivo cytokine production during a dexamethasone (DEX) challenge. Holstein steers (125.1 ± 8.16 kg; $N = 32$) were assigned to treatments including 0, 20, 40, or 60 g/head/d of prototype ($n = 8$). Calves were housed for 21 d in dry lot corrals with four calves per pen (2 pens/treatment). Calves were offered ad libitum access to a 50/50 TMR of a commercially available 16% crude protein pelleted grower and 18% CP chopped alfalfa hay. Treatments were top dressed. The quantity of feed offered and orts were measured daily. After the 21 d adjustment to diets, calves were jugularly catheterized and moved into individual stations (2.13 × 0.76 cm) in an environmentally controlled barn and allowed 48 h to adapt before the first DEX injection. Blood samples were collected at –24, –6, 0, 6, 12, 18, 24, 48, and 72 h relative to the first DEX injection. DEX was administered via jugular catheter at 0.1 mg/kg BW at 0, 6, and 12 h. Peripheral blood neutrophil (PMN) concentrations increased ($P < 0.001$) at 6 h and remained elevated through 72 h in all steers. Neutrophil L-selectin and PMN and monocyte (MONO) oxidative burst (OB) and phagocytosis (PHAG) of an environmental *Escherichia coli* decreased ($P < 0.059$) at 6 h in all steers. L-selectin returned to baseline at 72 h while OB and PHAG failed to return to baseline by 72 h. Total leukocyte counts ($P < 0.001$) and PMN concentrations ($P = 0.001$) increased linearly with prototype dose. PMN L-selectin concentrations did not differ ($P = 0.684$) among treatments. Oxidative burst intensity in PMN ($P = 0.025$) and MONO ($P = 0.003$) increased linearly with prototype dose at 72 h, as well as in MONO PHAG intensity ($P = 0.004$) at 6 h. The percentage of PMN ($P = 0.012$) and MONO ($P = 0.013$) that were both PHAG and OB positive increased linearly with prototype at 72 h. Ex vivo whole blood lipopolysaccharide stimulated TNF-α concentrations was greater ($P = 0.026$) in prototype steers than control steers at –24 h. Overall, these data demonstrate that the dexamethasone challenge induced severe leukocyte dysfunction, and prototype supplementation influenced plasma neutrophil concentrations and may have increased recovery of neutrophil and monocyte function.

Key Words: dairy, health, yeast fermentation product

0103 Effects of climatic conditions before and after birth on growth rate of Holstein calves in a hot environment. E. L. Lopez-Rodriguez[*1], A. Martinez[2], and M. Mellado[3], *[1]Universidad Autonoma Agraria Antonio Narro, Torreon, Mexico, [2]UAAAN, Saltillo, Mexico, [3]Autonomous Agrarian University Antonio Narro, Saltillo, Coahuila, Mexico.*

Birth weight and growth records, representing 5938 Holstein calves from three large commercial dairy herds in northern Mexico (26° N; 24.2°C mean annual temperature) were analyzed to document the effects of environmental factors on growth traits of dairy calves from 2013 to 2015. Climate variables indicative of heat stress [e.g., maximum ambient temperature (MaxT) and temperature-humidity index (THI)] were considered, 1 or 2 mo before calving and at calving. Growth traits were birth body weight (bBW), weaning weight (WW), preweaning daily weight gain (DWG). The effect of season, MaxT, and THI the day of calving and MaxT one and 2 mo before calving were analyzed by the GLM and REG procedures of SAS. The relationship between bBW and MaxT on the day of calving was negative and curvilinear. When MaxT and THI reached 34°C and 80 units, bBW had a noticeable drop ($P < 0.01$) compared with lower ambient temperatures (38.6 ± 3.6 vs. 39.2 ± 3.9 kg for calvings at MaxT < or > 34°C, respectively). Birth body weight was lower ($P < 0.01$) in calves born in spring than the rest of the year (38.3 ± 3.9 vs. 39.1 ± 3.8 kg; mean ± SD). Maximum ambient temperature one or 2 mo before calving did not affect bBW. Body weight at weaning and DWG of calves decreased gradually ($P < 0.01$) when MaxT and THI reached 28°C and 73 units at calving, respectively. A season effect was detected ($P < 0.01$) for DWG and WW. These traits were 403 ± 117 and 450 ± 110 g and 66.0 ± 8.5 and 69.2 ± 8.1 kg for summer and winter, respectively. It was concluded that, in this particular environment (high heat load for most of the year), heat stress markedly affects bBW and growth rate of Holstein calves. Thus, environmental management of the late gestation cow during hot summer months is warranted to optimize calf growth rates.

Key Words: birth body weight, growth traits, heat stress

0104 The hidden cost of a hidden disease: growth performance of calves as affected by bovine respiratory disease diagnosed using ultrasonography. C. Tejero[*1] and A. Bach[2,3], *[1]Rancho Las Nieves, Mallen, Spain, [2]ICREA, Barcelona, Spain, [3]IRTA, Caldes de Montbui, Spain.*

The aim of this study was to assess the consequences of bovine respiratory disease (BRD) during the first 60 d of life on subsequent growth performance. One thousand sixty-six calves (42.5 ± 6.9 kg of BW and 12.4 ± 5.6 d old) were raised, fed, and managed under exactly the same protocols in a contract heifer operation. Five hundred and thirty-three calves were diagnosed with BRD using an ultrasound and a 8–5 MHz linear probe with 12 cm scan depth, and the remaining coetaneous 533 calves were healthy and never diagnosed with BRD (NBRD). Ultrasonographic scans evaluated the right lung from the 10th intercostal space (ICS) cranial to the first ICS, and the left lung from the 10th ICS cranial to the second ICS. Calves were considered BRD positive when ≥1 cm of consolidation was present. Calves diagnosed with BRD were immediately treated with antibiotics. Respiratory disease was classified as lobular pneumonia type I (1 cm consolidation), type II (2 cm consolidation), and type III (3 cm consolidation), or lobar pneumonia (consolidated lobe). The potential impact of BRD and its severity on growth performance was assessed using a mixed effects model. The cranial area of the right cranial lung lobe was most commonly affected, followed by the right middle lung lobe, and the caudal area of the right lung lobe. Most BRD cases were diagnosed between 5 and 56 d of age (average 26.2 ± 12.6 d). Daily growth between 12.4 ± 5.6 and 50.8 ± 5.8 d was greater ($P < 0.001$) in NBRD (742 ± 4.9 g/d) than in BRD Type I (649 ± 8.4 g/d), and the latter had a greater ($P < 0.001$) ADG than BRD Type II calves (604 ± 13.9 g/d). Between 49.7 ± 2.5 and 111.6 ± 3.5 d, NBRD calves also grew (1176 ± 7.6 g/d) more ($P < 0.01$) than BRD calves (1084 ± 12 g/d), independently of the severity of the lung lesion. However, from 113.3 ± 7.3 to 162.8 ± 5.4 d, there were no differences in ADG (1116 ± 18 g/d) between NBRD and BRD calves. Therefore, BW at 50, 113, and 163 d was lower ($P < 0.01$) in BRD (66 ± 0.29, 135 ± 0.56, and 192 ± 0.76 kg, respectively) than in NBRD (70.9 ± 0.3, 143 ± 0.67, and 201 ± 0.98 kg, respectively) calves. It is concluded that having a lobular pneumonia with a lesion of ≥1 cm within the first 2 mo of life induces close to 10 kg of BW lag at 23 wk of age despite the application of antibiotic treatment on BRD diagnosis.

Key Words: health, lung, pneumonia

0105 Serum and colostrum antibody titers in Holstein cows, and the relationship between these titers and serum antibody titers in their calves. D. J. McLean[*1], J. D. Chapman[1], A. Woolums[2], D. J. Hurley[3], and L. O. Ely[3], *[1]Phibro Animal Health Corp., Quincy, IL, [2]Mississippi State University, Starkeville, [3]University of Georgia, Athens.*

Vaccination of cows in late gestation is sometimes used to improve maternal antibody titers in their calves. However, scant published research has reported the relationship between serum antibody titers to specific infectious agents in vaccinated cows, the colostrum of these cows, and the serum of calves consuming their colostrum. As part of a larger study, the relationship between cow serum and colostrum antibody titers and calf titers was evaluated. Fifty-four multiparous Jersey and Jersey-cross cows were vaccinated between dry-off and calving with commercially available vaccines containing bovine herpesvirus-1 (BHV-1), bovine viral diarrhea

virus (BVDV), bovine respiratory syncytial virus (BRSV), rotavirus, coronavirus, *E. coli* J-5, and *Salmonella* siderophore receptor and porin (SRP); blood was collected at dry off, mid-dry, and at calving. Calves born to enrolled cows were fed colostrum from only their dams; calf serum was collected at 7 and 30 d of life. Antibody titers against agents in the vaccine were measured in serum and colostrum of cows by standard neutralizing techniques or ELISA, and correlations between cow serum antibodies at 30 d before calving, cow colostrum, and calf serum antibodies at 7 d of life were evaluated. Correlations between cow serum antibodies and colostrum antibodies for different agents were significant ($P < 0.05$) but only moderately strong (Pearson correlation coefficient [PCC] range: 0.32–0.7), and varied for different agents. Similarly, correlations between cow colostrum antibodies and calf serum antibodies were usually significant, but only moderate (PCC range: 0.36–0.77). The R^2 value for the correlation between colostrum antibodies and calf antibodies ranged from 0.11–0.59, indicating that for most agents, the colostrum antibody titer to a given agent did not explain a majority of variation in the calf serum antibody titer to that agent. Antibody titers to specific agents in cows are significantly, but not strongly, correlated with their colostrum antibody titers, and colostrum antibody titers are significantly but not strongly, related to antibody titers in calves. These data suggest that, in addition to maternal antibody concentration, other factors have an important impact on serum antibody titers to specific infectious agents in young dairy calves.

Key Words: colostrum, antibody transfer, vaccination

0106 Evaluating preweaned calf housing and its impact on calf respiratory parameters on New York dairy farms. K. M. Morrill*, *Cornell University, Ithaca, NY.*

The objectives of this project were to (1) evaluate environmental and air quality parameters across different types of calf housing facilities; (2) evaluate rates of respiratory illness in preweaned calves; and (3) determine the impact of environmental factors, air quality, and housing type on calf health. This was an observational study in which calf facilities were evaluated on a single visit during June 2015. Housing included hutches ($n = 9$), individual pens in a barn ($n = 11$), and group pens in a barn ($n = 9$). Facility and calf pen evaluations included wind speed, temperature, relative humidity, heat stress index, bedding type, bedding composite sample for bacteria counts, nesting score of calf pens, calf health scoring, and airborne bacteria. Data were analyzed using SAS 9.3 to determine the impact of housing type, environmental, and air quality variables on calf respiratory score. A total of 29 facilities and 437 preweaned calves were evaluated. Calf facility temperature averaged 24.2°C (range 15.5 to 30.6°C) with a relative humidity of 21.5% (range 10 to 78%) and a heat index of 21.5°C (range 6 to 30.9°C). Temperature and airborne bacterial counts were greater in hutches as compared with individual and group pens ($P < 0.01$). Humidity was similar for hutches and group pens, but greater than individual pens. Gram negative airborne bacterial counts were lowest in individual pens. No difference in heat index was observed across housing type. Mean calf respiratory scores was 2.5 (range of 0 to 9) on a 12 point scale; 13.33% of calves evaluated scored greater than 5, indicating a respiratory challenge. Prevalence of respiratory illness in preweaned calves ranged from 0 to 50% of calves on a per farm basis (mean = 11.05% of calves/farm), with 44.82% of farms having no respiratory illness and 10.32% of farms having 30 to 50% of evaluated calves exhibiting signs of respiratory illness. There was a negative correlation between respiratory score and pen temperature ($R^2 = 0.90$). There was no influence on respiratory score by housing system, bedding type, ventilation system, relative humidity, airflow, or airborne bacterial counts. Data collected from this study suggests that respiratory illness continues to be a challenge, even when weather is temperate. Additional research is needed to evaluate rates of respiratory illness during cold stress and transitional weather, as well as to evaluate management factors that increase the risk of infection.

Key Words: calves, housing, respiratory

0107 Differential primary and secondary immune responses in calves fed heat-treated or unheated colostrum. S. L. Gelsinger* and A. J. Heinrichs, *The Pennsylvania State University, University Park.*

An experiment was conducted to compare immune responses between calves that received unheated or heat-treated colostrum. Half of a single, pooled batch of colostrum was frozen without heating; the other half was heated and maintained at 60°C for 60 min before freezing. Bull calves ($n = 26$) were randomly assigned to receive 8% of their birth weight as either unheated or heat-treated colostrum. Blood samples were collected at birth and 48 h of age to assess passive transfer. At 14 and 35 d of age, all calves received a subcutaneous injection of 0.2 mg ovalbumin per kg birth weight. Blood was sampled at 0, 4, 8, and 12 h, and daily on days 2 to 10 after each injection. Plasma was collected for analysis of total IgG, ovalbumin-specific IgG, interferon γ (IFNg), tumor necrosis factor α (TNFa), and interleukin 1 β (IL1b). Area under the curve was calculated for plasma cytokine and antibody concentrations, and all data were analyzed using Proc Mixed in SAS. Colostrum treatment, time point, and their interaction were included as fixed effects with calf as a repeated random effect. All calves achieved successful passive transfer of IgG. Calves fed unheated colostrum at birth had greater plasma IL1b and nonovalbumin IgG ($P < 0.05$) during the first challenge and tended to have greater nonovalbumin IgG during the second challenge ($P = 0.08$). Calves fed heat-treated colostrum at birth tended to have greater plasma IFNg during the second challenge ($P = 0.09$). These results imply that calves

fed heat-treated colostrum exhibit improved T-cell mediated but reduced innate and B-cell mediated immune response. Despite changes in cytokine and antibody production, neither body weight, body temperature, weekly feed (milk and starter) intake, nor total IgG concentration were different between groups through 45 d of age.

Key Words: calf, colostrum, immune response

0108 The effect of novel antiseptic compounds on umbilical cord healing and infection rates in the first week of life in dairy calves. A. L. Robinson*, L. L. Timms, K. J. Stalder, and H. D. Tyler, *Iowa State University, Ames.*

The objective of this study was to compare the effect of four umbilical dips on the healing rate and incidence of infection of umbilical cords using newborn Holstein and Jersey calves (n = 76). Calves were alternately assigned by birth order to four treatment groups: 7% iodine, a dry dip created using an antibacterial peptide (nisin) mixed with talc (formulation concentration = 3.105 g nisin per 100 g talc on a weight per weight basis), liquid nisin (64 ug/mL), and chlorhexidine mixed with alcohol in a 50:50 solution. Umbilical cords were dipped 30 min after birth. Before initial dipping, diameter of the umbilical cords (as an indicator of cord drying) were determined using digital calipers. As a potential indicator of umbilical infections, surface temperature of the umbilical stump (along with a reference point at the midpoint of the sternum) was measured using a dual laser infrared thermometer (Model 42570, Extech Instruments Nashua, NH). The IR and caliper measurements were all repeated at 24 ± 1 h, 48 1 h, and 72 1 h of age. Measurements of calf umbilical diameter were continued until the umbilical cord healed to the point of detachment. All data were analyzed using mixed model methods (PROC MIXED, SAS Version 9.2). Age at umbilical cord detachment tended to be different between treatments (P = 0.105); calves dipped with chlorhexidine mixed with alcohol detached at a mean age of 20 d compared with 15.5 d for the other three treatments. No treatment differences were noted (P > 0.05) between dips on drying rate of umbilical cords. Mean umbilical cord diameter was 17.81 ± 5.73 mm at birth and they healed to a mean diameter of 8.10 ± 5.07 mm at 24 h of age. Similarly, there were no treatment effects (P > 0.05) on incidence of umbilical infections (umbilical infection rate for all calves was 18.4%). Mean surface temperature of the umbilical stump was 27.4 ± 4.0°C at birth (0.1 ± 0.2°C lower than the sternal reference temperature). At 24 ± 1 h of age the mean temperature of the umbilical stump was 29.2 ± 4.3°C (0.4 ± 0.1°C lower than the sternal reference temperature). These data suggest that all four dips are effective in preventing umbilical infections and permitting healing of the umbilical cord when used within 30 min of birth.

Key Words: calves, umbilical cord, umbilical dip

0109 Effects of OmiGen-AF® and Provia 6086 on growth, leukocyte, and hematological variables of preweaned and immediately postweaned Holstein calves. Y. Liang*[1], R. E. Hudson[1], T. L. Harris[1], K. P. Sharon[1], J. P. Jarrett[2], D. McLean[2], J. D. Chapman[2], J. A. Carroll[3], and M. A. Ballou[1], *[1]Texas Tech University, Lubbock, TX, [2]Phibro Animal Health Corporation, Quincy, IL, [3]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objective of this study was to determine the effects of OmniGen-AF (OG) and Provia 6086 (PV) on the performance and health of preweaned and immediately postweaned Holstein calves. Holstein calves within 1 d of birth were randomly assigned to one of four dietary treatments (N = 80). The study was conducted in two consecutive periods with 40 calves/period (n = 10 calves/treatment/period). Dietary treatments were given in both the milk replacer and calf starter. Treatments were arranged and analyzed as a 2 × 2 factorial with OG and PV as the main fixed effects. Diets were formulated to supply approximately 10 g/d of OG and 2 billion CFU/d of PV if calves were consuming milk only or 1.36 kg of calf starter only. Calves were housed in an enclosed barn and fed 275 g of a 22% CP and 20% fat milk replacer daily at 0730 and 1630. Calves had ad libitum access to calf starter and water. The quantity of water and starter offered as well as refused was recorded and adjusted daily for approximately 10% orts. Calves were individually housed until they were weaned at 56 d when they were grouped within treatment with four calves/pen for an additional 28 d. There were no treatment or treatment × time differences on starter intake during either the preweaned ($P \geq 0.111$) or postweaned ($P \geq 0.297$) periods. Additionally, there were no treatment or treatment × time differences ($P \geq 0.500$) in ADG during either the preweaned (0.593 ± 0.096 kg/d) or postweaned (0.845 ± 0.096 kg/d) periods. The surface expression of CD14 on peripheral blood monocytes decreased ($P \leq 0.001$) with increased calf age; however, there were no treatment or treatment × time differences ($P \geq 0.339$). Similarly, there were no treatment or treatment × time differences ($P \geq 0.316$) on the surface expression of CD62L on peripheral blood neutrophils. There was an OG × PV × time interaction (P = 0.018) in peripheral blood neutrophil counts, whereas there was a tendency (P = 0.089) for the Control and OG + PV to have reduced neutrophils when compared with OG and PV calves at 21 d. Lastly, there were no treatment × time differences ($P \geq 0.430$) on hematocrit percentages; however, there was a significant time effect (P = 0.001), whereas hematocrits were elevated at 14 and 21 d. These data indicate that OmniGen-AF and Provia 6086 supplementation during the preweaned and immediate postweaned periods did not influence growth performance, leukocyte, or hematological measures in these Holstein calves.

Key Words: calf, growth, immunity

0110 Health status of dairy feeder calves arriving to a veal facility. D. L. Renaud*, T. F. Duffield, D. F. Kelton, S. J. LeBlanc, and D. B. Haley, *Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

There are approximately 959,600 dairy cows producing 479,800 male dairy calves every year in Canada. Based on information gathered from the 2015 Canadian National Dairy Study, less than 7% of male calves are euthanized at birth, leaving a significant number of male calves to enter the red meat industry. In Ontario and Quebec, the majority of male dairy calves flow into the veal industry. In 2015, 213,659 veal cattle from approximately 551 producers were slaughtered in Ontario and Quebec. Currently, there is little information about the fitness of dairy feeder calves (traditionally referred to as veal calves) entering the veal industry in Canada. The objective of this descriptive study was to evaluate the health status of calves arriving at a large veal farm. Using a scoring program (Calf Health Scorer App) developed by McGuirk et al. (2014) and supplemental scoring adapted from Wilson et al. (2000), Holstein and crossbred calves (n = 1356; 1335 male and 14 female) of unknown age were evaluated immediately on arrival at the commercial milk-fed veal facility in Southwestern Ontario. The results from the period of November 2015 until March 2016 were tabulated and confidence intervals (CI) were calculated (Wald's test) using Stata 14 (StataCorp College Station, Texas). Enlarged navels with at least heat or pain or moisture were found in 25.6% (95% CI: 23.3–27.9%) of calves, diarrhea was present in 16.7% (95% CI: 14.7–18.7%), fever (defined as greater than 39.5°C or 103.1°F) was present in 15.1% (95% CI: 13.2–17.0%), lack of subcutaneous fat or emaciated appearance was present in 22.4% (95% CI: 20.1–24.6%), depression or dullness was present in 26.8% (95% CI: 24.6–29.3%), signs of clinical dehydration (defined as >5% dehydration based on skin tent, attitude, presence or absence of suckle reflex and eye recession) were present in 26.5% (95% CI: 24.2–28.9%), and respiratory disease (defined as a combination of abnormal nasal and ocular discharge, ear and head position, cough and temperature) was present in 9.2% (95% CI: 7.6–10.7%). Based on the results gathered thus far, a significant proportion of calves (42.7% [95% CI: 40.0–45.3%]) are entering the facility with at least one identifiable health abnormality. This represents a significant welfare concern and the causes of the abnormalities need to be further understood to motivate a change in the way dairy feeder calves are treated.

Key Words: dairy calf health, health screening, veal production

0111 Acute immunological responses to a combined viral-bacterial respiratory disease challenge in feedlot heifers supplemented with yeast. A. B. Word*[1], P. R. Broadway[2], N. C. Burdick Sanchez[2], Y. L. Liang[3], K. P. Sharon[3], S. L. Roberts[4], J. T. Richeson[4], P. J. Defoor[5], M. D. Cravey[6], J. R. Corley[7], M. A. Ballou[1], and J. A. Carroll[2], *[1]Texas Tech University, Lubbock, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]Texas Tech University, Department of Animal and Food Sciences, Lubbock, [4]Department of Agricultural Sciences, West Texas A&M University, Canyon, [5]Cactus Feeders, Canyon, TX, [6]Phileo Lesaffre Animal Care, Milwaukee, WI, [7]Phileo Lesaffre Animal Care, Cedar Rapids, IA.*

Two treatments were evaluated in commercial feedlot heifers to determine the effects of a yeast supplement on immune responses to a combined viral-bacterial respiratory challenge. Thirty-two beef heifers (325 ± 19.2 kg BW) were selected and randomly assigned to one of two treatments, and fed for 31 d: (1) Control (CON), receiving a standard feedlot ration without a yeast supplement, or (2) Yeast (YEAST), control ration plus a combination live yeast (2.5 $g \cdot hd^{-1} \cdot d^{-1}$) and yeast cell wall (2.5 $g \cdot hd^{-1} \cdot d^{-1}$) supplement (Phileo-Lesaffre Animal Care, Milwaukee, WI). All cattle were challenged intra-nasally with 1×10^8 PFU bovine herpesvirus-1 (BHV-1) on d –3 and then allowed to rest in outdoor pens for 3 d. On study d 0, each animal was challenged intratracheally with an average dose of 3×10^7 CFU *Mannheimia haemolytica*, was fitted with an indwelling jugular catheter and an indwelling vaginal temperature recording device, and was moved into individual stanchions in an environmentally-controlled barn. Whole blood samples were collected at the time of BHV-1 challenge at 1-h (serum) or 2-h (complete blood cell counts) intervals from 0 to 8 h, and at 12, 24, 36, 48, 60, and 72 h relative to *M. haemolytica* challenge. Data were analyzed using the mixed procedure of SAS specific for repeated measures with fixed effects of treatment, time, and their interaction. Water intake per hour tended (P = 0.06) to be greater in the YEAST group compared with CON. Nasal lesion scores tended (P = 0.07) to be decreased in the YEAST group compared with CON (2.50 ± 0.26 vs. 3.19 ± 0.26, respectively). There was no difference in cortisol concentrations or vaginal temperature between treatment groups ($P \geq 0.37$). There was no treatment difference (P = 0.21) in total white blood cell counts following BHV-1 challenge. There was a trend (P = 0.13) for serum haptoglobin concentration to be reduced in the YEAST (11,757.3 ± 1631.7 μg/dL) group compared with CON (15,396.174 ± 1631.7 μg/dL). Cattle in the CON group tended (P = 0.07) to have greater neutrophils than YEAST (6.39 ± 0.39 vs. 5.37 ± 0.37 K/μL, respectively). In summary, feeding a combination live yeast and cell wall yeast supplement tended to reduce nasal lesion score, inflammatory response, and neutrophil count with no

effect on febrile response in beef heifers. Further research is warranted to determine if other measures of the inflammatory response were influenced by yeast supplementation in this model of respiratory disease challenge.

Key Words: feedlot health, respiratory disease challenge, yeast

0112 SafmannanTM and ActiSafTM supplementation in milk replacer modulates health and performance in high-risk, preweaned Holstein calves.

T. L. Harris*[1], Y. Liang[1], R. E. Hudson[1], K. P. Sharon[1], J. A. Carroll[2], and M. A. Ballou[1], *[1]Texas Tech University, Lubbock, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objectives of the study were to determine if supplementing milk replacer with Safmannan (SM) and ActiSaf (AS) would affect calf growth and health throughout the preweaned and immediate postweaned periods. The study was performed over 67 d, with 39 Holstein bull calves. Calves were housed in individual pens in an environmentally controlled barn, and were provided ad libitum access to a texturized calf starter and water, as well as offered 350 g of milk replacer solids, 22% CP and 20% fat, at 0700 and 1600 from d 0 to 56. Calf starter and water refusals were recorded daily and intakes calculated. Calves were randomly assigned to treatments that included CON, milk replacer with no added supplements; SM, milk replacer with 5 g SM/calf/d; and SM + AS, milk replacer with 2 g SM/calf/d and 3 g AS/calf/d. Individual BW was measured on d 0, 21, 42, 56, and 67. Blood samples were collected and analyzed for hematology on d 10, 28, and 56; while plasma and whole blood were collected and analyzed for plasma haptoglobin concentrations, neutrophil surface expression of CD62L, and neutrophil phagocytosis and oxidative burst capacity to an environmental *E. coli* on d 0, 10, 28, and 56. All data were reported as CON, SM, and SM + AS, respectively. The LSMeans with various superscripts differ ($P \leq 0.05$). Individual calf starter intake did not differ over the entire study, although from 0 d to 21 d, calves receiving the SM + AS supplement consumed more starter (0.025^{a}, 0.034^{ab}, $0.074^{b} \pm 0.018$ kg/d; $P < 0.05$). Neither ADG (0.63, 0.68, 0.69 ± 0.054 kg/d; $P = 0.699$), nor feed:gain (1.74, 1.74, 1.73 ± 0.070 kg/kg; $P = 0.990$) differed among treatments. Total leukocyte counts were greater in the CON calves on d 10 than the other treatments (14.2^{a}, 9.2^{b}, $11.1^{b} \pm 1.2$ 10^{6}/mL; $P < 0.05$) and was lower in the SM calves on d 28 than the CON and SM + AS treatments (10.4^{a}, 7.9^{b}, $10.6^{a} \pm 0.87$ 10^{6}/mL; $P < 0.037$). Neutrophil surface expression of CD62L was greatest in SM calves when compared with CON calves ($92{,}772^{a}$, $110{,}441^{b}$, $94{,}526^{ab} \pm 5334$ mean fluorescence intensity; $P = 0.052$). Additionally, there were treatment × time interactions on neutrophil phagocytosis and oxidative burst $P \leq 0.024$), whereas SM calves had greater percentages of neutrophils phagocytizing and producing an oxidative burst on d 28. These data suggest that both yeast supplementation strategies may influence the health of high-risk, preweaned Holstein calves.

Key Words: calf, growth, yeast

0113 Evaluation of horn bud wound healing following cautery disbudding of preweaned dairy calves treated with aluminum-based aerosol bandage.

K. L. Huebner*, A. K. Kunkel, C. M. McConnel, R. J. Callan, R. P. Dinsmore, and L. S. Caixeta, *Colorado State University, Fort Collins.*

Dehorning pain management has been extensively studied, though few studies have evaluated the effects of cautery disbudding on wound healing. Inflammation and delayed healing are common postdisbudding, with undocumented significance for health. Our objective was to determine healing following disbudding with or without treatment using topical aluminum-based aerosol bandage (ALU). In a prospective study, Holstein heifer calves raised at three commercial dairy farms were disbudded within 3 wk of life. Local anesthesia and analgesia were performed before disbudding, and ALU treatment was randomly allocated to the right or left bud within each calf. Disbudding site (DS) healing was evaluated thereafter on a weekly basis for 3 wk and lesion score (LS) was categorized as: (1) no scab or discharge; (2) dried scabs; and (3) purulent discharge. LS was dichotomized (normal: LS = 1; and abnormal: LS > 2) to facilitate analysis and interpretation of results and logistic regression was used for statistical analysis. Results were considered statistically significant when $P < 0.05$ and tendency was considered when $0.05 < P < 0.10$. In total, 220 calves were enrolled. There was no difference in LS between groups during the first 2 wk postdisbudding, but at the third week postdisbudding, the proportion of LS = 3 was greater for control DS compared with ALU (16.8 vs. 8.1%, respectively; $P = 0.02$). Similarly, the odds of having LS > 2 were only different during the third week postdisbudding with control DS being 1.42 times more likely to have LS > 2 than ALU treated DS (95% CI = 0.964– 2.10; $P = 0.07$). Abnormal healing during week 1 increased the odds of having abnormal healing in week 2 (OR = 5.36; 95% CI = 2.96–9.69; $P < 0.01$). Likewise, abnormal healing during week 2 increased the odds of abnormal healing during week 3 (OR = 4.22; 95% CI = 2.72– 6.54; $P < 0.01$). A reduction in LS at the third week postdisbudding was observed when using ALU. Once abnormal healing started, it increased the likelihood of abnormal healing later. Discharge and/or scabs may be a part of the normal healing process; however, in this study, it was considered abnormal since no cultures were performed to rule out DS infection. Our data indicates that use of ALU may benefit healing after cautery disbudding in preweaned dairy calves.

Key Words: dairy calves, dehorning, wound healing, well-being

0114 Automated milking systems: using productivity and behavioral data to detect illness in dairy cows. M. T. King*[1], E. A. Pajor[2], S. J. LeBlanc[3], and T. J. DeVries[1], [1]*Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada,* [2]*University of Calgary, Calgary, AB, Canada,* [3]*Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

To develop better ways of using milking activity, productivity, and behavioral data to detect illness, we collected longitudinal data throughout the lactation of 57 Holstein dairy cows (19 PP, 38 MP; 3.1 ± 1.1 lactations) housed in a free-stall barn equipped with an automated milking system (AMS). Cases of illness were recorded, including subclinical ketosis (SCK; n = 23), calving-related disease (CRD; n = 14), hoof disorders and severe lameness (n = 16), pneumonia (n = 8), and gastrointestinal issues and displaced abomasum (DA; n = 7). We collected continuous milking activity data from the AMS. Lying, rumination, and activity data were recorded by electronic data loggers. Data were analyzed in repeated measures mixed linear regression models. Days relative to the day of diagnosis/treatment (d 0) were analyzed as a fixed effect for each illness separately, with data extending back to d –14. Analyses were performed between: (a) the day from which each outcome variable deviated significantly from baseline production/behavior (Tukey's tests were used to make day-by-day comparisons), and (b) d –1, since recovery had begun following treatment on d 0. Outcome variables tested were milk yield (3-d rolling average), daily rumination time, activity (unit-less measure of head and neck motion), and lying behavior (lying time, bout frequency, bout length). Mean milk production declined by 4.3 and 4.1 kg/d from d –4 to diagnosis of DA ($P < 0.001$) and pneumonia ($P = 0.01$), respectively. From d –14 to diagnosis of hoof disorders, production steadily declined by 0.6 kg/d ($P < 0.001$). Mean rumination time declined by 54 and 55 min/d from d –5 to diagnosis of DA ($P < 0.001$) and pneumonia ($P = 0.03$), respectively. Before SCK diagnosis (2 tests/fresh cow ~1 wk apart), rumination decreased by 13 min/d from d –6 to diagnosis ($P = 0.05$); this was most drastic d –3 to –1 (–34 min/d; $P = 0.001$). Activity levels declined by 40 units/d from d –4 to diagnosis of DA ($P < 0.001$), but decreased gradually from d –14 to diagnosis of SCK (–15 units/d; $P < 0.001$) and CRD (–23 units/d; $P < 0.001$). Lying behavior was less predictive of illness, as it did not vary until the day of diagnosis of any illness. These results suggest that the effects of illness on rumination, activity, and productivity are apparent several days before diagnosis and could be used to earlier identify illness in AMS herds. Since behavior and productivity appear to respond differently to various types of illness, it is possible that certain parameters may be illness-specific.

Key Words: automated milking, dairy cow behavior, illness

0115 Occurrence of mycotoxins in the 2015 U.S. corn crop. P. N. Gott*[1], B. G. Miller[1], R. Beltran[2], and G. R. Murugesan, *BIOMIN America Inc., San Antonio, TX.*

Mycotoxins are toxic metabolites produced by filamentous fungi which commonly contaminate feedstuffs harvested for both human and livestock consumption. Although the different types of mycotoxins have variable effects on different livestock species, exposure to mycotoxins can impair health and adversely affect animal performance. The objective of the current study was to determine the occurrence of mycotoxins in the 2015 corn crop in the United States and to assess the potential risk to livestock species. From September 2015 to January 2016, 381 corn samples were collected from 20 states as part of the annual Biomin Mycotoxin Survey. Samples were analyzed either by high performance liquid chromatography (HPLC) or liquid chromatography tandem mass spectrometry (LC-MS/MS) techniques, which are highly sensitive in detecting very low mycotoxin concentrations. The major mycotoxin groups analyzed were aflatoxins (Afla), zearalenone (ZEN), trichothecenes including deoxynivalenol (DON) and T-2 toxin (T-2), fumonisins (FUM), and ochratoxin A (OTA). Mycotoxins were detected in 94% of the corn samples tested and 50% of the positive samples contained more than one mycotoxin. Co-occurrence of mycotoxins may lead to synergism and enhanced toxicity in animals which consume contaminated feed. The percentage of positive samples, mean of positives (ppb), maximum of positives (ppb), and risk threshold (ppb) for the six major mycotoxins are presented in Table 1. The occurrence of Afla, T-2, and OTA were minimal in relation to ZEN, DON, and FUM in these samples. The highest threat in these corn samples was posed by DON due to its high prevalence and number of samples above the FDA recommended level. As a result of their common co-occurrence, ZEN also presents a major threat. In terms of occurrence, FUM ranks second among the six major mycotoxins analyzed in these samples. With the increased occurrence and co-occurrence levels in 2015 compared with the previous year, DON, FUM, and ZEN pose a higher risk to livestock production in 2016.

Key Words: mycotoxins, deoxynivalenol, fumonisin

0116 Associations of hygiene and lying behavior with the risk of elevated somatic cell count and lameness. I. Robles*[1], D. F. Kelton[2], H. Barkema[3], G. P. Keefe[4], J. P. Roy[5], M. A. von Keyserlingk[6], and T. J. DeVries[1], *[1]Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, [2]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, [3]University of Calgary, Calgary, AL, Canada, [4]Atlantic Veterinary College, University of Prince Edward Island, Charlottetown, PE, Canada, [5]Faculté de Médecine Vétérinaire, University of Montreal, St. Hyacinthe, QC, Canada, [6]Animal Welfare Program–University of British Columbia, Vancouver, BC, Canada.*

The objective of this study was to identify how cow-level factors and housing management affect the risk of elevated SCC (eSCC) and lameness in lactating dairy cows. Cows from six commercial free-stall dairy herds in Ontario, Canada, were enrolled in a longitudinal study. Ten Holstein cows/herd were randomly selected based on days in milk (DIM; <120 d), absence of mastitis treatment in the last 3 mo, and somatic cell count (SCC < 100,000 cells/mL). Data on SCC were collected through DHI testing (~5 wk intervals). The study began within 7 d after a DHI-milk test, continued until three tests were completed (~105d), for a total of three observation periods/cow. Elevated SCC was used to indicate subclinical mastitis. An incident of eSCC was defined as a cow having a SCC > 200,000 cells/mL at the end of a period when SCC was <100,000 cells/mL at the beginning of that period. Lying behavior was recorded for 6 d after each milk sampling using data loggers. On d 1 of each recording period, a trained observer scored cows for lameness (5-point numerical rating scale, NRS $\geq$ 3 = lame). Hygiene scoring (four-point scale), also done by a trained observer, occurred on each visit. Cows were categorized as clean (1, 2) or dirty (3, 4). Stall cleanliness was assessed with a 1 m^2 metal grid, containing 88 squares, centered between stall partitions of every 10th stall, and then counting the squares containing visible urine and/or fecal matter. Data were analyzed using multivariable logistic regression models. Cows averaged (mean ± SD) 627 ± 107.7min/d lying, 9 ± 2.8 lying bouts/d, and 72 ± 19.9 min/bout. Over the study period, 13 eSCC were detected, resulting in an incidence rate of 0.73 eSCC/cow-year at risk. The risk of experiencing an eSCC increased 1.4× ($P < 0.01$) with every 20,000 cells/mL SCC increment at the beginning of the study. Mean proportion of soiled squares/stall was 27%. Each SD (18.8%) increment in proportion of dirty squares/stall was associated with lameness (NRS $\geq$ 3; OR = 1.5; $P = 0.05$) and increased the odds of having a dirty udder (DU; OR = 2.4; $P = 0.02$). Each SD (108min/d) increment in lying time/d increased the risk of having dirty upper legs and flank (DULF; OR = 2.1; $P < 0.01$), and tended to increase the risk of having a DU (OR = 1.44; $P < 0.08$). For each 9.6% increase above mean (100%) cow/stall stocking density, the risk of having DULF increased by 1.7× ($P = 0.03$). These results indicate that lower stocking density and management practices that improved stall hygiene and should be encouraged to reduce the risk of poor hygiene and clinical lameness in dairy cows housed in free-stall barns.

Key Words: subclinical mastitis, lameness, cleanliness

0117 Using milk fat-to-protein ratio to evaluate dairy cows energy balance status. T. Schcolnik*, *Afimilk, Afikim, Israel.*

The objective of the present study was to establish the association of negative energy balance status of the calving cow with the duration of high daily fat-to-protein ratio (FPR). Such an association could be utilized to evaluate fresh cow's energy balance status. A dairy cow's physiological condition is reflected in the composition of its milk. AfiLab™ is a real-time milk analyzer measuring individual cows' milk fat, protein and lactose contents during each milking. Fat-to-protein ratio is a combination of milk protein production rate with body fat mobilization rate; that is, it reflects energy availability to a cow's body needs of maintenance and production. Negative energy balance (NEB), ketosis, and body condition score losses are related to reduced conception rate and decreased milk yield. Utilizing FPR for evaluation of cows energy status provides valuable indications, which enable prompt intervention and increase economic profit. Daily milk component data, extracted from the ICBA Israeli HerdBook, included 117,846 observations (days in milk [DIM] periods) of 23,192 cows at first lactation or more, calving through 2014, in 44 Israeli Holstein herds using Afilab. Analysis was done by SAS®PROC GLIMMIX. Means of FPR up to 50 DIM were calculated for 3 periods: 1–15, 16–35, and 36–50 DIM. Four categories were defined by FPR threshold of 1.4: (1) means of all periods < 1.4, (19,181 cows); (2) mean of any one period $\geq$ 1.4 (2979 cows); (3) means of any two periods $\geq$ 1.4 (779 cows); and (4) means of all three periods $\geq$ 1.4 (253 cows). The results establish valid associations between production and fertility traits and the duration of NEB after calving. Least squares means of conception to first AI service were 35.34, 31.62, 30.17, and 33.0% for groups 1, 2, 3, and 4, respectively. Differences between groups 2 and 3 vs. group 1 were statistically significant. The least squares means of days open for the same groups were 122, 125, 129, and 128 d, respectively. The least squares means for 180 d milk yield were 7621, 7685, 7636, and 7468 kg, respectively. Differences between groups 1, 2, and 3 vs. group 4 were statistically significant. We concluded that the intensity of the negative effects of NEB on fertility and production variables examined, relates to the duration of NEB after calving. Therefore, real-time detection of NEB per individual cow allows for specific and prompt treatment.

Key Words: energy status, fat-to-protein ratio, production

0118 Evaluation of three lameness detection strategies on the odds of cure in dairy cows. E. M. Wynands*, D. Moe, and G. Cramer, *Department of Veterinary Population Medicine, College of Veterinary Medicine, University of Minnesota, St. Paul.*

The high prevalence of lameness in U.S. freestall dairy herds is both an animal welfare and an economic concern. To achieve a low prevalence of lameness, strategies to lower incidence need to be combined with methods to decrease duration. This requires methods to detect and treat lameness. The objective of this study was to evaluate the impact of three lameness detection strategies on the odds of cure. A trial was conducted from June to August 2015 on a dairy farm in Minnesota. Three pens of cows were randomized to different lameness detection strategies. The strategies were: (1) locomotion scoring using a 3-point scale (VLS), (2) headlock scoring by observing leg posture and weight-bearing while cows were restrained (HS), and (3) casual observation at unspecified times (farm's current strategy), serving as the control group (C). Cows newly detected as lame by the different strategies were evaluated in a hoof trimming chute and treated for the cause of lameness. All groups were locomotion scored for lameness once per week (LS) as cows exited the parlor. The weekly LS were used as the outcome measure to assess odds of cure. Cows that began nonlame as defined by LS and who were subsequently diagnosed as lame by LS were included in the analysis. The scores from the LS system showed a high degree of week-to-week variability. Logistic regression models were constructed for the odds of cure at 3 wk (n = 486) and 6 wk (n = 290) following lame diagnosis. At the 3 wk follow-up, 176 individuals (36.2%) remained lame. Primiparous cows had higher odds of recovering than multiparous cows (OR, 1.79; CI, 1.20–2.67). Days in milk at enrollment were negatively associated with odds of cure (P = 0.03). There was no significant association between detection strategy and odds of cure at 3 wk. At the 6 wk follow-up, 125 individuals (43.1%) remained lame. Primiparous cows had higher odds of recovering than multiparous cows (OR, 2.71; CI, 1.62–4.53). The odds of cure were higher in the VLS group compared with the C group (OR, 2.15; CI, 1.12–4.12). The week-to-week variability in individual cow LS identified a limitation of the LS system, as this variation is inconsistent with the pathology of lameness. These results show that the odds of cure improved when the VLS active detection protocol was implemented.

Key Words: dairy, lameness, locomotion scoring

0119 Risk factors for subclinical ketosis in grazing dairy herds in Brazil. R. R. Daros*[1], M. J. Hötzel[2], S. J. LeBlanc[3], J. A. Bran[2], A. J. Thompson[1], and M. A. von Keyserlingk[1], *[1]Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada, [2]Universidade Federal de Santa Catarina, Florianopolis, Brazil, [3]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

Minimizing disease, including subclinical ketosis (SCK), continues to be a challenge for the dairy industry. Work on SCK has focused on confinement systems, with little work on pasture-based dairies. The aim of this study was to determine the prevalence and herd-level risk factors for SCK in cows housed on pasture. We visited 48 pasture-based farms in southern Brazil between February and September 2015. All farms used a rotational grazing system (2 to 3 paddocks per day). Cows (n = 13 per farm) between 3 and 21 d in milk were assessed for SCK based on blood β hydroxybutyrate ≥ 1.2 mmol/L. Data regarding number of recumbent cows up to 3 d after partum (a crude measure of milk fever) over the course of 1 yr, supplemental feeding, and transition cow management were collected using a questionnaire by interview and environmental inspection. Herds were categorized either as Holstein or crossbred (crossbred Holstein and Jersey, or a mix of Holstein and Jersey). Herd-level prevalence of down cows was categorized into low (0–5%), medium (5–10%), and high (>10%). Herd prevalence of SCK was log transformed. Univariable linear regression models were used to select variables associated with SCK (P < 0.2). Variables from the final multivariable model were back transformed for interpretation. The overall prevalence of ketosis was 21%. Breed, down cow prevalence, and access to water (free versus limited access), were retained in the final model. Referent herds had 8% (95% confidence interval [CI]: 5–11%) SCK prevalence and consisted of Holsteins with free access to water and low prevalence of down cows. Compared with referent herds: Crossbred herds had 1.7 times higher predicted prevalence of SCK (95% CI: 1.14–2.55; P = 0.01); limited access to water increased herd level predicted prevalence of SCK by 1.5 times (95% CI: 1.05– 2.31; P = 0.03) and herds with high predicted prevalence of down cows had three times higher prevalence of SCK (95% CI: 1.75–5.09; P < 0.01). Pasture-based dairies appear to have similar point prevalence of SCK to confinement systems, but the risk factors are different. This work indicates that crossbred herds have higher levels of SCK, so prevention methods for SCK in these herds is especially important. Improved feeding and management that would prevent down cows and allowing cows to have free access to water should decrease the prevalence of SCK in grazing dairy herds.

Key Words: health, hyperketonemia, transition period

0120 Mortality risk factors for calves entering a multilocation white veal farm in Ontario.
C. B. Winder*[1], D. F. Kelton[2], and T. F. Duffield[2], [1]*University of Guelph, Guelph, ON, Canada,* [2]*Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

Mortality in preweaned dairy breed calves of both sexes represents a potential welfare issue and a source of economic loss for the industries involved. While morbidity and mortality in veal production has been described, this work reflects a wide range of management practices and requirements throughout the world. In preweaned dairy heifers, rates of morbidity and mortality can also range dramatically, due in large part to differing management strategies. It has been over two decades since mortality in veal calves in Ontario was last described. The objective of this retrospective cohort study was to determine if recorded on-arrival data collected from a large white veal farm could be used as predictors of mortality. Data was collected from 10,910 calves entering seven barns of a single white veal farm, all locations of barns within Ontario, from 1 Jan. to 31 Dec. 2014. Calves were followed until death or marketing; no calves were culled during the year. Three logistic regression models were used to determine the effects of weight on arrival, season of arrival, supplier, sex, barn, and standardized purchase price on the risk of overall mortality, mortality in the first 21 d after arrival, and mortality after the first 21 d. In the overall mortality model, significant associations ($P < 0.05$) were seen with season, barn, supplier and weight, with lighter weight calves arriving in winter being at increased odds of mortality. The early mortality model contained significant ($P < 0.05$) associations with weight, season, barn, supplier and tended ($P < 0.10$) to have an association with standardized price; lighter weight calves arriving in winter at lower prices were at increased odds of mortality. The late mortality model had significant ($P < 0.05$) associations with season of arrival, barn and supplier. While not a proxy for body condition, increased weight on arrival being protective for early mortality may have somewhat reflected this, as the distribution of weights was fairly tight and likely represented calves at a week of age or less. Although failure of passive transfer is a significant risk factor for mortality, the seasonal association we saw could reflect early life nutrition stress as opposed to seasonal variation in passive transfer. A further exploration of dairy farm of origin risk factors for veal calf mortality may serve to improve the productivity and welfare of dairy calves of both sexes.

Key Words: calf, mortality, veal

0121 Assessment of tubal patency by hysterosalpingo-contrast sonography in cow.
K. Itoh[1], N. Endo[1], S. I. Kataoka[2], and T. Tanaka*[1], [1]*Tokyo University of Agriculture and Technology, Fuchu, Tokyo, Japan,* [2]*Tokyo Metropolitan Agriculture and Forestry Research Center, Ome, Tokyo, Japan.*

Recently, several studies have reported the use of ultrasound contrast media to assess tubal patency during transvaginal ultrasound in the imaging of infertile women. However, in the field of veterinary medicine, there is little information regarding the use of hysterosalpingo-contrast sonography to test for tubal patency. The present study aimed to estimate the clinical usefulness of hysterosalpingo-contract sonography for tubal patency in cows. Five nonlactating Holstein cows were used, and four of them were treated twice. Sixteen microliters of perflubutane (Sonazoid® for injection, Daiichi-Sankyo) was diluted with 60 mL of saline as echo-contrast medium. At the luteal phase (around 10 d after ovulation), a 16 Fr balloon catheter was gently inserted into one uterine horn, the balloon was placed approximately 5 cm cranial to the uterine bifurcation. The linear probe of the ultrasound (5.0 MHz) was inserted rectally and 30 mL of echo-contrast medium was injected slowly into the uterine horn through the catheter. After the injection, the flow of contrast medium in the uterus, uterotubal junction, and oviduct was monitored with the ultrasound for 20 min. The opposite oviduct was tested in the same way. Tubal patency was diagnosed if the contrast medium was visualized at the infundibulum of the oviduct. Twelve of 18 cases were diagnosed as tubal patency. Contrast medium was first observed within the uterus and then immediately moved toward the oviduct. In the case of tubal patency, it was visualized as a funnel-like appearance adjacent to the ovary at the infundibulum of the oviduct. The transit time of the contrast medium to reach the infundibulum of the oviduct after injection was 6.5 ± 3.3 min ($n = 12$). Two cases were diagnosed as tubal obstruction. Although the contrast medium was clearly visualized in the uterus and the isthmus of the oviduct, an accumulation of contrast medium was found at the position of the ampulla of the oviduct in one of them. The other four cases were inconclusive because of poor image quality due to posterior echo enhancement and technical artifact. The present study demonstrated that the flow of the contrast medium injected to the uterus was visualized at the infundibulum of the oviduct, suggesting that hysterosalpingo-contrast sonography is useful as a diagnostic tool for tubal patency in cows. However, further technical improvement is required to reduce inconclusive cases for accurate diagnosis.

Key Words: tubal patency, hysterosalpingo-contrast sonography, cow

0122 Retained placenta and subclinical endometritis: Prevalence and relation with reproductive performance in crossbred dairy cows. R. R. Buso, C. C. Campos, T. R. Santos, J. P. E. Saut, and R. M. Santos*, *FAMEV-UFU, Uberlândia, Brazil.*

Our objective was to determine the effects of type of calving (eutocic vs. dystocic) and season of the year (rainy vs. dry) on retained placenta (RP) and subclinical endometritis (SE) prevalences verify the relationship between these two diseases, and effects of RP and SE on culling rate, calving to conception interval, and number of AI/conception in crossbred dairy cows. The study was conducted in nine different dairy farms located in Minas Gerais state, Brazil. Retention of fetal membranes was recorded on the first day postpartum. Endometrial cytology was performed between 30 and 80 d in milk (DIM) and the threshold used for SE diagnosis was ≥5% neutrophils. Data were analyzed by logistic regression and ANOVA on Minitab program. The prevalence of RP was 14.93% (69/462) and of SE was 27.49% (127/462). A tendency of effect of RP on SE prevalence was detected (35.82 vs. 26.07%; $P = 0.10$). Dystocia increased RP prevalence (68.42 vs. 12.19%; $P < 0.05$). Cows, which calved during rainy season, had greater SE prevalence (35.48 vs. 20.41%; $P < 0.05$). RP increased culling rate (19.40 vs. 6.08%; $P < 0.05$), calving to conception interval (177.46 vs. 131.19 d; $P < 0.05$) and number of AI/conception (3.30 vs. 2.46; $P < 0.05$), although SE occurrence did not affect these variables ($P > 0.05$). In conclusion, RP showed to be a risk factor for SE, dystocia is a predisposing factor for RP and cows calving during the rainy season had an increase in SE prevalence. There is a negative impact of retained placenta on reproductive efficiency of crossbred dairy cows. Supported by FAPEMIG e CnPQ.

Key Words: cytological endometritis, reproductive efficiency, dairy cows

0123 Association of rumination time and health status with milk production in early lactation dairy cows. V. H. Asselstine[1], E. I. Kaufman[1], S. J. LeBlanc[2], B. W. McBride[1], T. F. Duffield[2], and T. J. DeVries*[1], *[1]Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, [2]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to characterize the associations of rumination time (RT) and health status with milk yield (MY) and milk composition in early lactation dairy cows. A total of 339 dairy cows (first lactation, $n = 107$; second lactation, $n = 112$; ≥ third lactation, $n = 120$) on 4 commercial dairy farms in Ontario, Canada, were monitored from 1 to 28 d in milk (DIM) for rumination behavior (24h/d using an automated system), milk composition (fat, protein, somatic cell count, and milk urea N 1×/wk), and hyperketonemia (HYK; blood β hydroxybutyrate ≥ 1.2 mmol/L, measured 1×/wk). Cows were milked 3 times/d at each farm; Two farms recorded milk weights at each milking to determine daily MY ($n = 170$). Cases of retained placenta, metritis, milk fever, or mastitis during the study period were recorded. Cows were categorized into 1 of 3 groups: healthy (HLT) cows had no HYK or any other recorded disease ($n = 139$); HYK cows with no other health problems during transition ($n = 97$); or hyperketonemic plus (HYK+) cows that had HYK and ≥1 other health problems ($n = 53$). Data were summarized by week and analyzed in repeated measures general linear mixed models. A positive association was found between weekly summarized RT and MY in first (+0.006 ± 0.003 kg milk/min RT, $P = 0.04$) and second lactation (+0.01 ± 0.004 kg milk/min RT, $P < 0.01$) cows from 4 to 28 DIM. A positive association was also seen in parity 3+ cows, however, the relationship between RT and MY differed ($P < 0.01$) across weeks (wk +1: +0.05 ± 0.007 kg/min RT; wk +2: +0.06 ± 0.008 kg/min RT; wk +3: +0.05 ± 0.011 kg/min RT; wk +4: +0.04 ± 0.014 kg/min RT). During wk +2 and +3, second lactation HYK cows had lower milk protein percentage compared with HLT cows (0.08 ± 0.043w/w% and 0.12 ± 0.041w/w%, respectively; $P \leq 0.05$). Hyperketonemia+, second lactation cows also had lower milk protein content compared with HLT cows in wk +1, and +2, (0.14 ± 0.068w/w% and 0.20 ± 0.089w/w%, respectively; $P \leq 0.05$). Over the 4 wk observation period, first lactation HYK+ cows tended to have lower protein compared with HLT cows ($P = 0.1$) and ≥ third lactation HYK and HYK+ cows produced less protein than HLT cows ($P \leq 0.03$). Second lactation cows in HYK+ produced less milk than HLT cows during wk +1 (7.1 ± 2.9 kg/d, $P = 0.02$), +2 (14.2 ± 4.0 kg/d, $P < 0.001$), +3 (13.8 ± 4.5 kg/d, $P = 0.003$), and +4 (10.6 ± 5.3 kg/d, $P = 0.05$). Ketosis decreased MY and protein percentage variably with parity. Rumination time was shown to have a positive association with MY in early lactation dairy cows.

Key Words: hyperketonemia, milk production, rumination behavior

0124 Associations of cow-level factors with the risk of poor hygiene. I. Robles[*1], D. F. Kelton[2], H. Barkema[3], G. P. Keefe[4], J. P. Roy[5], M. A. von Keyserlingk[6], and T. J. DeVries[1], *[1]Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, [2]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, [3]University of Calgary, Calgary, AL, Canada, [4]Atlantic Veterinary College, University of Prince Edward Island, Charlottetown, PE, Canada, [5]Faculté de médecine vétérinaire, University of Montreal, St. Hyacinthe, QC, Canada, [6]Animal Welfare Program, University of British Columbia, Vancouver, Canada.*

The objective of this study was to identify how cow-level factors affect the risk of having poor hygiene. Cows from 68 commercial dairy herds in Ontario, Canada, were enrolled in a cross-sectional study. Cows were housed in free-stall (FS, n = 43) or tie-stall (TS, n = 25) barns. Twenty-five percent of the cows in each lactating pen (FS) or row of stalls (TS) in herds with > 160 cows, or a minimum of 40 cows per herds with <160 cows were randomly selected for hygiene scoring (n = 2594 cows). Cows were scored for cleanliness on each of three visits (7d apart), on a scale of 1 (clean) to 4 (dirty), in each of three zones (lower leg, udder, and upper leg and flank); scores were categorized as: clean $\leq$ 2 or dirty $\geq$ 3. DHI data from the test closest to the first visit and another test closest to the last visit were obtained. Data were analyzed using multivariable logistic regression models. DIM (mean ± SD) was 171.6 ± 106.1 for cows housed in FS barns and 177.4 ± 114.0 for those in TS barns. In FS barns, first and second parity cows were at 1.5× and 1.4×, respectively, greater risk ($P < 0.01$) of having dirty lower legs (DLL) compared with $\geq$ 3 parity cows. Also in FS barns, first parity cows had a lower risk of having a dirty udder (OR = 0.40; $P < 0.05$), as well as dirty upper legs and flank (DULF; OR = 0.84; $P = 0.01$), when compared with $\geq$3 parity cows. In TS barns, first lactation cows had a 2.3× greater risk ($P < 0.01$) of having DLL compared with $\geq$3 parity cows. First and second parity cows in TS barns had greater risk (OR = 1.9 and 1.3, respectively) of having DULF ($P < 0.01$). Each SD (114.0) increment in DIM was associated with lower risk of having DLL (OR = 0.41; $P < 0.01$) and dirty upper legs and flank (DULF; OR = 0.60; $P < 0.01$) for cows in TS barns. Each SD (106.1) increment in DIM was associated with lower risk of having a dirty udder (OR = 0.90; $P = 0.03$) and DULF (OR = 0.84; $P < 0.01$) for cows housed in FS barns. The results suggest that cow hygiene varies by parity and stage of lactation in both free-stall and tie-stall barns.

Key Words: hygiene, housing, parity

0125 Genomic markers associated with hyperketonemia in Jersey cows. R. S. Pralle[*1], H. A. Adams[2], T. L. Chandler[1], and H. M. White[1], *[1]Department of Dairy Science University of Wisconsin, Madison, [2]CRI International Center for Biotechnology, Mount Horeb, WI.*

Hyperketonemia is a metabolic disorder in dairy cattle commonly attributed to a parturition-induced negative energy balance. Prevalence of this disorder is variable among dairy operations with similar management strategies, as well as among dairy breeds. This suggests differences in genetic selection practices among farms and breeds that may alter a cow's predisposition to hyperketonemia. Identification of genomic markers for hyperketonemia could assist dairy producers in identifying transition cows requiring intensive management. The objective of our study was to identify genetic markers associated with the hyperketonemia phenotype. Genomic marker association was performed on 387 Jersey cows genotyped with the *GeneSeek* Genomic Profiler LD v3 chip. Blood and hair samples were collected at a single time-point from Wisconsin (5–21 d in milk [DIM], five herds) and New England (2–30 DIM, five herds) Jersey cows. Serum β-hydroxybutyrate (BHBA) concentration was determined by a colorimetric assay. Samples were diagnosed into categorical phenotypes for threshold and gap analysis, generating two case-control phenotype sets based on serum BHBA concentrations. Threshold hyperketonemia cases were defined as BHBA concentration $\geq$ 1.2 mM, and remaining cows were controls; gap cases were BHBA concentrations $\geq$ 1.2 mM, and controls were BHBA concentrations $\leq$ 1.0 mM. A log-additive model that accounted for parity group was applied to the data, using the SNPassoc package in R, to identify markers significantly associated with hyperketonemia status. Means ± standard error are reported. Markers were considered significant at a false discovery rate-corrected $P \leq 1 \times 10^{-6}$. The mean DIM at sample collection was 15.0 ± 0.73. The prevalence of hyperketonemia within the dataset was 22.0%. Blood BHBA was 0.68 ± 0.01 mM for controls and 2.08 ± 0.13 mM for cases. Thirteen markers were found to be significant in the gap and/or threshold analyses. Six markers were significant across both analyses. Of the significant markers identified in threshold or gap comparisons, markers were identified within exonic regions of eight genes: periphilin 1, multimerin 2, alkB homolog 1 histone H2A dioxygenase, Parkinson disease protein 2 co-regulated-like, ataxin 1, protein phosphatase 1, β-γ crystallin domain containing 3, and 2,3-cyclic nucleotide 3 phosphodiesterase. Although gene functions are not exclusive to energy metabolism, the research objective was to identify markers consistently associated with hyperketonemia, which may serve as valuable genetic markers. Identification of these markers can aid in establishing a marker-assisted management program for Jersey dairy producers striving to effectively

manage hyperketonemia.

Key Words: Jersey, hyperketonemia, genome association study

0126 Meta-analysis of factors influencing new intramammary infection rate in experimental challenge teat dip efficacy trials. B. D. Enger[*1], R. R. White[1], S. C. Nickerson[2], L. K. Fox[3], *[1]Virginia Tech, Blacksburg, [2]University of Georgia, Athens, [3]Washington State University, Pullman.*

Using an effective teat dip before and after milking reduces the incidence of new intramammary infection (IMI) on dairies. Many factors influence a teat dip's efficacy, and this is why all teat dips should be confirmed efficacious before commercial circulation. To date, many teat dip efficacy trials have been conducted and are published in peer-reviewed journals. The objective of the present study was to conduct a meta-analysis of data from peer-reviewed teat dip efficacy trials that used an experimental challenge study design to identify factors influencing the new IMI rate. A dataset of 21 studies (148 observations) was created. The new IMI rate, based on percentage of new quarter infections/month (PNQI/mo), was calculated for each recorded observation and used as the dependent variable for model derivation. A linear, mixed-effects model with a random study effect, weighted for the standard error of the measurement was derived in a stepwise manner where parameters were sequentially eliminated for nonsignificance. The final mixed model included the terms for the causative mastitis pathogen ($n = 2$; $P = 0.55$), postmilking treatment ($n = 4$; $P < 0.01$), geographic region where the trial was conducted ($n = 3$; $P = 0.02$), and interaction between study region and pathogen group ($P < 0.01$) and postmilking treatment and pathogen group ($P < 0.01$). Overall, the new IMI rate between the causative mastitis pathogens, *Staphylococcus aureus*, 0.0409 ± 0.0097 PNQI/mo and *Streptococcus agalactiae*, 0.0344 ± 0.0096 PNQI/mo, were similar. Quarters not dipped with a postmilking teat dip, 0.0859 ± 0.0087 PNQI/mo, had a greater new IMI rate than those dipped with a postmilking teat dip containing either iodine, 0.0127 ± 0.0099 PNQI/mo, a chlorine compound, 0.0258 ± 0.0095 PNQI/mo, or an "other" active ingredient, 0.0263 ± 0.0106 PNQI/mo ($P < 0.05$). Quarters dipped with postmilking teat dips had similar new IMI rates ($P > 0.05$). Studies conducted in the southern United States, 0.0531 ± 0.0040 PNQI/mo, had a higher new IMI rate than those conducted in the Pacific Northwest, 0.0072 ± 0.0141 PNQI/mo ($P < 0.05$), but not those in the eastern United States, 0.0527 ± 0.0206 PNQI/mo ($P > 0.05$). The results of this meta-analysis indicate that using an efficacious postmilking teat dip has a greater impact on the new *Staphylococcus aureus* and *Streptococcus agalactiae* IMI rate than the active germicidal ingredients present in the postmilking teat dip itself.

Key Words: active ingredient; mastitis; teat disinfectant

0127 The effects of short-term feeding of tocopherol mix (α-, β-, γ-, and δ) on blood neutrophil function and immunometabolic-related gene expression in lactating dairy cows. Y. Qu[*1], T. H. Elsasser[2], M. Garcia[1], C. M. Scholte[1], E. E. Connor[3], J. R. Newbold[4], and K. M. Moyes[1], *[1]Department of Animal and Avian Sciences, University of Maryland, College Park, [2]USDA-ARS, Animal Biosciences and Biotechnology Laboratory, Beltsville, MD, [3]USDA-ARS, Animal Genomics and Improvement Laboratory, Beltsville, MD, [4]Cargill Innovation Center, Velddriel, the Netherlands.*

Alpha-tocopherol has been well-studied regarding improving neutrophil function, especially its involvement in respiratory burst. However, no studies have identified the effect of feeding a tocopherol mix, which contains additional isoforms, on immune cell function. The objective of this study was to investigate how short-term feeding of tocopherol mix alters bovine blood neutrophil (BBN) function and immunometabolic-related gene expression. Twelve healthy, multiparous Holstein cows (DIM: 179 ± 17d) were fed a vegetable-derived tocopherol oil supplement (Tmix) enriched with γ- and δ-isoforms (9% α-, 1% β-, 24% δ-, and 62% γ-tocopherol) at ~620 g Tmix·cow^{-1}·d^{-1} top dressed for seven consecutive days. Jugular blood (~200 mL) was collected from all cows on d 0 before feeding and on d 7 postfeeding of Tmix. Whole blood was then used to measure respiratory burst response via chemiluminescence analysis. Isolated BBN (3×10^6 cells/mL) were used for chemotaxis and immunometabolic-regulated gene expression analysis by quantitative real-time PCR. For gene expression analysis, cells were incubated with lipopolysaccharide (LPS) at a final concentration either of 0.0 or 1.5µg/mL for 2 h at 37°C, 95% humidity, and 5% CO_2. Data were analyzed as a complete randomized design. Significance was declared at $P \leq 0.05$. With regard to function, Tmix improved ($P = 0.04$) BBN chemotaxis function but did not alter ($P = 0.9$) the respiratory burst response in whole blood. For gene expression analysis, LPS challenge increased the expression of proinflammatory genes tumor necrosis factor-α and interleukin-6. However, Tmix did not alter the expression of genes associated with the immune or metabolic response. In conclusion, short-term feeding of Tmix did not impair BBN function of respiratory burst but improved chemotaxis, and Tmix did not alter the immunometabolic response of genes in BBN. Additional evaluations of the effect of individual tocopherol isoforms will offer valuable information regarding their specific roles on bovine immune cell function and gene expression.

Key Words: bovine, neutrophil, tocopherol

0128 Predicting hyperketonemia prevalence in Jersey herds from milk composition and cow test-day information using multiple linear regression.

T. L. Chandler*[1], N. Zhang[1,2], M. R. Skiba[1], S. G. Moore[3], M. O. Caldeira[3], S. E. Poock[3], G. R. Oetzel[4], C. W. Wolfe[5], R. H. Fourdraine[6], and H. M. White[1]. *[1]Department of Dairy Science University of Wisconsin, Madison, [2]Feed Research Institute Chinese Academy of Agricultural Sciences, Beijing, China, [3]University of Missouri, Columbia, [4]Department of Medical Sciences, School of Veterinary Medicine, University of Wisconsin, Madison, [5]American Jersey Cattle Association, Reynoldsburg, OH, [6]CRI International Center for Biotechnology, Mount Horeb, WI.*

Multiple linear regression models have been validated to predict hyperketonemia in Holstein herds; however, potential differences in milk composition and hyperketonemia prevalence warranted further sampling and distinct models for Jersey herds. The objective of this study was to validate the use of multiple linear regression models to predict β-hydroxybutyrate (BHBA) from milk composition and continuous test-day variables in Jersey cows to serve as a diagnostic tool for determining herd-level ketosis prevalence. Blood samples were collected on the same day as milk sampling from 468 Jersey cows 5 to 20 DIM on six dairy farms. Serum BHBA concentration was quantified by colorimetric assay (Stanbio, Boerne, TX). Milk samples were analyzed for concentrations of milk BHBA, acetone, and fatty acid (FA) groups (saturated, unsaturated, trans, short, medium, and long chain FA) by fourier transform infrared (FTIR) spectrometry from MilkoScan FT+ (FOSS Analytical A/S, Hillerød, Denmark), in addition to standard milk analysis variables. Continuous test-day variables were exported from DairyComp305 (Valley Ag Software, Tulare, CA) records. Models were built in the REG procedure of SAS 9.4 (SAS Institute Inc., Cary, NC) using forward stepwise selection by excluding variables with a P-value > 0.15 and using selection criterion of sequential sums of squares, error sums of squares, and Akaike's information criterion. Statistical parameters (R^2, adjusted R^2, root mean square error) were calculated to evaluate model performance. Hyperketonemia, defined as a serum BHBA $\geq$ 1.2 mM, prevalence within the sample set was 20%. Data interrogation justified development of separate models for primiparous and multiparous groups, as well as 5 to 11 and 12 to 20 DIM groups. Significant variables were BHBA, acetone, fat %, protein %, somatic cell count, FA groups, pervious days carried calf, age at calving, previous ME305 milk production, test-day DIM and milk production. Overall, model accuracies were 91% for multiparous cows 5 to 11 DIM (R^2 = 0.85), 86% for multiparous cows 12 to 20 DIM (R^2 = 0.64), 90% for primiparous cows 5 to 11 DIM (R^2 = 0.64), and 90% for primiparous cows 12 to 20 DIM (R^2 = 0.83). Collectively, models predicted animals with hyperketonemia at the 1.2 mM threshold with 86% accuracy. Results suggest that modeling blood BHBA based on milk composition data and cow-test day information provides a practical tool for monitoring hyperketonemia prevalence in Jersey herds.

Key Words: *ketosis, linear regression, Jersey*

0129 Liver transcriptome modifications by nutrient restriction in early lactation Holstein cows challenged with intramammary lipopolysaccharide.

K. Pawlowski[1], C. Leroux[1], Y. Faulconnier[1], C. Boby[2], A. de la Foye[2], D. Durand[1], and J. A. A. Pires*[1], *[1]UMR1213 Herbivores, INRA, VetAgroSup, Saint-Genes-Champanelle, France, [2]PFEM, INRA, Saint-Genes-Champanelle, France.*

The objective was to test effects of nutrient restriction on liver transcriptome 24 h after an intramammary lipopolysaccharide (LPS) challenge in early lactation cows. At 24 ± 3 d in milk, multiparous cows were either allowed to continue ad libitum intake of a lactation diet (CON, n = 6), or the ration was diluted with barley straw (48% DM) for 4 d (RES, n = 6). On d 3, one healthy rear mammary quarter was infused with 50 µg of LPS (*E. coli* 0111:B4). Blood and liver biopsies were collected on d 4, corresponding to 24 h after LPS challenge. Liver transcriptome was analyzed with 44K bovine microarrays (Agilent Technologies). Blood and transcriptomic data were analyzed using SAS mixed models and GeneSpring (moderated t test with Westfall-Young correction, $P < 0.05$), respectively, and data mining was performed using Panther and Pathway Studio software. Energy balance did not differ before diet change. By experimental design, energy intake was limited to 41 and 97 ± 15% of NE_L requirements in RES and CON, respectively (mean ± SD; $P < 0.001$). Plasma NEFA and BHBA were greater, and glucose was lower for RES compared with CON (1221 vs. 382 µM, 2.67 vs. 0.70 mM, 56 vs. 69 mg/dL respectively, $P \leq 0.05$, before biopsy), which is consistent with 4 d of nutrient deficit in REST. We detected 77 differently expressed genes (DEG) between CON and RES, with 29 down-regulated and 48 up-regulated in RES. Genes involved in fatty acid synthesis (*ACAT2*, *FASN*, *SCD*), lactate metabolism (*LDHC*), and cortisol binding (*SERPINA6*) were down-regulated in RES, whereas those involved in fatty acid oxidation, detoxification, cholesterol synthesis, lipoprotein lipid secretion, and gluconeogenesis (*ACADVL*, *CPT1A*, *CPT1B*, *ANGPTL4*, *CYP4A11*, *HMGCSA*, *APOA1*, *APOA4*, *GK*, *PC*, and *PCK2*) were up-regulated in RES. Overall, DEG were in agreement with negative energy balance and plasma metabolite profile, and reflect a state intense lipomobilization, glucose deficit and ketogenesis in RES. Preliminary results suggest that nutrient restriction did not change liver expression of genes directly involved in immune function 24 h after

an intramammary LPS challenge.

Key Words: inflammation, liver transcriptome, undernutrition

0130 Growth and transcriptional profile analysis following oral probiotic supplementation in dairy cows.

M. Worku*, S. Adjei-Fremah, K. Ekwemalor, E. Asiamah, and H. Ismail, *North Carolina Agricultural and Technical State University, Greensboro.*

The objective of this study was to assess the impact of probiotic administration on growth and global gene expression profile in dairy cow. Use of probiotic supplements is a nonchemical approach to promote animal health. Understanding the mechanism of action of probiotics in cows may aid in sustainable dairy production. Lactating Holstein-Friesian cows (n = 10) received daily oral doses (50ml) of a commercial probiotic FASTtrak microbial pack (Conklin Company, Kansas City, MO) (containing *Lactobacillus acidophilus, Saccharomyces cerevisiae, Enterococcus faecium*, *Aspergillus oryza*, and *Bacillus subtilis*) over a 60-d period. Body weight was recorded weekly. Whole blood was collected at the beginning (d 0) and end of the study (d 60). Blood samples were analyzed for total and viable cell count, packed cell volume (PCV), white blood cell differential counts (WBC), and total protein concentration in plasma. Daily supplementation of probiotics had no effect on BW, PCV, and total protein concentration in plasma at the end of the study ($P > 0.05$). Percentage lymphocyte count increased ($P < 0.05$), and percentage neutrophil count ($P < 0.05$) decreased in probiotic-treated animals. Gene expression analysis identified 10,859 differentially expressed genes, 1168 up-regulated and 9691 down-regulated genes respectively following probiotic administration. Pathway analysis identified 87 bovine pathways impacted by probiotic treatment. These pathways included the Toll-like receptor signaling pathway, inflammation response and Wnt signaling pathways. Oral administration of probiotic to dairy cows has a systemic effect on global gene expression, including genes involved in immunity and homeostasis (Wnt). The results of this study show that the utilization of probiotics in animal agriculture impacts genes important to dairy cow health and production. Further definition of the interaction between the pathways involved may aid in the design of the most effective probiotics for optimum dairy production and health.

Key Words: dairy cows, innate immunity, microarray, probiotic

0131 Mammary gland transcriptome and proteome modifications by nutrient restriction in early lactation Holstein cows challenged with intramammary lipopolysaccharide.

K. Pawlowski[1], C. Chambon[2], C. Boby[2], A. de la Foye[2], Y. Faulconnier[1], J. A. A. Pires*[1], C. Leroux[1], [1]*UMR1213 Herbivores, INRA, VetAgroSup, Saint-Genes-Champanelle, France,* [2]*PFEM, INRA, Saint-Genes-Champanelle, France.*

The objective was to evaluate the effect of nutrient restriction and intramammary lipopolysaccharide (LPS) challenge on mammary gland (MG) gene expression in early lactation cows. At 24 ± 3 d in milk, multiparous cows were either allowed to continue ad libitum intake of a lactation diet (CON, n = 6), or the ration was diluted with barley straw (48% DM) for 4 d (RES, n = 6). On d 3, one healthy rear mammary quarter was infused with 50 µg of LPS. Mammary biopsies were performed 24 h after LPS challenge. RNA and proteins analyzed using bovine 44 K microarrays (Agilent Technologies) and micro-LC-MS/MS, respectively. Transcriptomic data were analyzed using GeneSpring (moderated-t test with Westfall-Young correction, $P < 0.05$). Proteins were analyzed with Progenesis LC-MS software v.4.1 (Nonlinear Dynamics). Production and energy balance did not differ before diet change. Negative energy balance was aggravated in RES (41 vs. 97 ± 15% of requirements, mean ± SD; $P < 0.001$). A total of 87 differentially expressed genes (DEG) were highlighted through the comparison of RES vs. CON group. Among the 33 DEG identified in the transcriptomic analyses, 11 and 22 were down- and up-regulated by restriction, respectively. Among the up-regulated DEG, there were *PDK4* and *CPT1A* which are involved in the regulation of fatty acid, ketone, and glucose metabolism. *CPT1A* is the key enzyme in the carnitine dependent fatty acid transport, promoting fatty acid oxidation. Genes involved in immune response such as *PGLYRP3* and *TRIB2* were up-regulated, suggesting a higher inflammatory response in RES than CON. Proteomic analysis identified 54 proteins with 14 up- and 40 down-regulated in RES cows. Up-regulated proteins were mostly involved in gene expression mechanisms such as translation, RNA splicing and cellular protein modification. The down-regulated proteins (*e.g.*, EIF3H, RS27A, RS15) take part in protein metabolism. This is coherent with transcriptomic results, namely the down-regulation of *RPL 37A*, a component of ribosomal complex, which catalyzes protein synthesis and may partially explain the lower milk protein yield in RES (834 vs. 1163 g/d; P = 0.02). Proteins involved in antigen processing and presentation were down-regulated in RES compared with CON, suggesting an impaired ability to counteract inflammation in RES MG. Preliminary transcriptomics and proteomics analyses show that undernutrition may influence the MG response

to inflammation at each level of gene expression.

Key Words: mammary omics, undernutrition, inflammation

0132 Methionine supplementation modulates the inflammatory response of dairy cow blood neutrophils in response to lipopolysaccharide.

M. Vailati Riboni*[1], B. Qadir[2], J. J. Loor[1], *[1]University of Illinois, Urbana, [2]Veterinary division, Sulaymaniyah veterinary department, Ministry of agriculture and water resource, Kurdistan region Government, Sulaymaniyah, Iraq.*

Methionine (Met) is among the two most-limiting amino acids for milk production in dairy cow diets. The accepted optimal ratio when formulating diets is a Lys:Met of 3:1. However, blood from cows fed corn silage-based diets without supplemental rumen-protected Met averages ~3.6:1. Our recent in vivo research on immunonutrition revealed the immune system could benefit from additional Met. To study the effect of different Lys:Met ratios, blood neutrophils were isolated from five mid-lactating pluriparous Holstein cows (238 ± 20 DIM, 33.8 ± 3.9 kg/d average milk production) to obtain a homogenous pool. Neutrophils were then incubated at a concentration of 6 × 10^6 cells/mL for 2 h in a sterile incubator at 37°C and 5% atmospheric CO_2. A 3 × 2 factorial arrangement of treatments including three Lys:Met ratios (3.6:1, 2.9:1, 2.4:1) and two levels of lipopolysaccharide (LPS, 0 and 50 μg/mL) were evaluated in triplicate. After incubation, cellular RNA was used to measure expression of genes related to immune function and oxidative stress. Data were $\log_2$ normalized and subjected to ANOVA using the Proc MIXED procedure of SAS. As expected, LPS increased ($P < 0.05$) the expression of pro- and noninflammatory cytokines (*IL1B*, *IL10*, *IL6*, *TNF*) and immune-related nuclear receptors (*NFKB1*, *NR3C1*). However, LPS decreased ($P < 0.05$) the expression of chemokine *CXCR1* and antimicrobial enzyme *LYZ*, the latter only when cells were incubated with higher Met (2.9:1 or 2.4:1), and had no effect ($P < 0.05$) on other pathogen killing mechanisms (*MPO, SOD1*). Among genes related to Met metabolism, LPS increased ($P < 0.05$) expression of *MAT1A*, while reducing expression of *GPX1* and *GSR*, suggesting a greater use of Met and a reduced antioxidant system during the inflammatory response. Compared with the lowest level of supplemental Met (3.6:1 Lys:Met) the highest level (2.4:1 Lys:Met) decreased ($P < 0.05$) expression of *NFKB1*, *NR3C1*, and *GSR*, while it increased ($P < 0.05$) *IL6* independently of the LPS level. Furthermore, expression of the noninflammatory cytokine *IL10* was greatest ($P < 0.05$) at 2.4:1 Lys:Met and in non-LPS challenged cells, indicating that supplemental Met improved the oxidative status and the noninflammatory conditions of neutrophils. Overall, data support the idea that Met supplementation could improve the inflammatory and oxidative status of bovine neutrophils.

Key Words: LPS, methionine, neutrophils

0133 Feasibility and safety of nitric oxide releasing solution as a treatment for bovine mastitis.

G. Regev-Shoshani, J. Martins*, J. Leemhuis, N. Dinn, and C. Miller, *University of British Columbia, Vancouver, BC, Canada.*

Nitric oxide releasing solution (NORS) is a liquid formulation that releases nitric oxide (NO). NO is a broad, nonspecies-specific nonmicrobial nanomolecule, endogenously produced during the innate response in mammals. The objective of this study was to explore the feasibility of NORS as a potential treatment for bovine mastitis (BM). Two common pathogens found in BM (10^6 CFU/mL of *Escherichia coli* and *Staphylococcus aureus*) were added to raw milk from healthy cows, as an in vitro model, to determine the antimicrobial efficacy of NORS at different concentrations (100–400 mM) and at two different NORS:milk ratios (2:1 and 1:1). Next, 10 ex vivo samples of milk from dairy cows presenting with clinical mastitis were obtained and treated with NORS to confirm efficacy. A dose escalating safety study was then performed using three dairy cows, where 40 mL of increasing concentrations of NORS (50–400 mM) were infused into the teat. Nitrite and methemoglobin levels were measured 5, 30, and 460 min posttreatment and nitrites in milk were measured 8 and 24 h posttreatment. Nitrite was measured by chemiluminescence, while methemoglobin was measured using a CO-Oximeter. Results show that NORS could eradicate, in vitro, both bacteria, and was dilution and time dependent. In the 2:1 ratio, NORS significantly ($P < 0.05$) reduced bacterial concentration in milk both in vitro and ex vivo within 2 min, and had no detectable bacteria after 5 min of exposure. In the 1:1 ratio, a significant bacterial load reduction ($P < 0.01$) occurred within 10 min and no detectable bacteria within 20 to 30 min. In the safety study we found an increase in blood nitrites ($P < 0.05$) within 5 min of the NORS treatment at all concentrations. After 8 h, the blood values at all concentrations returned to baseline ($P = 0.27$). Blood methemoglobin changes were nominally increased in the 5 and 30 min samples post 400 mM NORS and no detectable change was seen after 8 h. Eight hours posttreatment, before the evening milking, milk nitrites were 18 times higher than baseline, while 24 h posttreatment nitrites returned to baseline level ($P = 0.36$). NORS was found to eradicate bacteria in milk and, clinically, the treatment was well tolerated. This suggests that NORS has a potential to be a safe and effective nonmicrobial treatment for BM and may allow salable milk during antimicrobial treatment of mastitis. Further, it would provide an alternative to antibiotics, thus contributing to the reduction of antibiotic drug resistance. Further studies are justified.

Key Words: mastitis, nitric oxide, safety study, treatment

0134 Methionine coupled with choline supplementation alters inflammation and oxidative stress gene network expression of dairy cow blood neutrophils. M. Vailati Riboni[*1], A. Bellingeri[2], I. Khan[3], and J. J. Loor[1], [1]*University of Illinois, Urbana,* [2]*Università Cattolica del Sacro Cuore, Piacenza, Italy,* [3]*University of Agriculture, Peshawar, Pakistan.*

The nutritional status of dairy cows is tightly-correlated to the maintenance of proper immune function and health. Methionine (Met), besides being one of the first-limiting amino acids, has stimulatory effects on immune cells both directly and indirectly as a source of antioxidants. The objective of this study was to investigate the effect of supplementing Met or choline as its potential precursor on neutrophil gene expression. Blood neutrophils were isolated from five lactating multiparous Holstein cows (153 ± 5 DIM, 34.6 ± 2.7 kg/d average milk production) to obtain a homogenous pool. Cells were then incubated at a concentration of 6×10^6 cells/mL for 4 h in a sterile incubator at 37°C and 5% atmospheric CO_2. A 3 × 3 factorial arrangement of treatments, including three Lys:Met ratios (3.6:1, 2.9:1, 2.4:1) and three levels of choline chloride (3, 400, 800 μg/mL), were evaluated in triplicate cultures. Cellular RNA was used to measure expression of genes related to inflammation, antioxidant status, and the Met cycle. Data were $\log_2$ normalized and subjected to ANOVA using the Proc MIXED procedure of SAS. The greater expression ($P < 0.05$) of *MTR* at 2.9:1 and 2.4:1 Lys:Met indicated greater flux through the Met cycle compared with 3.6:1 Lys:Met. Both *BHMT* and *CHDH* were undetectable, indicating that neutrophils cannot generate Met from choline through the betaine pathway. Compared with the lowest level of supplementation (3 μg/mL), at the highest level of choline (800 μg/mL) there was lower expression ($P < 0.05$) of pro- (*IL6*, *IL1B*) and noninflammatory (*IL10*) cytokines, and antimicrobial mechanisms (*MPO*, *SOD1*), coupled with lower expression ($P < 0.05$) of genes related to the antioxidant system (*CDO1*, *CSAD*, *CTH*, *GSR*, *GSS*). These indicated a degree of inflammation, together with oxidative stress in neutrophils at the low choline level. In contrast, the interaction among treatments revealed that at higher (2.9:1 and 2.4:1 Lys:Met) Met and low choline (3 μg/mL) supplementation level the expression of *GSS*, *GSR*, *IL1B*, and *IL6* was lower ($P < 0.05$), hence, limiting the negative effect of a low choline level. Furthermore, higher Met supplementation increased ($P < 0.05$) neutrophil recognition capacity (*TLR4*, *SELL*) when incubated together with 400 μg/mL of choline. Overall, data indicate a choline requirement in bovine neutrophils that could potentially be overcome by Met supplementation. Despite this, neutrophil function appeared to be enhanced at high Met together with adequate choline supplementation.

Key Words: methionine, choline, neutrophils

0135 Impact of a BRDC vaccine with a MLV or KV IBR component on the innate inflammatory profile of nulliparous heifers. C. L. Widener*, D. J. Hurley, W. M. Graves, A. H. Nelson, D. A. L. Lourenco, and J. F. Bohlen, *University of Georgia, Athens.*

To investigate the difference in the inflammatory response between bovine respiratory disease complex (BRDC) vaccines containing either a modified live vaccine (MLV) or a killed component for infectious bovine rhinotracheitis (IBR), 28 Holstein heifers (mean ± SD; 12.4 ± 0.5 mo) in two replicates (spring $n = 12$ and fall $n = 16$) were synchronized for estrus using a 7-d CIDR protocol. This protocol included two injections of $PGF_{2\alpha}$, one at CIDR removal and a follow-up injection 16 h later. All animals were calf-hood vaccinated with an available BRDC vaccine with a modified live IBR component. At approximately Heat 2, heifers were vaccinated with either the calf-hood MLV ($n = 14$) or a BRDC vaccine with a killed ($n = 14$) IBR component. Heifers were vaccination blocked according to prevaccination bovine viral diarrhea virus (BVDV) serum neutralizing (SN) titers. On d –7, relative to vaccination, a complete blood count (CBC) and an assay to measure neutrophil activity, as indicated by the relative presence of reactive oxygen species (ROS) were performed to establish a baseline immune profile. Two heifers were removed from the trial for preexisting immunological challenge. These assays were repeated on d 1 postvaccination, d 3 postvaccination, and then weekly until the heifer was bred (Heat 4). Data were analyzed with the PROC MIXED procedure of SAS. The fixed effects for the model were: season, vaccine type, and week relative to vaccination. There was no difference ($P > 0.05$) in postvaccination SN titers. Vaccine type had no significant effect ($P > 0.05$) on any of the cell types measured by the CBC. Season did have a significant effect ($P = 0.0008$) on the circulating lymphocytes, with the fall heifers exhibiting higher average lymphocytes on d 1 and wk 2, 3, 4, 5, and 6 postvaccination. The ROS response ratio was not impacted by vaccine ($P > 0.05$) but was influenced ($P < 0.0001$) by both season and the season × week interaction. When comparing seasons, spring heifers maintained a higher average response ratio when compared with the fall heifers on d 3 and wk 1, 2, 3, 5, and 6 postvaccination, which is substantiated by their higher average circulating granulocytes ($P < 0.05$). These seasonal differences may be a consequence the severe immunological challenge experienced by the fall group shortly after vaccination, which may have obscured their true vaccine response.

Key Words: neutrophil, ROS, IBR MLV

0136 Association between bovine milk infrared temperature and bacteriological results from CHROMagar Mastitis Plates and PathoProof Mastitis Complete-16 Kit. M. G. Marrero-Pérez*, J. Curbelo-Rodríguez[2], G. Ortiz-Colón, H. L. Sánchez-Rodríguez, and Y. R. Vélez-Robles, *University of Puerto Rico, Mayagüez Campus, Mayagüez, Puerto Rico.*

Pathogen identification is an important tool for dairy farmers to treat mastitis infections properly. Alternative tools for early identification of mastitis cases should help farmers to increase milk quality and animal health. Infrared thermography (IRT) was used to determine the milk's temperature profile through the short milking tube, and its association with CHROMagar Mastitis plates (CHROM) and the PathoProof Mastitis Complete-16 Kit (PtoPrf-16) bacteriological results were evaluated. Individual mammary quarters (n = 23) with subclinical mastitis (determined by the California Mastitis Test) from two dairy herds in Puerto Rico were evaluated. Milk samples (10 mL in duplicates) were collected and stored in ice for subsequent evaluation. During the morning milking (from 0300 to 0600 h), IRT images were collected 2 min postmilking unit attachment in 30s intervals using an IRT camera (FLIR-E8). Temperature and relative humidity were also recorded using HOBO-U23Prov2Data Loggers. Somatic cell count (SCC) and bacterial identification were determined using a DeLaval Cell counter and CHROM, respectively. Additional samples were sent to the Dairy Herd Improvement Association (Manheim, PA) for bacterial identification using the PtoPrf-16, to be compared with CHROM results. A PROC GLIMMIX in SAS (University Edition version) was used to determine differences in IRT and logSCC by bacteriological results (CHROM vs. PtoPrf-16). The two herds had no difference in logSCC and IRT (P = 0.10); therefore, quarters were analyzed collectively. No differences in IRT or logSCC were found when mastitis pathogens were or not isolated in quarter milk samples using the PtoPrf-16 (P = 0.29 and P = 0.07) and CHROM (P = 0.80 and P = 0.67), respectively. No differences in IRT were observed when PtoPrf-16 (P = 0.69) and CHROM results (P = 0.91) were further categorized by Gram-positive, Gram-negative, mixed isolation, and no-detection, with mean IRT and standard error values of 33.61 ± 0.05 and 33.11 ± 0.36, 33.26 ± 0.62 and 33.75 ± 0.45, 33.86 ± 0.55 and 32.67 ± 0.57, and 32.98 ± 0.43 and 33.36 ± 0.72, respectively. The CHROM and PtoPrf-16 tests can identify 10 and 15 different mastitis pathogens, respectively. However, only 34.78% of bacteriological results concurred among them. The IRT was affected by relative humidity (P < 0.05) but not by ambient temperature (P = 0.16). More data is required to characterize the use of IRT as a tool to discriminate quarters with mastitis. The lack of association among IRT and mastitis pathogens could be attributed to environmental factors such as relative humidity. The discrepancies among bacteriological results among CHROM vs. PtoPrf-16 suggest that additional studies are required to further characterize these differences.

Key Words: CHROMagar, infrared thermography, PathoProof Mastitis

0137 The endometrial microbiome in transition cows fed an energy-restricted diet. G. Esposito*[1,2], J. J. Lim[3], T. Tasara[4], P. C. Irons[2,5], E. C. Webb[2], and A. Chapwanya[3], *[1]Department of Production Animal Studies, Faculty of Veterinary Sciences, University of Pretoria, Pretoria, South Africa, [2]Institute of Food, Nutrition and Well-being, University of Pretoria, Pretoria, South Africa, [3]Ross University School of Veterinary Medicine, Basseterre, Saint Kitts and Nevis, [4]3Institute for Food Safety and Hygiene, Vetsuisse Faculty University of Zurich, Zurich, Switzerland, [5]Department of Production Animal Studies, Faculty of Veterinary Sciences, University of Pretoria, Onderstepoort, South Africa.*

The objective of this study was to evaluate the effect of negative energy balance (NEB) on the endometrial microbiome of transition cows. Ten Holstein cows blocked by parity, BW, and BCS were randomly assigned to two groups: control (CTL) and NEB (80% of the net energy required). Endometrial cytobrush samples were collected at 14 and 35 d postpartum (DPP) and DNA was extracted using a QIAamp DNA Micro Kit. Based on next generation sequencing of 16S rRNA genes, 403 operational taxonomic units (OTUs) were detected. All continuous variables were analyzed by ANOVA. A comparison of the alpha diversity, based on the number of OTUs present, revealed no significant differences in uterine microbiome diversity between 14 and 35 DPP in the CTL group, but significantly (P < 0.05) lower diversity 14 and 35 DPP within the NEB group. The CTL group microbiome on 14 DPP showed significantly (P < 0.05) higher diversity compared with the NEB group. At genus level, the majority of OTUs detected were shared between 14 and 35 DPP (CTL, 47/68 [69%]; NEB, 40/65 [61.5%]) within both groups. However, in the CTL group, there were 16 OTUs detected at 14 DPP that were not present at 35 DPP, while 5 OTUs found at 35 DPP were not detected at 14 DPP; in the NEB group, 4 OTUs at 14 DPP were not detected at 35 DPP, whereas 21 OTUs detected at 35 DPP were not present on 14 DPP. At phylum level, on 14 DPP, Proteobacteria (39.2 vs. 0.46%) and Firmicutes (44.3 vs. 33.7%) were higher in CTL compared with the NEB uterine microbiome; Bacteroidetes (29.9 vs. 8.9%), Fusobacteria (14.3 vs. 3.4%), and unassigned (20.1 vs. 1.4%) phyla predominated in NEB compared with CTL. On 35 DPP, the CTL microbiome was predominated by Cyanobacteria and Proteobacteria sequences, while the NEB microbiome was predominated by Firmicutes and Bacteroidetes. Differences in Proteobacteria and Bacteroidetes levels at 14 and 35 DPP, respectively, were statistically significant (P < 0.05). Relative

abundances of Actinobacteria, Cyanobacteria, and Proteobacteria were significantly higher at 35 DPP compared with 14 in NEB cows. No significant differences were detected in CTL. Our preliminary data although inconclusive due to small sample size and individual animal microbiome variations suggest that there might be some microbiome composition differences between the CTL and NEB at 14 and 35 dpp.

Key Words: NEB, endometrial microbiome, next generation sequencing

0138 Fecal microbial shifts of the German Holstein dairy cows with left-sided displacement of the abomasum.

M. K. Shim[*1], B. R. Kim[2], J. W. Shin[2], S. H. Hong[1], and H. B. Kim[2], *[1]Dankook University, Cheonan, the Republic of Korea, [2]Department of Animal Resource & Science, Dankook University, Cheonan, the Republic of Korea.*

One of the most common diseases in high-performance German Holstein dairy cows is left-sided displacement of the abomasum (LDA). Hypomotility of the abomasum is detrimental during the pathogenesis of LDA. Also, it is known that the improper interactions between the gut microbiota and the enteric nervous system contribute to dysfunctions of gastrointestinal motility. Therefore, we hypothesized that the gut microbial composition will be different between German Holstein dairy cows with and without LDA. We compared the fecal microbiota between cows with and without LDA using 16S ribosomal RNA (rRNA) gene analysis. A total of 20 German Holstein dairy cows at one dairy farm in South Korea, including eight cows without LDA (control group) and 12 cows with LDA (LDA Group), were enrolled in this study. All cows were housed under the same conditions and were fed the same feed without any antibiotics or supplementary additives. Right after LDA was diagnosed, fecal samples were collected immediately from the rectum. Total DNA representing the fecal microbial communities was extracted from individual fecal samples using the stool DNA extraction kit, and the 16S universal primers 27F (5′ GAGTTTGATCMTGGCTCAG 3′) and 800R (5′ TACCAGGGTATCTAATCC 3′) were used to amplify 16S rRNA genes (V1-V4 hyper variable regions). The composition and relative abundance of each member of the microbiota in feces from the control group were different from the LDA group. The proportion of Spirochaetes was significantly different between groups at the phylum level ($P <$ 0.001). An average of 1.5% of the microbiota was members of Spirochaetes in the feces of the control group. On the other hand, there were no Spirochaetes detected in the feces of the LDA group. At the genus level, relative abundance of five genera was significantly different between groups. The proportion of the genus *Enterohabdus* (a member of Actinobacteria), the proportions of members of Firmicutes including *Cellulosilyticum*, *Streptococcus*, and *Turicibacter*, and the proportion of *Treponema* (a member of Spirochaetes) were all significantly higher in the control group than in the LDA group. However, further studies will be needed to elucidate the roles of these genera in the pathogenesis of LDA. Overall, results from this study show that the fecal microbial compositions of German Holstein dairy cows with LDA shifted and were less diverse than those in normal cows.

Key Words: German Holstein dairy cow, microbiome, LDA

0139 Genetic parameters and impact of postpartum diseases on lactation curves in dairy cattle.

H. Jeong[*1], D. Gonzalez-Pena[2], T. M. Goncalves[1], P. J. Pinedo[3], J. E. P. Santos[4], G. M. Schuenemann[5], G. J. M. Rosa[6], R. O. Gilbert[7], R. C. Bicalho[7], R. Chebel[4], K. N. Galvão[8], C. M. Seabury[9], W. W. Thatcher[10], and S. L. Rodriguez Zas[1], *[1]University of Illinois, Champaign-Urbana, [2]Zoetis, Kalamazoo, MI, [3]Colorado State University, Fort Collins, [4]University of Florida, Gainesville, [5]Department of Veterinary Preventive Medicine, The Ohio State University, Columbus, [6]University of Wisconsin-Madison, Madison, [7]Cornell University, Ithaca, NY, [8]Department of Large Animal Clinical Sciences; University of Florida, Gainesville, [9]Texas A&M University, College Station, [10]Department of Animal Sciences, University of Florida, Gainesville.*

Genetic improvement for milk yield in dairy cattle has impacted the shape of the lactation curve, in addition to the total production. Likewise, incidence of diseases early in the lactation can affect the lactation curve. The objective of this study was to investigate simultaneously health and genetic factors influencing the lactation curve. Test-day milk records on more than 6000 Holstein cows across four states (California, Florida, Minnesota, Texas) and nine herds were evaluated. The trajectory of the lactation curve was modeled using nonlinear mixed effects models including Wood's and Wilmink's functions. The effects of environmental and health indicators on the level of milk yield, increase in milk production early in lactation (Wood's) or milk yield at peak (Wilmink's), and persistency thereafter were evaluated. These effects included: season (summer or winter), state, parity, vaginal mucus score at 7 d postpartum, metritis at 7 d postpartum, mastitis cases within the first 60 d postpartum, blood β-hydroxybutyrate (BHBA) indicating subclinical ketosis, body condition score at 35 d (BCS35), displaced abomasum (DA) by 60 d postpartum, respiratory illness by 60 d postpartum (Resp), and lameness at 35 d. Sire of cow was included in the model as random effect. Estimates from the Wood's model indicated that multiparous cows have significantly higher levels of milk yield immediately after calving and lower persistency than primiparous cows. Lactation curves in winter had higher yield immediately after calving and lower persistency than in summer. Metritis had a negative effect on milk yield level immediately

after calving as well as on persistency. Mucus score and DA had a negative impact on milk yield immediately after calving. Consistent with Wood's estimates, Wilmink's estimates indicated that multiparous cows have higher milk production and lower persistency than primiparous cows. Number of mastitis cases and DA were associated with lower overall milk production and higher persistency. Beta hydroxybutyrate was associated with a higher level of milk yield and lower persistency. The ratio of sire to residual variance estimates from Wood's and Wilmink's functions were consistent and approximately 0.4. Wood's model offered a better fit for the lactation curves considered. Our findings demonstrate the need to incorporate disease indicators on the assessment of the genetic component influencing the trajectory of the lactation curve. These findings contribute to a long-term multistate project database (USDA-NIFA-AFRI-003542) for direct measures of fertility.

0140 Genetic and environmental components of disease traits in dairy cattle.

T. M. Goncalves*[1], D. Gonzalez-Pena[2], H. Jeong[1], P. J. Pinedo[3], J. E. P. Santos[4], G. M. Schuenemann[5], G. J. M. Rosa[6], R. O. Gilbert[7], R. C. Bicalho[7], R. Chebel[4], K. N. Galvão[8], C. M. Seabury[9], W. W. Thatcher[10], and S. L. Rodriguez Zas[1], *[1]University of Illinois, Champaign-Urbana, [2]Zoetis, Kalamazoo, MI, [3]Colorado State University, Fort Collins, [4]University of Florida, Gainesville, [5]Department of Veterinary Preventive Medicine, The Ohio State University, Columbus, [6]University of Wisconsin–Madison, Madison, [7]Cornell University, Ithaca, NY, [8]Department of Large Animal Clinical Sciences; University of Florida, Gainesville, [9]Texas A&M University, College Station, [10]Department of Animal Sciences, University of Florida, Gainesville.*

Diseases in U.S. Holstein are responsible for losses of approximately $ 1 billion annually in dairy production due to reduced milk production and increased costs. The objective was to assess the impact of environmental factors and magnitude of genetic parameters on the incidence of diseases in dairy cows early (<10 d) and late (35 to 60 d) postpartum. Binary and multinomial disease records on approximately 6000 Holstein cows from farms in Texas, Minnesota, California, and Florida were evaluated using mixed effects logistic and Poisson models. Early postpartum binary diseases included: dystocia, retained placenta, subclinical ketosis (blood β-hydroxybutyrate BHBA > 1), and metritis. Late postpartum binary diseases included: displacement of abomasum, mastitis, respiratory problems, and clinical endometritis. Mucus score at 7 d, number of mastitis cases up to 60 d, and lameness at 35 d (five levels) were analyzed assuming a Poisson model. Fixed effects in all models included: lactation number (3 levels), season (summer and winter), U.S. region, and farm. Other fixed effects evaluated depending on the disease included: twins, body condition score, BHBA level, calf gender, stillbirth, first test-day milk production record, and other diseases. The cow's sire was included as a random effect in the models. Overall lactation, region, and season had a significant effect on the incidence of all diseases, except for lactation on respiratory problems, and season on mastitis and displacement of abomasum. First lactation cows exhibited the highest incidence of dystocia, metritis, and clinical endometritis and lowest incidence of mastitis, retained placenta, lameness, and displacement of abomasum. Clinical endometritis, metritis, lameness, and respiratory problems were lower in summer than winter. Dystocia, retained placenta, and subclinical ketosis were positively and significantly associated with clinical endometritis and metritis. Subclinical ketosis and dystocia were positively and significantly associated with displacement of abomasum. Mastitis was negatively and significantly associated with milk yield at first test-day. Heritability estimates for the diseases ranged from 0.06 (retained placenta) to 0.4 (respiratory problems). The differences in genetic parameter estimates among alternative disease descriptors offer insights into effective approaches to lower the incidence of disease through genetic selection. These findings contribute to a long-term multistate project database (USDA-NIFA-AFRI-003542) for direct measures of fertility.

Key Words: metritis, postpartum, production

0141 Undernutrition alters metabolic responses to acute inflammation in early lactation cows.

J. A. A. Pires*[1], K. Pawlowski[1], J. Rouel[1], C. Delavaud[1], G. Foucras[2], P. Rainard[3], P. Germon[3], and C. Leroux[1]. *[1]UMR1213 Herbivores, INRA, VetAgroSup, Saint-Genes-Champanelle, France, [2]UMR1225 IHAP, INRA, Toulouse, France, [3]UMR1282 ISP, INRA, Nouzilly, France.*

The objective was to test effects of nutrient restriction on responses to an intramammary lipopolysaccharide (LPS) challenge in early lactation cows. Multiparous Holstein cows were either allowed ad libitum intake of a lactation diet throughout the study (CON, n = 9, 7.1 MJ/kg DM NE_L, 17.4% CP), or the ration was diluted with barley straw (48% DM) for 4 d (RES, n = 8, 5.2 MJ/kg DM NE_L, 12.2% CP) starting at 24 ± 3 d in milk. After 72 h, one healthy rear mammary quarter was infused with 50 µg of LPS (*E. coli* 0111:B4). Blood samples were collected at –1.5, –0.5, 1, 2, 4, 6, and 10 h relative to LPS. Data were analyzed using SAS mixed models. Intake, milk, and protein yields and NE_L balance did not differ before diet change (21.8, 39.0, 1.15 kg/d, and –5.6 MJ/d, respectively, on d –1), but were significantly affected in RES (9.8, 28.3, 0.79 kg/d and –74 MJ/d, respectively, on d 3 of restriction and before LPS), as were plasma indicators (Table 1). Insulin response (area under the curve, AUC) to LPS was lower

Table 0141.

Table 1. Plasma insulin and metabolite concentration at 72 h of dietary treatments and response to LPS challenge. $P < 0.01$ for all variables.

	Treatments	
	CON	RES
Insulin (μIU/mL)		
72 h	17	11
AUC_{10h} [1]	174	42
NEFA (μM)		
72 h	370	1672
AUC_{10h}	-1,957	-9,047
BHBA (mM)		
72 h	0.69	2.98
AUC_{10h}	3.68	-6.05
Glucose (mg/dL)		
72 h	69	50
AUC_{10h}	-17	64

[1] Incremental area under the curve during 10 h post-LPS, concentration units per 10 h.

in RES compared with CON, but it was greater for NEFA, BHBA, and glucose. The NEFA nadir post LPS was 599 and 101 μM at 4 h for RES and CON ($P \leq 0.001$), respectively, and it preceded insulin change in RES. The BHBA decrease in RES was consistent with NEFA response to LPS, but BHBA increased from a low baseline in CON (treatment × time interactions, $P \leq 0.05$). The negative glucose AUC in CON could be related to the insulin increase post LPS. Rectal temperature increase did not differ between treatments (+2.1 ± 0.15°C at 6 h). Nutrient restriction altered peripheral metabolic responses to an intramammary LPS challenge.

Key Words: inflammation, undernutrition, dairy cow

0142 Potential modulation of the toxic effects of *Escherichia coli* in bovine endometrium by lactic acid bacteria. S. Genís[*1], A. Sánchez-Chardi[2], A. Bach[3,4], and A. Arís[1]. [1]*Department of Ruminant Production, IRTA, Caldes de Montbui, Spain,* [2]*Servei de Microscopia, UAB, Cerdanyola del Valles, Spain,* [3]*ICREA, Barcelona, Spain,* [4]*IRTA, Caldes de Montbui, Spain.*

The ultrastructural assessment of toxic effects using field emission scanning electron microscopy (FESEM) and transmission electron microscopy (TEM) can provide important information to elucidate the mechanisms of infection and to develop preventive strategies. The aim of this study was to evaluate the effects of a lactic acid bacteria (LAB) combination, based on *L. rhamnosus* MOI 25, *P. acidilactici* MOI 25, and *L. reuteri* MOI 2, at preventing *Escherichia coli* infection and maintaining bovine endometrial tissue health. Triplicate samples of epithelial cell cultures were studied in a 2 × 2 factorial design in the presence or absence of an *E. coli* infection and with or without LAB. Samples were mounted in FESEM stubs and observed without coating in a Zeiss Merlin microscope. A qualitative assessment of general structure of the epithelium (size and shape of cells, ultrastructure, and amounts of ultrastructure of microvilli), presence of *E. coli* and LAB in cell surface, cell debris, presence of mucus in the cell surface, mitochondrial damage, and cell death was performed by the analysis of 10 random selected areas for each treatment. For TEM, contrasted ultrathin sections were observed in a Jeol 1400 operating at 80kV. A semiquantitative approach was performed by the analysis of 10 random selected sections in three areas for each treatment and data were analyzed using a Fisher exact test. *Escherichia coli* alone or with LAB appeared in low numbers in epithelial cells surface and in no case formed biofilms or interactions between each other. *Escherichia coli* abundance was lower ($P < 0.05$) in samples treated with LAB than in those infected with *E. coli* alone. Healthy epithelium was observed in cells treated with LAB (epithelial cells with normal size and shape and normal aspect of microvilli), whereas in cultures infected with *E. coli*, abundant areas with cell debris and bacilli in epithelial cell surface were observed. The incidence of necrosis (as assessed by TEM) in *E. coli* samples tended ($P = 0.07$) to be greater than in noninfected cultures. Control or LAB preincubated cells showed less mitochondrial damage ($P = 0.01$) than nontreated cells, a parameter strongly related to cell death. Overall, LAB appear to offer protection against *E. coli*, by mechanism different than the formation of biofilms, and thus, LAB combinations could be used as a preventive strategy for metritis.

Key Words: endometrium, FESEM, TEM

0143 **Meta-analysis of factors influencing new intramammary infection rate in natural exposure teat dip efficacy trials.**

0144 Effects of lactic acid bacteria on metritis prevalence and endometrium inflammation in dairy cows. S. Genís*[1], R. L. A. Cerri[2], A. Bach[3,4], B. F. Silper[2], J. Denis-Robichaud[5], and A. Arís[1], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada, [3]ICREA, Barcelona, Spain, [4]IRTA, Caldes de Montbui, Spain, [5]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

The aim of this study was to evaluate the effects of a treatment with *Lactobacillus rhamnosus*, *Pediococcus acidilactici*, and *Lactobacillus reuteri* (LAB) on the prevalence of metritis and the modulation of endometrial inflammation in dairy cows. In Experiment 1, 135 cows were enrolled 3 wk before calving and randomly assigned to treatments to ensure similar frequencies for parity and previous illness in all treatment groups. The treatment groups were: (1) two intravaginal doses of lactic acid bacteria (LAB) per wk during 3 wk precalving (vaginal); (2) 1 intrauterine dose 1 d after calving (endometrial); and (3) no intervention (control). Metritis was diagnosed at d 6 when body temperature > 39.5°C and purulent vaginal discharge (>50% pus or worse) was observed. Data were analyzed using a chi-square. Vaginal treatment reduced ($P < 0.05$) metritis prevalence up to 62% compared with the Control group. However, prevalence of metritis did not differ between the endometrial and control groups. In Experiment 2, a combination of in vivo and ex vivo assays to evaluate whether LAB exerted some effects on the endometrium was designed. Twenty healthy do-not-breed cows were enrolled in Experiment 2, and 3 wk before culling were randomly distributed into two treatment groups: (1) 2 doses of vaginal LAB per wk during 3 wk (LAB); and (2) two vaginal doses of carrier (sterile sodium chloride 0.9%) per wk during 3 wk (CTRL). Endometrium was recovered at slaughterhouse and cut in the laboratory in 0.8 cm^2 explants that were incubated by sixtiplicate in 24 well-plates and either infected with *Escherichia coli* or maintained in medium for evaluating the basal expression of proinflammatory genes in the endometrium. Supernatant was collected for IL-8, IL-1β, and IL-6 analysis by ELISA. Explants were recovered for the quantification of proinflammatory gene expression by qPCR. Data were analyzed using an ANOVA, considering treatment and infection as fixed effects and animal as a random effect. Neither the expression of proinflammatory genes nor the direct quantification of IL-8, IL-1b, or Il-6 differed between infected and noninfected explants. In conclusion, when an intravaginal treatment of LAB is applied there is an important reduction on metritis prevalence although this reduction is not mediated by a direct effect the probiotic on the endometrium neither by increasing the protection against *E. coli* nor by reducing basal inflammation.

Key Words: *Escherichia coli*, LAB, metritis.

0145 Metritis severity score misclassification underpredicts consequence cost of disease. M. M. McCarthy* and M. W. Overton, *Elanco Animal Health, Greenfield, IN.*

The objective of this research was to determine the impact of disease misclassification on the estimated impact of metritis on milk production and time to pregnancy. Differential misclassification introduces bias that usually results in underestimating the true association. A convenience sample of DairyComp305 data representing 1 yr of calvings ($n = 3485$) from one midwestern Holstein herd was used. This herd was chosen because it had good recorded incidence of both mild and severe metritis cases. The original dataset included metritis recorded as mild or severe, or not recorded (NR) where no metritis was observed, and was considered to contain the metritis true severity (TS). First, to evaluate the impact of misclassification bias, we retrospectively randomized 40% of mild metritis to be classified as NR to represent inconsistent disease recording (IR); then, all mild metritis cases were changed to NR to represent poor disease recording (PR). The TS, IR, and PR datasets were analyzed separately in JMP. ANOVA was conducted for second test 305 d mature equivalent (2nd305ME), and a multivariate Cox proportional hazards model was conducted for time to pregnancy, censoring at 300 d in milk. Nonsignificant variables were removed when $P > 0.10$, but the variable metritis was forced into all models. Based on the TS model, adjusting for effects of lactation group, month fresh, early lactation mastitis and displaced abomasum, a case of mild metritis was associated with 405 kg less 2nd305ME and a case of severe metritis was associated with 1106 kg less 2nd305ME compared with no metritis. For the IR model, a case of mild metritis was associated with 376 kg less 2nd305ME and a case of severe metritis was associated with 1050 kg less 2nd305ME compared with no metritis. For the PR model, severe metritis was associated with 990 kg less 2nd305ME compared with NR. The IR and PR models underestimated 2nd305ME loss for severe metritis cases by 56 and 116 kg/cow, resulting in 8721 and 18,007 kg of milk loss unaccounted for at the herd level, respectively, compared with TS. For the TS model, cows that did not have metritis were 1.31 times more likely to get pregnant than cows with severe metritis ($P = 0.01$). The risk ratio difference in IR and PR models were 0.03 and 0.08, respectively. Overall, misclassification of metritis cases results in greater bias and largely underestimates the true association between metritis

and consequence costs of the disease.

Key Words: disease consequence, metritis severity, misclassification bias

0146 Subacute ruminal acidosis negatively affects conception rate in Holstein heifers. H. Khalouei*[1], A. A. Alamouti[2], A. Mohammadi-Sangcheshmeh[2], N. Farzaneh[3], J. C. Plaizier[1], and E. Khafipour[1], *[1]Department of Animal Science, University of Manitoba, Winnipeg, Canada, [2]Department of Animal and Poultry Sciences, Aburaihan Campus, University of Tehran, Pakdasht, Tehran, Iran, [3]Faculty of Veterinary Medicine, Ferdowsi University, Mashhad, Iran.*

Symptoms of subacute ruminal acidosis (SARA) have been studied at length, but its effects on reproductive performance are not fully understood. Our objective was, therefore, to determine if experimentally induced SARA reduces conception rates of Holstein heifers. One hundred and ten heifers were synchronized for artificial insemination by two injections of $PGF_{2\alpha}$ in a 13 d interval, and assigned randomly to two treatments. The control heifers received a diet containing 32% (DM basis) barley-based concentrate, while the SARA challenge group received a diet containing 68% of this concentrate. The remainder of the diet consisted of corn silage, alfalfa hay, wheat straw, soybean meal, wheat bran, and a vitamin-mineral supplement. Diets were fed ad libitum. The SARA challenge diet started 3 d after the second $PGF_{2\alpha}$ injection, and continued for 7 d. Forty one heifers from the SARA group and 39 heifers from the control group showed visible signs of heat and were inseminated. Heifers in SARA group had higher DMI (10.4 vs. 9.0 kg d^{-1}, $P < 0.01$) and lower rumen pH (6.02 vs. 6.45, $P < 0.01$) and fecal pH (6.71 vs. 6.97, $P < 0.01$) at 6 h post feeding compared with control heifers. The SARA challenge increased rumen concentrations of ruminal lactate, propionate, and valerate, but did not affect the concentrations of acetate, butyrate, and isovalerate. The challenge did not affect glucose, urea nitrogen, aspartate aminotransferase, calcium, and cortisol concentrations in blood, but it lowered blood β-hydroxybutyrate ($P < 0.01$). Induction of SARA markedly reduced first service conception rate tested by ultrasonography 28 d after insemination (53.7 vs. 71.8%, $P < 0.05$). Additionally, 100% of control heifers that were confirmed as pregnant in the 28 d test were also pregnant at 60 d test, whereas this ratio was only 73.9% ($P < 0.01$) in SARA-challenged heifers, suggesting that SARA had a persistent effect on reproduction that lasted at least 60 d after insemination. Results suggest a negative effect of SARA on fertility of dairy heifers. Further studies are required to investigate the possible effects of lipopolysaccharide translocation and systemic immune response that is associated with SARA on embryo survivability to fully elucidate the mode of action of SARA on reproductive performance.

Key Words: conception rate, fertility, subacute ruminal acidosis

0147 Evaluating milk fat to protein ratio and milk fat to lactose ratio as indicators for early lactation disease. S. Paudyal*[1,2], F. P. Maunsell[3], C. A. Risco[3], A. Donovan[3], A. De Vries[4], D. Manriquez[1], and P. J. Pinedo[1,5], *[1]Department of Animal Sciences, Colorado State University, Fort Collins, [2]West Texas A&M, Canyon, [3]College of Veterinary Medicine, University of Florida, Gainesville, [4]Department of Animal Sciences, University of Florida, Gainesville, [5]Texas A&M AgriLife Research, Amarillo.*

The objective was to evaluate the potential of milk fat to protein (FP) and milk fat to lactose (FL) ratios for detection of clinical disease before evident clinical signs. Milk component data from 198 Holstein cows were recorded until 60 days in milk (DIM), using the AfiLab® milk analysis system at the University of Florida (UF) Dairy Unit. Milk components were recorded as an average of AM and PM milkings. Occurrence of health disorders (mastitis [MAS], metritis [MET], clinical hypocalcemia [HYC], digestive disorders [DIG], lameness [LAM], and ketosis [KET]) were assessed by UF veterinarians and farm personnel. Two indices were developed: (i) Cow index (CI) = measurement on the day of diagnosis (d 0) minus –3 to –5 d average relative to d 0, divided by the –3 to –5 d average; and (ii) mates index (MI) = (–3 to –5 d average minus pen mates –3 to –5 d average value)/pen mates d 0 value. Cow alert value (CAV) and mates alert value (MAV) were set when the respective index value was less than –0.1 or more than +0.1.The correlation between FP and FL was intermediate for both sick and healthy cows ($r = 0.50$ and 0.56, respectively). The odds (95% CI) of MAS multiplied by 1.16 (1.01–1.34) and 1.36 (1.26–1.47), for each decimal unit increment in FP and FL, respectively. For each decimal unit increment in FP and FL, the odds of MET multiplied by 1.38 (1.25–1.54) and 1.36 (1.25–1.47), respectively; the odds of KET multiplied by 1.43 (1.31–1.57) and 1.34 (1.24–1.44); the odds of HYC multiplied by 0.40 (0.22–0.73) and 1.39 (1.14–1.69); and the odds of DIG multiplied by 1.31 (1.22–1.39) and 1.35 (1.24–1.47). The odds of LAM were only significant for changes in FL [1.28 (1.12–1.45)]. Sensitivity and specificity calculations (Table 1) suggested that changes in both FP and FL may be used as indicators of disease; MAS and KET were better detected using FL, whereas FP was more effective for HYC detection. Overall, MAV was more effective than CAV on disease detection.

0148 Associations between multiple activity and physiological parameters around the time of disease diagnosis and calving in Holstein cows.

D. Manriquez*[1], F. P. Maunsell[2], S. Paudyal[1], A. Donovan[2], A. De Vries[3], and P. J. Pinedo[4], *[1]Department of Animal Sciences, Colorado State University, Fort Collins, [2]College of Veterinary Medicine, University of Florida, Gainesville, [3]Department of Animal Sciences, University of Florida, Gainesville, [4]Texas A&M AgriLife Research, Amarillo.*

Our objective was to describe the associations between multiple activity and physiological parameters around the time of disease diagnosis and calving in Holstein cows. Health disorders included mastitis (MAS), metritis (MET), milk fever (MF), depression-dehydration-fever (DDF), digestive problems (DIG), lameness (LAM), and clinical ketosis (KET). Behavioral activity included general activity index (HEAD, activity units), rumination time (RUM, min/d), steps (STEP, *n*/d), steps per hour (SH, *n*/h), and lying bouts (LB; *n*/d) from –15 to 15 d relative to disease diagnosis and calving. Data were collected from 198 Holstein cows from –15d from due date to 60 d in milk, at the University of Florida Dairy Unit. HEAD and RUM data were recorded using a neck collar containing rumination loggers (Hr-Tag®, SCR Engineers Ltd., Netanya, Israel), and STEP, SH, and LB data were recorded by a device attached on one hind leg (Pedometer plus®, Afikim, Israel). Data were log transformed and analyzed using MIXED procedures of SAS. To assess associations between activity variables, Spearman's *P* correlations and *P*-values were calculated using JMP12 (Table 1). The only significant negative correlation was found between SH and LB (–0.60) in cows diagnosed with MAS, showing reduced SH from –9d to –4d and an increased LB activity from –8 to –2 d. Correlations between HEAD and RUM were positive and significant for all the diseases, showing a marked decrease from –6 to –5 d to the time of diagnosis with a subsequent increase until 10 d after diagnosis. In addition, significant positive correlations were determined in MAS cows (RUM/STEP, $r = 0.41$); MET cows [RUM/SH ($r = 0.46$); RUM/LB ($r = 0.53$); and SH/LB ($r = 0.59$)]; MF cows [RUM/STEP ($r = 0.63$); and HEAD/SH ($r = 0.54$)]; DDF cows [RUM/LB ($r = 0.52$); and STEP/LB ($r = 0.43$)]; DIG cows (HEAD/RUM, $r = 0.65$); LAM cows [HEAD/STEP ($r = 0.44$); HEAD/LB ($r = 0.40$); and RUM/LB ($r = 0.62$); KET cows [HEAD/STEP ($r = 0.40$); HEAD/SH ($r = 0.57$); HEAD/LB ($r = 0.51$); RUM/SH ($r = 0.52$); and RUM/LB ($r = 0.39$)]. Significant positive correlations at calving included HEAD/SH ($r = 0.93$), RUM/STEP ($r = 0.91$), RUM/LB ($r = 0.93$) and STEP/SH ($r = 0.94$). Correlation patterns between activity and physiological parameters were dependent on specific diseases, suggesting differential potentials as indicators for early disease that could be used in dairy health monitoring programs.

0149 DI/LC-MS/MS-based metabolomics identifies early predictive serum biomarkers for ketosis in dairy cows. B. N. Ametaj*[1], G. Zhang[1], E. Dervishi[1], S. M. Dunn[1], R. Mandal[2], D. S. Wishart[2], [1]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada,* [2]*University of Alberta, Edmonton, Canada.*

Subclinical ketosis is a prevalent metabolic disease in transition dairy cows that affects 30 to 40% of the cows during early lactation. Cows with ketosis have lower milk yield and reproductive performance, greater risk of other periparturient diseases, and higher culling rate. The objectives of this study were to retrospectively evaluate alterations of metabolites in the serum of dairy cows with ketosis before, during, and after

the diagnosis of disease and identify monitoring and diagnostic serum metabolite biomarkers for ketosis. One hundred transition dairy cows, 20 healthy cows (CON), and six cows with ketosis were sampled during d –8, –4, at disease diagnosis, and wk +4 and +8 relative to parturition. One hundred and twenty-eight serum metabolites were quantitatively profiled in CON and ketosis cows using a targeted metabolomics approach based on DI/LC-MS/MS at all time points. Univariate and multivariate data analyses were conducted at each time point to examine alterations of serum metabolites throughout the progress of ketosis. Significant changes were detected in the concentrations of several molecular species of amino acids, glycerophospholipids, sphingolipids, acylcarnitines, biogenic amines, and hexose in the serum of cows with ketosis during the entire experimental period. Multivariate analysis (i.e., PCA and PLS-DA) also showed clear distinctions between the two groups on the basis of the measured 128 serum metabolites at five time points. Furthermore, several metabolic pathways including Lys degradation, biotin metabolism, Try metabolism, urea cycle, Arg-Pro metabolism, protein biosynthesis, Met metabolism, phospholipid biosynthesis, Val-Leu-Ile degradation, betaine metabolism, Asp metabolism, His metabolism, and β-Ala metabolism were perturbed in cows with ketosis during the onset and progression of disease. These new findings give insights into further understanding of the pathobiology of ketosis in dairy cows. Biomarker analysis showed that AUCs for ROC curves were 0.996 (95% CI, 0.969–1) at –8 wks, 0.995 (95% CI, 0.938–1) at –4 wks, 0.99 (95% CI, 0.882–1) at disease wk, 1 (95% CI: 1–1) at +4 wks and 0.985 (95% CI: 0.806–1) at +8 wks, respectively, which suggest that serum biomarkers identified have pretty accurate predictive, diagnostic, and prognostic abilities for ketosis in transition dairy cows.

Key Words: amino acid, biomarkers, dairy cows, ketosis, lipid profiles

0150 Targeted metabolomics reveals multiple metabolite alterations in the urine of transition dairy cows preceding the incidence of lameness.

B. N. Ametaj*[1], G. Zhang[1], E. Dervishi[1], S. M. Dunn[1], R. Mandal[2], and D. S. Wishart[2], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]University of Alberta, Edmonton.*

Lameness (Lam) is a major issue of transition dairy cows consuming high grain diets affecting 25–35% of the herd. It is associated with decreased milk production, fertility problems, and high culling rates and treatment costs. Various hypotheses have been forwarded during the years with regards to the causes of lameness including rumen histamine, endotoxin, or biogenic amines. Although much is known about non-mechanical lameness, the precise pathobiology is not known. The objectives of this study were to evaluate weekly metabolite composition of urine in dairy cows starting from the beginning of dry off until 8 wks postpartum. Urine samples were collected from 100 cows at −8, −4, disease week, +4, and +8 wk around calving and stored at −80 C until analyzes. DI/LC-MS/MS analyzes were conducted on samples collected from 20 healthy control cows (CON) and 6 cows diagnosed only with lameness (no other periparturient diseases). A total of 154 metabolites including 41 carnitines, 9 lysophosphatidylcholines, 74 phosphatidylcholines, 15 sphingomyelines, 11 amino acids, 2 biogenic amines, hexose, and carnosine were identified and quantified. Data were processed statistically by MetaboAnalyst and univariate analyses. Results showed that 41, 29, 59, 26, and 40 metabolites were identified and measured to be different between the two groups on −8, −4, disease week, +4, and +8 wks around calving, respectively. The highest number of altered metabolites was identified during the week of diagnosis of Lam. Several metabolic pathways were found to be associated with the disease including amino acid metabolism, catecholamine biosynthesis, protein biosynthesis and urea cycle at −8 wks precalving; cysteine, glutamate, tyrosine, and glutathione metabolism at −4 wks precalving; and β-alanine metabolism during the week of disease. ROC analyses, for determination of specificity and sensitivity of potential biomarkers, identified several metabolites with AUCs for ROC curves 0.96 (95% CI, 075–1.0) at −8 wks; 0.971 (95% CI, 0.905–1.0) at −4wks; 1.0 (95% CI, 1.0–1.0) at disease week; 1.0 (95% CI, 1.0–1.0) at +4wks; and 1.0 (95% CI, 1.0–1.0) at +8wks postpartum. PLS-DA analysis also showed clear separation between the two groups of cows with regards to altered metabolites. In conclusion, targeted metabolomics can be used to identify metabolic alterations in the urine of dairy cows before, during, and after diagnosis of Lam; it can also help to better understand the pathobiology of disease, identify cows more susceptible to Lam, and develop new preventive strategies.

Key Words: dairy cows, DI-/LC-MS/MS, lameness, targeted metabolomics, urine

0151 Elevated serum amyloid A concentrations in the first days after calving are an early disease indicator in dairy cows.

G. Bobe*[1] and S. Walker[2], *[1]Department of Animal and Rangeland Sciences, Oregon State University, Corvallis, [2]Oregon State University, Corvallis.*

Early disease detection is critical for maintaining cow health and productivity. Serum amyloid A (SAA) is an acute phase protein that is primarily produced in the liver and is elevated in response to infections and tissue damage in dairy cows. To evaluate whether serum concentrations of SAA may assist in early disease detection, blood samples were taken from 57 Holstein cows at d −21, −14, −7, −3, −1, 0, 1, 3, 7, 14, 21, and 28 relative to calving and analyzed for SAA concentrations. Cows were grouped based on severity of diseases

(no disease, subclinical, mild clinical, and moderate clinical), class of diseases (no disease, metabolic, infectious, both types), time of diagnosis (no disease, 0–3 d, 4–7 d, 8–28 d after calving), and birth complications (yes, no) in early lactation and examined for group differences. Serum amyloid A concentrations in the first days after calving were higher and elevated longer in cows that developed diseases in early lactation. Observed group differences reflected the severity of disease and preceded clinical disease diagnosis irrespective of disease class. Group differences were strongest 1 d after calving, when 0% (healthy), 43% (subclinical disease), 57% (mild clinical disease), and 72% (moderate clinical disease) of cows had SAA above 125 mg/L (sensitivity for any disease: 66%; specificity: 100%). Cows with birth complications had higher SAA concentrations 2 wk before calving than cows without birth complications. Our results support our hypothesis that greater tissue damage and disproportionate inflammatory responses after calving are gateway disorders that increase disease risk in early lactation. Serum amyloid A can detect those risk factors 1 d after calving and thereby opens opportunities for prevention and early treatment.

Key Words: biomarker, dairy cows, diseases, serum amyloid A

0152 The effect of dry period length and antibiotic treatment at drying off on somatic cell counts across the dry period. R. J. Vanhoeij[*1], A. van Knegsel[2], B. Kemp[2], and T. J. G. M. Lam[3,4], *[1]Wageningen University, Netherlands, [2]Adaptation Physiology Group, Wageningen University, [3]Animal Health Service, Deventer, Netherlands, [4]University of Utrecht, Department of Farm Animal Health, Netherlands.*

Management measures to reduce the risk of new intramammary infections (IMI) during the precalving period include use of dry cow antibiotics. Blanket dry cow therapy is not allowed in several European countries, among which is the Netherlands. Moreover, shorter dry periods are of interest because of beneficial effects on the energy balance and metabolic status in the subsequent lactation. The aim was to study the effect of dry period (DP) length on SCC in the subsequent lactation and occurrence of IMI, based on SCC, across the dry period. This aim was approached in 2 separate experiments: Experiment 1 was conducted with use of dry cow antibiotics and experiment 2 without use of dry cow antibiotics. In experiment 1 Holstein-Friesian cows (n = 167) were randomly assigned to three DP lengths (0, 30, 60 d). Cows with a 30-d or 60-d DP were treated with dry cow antibiotics (Supermastidol®, Virbac Animal Health, Barneveld, Netherlands) at drying off. In experiment 2, Holstein-Friesian cows (n = 127) were randomly assigned to two DP lengths (0 or 30 d) and were not treated with dry cow antibiotics. Data were analyzed using a logistic regression model (SAS Institute Inc., 2011), including DP length as fixed effect. Somatic cell count was log transformed before statistical analysis (LnSCC). Data are expressed as LMEANS ± SE. In experiment 1, cows with a 0-d DP had a greater average SCC in the subsequent lactation (LnSCC 5.01 ± 0.06) than cows with a 30-d (LnSCC 4.68 ± 0.06) or 60-d DP (LnSCC 4.52 ± 0.06) ($P < 0.01$). The proportion of cows with a chronic IMI (SCC ≥ 200,000 both pre- and postpartum) was greater in cows with a 0-d DP (5/10), than in cows with a 30-d DP (1/13) or a 60-d DP (1/12) ($P = 0.04$). In experiment 2, cows with a 0-d DP had a greater postpartum average SCC (LnSCC 4.51 ± 0.04), than cows with a 30-d DP (LnSCC 4.24 ± 0.04) ($P < 0.01$). The proportion of cows with a chronic IMI during the precalving period was not different between cows with a 0-d DP (6/11) or a 30-d DP (2/6) ($P = 0.47$). Postpartum average SCC for lactation is greater in cows with a 0-d DP, than in cows with a 30-d DP, regardless of use of dry cow antibiotics. Studies are ongoing to evaluate whether the greater SCC in early lactation in cows with a 0-d DP is actually correlated with intramammary bacterial infections.

Key Words: continuous milking, mastitis, somatic cell count

0153 Enhancement of the dry-off process by intramammary infusion of metalloproteinase 9 nanoparticles. S. Parés[*1], O. Cano-Garrido[2], E. Garcia-Fruitós[1], F. Fàbregas[1], A. Bach[3,4], N. Ferrer-Miralles[2], M. Terré[3], A. Villaverde[2], and A. Arís[1], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]Departament de Genetica i de Microbiologia, UAB, Cerdanyola del Valles, Spain, [3]IRTA, Caldes de Montbui, Spain, [4]ICREA, Barcelona, Spain.*

The dry-off of dairy cows is associated to welfare and high risk of intramammary infections that could be improved by fostering involution and immune system during early dry period. Metalloproteinase 9 (MMP-9) is a tissue-remodeling enzyme physiologically released in the mammary gland during the dry period. The objective of this study was to explore the role of the infusion of MMP-9 at dry-off. MMP-9 was produced in *Lactococcus lactis* as a soluble protein and nanoparticulated (NP) format. Twelve cows with Somatic Cell Count (SCC) < 200.000 and > 15 kg of milk/d at dry-off were enrolled in the study. Treatments were randomly assigned to the front or rear quarters, thus 24 quarters were distributed in 2 treatments: 1 mg of soluble MMP-9 and 100 mg of NP MMP-9, providing both the equivalent metalloproteinase activity measured by zymography. Saline solution was infused in the contralateral quarters as a negative control for each treatment. Samples of mammary secretion were collected at 0, 1, 2, 3, and 7 d relative to dry-off and processed for SCC determination or kept frozen for subsequent determination of MMP-9 activity, and bovine serum albumin (BSA), lactoferrin, sodium, and potassium concentrations. SCC was analyzed with a Scepter

cell counter, MMP-9 activity by zymography, lactoferrin by ELISA, BSA using a colorimetric assay, and sodium and potassium by ICP–OES. All data were analyzed by ANOVA. As expected, both the soluble and NP forms increased ($P < 0.0001$) the metalloproteinase activity in mammary gland compared with controls. However, only the NP form was able to modulate some involution and immune markers. The NP form increased immunity markers including SCC up to 400 fold ($P < 0.001$) at d 1–7, and lactoferrin concentration up to 1.8-folds ($P < 0.05$) at d 1 and 2 after dry-off, compared with saline controls. Also, there was an increase ($P < 0001$) in involution markers. Concentration of BSA in mammary secretion raised up to eightfold at 1, 2, and 3 d and the sodium/potassium ratio ($P < 0.001$) by 4.5-fold at D1 after dry-off, compared with controls. In conclusion, infusions of either soluble or NP forms of MMP-9 at dry-off, increased the metalloproteinase activity in mammary gland, but only the NP form enhanced the of the involution process and immune system.

Key Words: dry period, nanoparticles, metalloproteinase 9

0154 Effects of inhibiting prolactin production with cabergoline on the physiology of the cow-dry period. S. Parés[1], A. Arís*[1], M. Terré[2], F. Fàbregas[1], E. Garcia-Fruitós[1], J. Ruberte[3], V. Nacher[3], A. De-Prado[4], and A. Bach[2,5], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]IRTA, Caldes de Montbui, Spain, [3]CBATEG Universitat Autònoma de Barcelona, Bellaterra, Spain, [4]Ceva Santé Animale, Libourne, France, [5]ICREA, Barcelona, Spain.*

Cabergoline is an ergot derivative with a high affinity for the D2 dopamine receptor whose dopaminergic effects cause inhibition of prolactin (PRL) secretion, and has been recently released as a dry-off facilitator (Velactis®, Ceva, France). A deep study of its effects along the dry period can help to understand the physiology of the mammary involution. Twenty-four Holstein cows (6 primiparous and 18 multiparous) were distributed in 2 treatments: i.m. injection of either 5 mL providing 5.6 mg of cabergolin (CAB) or 5 mL of saline solution (CTR) at the moment of dry-off. Mammary gland biopsies of posterior quarters and tail blood samples were taken at −10, 9, and 23 d relative to dry-off and −9 and 21 d relative to calving to evaluate the effects of PRL inhibition on hormonal and tissue involution markers along the dry period and onset of the subsequent lactation. Blood concentrations of insulin, PRL, IGF1, IGFBP5, GH, and progesterone were determined using immunoassays. Expression of genes coding for *p16, ki67, igf, igfbp5, upa, mmp9, prlr, occludin, and caspase 3* was determined by qPRC. Lastly, immunohistochemical detection of Ki67, SIRT1 and P16 was performed and quantified by light microscopy. As expected, cows on CAB tended ($P = 0.07$) to have lower serum PLR concentrations (23.5 ± 0.29 ng/mL) than cows on CTRL (36.4 ± 0.25 ng/mL), and had a lesser ($P < 0.001$) expression of PRL receptor (*prlr*) in the mammary tissue (2.09 ± 0.455 vs. 1.77 ± 0.423 relative expression units, respectively). Cabergolin increased ($P < 0.05$) blood insulin concentration (14.3 ± 1.28 μU/mL) compared with CTR (10.7 ± 1.14 μU/mL), but blood concentration of the remaining hormones were not affected although decreased ($P < 0.05$) as the dry period progressed. The expression of *igf1* in the mammary gland increased ($P < 0.05$) in CAB cows in the dry period and decreased at the beginning of next lactation. Also, CAB cows had greater ($P < 0.05$) expression of *mmp9* and *occludin*, which indicates a greater tissue involution and remodeling ($P < 0.05$). Also, immunohistochemical analyses showed an increase ($P < 0.05$) in sirt1 (a gene related with cell proliferation and insulin sensitivity) in CAB animals (75.9 ± 12.02 relative units) compared with CTR (56.9 ± 12.31 relative units) at the onset of the subsequent lactation. In conclusion, this study demonstrates that PRL inhibition by cabergoline at dry-off induces an increased proliferation and tissue remodeling of the mammary gland.

Key Words: dry period, prolactin, tissue remodeling

0155 The treatment of only environmental Streptococci clinical mastitis cases reduced antibiotic use, days out of the tank, recurrence of clinical mastitis and a tendency to reduce culling. A. Lago*, C. Tovar, J. Zaragoza, D. Luiz, and D. Pearce, *DairyExperts Inc., Tulare, CA.*

This study objective was to compare antibiotic use, clinical and bacteriological outcomes for selective treatment of only clinical cases where environmental streptococci were isolated versus blanket therapy. Cows with mild or moderate clinical mastitis (CM) from a California Central Valley dairy herd were assigned to either a) a positive-control treatment group (PC) or b) a laboratory-culture-based treatment group (CB). Quarter cases assigned to PC received immediate intramammary (IMM) treatment with ceftiofur (Spectramast LC; Zoetis Inc., New York, NY) and repeated once a day for a total of 3 d. Quarters assigned to CB underwent culture over a 24 h period at DairyExperts Laboratory (DairyExperts Inc., Tulare, CA). Only quarters showing environmental streptococci growth were treated the next day with the same therapy as cases assigned to PC. Mixed Models were used with cow included as a random effect. A total of 276 quarter cases of clinical mastitis from 223 cows were enrolled into the study. Results are summarized on Table 1. The selective treatment of only CM cases from which environmental streptococci were isolated resulted in about a two-thirds reduction both in the number of cases treated and in the number of IMM tubes used, as well as a reduction of 1 d out of the tank. Interestingly, CM recurrence was significantly lower and removal from herd tended to be lower when only environmental streptococci were treated with IMM antibiotics.

Key Words: clinical mastitis, selective treatment, streptococcus

0156 Effect of the selective treatment of gram-positive clinical mastitis cases versus blanket therapy. A. Lago*, D. Luiz, D. Pearce, C. Tovar, and J. Zaragoza, *DairyExperts Inc., Tulare, CA*.

This study objective was to compare antibiotic use, clinical and bacteriological outcomes for selective treatment of only Gram-positive clinical cases versus blanket therapy. Cows with mild or moderate clinical mastitis (CM) from a California Central Valley dairy herd were assigned to either a) a positive-control treatment group (PC) or b) a laboratory-culture-based treatment group (CB). Quarter cases assigned to PC received immediate intramammary (IMM) treatment with ceftiofur (Spectramast LC; Zoetis Inc., New York, NY) and repeated once a day for a total of 3 d. Quarters assigned to CB underwent culture over a 24 h period at DairyExperts Laboratory (DairyExperts Inc., Tulare, CA). Only quarters showing Gram-positive growth were treated the next day with the same therapy as cases assigned to PC. Mixed Models were used with cow included as a random effect. A total of 473 quarter cases of clinical mastitis from 425 cows were enrolled into the study. Results are summarized on Table 1. The selective treatment of only CM cases from which Gram-positive bacteria was isolated resulted in about half reduction both in the number of cases treated and in the number of IMM tubes used. Furthermore, the withholding of antibiotic treatment did not have any deleterious effect on time for milk to return visibly normal, bacteriological cure, new infection risk, CM recurrence or removal from the herd.

Key Words: clinical mastitis, selective treatment, gram-positives

0157 Comparison of PCR and culture methods for detecting mastitis causing mycoplasma in bulk tank milk from commercial dairy herds. A. M. Britten, E. D. Tretter*, and M. Gurajala, *Udder Health Systems Inc., Meridian, ID*,

In this study we compared the mycoplasma detection of direct culture, broth enhanced culture and PCR from 1299 bulk tank

Table 0156.

and composite pen milk samples collected from 62 commercial dairies in 11 states. Culture of bulk tank milk directly onto specialized mycoplasma culture media (such as modified Hayflick agar) has proven effective in detection of mycoplasma mastitis outbreaks. Many laboratory methods also incorporate a mycoplasma broth enhancement protocol to increase sensitivity. This routine, direct and broth enhanced mycoplasma culture protocol, of bulk tank milk samples and pooled pen samples is widely practiced as a primary screening method for detection of mycoplasma infection status of a herd. However disease detection can be delayed up to 10 d due to slow colony formation with culture. Direct mycoplasma detection in enriched broth by the use of PCR may have the advantage of detecting the pathogen much sooner, if it is shown to detect the pathogen in bulk tank milk at least as well as culture. All samples in the study were cultured by plating 10 μL of the milk sample directly onto commercial mycoplasma isolation agar. All samples also were enriched by inoculating a 100-μL aliquot into 3 mL of mycoplasma broth and then incubated for 48 h, before plating a 10-μL aliquot of this enriched broth onto mycoplasma agar. Any sample where one or more colonies were detected by either direct or broth enrichment were deemed culture positive. A 2-μL aliquot of the same enriched broth from the culture method was used for the PCR detection method. The PCR method used was a four-way multiplex real time assay including primers for general *Mycoplasma* spp., *Mycoplasma bovis*, *Mycoplasma bovigenitalium*, and an internal positive control. When an organism was detected by any of the mycoplasma primers, the sample was deemed to be PCR positive. Of the 58 PCR detection events 35 (60.3%) were classified as Mycoplasma *bovis*, 16 (27.6%) as *Mycoplasma bovigenitalium*, and 7 (12.1%) were only detected by the *Mycoplasma* spp. primers. The comparison summary presented below shows a high level (98.6%) of agreement between the two methods. Direct PCR amplification of a broth enriched milk sample can rapidly detect *Mycoplasma* spp. in bulk tank and pen samples, and can give results comparable to conventional culture methods. PCR also offers the possibility of providing species differentiation of positive samples.

Key Words: mastitis, mycoplasma, PCR

0158 Effects of antibiotic dry cow therapy and internal teat sealant (Teatseal) on milk somatic cell counts, clinical, and subclinical mastitis in early lactation.

H. M. Golder[*1], A. Hodge[2], and I. J. Lean[1], [1]*Scibus, Camden, Australia,* [2]*Zoetis Australia Research and Manufacturing Pty. Ltd., Parkville, Australia.*

A randomized multi-site clinical trial was performed to determine the efficacy of an internal teat sealant (TS; Teatseal; Zoetis Australia, Silverwater, NSW, Australia), when used in combination with antibiotic dry cow therapy (ADCT), on milk individual cow cell count (ICCC), milk production and components, and the incidence of clinical and subclinical mastitis in cows up to 60 d in milk (DIM), and when compared with ADCT only. Multiparous Holstein, Jersey, or Holstein cross cows (n = 2200) from 8 farms in Southern and Eastern Australia were randomly assigned to treatment in all 4 quarters with an ADCT alone or with ADCT + TS at dry-off. Individual milk yield, fat and protein percentage, and ICCC were measured at 14 ± 3 d intervals for the first 60 DIM for cows that calved 40 to 100 d after dry-off. The first measurement occurred between 10 and 24 DIM. Clinical mastitis and health events were recorded from dry-off to 60 DIM. Milk yield, ICCC weighted by milk yield, and fat and protein percentage were not affected by treatment or time or their interaction in a generalized linear model. Treatment with ADCT + TS decreased geometric mean ICCC (P = 0.021), compared with treatment with ADCT alone. Geometric mean ICCC (x1000 cells/mL) was 32.0 (95% CI: 26.8 to 38.3) and 43.5 (95% CI: 36.2 to 52.1), respectively. The odds of at least 1 case of subclinical mastitis (ICCC $\geq$ 250,000 cells/mL) were 1.9 times higher (95% CI: 1.4 to 2.6) with ADCT alone, compared with ADCT + TS. Four cows had a first case of clinical mastitis in the dry period; while, 5% of cows had a first case of clinical mastitis between 0 and 60 DIM. Of the 1528 cows included in this analysis, 43 cases (5.7%) and 33 (4.3%) were from the ADCT and ADCT + TS groups, respectively (P = 0.194). Proportional hazards estimates of survival showed no difference in the number of d post-calving to detection of first cases of clinical mastitis between treatments over the first 60 DIM (P = 0.153). The estimated hazard ratio for clinical mastitis over this period in the ADCT + TS cows (relative to ADCT alone) was 0.70 (95% CI: 0.43 to 1.14). The combination of ADCT and TS provides benefits over ADCT alone through improved prevention of subclinical mastitis and reduced ICCC in the first 60 DIM.

Key Words: intra-mammary infection, survival analysis

0159 A new protocol for the isolation of key recombinant proteins in livestock production using lactic acid bacteria as a cell factory.

L. Gifre[*1], O. Cano-Garrido[2,3,4], F. Fàbregas[1], J. Seras-Franzoso[2,3,4,5], R. Roca[1], N. Ferrer-Miralles[2,3,4], A. Villaverde[2,3,4], A. Bach[1,6], A. Arís[1], and E. Garcia-Fruitós[1], [1]*Department of Ruminant Production, IRTA, Caldes de Montbui, Spain,* [2]*Departament de Genetica i de Microbiologia, UAB, Cerdanyola del Valles, Spain,* [3]*CIBER de Bioingenieria, Biomateriales y Nanomedicina (CIBER-BBN), Cerdanyola del Valles, Spain,* [4]*Institut de Biotecnologia i de Biomedicina, UAB, Cerdanyola del Valles, Spain,* [5]*Cibbim-Nanomedicine, Hospital Vall d'Hebron, Institut de Recerca de la Vall d'Hebron (VHIR), Barcelona, Spain,* [6]*ICREA, Barcelona, Spain.*

Escherichia coli is one of the most widely used expression hosts for the production of recombinant proteins. However,

obtaining pure and active proteins is not an easy task, especially considering difficult-to-express proteins, such as membrane or aggregation-prone proteins. Besides, *E. coli* contains lipopolysaccharide (LPS) that must be removed, which involves costly and time-consuming purification processes. Interestingly, *Lactococcus lactis*, which does not produce LPS, is able to form protein nanoclusters (aggregates) rich in the recombinant protein produced. The objective of this study was to develop an economically-affordable protocol to extract functional proteins from protein nanoclusters of *L. lactis*. For that, interleukin-8 (IL-8) stimulating protein (IL8SP), a difficult-to-express protein, and metalloproteinase 9 (MMP-9), an aggregation-prone protein, were used as model proteins. These proteins, that play important roles during the dry period of cows and have important economical potential, were recombinantly produced in *L. lactis* in the form nanoclusters. Next, IL8SP and MMP-9 nanoclusters were isolated and solubilized followed by some washing steps. Solubilized proteins were further purified following standard procedures for His-tagged proteins. Purified IL8SP and MMP-9 were quantified by Bradford assay and Western blot. The biological activity of IL8SP was measured in vitro by determining the expression of *interleukin-8 (IL-8*) in bovine mammary gland epithelial cell cultures. Specifically, cells were treated with 2 doses of IL8SP (9 and 90 μg). MMP-9 activity was determined by zymography. Data were analyzed using ANOVA. High aggregation ratios in nanoclusters were obtained for MMP-9 (99.24 ± 0.02%), whereas lower ratios were observed for IL8SP (37.32 ± 0.34%). Concerning biological activity, purified IL8SP showed a 1.6 and threefold-increase ($P < 0.0001$) of *IL-8* expression, compared with the control cells, using 9 and 90 μg, respectively. Protein MMP-9 obtained with this protocol was also fully active when tested by zymography. In summary, these results show that it is possible to obtain soluble, pure and fully-active proteins from *L. lactis* protein-rich nanoclusters through a novel, cost-effective, and easy protocol.

Key Words: nanoclusters, protocol, recombinant protein

0160 The negative effects of electromagnetic field exposure in male New Zealand White rabbits.

O. Yildiz Gulay*[1], M. S. Gulay[1], A. Balic[2], and A. Ata[1], *[1]Mehmet Akif Ersoy University, Burdur, Turkey, [2]Sakarya Research Hospital, Turkey.*

The objective of the current study was to understand the possible effects of EMF on liver enzymes and organs of male New Zealand White rabbits under ecological conditions. Rabbits were assigned randomly to 2 treatment groups of 8 each; treatment group (T) was housed directly beneath high voltage power lines (21 μT, 380 kV), whereas controls (C) kept 500 m away from the power lines (0.21 μT) for 7 wk. At the end of 7 wk, blood samples were taken from each rabbit and 4 rabbits per treatment were euthanized. Remaining rabbits were kept in normal laboratory condition for another 7 wk for recovery. The liver enzymes and organ weights were analyzed by Proc T-Test procedure. The exposure to EMF significantly increased the serum γ glutamyltransferase (C = 12.1 ± 1.7 vs. T = 17.2 ± 2.9 IU/l, $P < 0.05$), alkaline phosphatase (C = 71.7 ± 4.9 vs. T = 84.3 ± 6.2 IU/l, $P < 0.05$), aspartate aminotransferase (C = 23.5 ± 2.6 vs. T = 31.4 I ± 3.1 IU/l, $P < 0.05$) and alanine transaminase (C = 35.3 ± 3.8 vs. T = 45.5 ± 5.2 IU/l, $P < 0.05$) levels. Although liver, kidney, heart, testis and brain weights between groups did not differ, significant histopathological alterations were apparent in the treated animals. Histopathological examination of the liver showed dilated sinusoids, degenerative changes in hepatocytes, moderate fatty vacuolation and infiltration of a small amount of inflammatory cells in the portal area. Hyalinated cylinders in tubule lumens, vacuolated renal tubules and infiltration of leukocytes were seen in the kidney. The decrease in seminiferous tubule diameters in testis, and vacuolation of neurons and focal gliosis in the brain was noted in treated rabbits. However, serum liver enzymes and histopathological lesions were transient and returned to normal by wk 7 of recovery. Therefore, EMF exposure may have an adverse effect on the male rabbits, but this effect was not permanent.

Key Words: liver enzymes, histopathology, EMF

0161 Embracing innovation in the animal drug approval process.

D. M. Sholly* and C. Taylor-Edwards, *U.S. Food and Drug Administration/ CVM, Rockville, MD*,

The mission of the Center for Veterinary Medicine (CVM) in the U.S. Food and Drug Administration (FDA) is to protect human and animal health. CVM's Office of New Animal Drug Evaluation encourages the development of new innovative technologies and non-traditional therapeutic indications as one means of facilitating this mission and to meet the growing needs in the animal care and food and fiber production sectors. CVM is committed to maximizing use of all forms of available information to meet this challenge. Current tools being implemented and/or investigated include use of scientific focus groups/technology teams, evaluation of "Early Information," pre-development meetings with drug sponsors, and CVM Outreach to academic bench scientists through, webinars and industry meeting presentations. These tools allow CVM to gather information, identify data gaps, and implement benefit-risk analysis decisions early in the drug approval process. Drug application review also affords the opportunity for continued communication between CVM, research scientists, and sponsors, as well as providing a channel for end-user feedback to CVM. Additional tools include expanded use of literature to support data requirements, use of electronic data capture, systematic reviews and meta-analyses, and collaborative data sharing within CVM and across international regulatory groups. Many of these new tools and approaches rely heavily on the academic research community

through consultations, published peer-reviewed information, and as study investigators. Scientists should consider and identify the applicability of their research and, just as importantly, foster productive partnerships with drug sponsors. An understanding of the regulatory processes underlying animal drug development and the tools used by CVM to evaluate data to support drug development is critical to the growth of the animal drug industry and the animal sciences industries. The benefit of innovative approaches to drug sponsors includes but is not limited to early and continual feedback from CVM, increased predictability of drug development requirements, and consistent application of requirements leading to global approval and use of an animal drug. The benefit to the researcher is continued partnerships with the animal drug industry and increased communication on how their scientific program could support drug development. The benefit to the public is increased availability of safe and effective drugs for use in production animals.

Key Words: animal health, drug, FDA, food, innovation, livestock

0162 Regulation of animal drugs and foods in the 21st century: Enhancing communication among industry, academics, regulators, and the public.

C. Taylor-Edwards* and D. M. Sholly, *U.S. Food and Drug Administration/CVM, Rockville, MD.*

The mission of the Center for Veterinary Medicine (CVM) in the Food and Drug Administration (FDA) is to protect human and animal health. One aspect of CVM's role is to ensure that animal drugs and foods are safe, have proper manufacturing processes and labeling, and that any food products from treated animals are safe. Scientists at CVM rely on communication with researchers, veterinarians, and producers to stay informed of common industry practices and any scientific information that may influence the conduct of safety and the effectiveness of studies for approval. CVM also conducts outreach to educate a variety of stakeholders on the wide array of information publicly available on the CVM website and in partnership with professional scientific and industry societies. These resources are valuable to individuals involved with drug and food additive development, including basic research, clinical and laboratory studies, and post-market evaluations. By understanding and implementing the appropriate regulatory requirements and guidance for animal drug or food approvals, researchers are more likely to generate high-quality data and improve CVM's ability to use that information as part of the approval process. The CVM website contains information on important initiatives needing further research, such as antiparasitic resistance, antimicrobial resistance, and unapproved drugs, and provides information for the Center's internal research efforts. Special initiatives to increase the availability of approved drugs for minor uses and minor species include conditional approval, expanded exclusivity, available funding for some designated product studies, and assistance with outside programs intended to support minor species drug approval. The CVM website also serves as an authoritative resource for important information on the use of approved drugs, labeling, and descriptions of the safety and effectiveness of studies supporting those approvals. CVM portals also serve a critical role in allowing end-users of CVM-approved products to report adverse events and complaints for animal drugs and food for pets, and livestock, allowing CVM to monitor for possible safety, effectiveness, and/or manufacturing concerns and take appropriate regulatory action. Continued education and outreach to researchers, veterinarians, and producers allows CVM to continue to make scientifically sound decisions and achieve our mission of protecting human and animal health.

Key Words: animal health, communication, FDA0

0163 Exploring a new presentation form of recombinant proteins for animal production.

O. Cano-Garrido[1,2,3], S. Parés[4], A. Sánchez-Chardi[5], L. Gifre[4], N. Ferrer-Miralles[1,2,3], A. Natalello[6], R. Cubarsi[7], A. Bach[8,9], A. Villaverde[1,2,3], A. Arís[4], and E. Garcia-Fruitós*[4], *[1]Institut de Biotecnologia i de Biomedicina, UAB, Cerdanyola del Valles, Spain, [2]Departament de Genetica i de Microbiologia, UAB, Cerdanyola del Valles, Spain, [3]CIBER de Bioingenieria, Biomateriales y Nanomedicina (CIBER-BBN), Cerdanyola del Valles, Spain, [4]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [5]Servei de Microscopia, UAB, Cerdanyola del Valles, Spain, [6]Department of Biotechnology and Biosciences, Università di Milano-Bicocca, Italy, [7]Departament de Matemàtica Aplicada IV, Universitat Politècnica de Catalunya, Barcelona, Spain, [8]ICREA, Barcelona, Spain, [9]IRTA, Caldes de Montbui, Spain.*

Bacterial cell factories are widely used for the biofabrication of recombinant enzymes, vaccines, and hormones. However, the use of treatments based on recombinant proteins in animal science is limited, mainly because the production of soluble proteins has two important drawbacks: low stability and high costs. In this scenario, we have developed an alternative based on protein nanoparticles produced in lactic acid bacteria (LAB) that can potentially revolutionize livestock production. These nanoparticles are a low-cost source of releasable, highly stable, and functional protein that can be easily produced through a fully-scalable process. The objective of this study was to demonstrate the potential of this new protein format by exploring the composition and the biological effect of nanoparticles composed of bovine metalloproteinase 9 (MMP-9) and 2 (MMP-2), which have critical roles during the dry period of cows. Because understanding the architecture of these protein nanoparticles is pivotal to tune and exploit their activity, stability, and slow-release properties, in a first

experiment, the particle size of MMP-9 and MMP-2 produced by 2 different strains was determined from 474 micrographs obtained by high-resolution microscopy techniques. Next, in Experiment 2, metalloproteinase activity was measured in vitro by zymography. Lastly, in a third experiment involving 12 Holstein cows at dry-off, we assessed the potential use of MMP nanoparticles in vivo. Briefly, 12 quarters were infused with MMP-9 nanoparticles and 12 with saline solution (control) and samples of mammary secretion were obtained during 7 d post-dry off. Data were analyzed using ANOVA. In Experiment 1, particle size was affected ($P < 0.0001$) by the combination of the specific protein and the bacterial strain used for their production (353.2 and 431.6 ± 8.47 nm for MMP-9 and 391.8 and 387.6 ± 8.47 nm for MMP-2 produced in strain A and strain B, respectively). In Experiment 2, MMPs tested in vitro showed activity in a strain- and protein-dependent manner (1.38 and 2.33 ± 0.16 AU for MMP-9 and 1.97 and 1.52 ± 0.16 AU for MMP-2 produced in strain A and strain B, respectively; $P = 0.0028$). Mammary secretions from the in vivo study (Experiment 3) indicated a clear increase ($P < 0.001$) in metalloproteinase activity in comparison with the control at d 1 and 3. In summary, this study shows that it is possible to produce tunable and fully functional MMP nanoparticles in LAB, proving an important combined effect of the strain and the protein used to define its final characteristics.

Key Words: metalloproteinase, nanoparticles, proteins

0164 Reduced severity of histological lesions in mink selected for tolerance to Aleutian mink disease virus infection- A field survey. A. H. Farid[*1] and L. E. Ferns[2], [1]*Department of Animal Science, Dalhousie University Faculty of Agriculture, Truro, NS, Canada,* [2]*Pathology Laboratory, Veterinary Services, Nova Scotia Department of Agriculture, Truro, Canada.*

Aleutian mink disease virus (AMDV) causes Aleutian disease (AD), which is a major problem for the mink industry worldwide. Chronically infected adult mink exhibit persistent antiviral antibody production, hypergammaglobulinemia, generalized plasmocytosis and immune complex-mediated glomerulonephritis and arthritis. The disease has no vaccine or treatment, and many years of testing for anti-viral antibodies by the counter-immunoelectrophoresis (CIEP) and eliminating seropositive animals has not been effective for virus eradication, encouraging some ranchers to select their herds for tolerance to the disease. The objective of this study was to assess the effect of selection for tolerance on the severity of AD histological symptoms. Carcasses of 680 sero-positive (CIEP-P) black mink from 28 ranches in Nova Scotia, Canada, and 132 sero-negative (CIEP-N) mink from 15 of these ranches were collected at pelting time. Animals on three of the ranches have been selected for tolerance to AMDV based on health, with or without the iodine agglutination test which identifies animals with high serum globulins. The severity of the AD lesions was assessed by histological examination of kidneys, lungs, heart, brain and liver. Only six unselected CIEP-P mink showed clinical symptoms of AD at necropsy, whereas histology confirmed the presence of AD-related microscopic lesions in at least one of the five organs in 89.5%, 68.1% and 66.7% of unselected CIEP-P, tolerant CIEP-P and unselected CIEP-N mink, respectively. The maximum intensity of lesion scores on any of the five organs showed that severe and very severe lesions in the unselected CIEP-P group (44.7%) was 5.7 and 29.8 times greater than those in the tolerant CIEP-P (7.8%) and unselected CIEP-N group (1.5%). A greater percentage of tolerant CIEP-P mink did not show any AD lesions on any of the organs (31.9%) or showed trace or minor lesions (44.8%) compared with unselected CIEP-P mink (10.5% and 24.7%). The GENMOD procedure of SAS with the cumulative logit model showed significant differences among the three groups for the maximum lesion score. The results implied that selection for AMDV tolerance was manifested as milder disease symptoms in infected mink.

Key Words: Aleutian disease symptoms, counter-immunoelectrophoresis, mink

0165 Type of blood tube affects haptoglobin concentration when analyzed with a colorimetric assay. M. A. Campbell[*1,2], J. W. Darrah[1], and H. M. Dann[1], [1]*William H. Miner Agricultural Research Institute, Chazy, NY,* [2]*University of Vermont, Burlington, VT.*

Haptoglobin, an acute phase protein, serves as a biomarker for stress and inflammation in dairy cows. Consequently, obtaining an accurate value for haptoglobin is vital for research and management decisions on-farm. Blood collection methods reported in peer-reviewed articles differ greatly when similar assays are performed. The objective of this study was to determine the effect of type of blood collection tube on haptoglobin concentration using a commonly used, commercially available colorimetric assay. Coccygeal blood was obtained from 21 early lactation, 9 sick, and 30 late lactation dairy cows from three farms to obtain a range in haptoglobin concentrations. For each cow, blood was collected into four separate 10-mL BD Vacutainer tubes: serum separator, lithium heparin, sodium heparin, and K_2–EDTA. Blood was then processed according to tube type. Plasma and serum were analyzed for haptoglobin concentration using a colorimetric assay (Tri-Delta Development Ltd; Maynooth, Ireland). Inter-assay and intra-assay CV were 3.2% and 4.3%, respectively. Data were separated into two categories; low haptoglobin (< 0.2 mg/mL; $n = 35$) or high haptoglobin (≥ 0.2 mg/mL; $n = 25$). Data were logarithmically transformed and analyzed using the MIXED procedure in SAS with cow as the experimental unit. Plasma samples from lithium heparin, sodium heparin, and K_2–EDTA tubes appeared cloudier than serum samples

following addition of assay reagents and interfered with the optical density reading. Haptoglobin concentrations were lower ($P < 0.01$) for serum separator tubes (0.09 mg/mL, 0.76 mg/mL; SEM = 0.02, SEM = 0.06) compared with lithium heparin (0.57 mg/mL, 1.60 mg/mL), sodium heparin (0.55 mg/mL, 1.57 mg/mL), or K_2–EDTA (0.62 mg/mL, 1.60 mg/mL) tubes for the low and high haptoglobin categories, respectively. To assess bias, data were analyzed for agreement between tubes using the Bland-Altman method with the serum separator tube serving as the gold-standard. A maximum allowable difference was determined to exceed the inter- and intra-assay variations set by the manufacturer at 0.15 mg/mL. Compared with serum, there was a significant lack of agreement ($P < 0.01$) with lithium heparin, sodium heparin, and K_2–EDTA (mean biases of 0.66, 0.64, and 0.69 mg/mL, respectively). In addition, lithium heparin, sodium heparin, and K_2–EDTA demonstrated slope biases of 0.42, 0.40, and 0.40, respectively, compared with serum. These results indicate greater disagreement among tubes at higher haptoglobin concentrations. The use of lithium heparin, sodium heparin, and K_2–EDTA tubes before haptoglobin analysis using the Tri-Delta colorimetric assay overestimates haptoglobin concentrations due to interference with assay reagents and is not recommended.

Key Words: haptoglobin, inflammation, vacutainer

0166 Health and production benefits of feeding cowpeas to goats. S. Adjei-Fremah*, A. Everett, R. Franco, K. Moultone, E. Asiamah, K. Ekwemalor, L. E. Jackai, N. Whitley, K. Schimmel, and M. Worku, *North Carolina Agricultural and Technical State University, Greensboro.*

The effect of grazing on cowpea forage on growth, parasite egg counts and markers of immunity was evaluated in goats. Spanish ($n = 24$) and Savannah goats ($n = 24$) were stratified by initial body weight (BW) (42.0 ± 7.0 kg) and fecal egg counts (FEC), and randomly assigned to 1 of 12 grazing plots (4 animals/plot) for 4 wks. Plots contained either of two varieties of cowpea commonly used in the Southern U.S., Mississippi silver (MS) and Iron and Clay (IC) or pearl millet (PM) grass as control. Body condition scores (BCS), BW, *FAMACHA* scores, and FEC were measured weekly. Initial and end of study blood samples were collected and analyzed for PCV, total and viable cells, and white blood cell differential counts. The concentration of total proteins, pro-inflammatory cytokines, prostaglandin E2 (PGE2) and total antioxidant capacity (TAC) were evaluated in serum. Body weight, BCS and *FAMACHA* score data were analyzed by repeated measures analysis using the PROC MIXED model procedure of SAS. The model included treatment, time (sampling day), breed, and the treatment x time x breed interaction. The FEC data were log-transformed before statistical analysis. Two-way ANOVA was performed on all other data. Goats fed cowpea forage, BW ($P = 0.01$), percent lymphocyte ($P = 0.008$), and percent neutrophils ($P = 0.013$) increased, and FEC decreased ($P = 0.03$) compared with goats fed control PM forage. A significant interaction ($P = 0.01$) was observed between goat breeds, cowpea varieties and measured parameters such as BW, percent lymphocyte, percent neutrophil and percent viable cells. The MS cowpea forage was associated with greater BW and neutrophil counts in the Savannah breed and with increased lymphocyte counts in Spanish goats. Although feed did not affect serum protein concentration ($P > 0.05$), a decrease in PGE2, TNF-α, IL-8, and IP10, and an increase in TAC, G-CSF, Rantes and IFNγ was observed over time ($P < 0.05$). Results from the study suggest potential benefits and impact of cowpea forage grazing, particularly MS variety on growth, internal parasites burden, and markers of immunity in goats. Feeding a cowpea diet to goats may stimulate and prime innate immune responses for defense against gastrointestinal parasites and warrants further study under different management conditions.

Key Words: cowpea forage, goats, gastrointestinal nematode, inflammation cytokines, immunity markers

0167 Exposure of bovine blood to pathogen associated and non pathogen associated molecular patterns results in transcriptional activation. K. Ekwemalor*, S. Adjei-Fremah, E. Asiamah, H. Ismail, and M. Worku, *North Carolina Agricultural and Technical State University, Greensboro.*

The effect of exposure of cow blood to non pathogen associated (probiotics) molecular patterns on the subsequent response to pathogen associated molecular patterns (PAMPS) was evaluated using transcriptional profiling. Probiotic supplements are beneficial for animal health and rumen function and represent non pathogen associated molecular patterns. Lipopolysacharides form gram negative bacteria are associated with inflammatory diseases and represent PAMPS. A global gene expression profile in whole blood collected from probiotics-supplemented cow was investigated in response to stimulation with lipopolysaccharide (LPS) in vitro. The recommended dose of FASTtrak microbial pack (Conklin Company, Kansas City, MO, USA) was administered orally in 50 ml of sterile water to Holstein-Friesian cows ($n = 10$) in mid lactation, for 60 d. Whole blood was collectedly aseptically and treated with 100 ng/ml of LPS and untreated samples served as control. Total RNA was extracted, and samples (0.5ug, RIN > 7) pooled together, were used for the microarray experiment on a bovine (v2) 4 × 44 arrays with 44,000 gene transcripts. A Real-time quantitative PCR was performed to validate the expression of Wnt signaling pathway and innate and adaptive immune response genes using RT-PCR profilers arrays (Qiagen) with 84 test genes each. Global gene expression analysis identified 13,658 differentially expressed genes

(fold change cutoff $\geq$ 2, $P < 0.05$), 3816 upregulated genes and 9842 downregulated genes. Treatment with LPS resulted in increased expression of TLR4 (Fold change (FC) = 3.16), TLR2 (FC = 2.4), TLR7 (FC = 2.13), WNT5A (FC = 2.68), and transcription factor NF-Kb (FC = 5.4). Genes downregulated in expression included WNT 11 (FC = -2.60), TLR1 (FC = -2.54), TLR3 (FC = -2.43), TLR10 (FC = -3.88), NOD2 (FC = -2.4), NOD1 (FC = -2.45) and pro-inflammatory cytokine IL1B (FC = -3.27). Thus, probiotic supplementation had an effect on the response to LPS exposure with specific effects on Toll-like receptor transcription. Exposure of bovine blood to pathogen associated (LPS) and non pathogen associated (probiotics) patterns resulted in transcriptional activation. Thus, probiotic supplementation may modulate the response to gram negative bacteria.

Key Words: probiotic, microarray, lipopolysaccharides, dairy cows

---

0168 Prevalence of *Brucella suis* in hunting dogs in Hawai`i.

B. S. McNeill, J. Odani, R. Jha*, and H. M. Zaleski, *University of Hawaii at Manoa, Honolulu.*

This study examined the prevalence of *Brucella suis* in hunting dogs that have had extensive contact with feral swine, and potential risks for domestic livestock. Increasing feral swine populations across the U.S. increase the risk of transmission of swine diseases, such as the *B. suis* bacterium, to other animals and humans. Blood serum was collected from hunting dogs on the islands of O`ahu and Hawai`i by cooperating veterinary clinics. Based on previously reported prevalence of *B. suis* in feral swine on O`ahu and Hawai`i islands of 20.6% and 10.5%, and an estimate by extension agents of 300 to 500 hunting dogs, sample size needed for detection was calculated as 47 dogs. Serum was tested for *B. suis* specific antibodies using the buffered acidified plate antigen test, and positives were confirmed with the rivanol test. Data on potential risk factors was collected in a pre-structured questionnaire. Areas sampled include Royal Summit, Aiea and Kaneohe Bay on O`ahu and Halaula, Hawi, and North Kohala on Hawai`i. On O`ahu 1/7 (14%) samples were positive for *B. suis* and on Hawai`i 2/49 (4%) of samples were positive for *B. suis*. All positive samples had significant antibody titers on the rivanol test (two at 1:200 and one at 1:100) with no presentation of symptoms in the dogs. The positive dogs hunted in the Halawa/Royal Summit area on O`ahu and in the Hawi and North Kohala areas on Hawai`i. Questionnaire results showed that 83% of dogs were not neutered, 74% had never seen a veterinarian, 25% had contact with domestic pigs, and 46% had contact with other livestock. This study concludes that hunting dogs may be a previously unidentified risk factor for transmission of *B. suis* to domestic swine and other livestock.

Key Words: *Brucella suis*, feral swine, hunting dogs

0169 Pulmonary arterial pressure in yearling Angus cattle managed at high altitude: Study of a non-synonymous SNP in the oxygen-dependent degradation domain of the endothelial PAS domain-containing protein 1 gene.

N. F. Crawford*[1], X. Zeng[1], S. J. Coleman[1], T. N. Holt[2], S. E. Speidel[1], R. M. Enns[1], J. H. Newman[3], R. Hamid[4], and M. G. Thomas[1], *[1]Department of Animal Sciences, Colorado State University, Fort Collins, [2]College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, [3]Department of Medicine, Division of Allergy, Pulmonary and Critical Care, Vanderbilt University School of Medicine, Nashville, TN, [4]Department of Pediatrics, Division of Medical Genetics and Genomic Medicine, Vanderbilt University School of Medicine, Nashville.*

Bovine pulmonary hypertension (bPH) has a complex pathophysiology and can progress to right heart failure. Mean pulmonary arterial pressure (mPAP) has been used for decades as an indicator of risk of developing hypoxia-related bPH at altitudes above 1800 m. Veterinarians typically describe yearling bulls and heifers as low, moderate, or high risk for developing bPH using mPAP data. The objective of this study was to evaluate the relationship of a non-synonymous SNP in the oxygen-dependent degradation domain (ODDD) of the endothelial PAS domain-containing protein 1 (EPAS1) gene with mPAP in yearling Angus cattle managed at high altitude. The EPAS1 gene, also known as hypoxia-induced factor (HIF2α), is located on chromosome 11 and several sequence variants have been identified in its ODDD including a downstream G/A SNP (rs208684340). The A allele of this polymorphism was previously associated with hypoxemia in Angus cattle. In the current study, records from Angus cattle (n = 5296 of 280 sires) were obtained from the Colorado State University Beef Improvement Center (CSU-BIC; elevation 2150 m). Risk categories were constructed by estimating the heritability of mPAP as a categorical outcome based on veterinary recommendations. The combination of these efforts yielded mPAP risk categories of low (< 41), moderate (41 to 49) and high (> 49 mmHg) with a categorical-trait heritability of 0.26 ± 0.04 in this population. The percentage of cattle in each of these categories was 50.7, 38.0, and 11.3%, respectively. Forty-seven bulls and heifers, progeny of 33 sires, from this population were genotyped for the G/A SNP using a TaqMan assay (ABI-Roche Molecular Systems, Inc.). The minor allele frequency (MAF; A allele) of this SNP was 32.3% and mPAP averaged 45.2 ± 1.5 with a range of 32 to 95 mmHg. The MAF for the low, moderate and high categories were 46.4, 26.1, and 25.0%, respectively. Genotype was not a predictor (P = 0.4) of mPAP using a generalized linear model analysis. Mean PAP has been a useful tool to predict risk of bPH in yearling cattle for decades and is a moderately heritable trait. However, the

genotype results of this particular variant in the ODDD of the EPAS1 gene does not appear in this preliminary study to be useful to designate Angus cattle from the CSU-BIC into mPA-P-bPH risk categories.

Key Words: Angus cattle, pulmonary hypertension, SNP

0170 Subclinical right heart failure may contribute to the development of liver disease in feedlot cattle during the finishing phase. A. K. Gulick*, K. M. Freeman, B. C. Bernhard, J. O. Sarturi, and J. M. Neary, *Texas Tech University, Lubbock.*

The objectives of this study were twofold: first, to evaluate the relationship between mean pulmonary arterial pressure and mean central venous pressure, and determine if they increase through the finishing period; and second, to determine if mean central venous pressure is associated with liver disease. A cohort of crossbred yearling steers (n = 22; initial BW = 364 ± 52 kg) was studied at an altitude of 975m. Steers were fed for 171 d. Vascular pressures were measured twice: 6 and 54 d before slaughter. Serum biochemistry and liver histology were performed on steers that had the greatest (n = 5) and lowest (n = 5) mean central venous pressure at 54 d before slaughter. Biochemistry included total bilirubin, AST, GGT, and albumin; blood samples obtained 6 and 54 d before slaughter were evaluated. Liver samples were collected from the caudate lobe and lesions scored semiquantitatively. Both central venous and pulmonary arterial pressures increased from 54 d to 6 d before slaughter: 24 ± 1 mmHg to 28 ± 1 mmHg (P = 0.03) and 47 ± 2 mmHg to 54 ± 2 (P < 0.01), respectively. There was a positive association between mean pulmonary arterial and central venous pressures at 6 d (P < 0.01) but not 54 d before slaughter (P = 0.41) indicating that increased pulmonary arterial pressure contributed to right heart failure in cattle closest to slaughter weight. Serum biochemistry was within normal limits even though all steers showed histological evidence of liver damage centered on the centrilobular region (zone 3). All steers showed hydropic degeneration and sinusoid dilation. Lesion severity was greatest in the high mean central venous pressure group: One liver had cirrhosis; another had multifocal necrosis. Congestion was moderate to severe and centered on zones 1 and 2. The findings of this study indicate that subclinical right heart failure secondary to pulmonary hypertension may contribute to hepatic congestion and disease in feedlot cattle during the finishing phase. Serum biochemistry analyses may not represent the insidious liver damage of cattle close to slaughter. Right heart failure secondary to pulmonary hypertension, or cor pulmonale, may contribute to the development of liver disease in feedlot cattle during the finishing phase.

Key Words: health, pulmonary hypertension, steer

0171 Evidence of cor pulmonale and liver disease in association with pneumonia in feedlot and dairy cattle at an altitude of 975 m. A. K. Gulick* and J. M. Neary, *Texas Tech University, Lubbock.*

The objective of this observational study was to determine if cor pulmonale is evident in cattle at the moderate altitude of 975 m. Cor pulmonale is defined as right ventricular enlargement and dysfunction due to diseases affecting the lung or pulmonary vasculature. Right ventricular dysfunction can manifest as congestive hepatopathy. A convenience sample of necropsies were performed on one feedlot (n = 16) and one dairy (n = 4) between May 16 and September 4, 2015. A case history was obtained, gross lesions were recorded, and the cardiac ventricles weighed to determine the ratio of right ventricular free wall to total ventricular myocardium (RV:T). Sections of the right diaphragmatic, middle, and cranial lung lobes and liver were collected for histology. Vascular and hepatic lesions were scored semiquantitatively. Of the 16 feedlot cattle necropsied, 2 died from cor pulmonale secondary to bronchointerstitial pneumonia, 8 died from pneumonia, and 6 died from miscellaneous causes. Dairy cattle died from interstitial pneumonia (n = 3) and miscellaneous causes (n = 1). The RV:T ratio varied according to cause of death (P < 0.001): 0.37 ± 0.02 in cattle that died of cor pulmonale, 0.28 ± 0.01 in cattle that died of pneumonia, and 0.25 ± 0.01 in cattle that died of miscellaneous diseases. All cattle showed histological evidence of pulmonary vascular remodeling regardless of the cause of death or degree of right ventricular hypertrophy. The predominant vascular lesions included pulmonary arterial adventitial hyperplasia and pulmonary venous distension. Anatomic reduction of the pulmonary vascular bed was evident in cattle with pneumonia. Liver disease, consisting of sinusoidal dilation, lipidosis, and necrosis, was most severe in cattle that died of cor pulmonale and pneumonia. These findings indicate that cor pulmonale may be more problematic in cattle at modest elevation than is currently appreciated and confirm our previous epidemiological findings that respiratory disease is a risk factor for cor pulmonale in cattle. Venous congestion secondary to cor pulmonale may have contributed to the development of liver disease in cattle with pneumonia. Systemic consequences of right heart failure result from a reduction in cardiac output and venous congestion; consequently, organs with high oxygen requirements, such as the liver, are most at risk of cellular dysfunction and death. Moreover, because respiratory disease is a risk factor for cor pulmonale and the clinical signs overlap, the true incidence of cor pulmonale may be greater than current estimates suggest.

Key Words: heart, hypertension, pulmonary

0172 Porcine intestinal explants as *ex vivo/in vitro* model to study gastrointestinal disease. N. Reisinger*, P. Fuhrmann, C. Emsenhuber, B. Grenier, E. Mayer, and G. Schatzmayr, *BIOMIN Research Center, Tulln, Austria.*

Intestinal diseases play an important role in livestock animals especially in pigs. To gain more knowledge about pathological processes during intestinal disease usually animal experiments are needed. However, alternatives to animal testing are highly recommended. Ex vivo cultivation of explants might provide an alternative tool to investigate intestinal diseases in pigs. We therefore evaluated the cultivation of porcine intestinal explants.

Intestinal tissue from pigs was obtained from a local abattoir. About 10 cm of the jejunum were transported in prewarmed PBS to the lab. Intestinal tissue was flushed with PBS and was cut open longitudinally. Thereafter, tissue was washed again with PBS and cut into small pieces. Explants were placed into 12-well plates (mucosa facing upward) prefilled with 1.5 mL cultivation medium (D-MEM containing antibiotics and 10% FBS) and were incubated for up to 72 h at 39°C and 5% CO_2. Viability was measured with the water soluble tetrazolium (WST) −1 assay after 2, 4, 24, and 72 h (n = 6). In addition, explants were frozen in liquid nitrogen after incubation for 0, 2, and 4 h and stored at −80°C (n = 9). Gene expression of three different pro-inflammatory cytokines (TNF-α, IL-6, and IL-8) was measured via RT-qPCR. Statistical evaluation was performed with IBM SPSS Statistics software. If data were normally distributed ANOVA was performed. If data were not normally distributed, the Kruskal Wallis Test was used as non-parametric test.

Viability was already significantly decreased after 4 h of incubation compared with fresh explants. Furthermore, there was a significant increase of TNF-α expression after 4 h (25-fold) and IL-6 expression after 2 and 4 h (50 and 320-fold) compared with fresh explants. No effect of incubation time was seen for IL-8 expression.

Our study highlights the importance of measuring viability when cultivating intestinal explants. In addition, dissection of the tissue and isolation of explants seem to stimulate expression of certain pro-inflammatory cytokines.

We can therefore conclude that ex vivo cultivation of intestinal explants might be an alternative screening tool. However, optimization of dissection and culture conditions is needed to prolong possible incubation time.

Key Words: pigs, explants, gastrointestinal diseases

0173 Comparison of strategies for combining dynamic linear models with artificial neural networks for detecting diarrhea in slaughter pigs. D. B. Jensen* and A. R. Kristensen, *University of Copenhagen, Department of Large Animal Sciences, Frederiksberg, Denmark.*

The drinking behavior of healthy pigs is known to follow predictable diurnal patterns, and these patterns are further known to change in relation to undesired events such as diarrhea. We therefore expect that automatic monitoring of slaughter pig drinking behavior, combined with machine learning, can provide early and automatic detection of diarrhea. To determine the best approach to achieve this goal, we compared 36 different strategies for combining a multivariate dynamic linear model (DLM) with an artificial neural network (ANN). We used data collected in 16 pens between November 2013 and December 2014 at a commercial Danish pig farm. The pen level water flow (liters/hour/pig) and drinking bouts frequency (bouts/hour/pig) were monitored. Staff registrations of diarrhea were the events of interest. Mean water flow and drinking bouts frequency were each modeled using three harmonic waves in a multivariate DLM. The DLM was optimized using the pen-groups for which no events were observed (n = 26). The forecast errors produced by the DLM were normalized by the forecast variance and used as inputs for the ANN. In addition, the forecast errors were categorized based on the direction (positive or negative) and simga-1, sigma-2, or sigma-3 cutoff thresholds. Furthermore, observations from between 0 and 48 h before the day of the observation, with steps of 6 h, were included in the ANN training window. Thus between 87 and 277 diarrhea-associated observations were included. The diarrhea-associated observations were paired with an equal number of observations from healthy groups, based on the observation date and the age of the pigs. The complete set of diarrhea positive and negative observations was divided into a training set (80%) and a test set (20%). The ANN's consisted of three layers: an input layer corresponding to the number of forecast error categories, a hidden layer with 50 nodes, and an output layer with one node. The various ANN's were applied to all observations in the test set. The observation-level performance of the ANN predictions was evaluated by the error rate, the specificity (SP), and the sensitivity (SE). The best performance was seen when using a training window of 42 h for the numerical forecast errors, which produced an error rate = 0.16, a specificity = 0.88, and a sensitivity = 0.80. For the other tested strategies, the ranges of error rates and the corresponding specificities and sensitivities were 0.55–0.28, 0.43–0.71, and 0.50–0.74, respectively.

Key Words: artificial neural network, diarrhea, dynamic linear model

0174 Heat stress increases gut permeability in pigs–application of a non-invasive assay. N. Reisinger[*1], S. Schaumberger[2], I. Dohnal[1], B. Doupovec[1], E. Mayer[1], and G. Schatzmayr[1], *[1]BIOMIN Research Center, Tulln, Austria, [2]BIOMIN Holding GmbH, Getzersdorf, Austria.*

Heat stress plays an important role in livestock animals. Several studies already described increased gut permeability in pigs during heat stress using invasive technologies e.g., Ussing Chamber. In human studies non-invasive sugar tests are quite often used to measure gut barrier function. We therefore evaluated the influence of heat stress on gut permeability of pigs with the dual sugar assay. Eight pigs were placed into metabolic cages (two pigs per cage) at D35 after weaning. Pigs were allowed to adapt to the cages for 4 d. At d 0 of the trial period pigs were kept at thermoneutral conditions (32°C, 24 h) and on d 1,2 and 3 pigs were exposed to heat stress conditions (6 h 35°C, 18 h 32°C). At d 0 and 2 the dual sugar permeability assay was performed. Therefore, agar containing lactulose (500 mg/kg body weight) and rhamnose (100 mg/kg body weight) was fed to the pigs. Urine was sampled 2, 4, and 6 h after sugar intake. Urine samples were frozen at- 20°C and lactulose and rhamnose concentrations were determined via HPLC-MS/MS. All data obtained in the experiment were analyzed with a nonparametric test. There was no significant difference between the cumulative rhamnose and lactulose excretion between d 0 (2.1%; 0.52%) and d 2 (1.2%; 0.84%). However, the lactulose rhamnose excretion ratio was significantly increased ($p = 0.0286$) of pigs under heat stress conditions (0.66) compared with thermoneutral conditions (0.24). Our study showed that the dual sugar assay can be used to evaluate gut permeability with a non-invasive method. We furthermore could once more highlight the negative impact heat stress can have on the welfare and health of pigs.

Key Words: gut permeability, heat stress, pigs

0175 The effect of various parameters measured at farrowing on subsequent pig performance. A. L. Robinson[*1], J. Colpoys[2], G. Robinson[1], E. A. Hines[1], E. Edwards[1], J. Bundy[1], A. K. Johnson[1], H. D. Tyler[1], *[1]Iowa State University, Ames, [2]Truman State University, Kirksville, MO.*

The objective of this study was to evaluate birth weight, gender, stall conditions at birth, umbilical diameter, ratio of umbilical diameter to birth weight (as a potential indicator of placental efficiency), and umbilical antiseptic treatment as predictors of pre-weaning mortality, incidence of umbilical hernias, and 150 d weight of pigs in a commercial facility. A total of 466 mixed gender commercial piglets from a breed-to-wean sow farm were enrolled. Piglets were alternately assigned by birth order within a litter to four umbilical treatment groups; iodine (2%), Zurex umbilical dip, a dry dip created using an antibacterial peptide (nisin) mixed with talc (formulation concentration = 3.105 g nisin/100 g talc on a wt/wt basis), and no treatment. At birth, stall conditions (wet/dry and clean/dirty) were evaluated on a 3 point scale (3 = most dirty or most wet and 1 = dry or clean). Before treatment, diameter of the umbilical cords were determined using digital calipers. All data were analyzed using mixed model methods. Models included the fixed effects of birth weight, umbilical diameter at birth, gender, stall conditions and treatment. Pre-weaning mortality was significantly affected by umbilical treatment ($p < 0.05$) and by ratio of umbilical diameter to birth weight ($p < 0.001$). Piglets treated with 2% iodine had a higher mortality rate than piglets treated with other antiseptics or those that were untreated. Piglets with the lowest umbilical cord diameter to birth weight ratio had the highest survival rate. Stall conditions at birth ($p < 0.005$) and the ratio of umbilical diameter to birth weight ($p < 0.05$) affected the incidence of umbilical hernias. Piglets born in wet stall conditions or those with a high umbilical cord to birth weight ratio had a higher incidence of umbilical hernias in the growing phase. Final 150 d weight of pigs was affected by the ratio of umbilical diameter to birth weight ($p < 0.0001$) and gender ($p < 0.0001$), and tended to be affected by stall conditions at birth ($p = 0.06$). Male pigs weighed 93.5 kg, while female pigs weighed 86.5 kg. Piglets with the highest ratio of umbilical cord diameter to birth weight and those born in wet stall conditions weighed less. In conclusion, measuring the umbilical cord to birth weight ratio was a much better predictor of pre-weaning mortality, incidence of umbilical hernias, and 150 d weight than birth weight alone.

Key Words: birth weight, piglet, pre-weaning mortality

0176 Environmental persistence of porcine epidemic diarrhea virus, porcine delta corona virus, and transmissible gastroenteritis in feed ingredients. M. P. Trudeau[*1], H. Verma[2], F. Sampedro[2], P. E. Urriola[1], G. C. Shurson[1], and S. M. Goyal[2], *[1]Department of Animal Science, University of Minnesota, St. Paul, [2]Veterinary Population Medicine, University of Minnesota, St. Paul.*

Porcine epidemic diarrhea virus (PEDV), porcine delta corona virus (PDCoV), and transmissible gastroenteritis (TGEV) are major threats to swine production. Investigations of recent outbreaks confirmed that contaminated feed plays a role in virus transmission. This risk makes it necessary to evaluate the survival of such viruses in various feed ingredients. The objective of our experiment was to characterize the inactivation of PEDV, PDCoV, and TGEV in various feed and ingredient matrices. To determine differences in virus survival, 5-g samples of complete feed, spray-dried porcine plasma, meat meal, meat and bone meal, blood meal, corn, soybean meal, and low, medium, and high oil dried distillers grains with solubles were weighed into separate scintillation vials. These samples were inoculated with 1 mL of PEDV, PDCoV,

or TGEV and incubated at room temperature for up to 56 d. At each time point, surviving virus was eluted and the supernatant was inoculated into vero-81 cells for PEDV, or swine testicular cells for PDCoV and TGEV. Cells were observed daily for 10 d for cytopathic effects, and this information was used to calculate a median tissue culture infectious dose ($TCID_{50}$) using the Karber method. Inactivation kinetics were determined using the Weibull model. A delta value was estimated from the model, indicating the time necessary to reduce virus concentration by 1 log. This delta value was then compared across ingredients using the mixed procedure of SAS, and correlations between ingredient proximate analysis data and delta values were determined. Results showed that soybean meal had the greatest delta value (7.50 d) for PEDV compared with other ingredients ($P < 0.06$). Likewise, PDCoV (42.04 d) and TGEV (42.00 d) delta values were highest in soybean meal ($P < 0.001$). There was a moderate positive correlation between moisture and the delta value for PDCoV ($r = 0.49$, $P = 0.01$) and TGEV ($r = 0.41$, $P = 0.02$). There was also a moderate negative correlation between lipid content and the delta value for TGEV ($r = -0.51$, $P = 0.01$), suggesting that TGEV is less stable in ingredients with greater lipid content compared with ingredients with less lipid content. In conclusion, these results indicate that the first log reduction of PDCoV and TGEV takes the greatest amount of time in soybean meal and it appears to be the result of greater moisture content.

Key Words: feed, inactivation kinetics, virus transmission

0177 Bovine macrophage phenotype influences inflammatory response to lipopolysaccharide.

W. Raphael* and G. A. Contreras, *Michigan State University, East Lansing.*

Severe inflammation during gram negative bacterial disease is common in periparturient dairy cows and increases the severity of diseases such as *Escherichia coli* mastitis. Tissue inflammation is partly orchestrated by macrophage responses to bacterial infection. Studies in monogastric species showed classical phenotype macrophages have proinflammatory responses and alternative phenotype macrophages have protective and restorative responses during disease. However, responses of diverse bovine macrophage phenotypes to lipopolysaccharide are unclear. The objective of this research was to compare the lipopolysaccharide-induced inflammatory response in several phenotypes of bovine primary monocyte-derived macrophages. Peripheral blood mononuclear cells were isolated from whole blood using Ficoll ($n = 8$ cows). Monocytes were identified using mouse anti-bovine CD172α monoclonal antibody and separated from lymphocytes using magnetic assisted cell sorting. Monocytes were cultured with interferon-γ or interleukins (IL) 4 and 13 to induce a classical or alternative macrophage phenotype, respectively, then stimulated with lipopolysaccharide. Macrophage mRNA was quantified in adipose using qPCR. Fold changes in mRNA concentration were calculated by $2^{-\Delta\Delta Ct}$, using the untreated cells as calibrator and three endogenous control mRNA. Treatment differences in mRNA expression were identified using Fisher pairwise comparisons and ANOVA ($P \leq 0.05$). Flow cytometry showed magnetic assisted cell sorting increased CD172α^+ cells from 22.3 ± 1.9 to 81.6 ± 2.8%. After 48 h *in vitro, CD68* expression increased and CD172α^+ was 95.2 ± 0.4%. Lipopolysaccharide increased *IL6*, *IL10*, *TNF,* and *CCL2* expression. Lipopolysaccharide stimulated *IL6* and *IL10* expression was decreased in alternative macrophages, whereas lipopolysaccharide stimulated *TNF* expression was increased in classical macrophages. Lipopolysaccharide stimulated *CCL2* expression was not different between macrophage types. Together these results show an exacerbated proinflammatory cytokine profile in a model of classical bovine macrophages during gram negative bacterial disease. Results suggest that macrophage phenotype could be involved with severe inflammatory responses seen during dairy cow periparturient periods characterized by prolonged and exacerbated lipolysis and increased disease susceptibility. Ongoing research will describe macrophage phenotype during bovine disease and identify factors contributing to phenotype change. Such factors could ultimately be manipulated to control the bovine macrophage inflammatory response.

Key Words: inflammation, macrophage, periparturient

0178 High immune response technology for use in commercial swine herds: A broad based approach to disease resistance.

J. D. Schmied*[1], S. L. Cartwright[1], P. Rupa[1], and B. Mallard[2], *[1]University of Guelph, ON, Canada, [2]Department of Animal Biosciences, Centre for Genetic Improvement of Livestock, University of Guelph, ON, Canada.*

Societal concern regarding food safety and animal health are increasing, encompassing issues including the presence of antibiotic residues in meat, antimicrobial resistant organisms and the risk of zoonotic disease. Therefore, effective economic alternatives, with the potential to improve productivity in addition to animal health and robustness, are essential to the industry's continued success. Previous research in pigs has clearly demonstrated favorable responses to breeding pigs for high immune response (HIR). However, this method has not been tested in commercial swine herds. Since the HIR technology identifies animals with increased capacity for immune response (IR) and subsequently increased disease resistance, its implementation and integration into commercial pig breeding programs is expected to bring health and production benefits. The HIR test measures IR to benign and carefully selected test antigens (Ag), one that elicits antibody-mediated IR (AMIR) and another that elicits cell-mediated IR (CMIR). The study objective was to re-establish and refine the HIR test for pigs in a pilot study and then to utilize this test within a commercial

facility. Two groups of weaned piglets, 24 piglets/group were HIR phenotyped. Antibody-mediated IR, as measured by antigen-specific ELISA, was greater in the older versus younger test piglets ($p < 0.0001$, un-paired t test). Cell-mediated IR, was observed by delayed-type hypersensitivity, measured by change in double-skin-fold thickness (DSFT) both 24 and 48 h after intradermal injection of CMIR-associated antigen, and did not differ between test groups. Results indicate it is possible to phenotype and rank pigs for IR using a standardized HIR protocol. Applying this protocol to approximately 3600 weaned F1-barrows from seven different swine genetics companies is now underway as part of a large collaborative Genome Canada project examining associations between IR with swine health, production and genomic information.

Key Words: broad-based disease resistance, immune response phenotype, swine

0179 Immunomodulatory activities of polyphenol extract from cowpea (*Vigna unguiculata*) on bovine polymorphonuclear neutrophils.

S. Adjei-Fremah*, L. E. Jackai, K. Schimmel, and M. Worku, *North Carolina Agricultural and Technical State University, Greensboro.*

The response of the bovine neutrophils to bacterial endotoxin and its significance in the inflammatory response has been studied widely. Studies have also shown that a cowpea diet is protein-rich and contains phenolic compounds with antioxidant properties beneficial for animal health and wellbeing. In this study, the effect of a polyphenol extract (CPE) from cowpea *(Vigna unguiculata)* on modulation of the response to endotoxin from gram negative bacteria was evaluated. Secretion of mediators of inflammation, such as cytokines, and prostaglandin E2 (PGE2), and expression of innate immune response genes by LPS stimulated bovine polymorphonuclear neutrophils (PMNs) were measured. Neutrophils were isolated from whole blood collected from Holstein-Friesian cows (n = 10) in mid-lactation. Lipopolysaccharide-stimulated PMNs were treated with 10 μg/ml of CPE. The secretion of cytokines (TNF-α, IFNγ, GM-CSF, G-CSF, IL-1A, IL-8, IP10, and RANTES), and prostaglandin E2 (PGE2) were measured using commercial ELISAs. Real-time qRT-PCR was performed using an innate and adaptive immune response array with 84 test genes. Cowpea polyphenolic extracts decreased PGE2 levels (8.2 ± 2.5 pg/ml) in LPS-stimulated PMNs, relative to control LPS-only treated PMNs (48.7 ± 4.1 pg/ml). Treatment with CPE resulted in decreased concentrations of six of the tested cytokines, except GM-CSF and IP10. Real-time qRT-PCR analysis of LPS-exposed PMNs revealed downregulation of proinflammatory cytokines (TNF-α, IL-1A, IL-1B, IL-8) and transcription factor NF-kB, and up-regulation of anti-inflammatory cytokine IL13(8.4-folds) by the cowpea phenolic extract. Thus cowpea polyphenolic extract may exert their anti-inflammatory activities and modulate innate immune response through modulation of the neutrophil under pathogen- induced conditions in cows. Therefore, integrating and utilizing cowpea into animal production system may enhance nutrition and improved health and needs further study.

Key Words: bovine, cowpea, cytokines, phenolic compounds, polymorphonuclear neutrophils, prostaglandin e2

0180 Prevalence of digital dermatitis in Canadian Holsteins classified as high, average, or low antibody and cell-mediated immune responders.

S. L. Cartwright*[1], F. Malchiodi[2], K. A. Thompson-Crispi[3], F. Miglior[4], and B. Mallard[5], *[1]University of Guelph, ON, Canada, [2]Centre of Genetic Improvement of Livestock, University of Guelph, ON, Canada, [3]Trouw Nutrition Agresearch, Guelph, ON, Canada, [4]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [5]Department of Animal Biosciences, Centre for Genetic Improvement of Livestock, University of Guelph, ON, Canada.*

Lameness is one of the major issues affecting production and animal welfare in the Canadian dairy industry, with digital dermatitis being the most common lesion. Studies have shown dairy cattle classified as high immune responders have lower incidence of disease, therefore it may be possible the immune response (IR) plays a role in preventing hoof lesions. The objective of this study was to compare the prevalence of digital dermatitis in Canadian dairy cattle that were classified for antibody (AMIR) and cell-mediated immune response (CMIR). Cattle (n = 341) from five commercial dairy farms in Ontario were evaluated for IR using a protocol that captures both AMIR and CMIR. They were classified as high, average and low responders based on standardized residuals for AMIR and CMIR. Residuals were calculated using a SAS general linear model that included the effects of herd, parity, stage of lactation and stage of pregnancy. Hoof health data was collected in 2012 by the farm's hoof trimmer using Hoof Supervisor software. Only the first trim date for each animal was included and multiple lesions per cow were considered. Trimmers scored each lesion for severity with 1 = least, 2 = moderate, 3 = most. Hoof health data was analyzed using a SAS general linear model which included the effects of herd, stage of lactation (at trim date), parity (at trim date) and IR category (high, average and low). Data is presented as prevalence within IR category. Preliminary results showed that high (17% of highs) AMIR cattle had a trend (P = 0.098) toward lower prevalence of digital dermatitis then average (28% of averages) AMIR cattle. It was observed that high (17% of highs) CMIR cattle had a trend (P = 0.081) toward lower prevalence of digital dermatitis compared with average (27% of averages) CMIR cattle and significantly (P = 0.04) lower digital dermatitis compared with low (30% of lows). Similarly high CMIR

cows also had significantly lower ($P = 0.03$) prevalence of the most severe type of digital dermatitis lesion compared with low CMIR cows. Since digital dermatitis is primarily caused by extracellular bacteria which is typically associated with AMIR these results still indicate that having a more robust or high IR is associated with lower prevalence of infectious hoof lesions. Therefore by breeding animals for high IR it is likely that improvements in hoof health can be made.

Key Words: digital dermatitis, immune response, dairy cattle

181 MiRNaseq of neutrophils during the transition period in cows with divergent metabolic phenotypes. M. A. Crookenden*[1], C. G. Walker[1], A. Heiser[2], J. J. Loor[3], K. M. Moyes[4], J. K. Kay[1], S. Meier[1], A. Murray[5], V. S. R. Dukkipati[5], M. D. Mitchell[6], and J. R. Roche[1], *[1]DairyNZ, Hamilton, New Zealand, [2]AgResearch, Palmerston North, New Zealand, [3]University of Illinois, Urbana, [4]Department of Animal and Avian Sciences, University of Maryland, College Park, [5]Massey University, Palmerston North, New Zealand, [6]University of Queensland, Australia.*

Several adaptations in leukocytes, i.e., neutrophils, are required for a successful transition to lactation in dairy cows. Micro RNA (miRNA) molecules are small non-coding RNAs that regulate gene expression; their importance in immune cell function has been well documented. We characterized the miRNA of neutrophils isolated from dairy cows divergent in their risk of infection or metabolic dysfunction, at three time points over the transition period: day of calving, 1 wk, and 4 wk post-calving. From a total of 150 cows, 10 cows were selected with high ($n = 5$; High Risk) and low ($n = 5$; Low Risk) concentrations of non-esterified fatty acids, β-hydroxybutyrate, and liver triacylglycerol during wk 1 and 2 post-calving. Neutrophils were isolated from whole blood using differential centrifugation. Flow cytometric analysis of these isolates revealed a median of 75% ± 2% neutrophils (± SEM). Total RNA was extracted from neutrophils using TRIzol®, size selected for miRNA, and sequenced on the Illumina HiSeq. The miRNA reads were mapped to the *Bos taurus* 6 genome (UMD 3.1) using Bowtie 2 and counted. Differential expression analysis was conducted using the limma/voom R-package and pairwise analyses were conducted to assess differential expression between risk categories and across time points, with a false discovery rate set at 0.05. There was no effect of risk category on miRNA expression on the day of calving or 4 wk post-calving. However, expression of mir-19b, mir-148a, and mir-21 in the Low Risk cows tended (adj $P = 0.1$) to be greater at 1 wk post-calving. When assessed for the effect of time relative to the day of calving, regardless of risk, expression of miR-150 and −486 increased ($P \leq 0.05$) at 1 wk post-calving and eight miRNA genes were differentially expressed at 4 wk post-calving ($P \leq 0.05$): miR-150 and −30c were greater, and miR-19b, −19a, −30d, −101–1, and −106b were lower. The results indicate that the divergent metabolic phenotype did not significantly alter miRNA in neutrophils during early lactation. However, the altered miRNA profile in neutrophils over time indicates an important role for miRNA in the regulation of immune cell function during the peripartum period.

Key Words: microRNA, dairy cows, transition

0182 Short chain nitrocompounds treatment of poultry excreta; in vitro survivability of *Salmonella*, *E. coli* and nitrogen metabolism. C. Arzola-Alvarez*[1], J. Corrales[1], O. Ruiz-Barrera[1], R. C. Anderson[2], M. E. Hume[2], Y. Castillo-Castillo[3], A. Corral-Luna[1], J. L. Guevara-Valdez[1], J. Salinas[4], and C. Rodriguez-Muela[1], *[1]Universidad Autonoma de Chihuahua, Mexico, [2]USDA-ARS, College Station, TX, [3]Universidad Autonoma de Ciudad Juarez, Chihuahua, Mexico, [4]Universidad Autonoma de Tamaulipas, Reynosa, Mexico.*

Poultry litter is a byproduct produced in large amounts by intensive poultry production systems. While it contains appreciable amounts of nitrogen as uric acid, which makes it an excellent crude protein feed supplement for ruminants, it is usually a carrier of enteropathogenic bacteria of importance to human health. The objectives of this study were to determine the bactericidal effectiveness of several nitrocompounds, assess their potential to produce a feedstuff that is environmentally safe and their potential as a sustainable technology to preserve the nitrogen contained in poultry litter. Twenty grams of 6-mo-old poultry litter (82.5 ± 1.1% dry matter) were distributed in 709-mL plastic containers, mixed with 7.5 mL of deionized water containing no added nitrocompound or 40 mM 2-nitroethanol, 2-nitro-1-propanol (2nitropropanol), nitroethane, 3-nitropropionic acid or ethylnitroacetate. Each container was then inoculated with approximately 2×10^4 CFU of a *Salmonella enterica* serovar Typhimurium (NVSL 951776), naturally resistant to 25 μg/mL novobiocin and made resistant to 20 μg/mL nalidixic acid, and incubated aerobically at 37°C for 24 h. Samples collected at 0, 6, and 24 h were enumerated for *Salmonella.* Generic *E. coli* were enumerated on 3M *E. coli*/coliform petrifilm in samples collected at 0 and 24 h. Samples were also analyzed spectrophotometrically for determination of uric acid. Data were analyzed for main effects of treatment, time of incubation and their potential interaction on temperature and pH as well as on microbiological concentrations by a repeated measures analysis of variance. Main effects of treatment ($P < 0.0001$; SEM = 0.159), time ($P < 0.0001$; SEM = 0.170) and their interaction ($P = 0.0001$; SEM = 0.417) were observed on *Salmonella* concentrations. *Salmonella* concentrations in samples treated with 44 mM 2nitroethanol, 2nitropropanol or ethylnitroacetate were decreased by 0.7 to 1.7 $\log_{10}$CFU/mL within the first 6 h of incubation. Main effects of treatment (P

= 0.0100; SEM = 0.108), time (P = 0.0020; SEM = 0.065) and their interaction (P = 0.0145; SEM = 0.160) were observed on generic *E. coli* concentrations. Main effects of treatment were observed on rates of ammonia accumulation and the residual uric acid concentrations. Urea concentrations were below the limit of detection which under conditions of use was 1 µmol/ml. Results indicate that these environmentally sustainable and safe nitrocompounds negatively impacted potential enteropathogens contained in poultry litter. Additionally, litter treated with these compounds maintained appreciable levels of nutritionally available nitrogen in the form of uric acid, enhancing the value of used poultry litter as a ruminant feed supplement.

Key Words: *E. coli*, poultry excreta, *Salmonella*, uric acid

0183 Effect of protected sodium butyrate on *Salmonella* spp. excretion in a pig fattening unit.

M. Puyalto*[1], C. Sol[1], J. J. Mallo[1], S. Andrés-Barranco[2], A. Casanova-Higes[2], and R. C. Mainar-Jaime[3], *[1]NOREL S.A., Madrid, Spain, [2]Unidad de Produccion y Sanidad Animal, Centro de Investigacion y Tecnologia Agroalimentaria de Aragon, Universidad de Zaragoza-CITA, Spain, [3]Departamento de Patología Animal, Facultad de Veterinaria, Instituto Agroalimentario de Aragón, Universidad de Zaragoza-CITA, Spain.*

This study was conducted to evaluate if the addition of protected sodium butyrate (SB) to a pig diet affected the level of *Salmonella* shedding in feces. The study was performed in a commercial *Salmonella*-infected fattening unit (8 pens, 110 pigs). Feed with 70% SB protected with vegetable fat (3 kg/t) was administrated to animals from 4 randomly selected pens during the fattening period (4 mo) (BUT). Pigs from the remaining 4 pens were fed the same diet without additive (CON). Individual serum and fecal samples were collected at 30, 60, and 90 d of fattening and at slaughter, where mesenteric lymph nodes (MLN) were also collected. Bacteriology on fecal and MLN samples were performed following the ISO 6579:2002 protocol. Serum samples were analyzed by means of an indirect ELISA using 3 cut-off values (OD% $\geq$ 10, $\geq$ 20 and $\geq$ 40). Chi-squared analyses were performed to compare microbiological and serological results between groups at different time periods, and a repeated measures analysis was used to estimate differences in mean OD% after taking into account sampling times and the interaction treatment × time. Although a lower proportion of positive animals in BUT was observed for samplings at 60d (4 vs. 0%), 90d (8 vs. 4%), and at slaughter (9.3 vs. 6.2%), no significant differences were detected, which was likely associated to the overall low prevalence of infection/shedding in both groups. In addition, the proportion of dead/withdrawn pigs in CON was significantly higher than in BUT (13.7 vs. 1.9%; P = 0.03). A higher (P < 0.05) seroprevalence was observed in CON compared with BUT for the sampling just before slaughter and for all cut-off values used (82.2 vs. 64.7%; 53.3 *vs*. 33.3% and 31.1 vs. 13.7%, at OD% $\geq$ 10, $\geq$ 20 and $\geq$ 40, respectively). Also, an overall significant positive relationship was observed between serology before slaughter (cut-off OD% $\geq$ 40) and shedding at slaughter (P < 0.01). The withdrawn of sick pigs in CON may have contributed to its low prevalence of infection/shedding, despite of which a higher seroprevalence was detected in this group at slaughter which, in general, appeared to be positively related to shedding. Thus, overall results suggested that the addition of protected SB at 3 kg/t may reduce the shedding of *Salmonella* spp. under farm conditions. The lowest number of pigs removed from pens in BUT also indicated an overall positive effect on health status of pigs in this group.

Key Words: *Salmonella*, protected butyrate, fattening pigs

0184 Study of genetic basis of immune response in gilts vaccinated with a modified live PRRS virus in a swine farm from southern Sonora Mexico.

P. Luna-Nevarez*[1], M. Pavlovich-Sotomayor[1], R. I. Luna-Ramirez[1], C. M. Aguilar-Trejo[1], G. Luna-Nevarez[1], X. Zeng[2], S. E. Speidel[2], R. M. Enns[2], and M. G. Thomas[2], *[1]Instituto Tecnologico de Sonora, Ciudad Obregon Sonora, Mexico, [2]Department of Animal Sciences, Colorado State University, Fort Collins.*

Porcine respiratory and reproductive syndrome (PRRS) is a disease of high negative impact on Mexican porcine production; one of the main reasons is the highly-variable response to vaccination. The objective of this study was to validate the favorable relationship among genotypes and immune response after PRRS vaccination for SNP previously associated with serum antibody response (SAR) and rectal temperature (RT). This study included 6-mo-old 3/4-Landrace × 1/4-Yorkshire replacement gilts (n = 100). After a 7-d acclimation period, all gilts were vaccinated with a modified live PRRS virus (d 0). The antibody response was measured from blood serum samples collected the d 7, 21, and 35 after vaccination using a commercial antibody ELISA kit (IDEXX Laboratories, Inc.). Rectal temperature data were collected the d 7, 14, 21, 28, and 35 using a digital GLA M750 thermometer (GLA Agricultural Electronics). A blood sample was also collected from each gilt approximately 40 d after vaccination and spotted onto FTA cards. All cards were processed for genomic analyses using a low-density chip to obtain genotypes from 8826 SNP (Infinium BeadChip, Illumina, San Diego, CA). In a previous analysis of these data, multi-locus mixed models performed in SNP Variation Suite 7 identified nineteen SNP associated with immune response (P < 0.001). The associative relationship between these SNP and the phenotypes SAR and RT was validated using a mixed effects model; this model included SNP genotype and age of

dam as fixed effects, and sire as a random. Allele substitution effect was also calculated using a regression model that included genotype term as a covariate. Mean S/P values for SAR were 2.26 ± 0.08 and mean values for RT were 39.0 ± 0.05°C. From the SNP previously identified, ASGA0019937, ALGA0025501 and H3GA0020133 were associated with SAR after PRRS vaccination ($P < 0.01$), and the favorable alleles increased S/P levels in 0.21 ± 0.06, 0.19 ± 0.07 and 0.46 ± 0.10, respectively. However, only ALGA0017541 was associated to RT ($P < 0.01$), and the favorable allele reduced 0.21 ± 0.01°C the rectal temperature. In conclusion, four specific genetic markers that underlie genetic variation in response of gilts to PRRS vaccination were validated using a SNP genotype to phenotype association analysis. We propose such SNP as candidates for use in a marker assisted selection program that further evaluates the immune response to PRRS vaccination in gilts of southern Sonora production systems.

Key Words: gilts, immune response, PRRS vaccination.

UNDERSTANDING INFLAMMATION AND INFLAMMATORY BIOMARKERS TO IMPROVE ANIMAL PERFORMANCE

0185 Overview of the inflammatory response and its nutritional costs.

K. C. Klasing*, *University of California, Davis.*

Innate immune cells respond quickly to a potential pathogen due to the presence of a common set of receptors on all phagocytic cells that recognize broad categories of pathogens. Thus, a very large number of cells can recognize invading microbes and respond to them quickly. A consequence of this is pathogen clearance, usually by phagocytosis, followed by the release of inflammatory cytokines and chemokines that amplify the local infiltration of additional inflammatory cells and activate them. If the challenge is large or if it is accompanied by damage to host tissue, cytokines are released in sufficient amounts that they have endocrine-like effects throughout the body. This cytokine storm induces metabolic changes, including increased protein degradation and insulin resistance in skeletal muscle, which diverts nutrients from muscle and other tissues so that they become available for the increased demands of leukocytes and for the production of protective proteins. Importantly the liver transitions from maintaining homeostasis and supporting the nutritional demands of growth or reproduction to the production of protective proteins such as complement, mannan binding protein, and C-reactive protein that aid in the detection and neutralization of pathogens. This transition is accompanied by hepatic hypertrophy. A study of the costs of a systemic inflammatory response in chickens to *Salmonella* that examined the amount of nutrients in 6 different leukocyte types in 5 different tissues (blood, spleen, bursa, thymus, bone marrow) and 12 protective proteins (acute phase proteins and immunoglobulins) found that the amount of essential amino acids in the protective proteins greatly exceed that in the cellular component of the immune system during both a normal and an inflammatory state. The ideal balance of amino acids for the acute phase of an inflammatory response differs greatly from that needed for growth and there is a critical need for additional cysteine and threonine. Ongoing research indicates that higher metabolic rate, decreased intake of food, a mismatch between the nutrient balance needed for the inflammatory response relative to that in body tissues and less efficient digestion that accompany a robust inflammatory response are, together, even more costly than the direct use of nutrients by inflammatory cells and the liver. Together, these costs result in decreased productivity that cannot be completely reversed by supplying additional nutrients.

Key Words: inflammation, cytokines, nutrients

0186 Ruminal microbes, microbial products, and systemic inflammation.

T. G. Nagaraja*, *Kansas State University, Manhattan.*

The ruminal ecosystem is inhabited by complex communities of microbes that include bacteria, archaea, protozoa, fungi and viruses. The immune system of the animal has evolved to maintain tolerance to innocuous gut commensals and induce protective responses to pathogens. Besides fermentative role, ruminal microbes do have the potential to influence the overall health of the host because of their ability to induce systemic inflammation. The ruminal epithelium-vascular interphase allows absorption of fermentation products and also serves as a selective barrier to prevent translocation and systemic dissemination of bacteria, bacterial toxins, and immunogenic factors. Ruminal dysbiosis that increases ruminal acidity and osmolarity may increase permeability and even induce a breach in the integrity of the epithelial and vascular endothelial barriers, thus facilitating entry of bacteria or bacterial antigens into the portal vein. A classic example is the delivery of ruminal bacterium, *Fusobacterium necrophorum,* into the liver to cause abscesses, which is facilitated by ruminal damage induced by excessive accumulation of lactic acid or VFA. Bacteria that manage to exit or bypass the liver can cause systemic inflammation in other organs, such as lungs, heart, joints, hoof, etc. Shifts in microbial populations associated with dysbiosis result in increased concentrations of potentially toxic and inflammatory substances, which include endotoxic lipopolysaccharide (LPS), biogenic amines, ethanol, etc. A bacterial product that has received a lot of interest is LPS, a component of all Gram negative bacteria. The entry of LPS into the systemic circulation, either from the rumen or the lower gut, could trigger release of proinflammatory cytokines, reactive oxygen and nitrogen intermediates, and bioactive lipids. The inflammatory response to the presence of ruminal LPS in the blood is evidenced by increase in acute phase proteins, such as haptoglobin and LPS binding protein.

Biogenic amines generated in the rumen that could lead to inflammation include histamine, tyramine, and ethanolamine. Histamine that is absorbed from the rumen or produced endogenously in tissues during inflammation plays a key role in the development of laminitis. Ethanolamine derived from bacterial phospholipids has the potential to enhance growth and virulence of certain gut pathogens. In conclusion, ruminal microbes and their products generate many complex interactions with the host immune system, and dysbiosis has the potential to induce systemic inflammation. Although inflammation is a protective reaction, the persistence of inflammatory mediators could have negative consequences for the host.

Key Words: ruminal microbes, dysbiosis, inflammation

0187 Usefulness (or not) of inflammatory biomarkers: The good, the bad, and ugly. C. Chase*, *South Dakota State University, Brookings.*

The innate immune system has the job of sensing the host's environment–looking for infections and tissue damage. It then does its second job, which is to recruit in the "right" cells to handle the problem. There is ample evidence that both physical and psychological distress can induce innate immune system pro- and anti-inflammatory cytokines that can cause immune dysfunction in animals, leading to an increased incidence of infectious disease. In livestock, there are several factors that will compromise immune function. There is the stress of transportation, dehydration, feed change (with the resulting negative energy balance), acidosis, and associated microbial changes in the gut. Overstimulation of the innate immune system can result in a pro-inflammatory cytokine storm, which will increase tissue damage. Both pro-inflammatory cytokines [such as tumor necrosis factor-α (TNF-α), interleukin-1, and interleukin-6] and anti-inflammatory cytokines (such as interleukin 10, transforming growth factor β and interleukin 1 receptor antagonist) can be elevated in the serum of animals experiencing a cytokine storm. These in addition to acute phase proteins are often monitored to "measure inflammation". An overview of "inflammation" and an experimental approach in cattle to study these local interactions will be discussed along with the proof of concept immunological measurements.

Key Words: innate immunity, inflammation, pro-inflammatory, anti-inflammatory

0188 Nutritional and management considerations in beef cattle experiencing stress-induced inflammation. R. F. Cooke*, *Oregon State University-EOARC, Burns.*

When transported to feedlots, beef cattle are exposed to several stressors within a short period of time that directly impact their performance and welfare. The main stressors associated with this "feedlot transfer phase" (FTP)—weaning, road transport, and feedlot entry—increased ($P < 0.05$) plasma concentrations of cortisol, pro-inflammatory cytokines, and acute-phase proteins (APP), while the magnitude of this response was negatively correlated ($r = -0.50$, $P < 0.01$) with feedlot receiving ADG and DMI. Further, feed and water deprivation elicited ($P < 0.01$) an APP response and reduced ($P < 0.03$) receiving performance similarly as in cattle transported for long distances. Hence, strategies to alleviate the APP response elicited during the FTP were evaluated: (1) Steers were assigned to continuous road transport for 1300 km (TRANS), or road transport for 1300 km with rest stops every 430 km (STOP). During feedlot receiving, ADG and G:F were similar ($P > 0.68$) between TRANS and STOP. Plasma concentrations of APP were greater ($P \leq 0.04$) in TRANS compared with STOP on d 1 of receiving. (2) Steers transported for 1300 km received (SUP) or not (CON) Ca soaps of soybean oil during a 28-d preconditioning. Upon transport, plasma TNF-α increased for CON but decreased for SUP steers ($P < 0.01$). Steers assigned to SUP had greater ($P = 0.02$) ADG compared with CON steers during the receiving phase. Upon slaughter, carcass yield grade and marbling were greater ($P < 0.05$) for SUP compared with CON. A subsequent trial evaluated the inclusion of camelina meal in similar research design. During feedlot receiving, SUP steers had reduced ($P < 0.01$) plasma APP concentrations and tended ($P = 0.10$) to have greater G:F compared with CON. 3) Steers were transported for 1300 km and administered flunixin meglumine (1.1 mg/kg BW) at truck loading and unloading, or meloxicam (1 mg/kg of BW) at loading and during the initial 7 d of feedlot receiving. Both anti-inflammatory drugs reduced ($P < 0.05$) the APP response elicited during the FTP compared with non-treated cohorts, but only meloxicam increased ($P < 0.04$) receiving ADG and G:F. In summary, inclusion of rest-stops during transport, preconditioning PUFA supplementation, and use of anti-inflammatory drugs are alternatives to alleviate the APP response elicited during the FTP, whereas PUFA and meloxicam administration enhanced feedlot performance of feeder cattle.

Key Words: beef cattle, inflammation, management, nutrition

CELL BIOLOGY SYMPOSIUM: MEMBRANE TRAFFICKING AND SIGNAL TRANSDUCTION

0189 Introduction: What is the relevance of this topic? J. L. Klotz*, *USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY.*

Knowledge of membrane dynamics and receptor-ligand related responses are critical to a complete understanding of many of the tissue-level and whole animal level observations made in physiologic, pharmaceutical and toxicological research. The outcome of this basic research can have significant implications in animal agriculture in terms of impact

of disease states, toxin exposure, and use of pharmaceutical and natural products on various aspects of animal production. Can studies that further the understanding of the membrane trafficking and cell signaling relationship be applied to solve problems relevant to livestock production? How do disease states alter the trafficking-signaling interconnection? To answer these questions, the objective of this symposium is to address protein and lipid aspects of transport within a membrane, how functions may change as a result of a pathological state, and how this basic science can be used to further the needs of livestock at the production level.

Key Words: cell signaling, livestock production, membrane trafficking

---

0190 SNAREs in exocytosis and membrane trafficking.
S. W. Whiteheart*, *University of Kentucky, Lexington.*

In 1993, Rothman and colleagues sought to explain the specificity of membrane trafficking between cellular compartments by proposing the SNARE hypothesis. Since that time, we have gained significant insights into the conserved mechanisms that control membrane fusion in all eukaryotes. Integral membrane proteins called SNAREs (Soluble NSF Attachment protein Receptors) mediate the membrane fusion that is required to move cargo from one cellular compartment to another. In general, SNAREs on cargo-carrying vesicles are known as v-SNAREs (also called R-SNAREs due to conserved arginines) and those on the destination or target membranes are called t-SNAREs (also called Q-SNAREs due to conserved glutamines). There are large families of both v- and t-SNAREs, all of which contain at least one amphipathic, helical domain that forms a four helical bundle with other SNAREs. This heteromeric complex spans the two membranes to promote lipid mixing for membrane fusion and cargo transfer. Though the significance of their diversity is unclear, certain SNARE combinations (v and t) are optimal for the fusion steps required for specific membrane trafficking steps. For extracellular secretion (exocytosis), t-SNAREs are a heterodimer of syntaxins and SNAP-23/35s. Despite being the minimal components required for fusion, in order for SNAREs to mediate physiologically significant processes, they must be controlled by regulators and post-translational modifications. The regulators affect, where, when, and how fast membrane fusion occurs. Most of the regulators affect the t-SNAREs. Syntaxins are controlled by chaperones of the Sec1/Munc18 (SM) family, which not only stabilize the syntaxins but also guide their binding to other SNAREs. SNARE-23/25s are dynamically anchored in the membranes via thioester-linked acyl groups. SNAP-23 also appears to be acutely controlled by phosphorylation. Regulation of the v-SNAREs appears less wide-spread. Several SNARE accessory proteins have C2 domains that enable calcium-dependent, membrane binding to acidic lipids. Syntaptotagmins are membrane proteins on vesicles thought to be key, calcium sensors that, together with complexins, control the final steps of membrane fusion. Other C2 domain-containing proteins, *e.g.,* Munc13 family members, are docking factors that bring the two membranes together to engage the SNAREs for subsequent vesicle-target membrane fusion. The Munc13 proteins work with small GTP-binding proteins, called Rabs, to promote docking. Together the SNAREs and SNARE regulators mediate the highly controlled membrane fusion events that underlie many diverse processes such as neurotransmission, hormonal regulation, and hemostasis.

Key Words: Munc, secretion, SNAREs

0191 Signaling endosomes and epithelial morphogenesis.
C. D'Souza-Schorey*, *University of Notre Dame, Notre Dame, IN.*

Tumor development in glandular tissues is associated with structural alterations in the hollow ducts and spherical structures that comprise such tissues. We have described a signaling axis that provokes dramatic changes in the organization of epithelial cysts, reminiscent of tumorigenic glandular phenotypes. In reconstituted basement membrane cultures of renal epithelial cysts, enhanced activation ARF6 (ADP-ribosylation factor 6) downstream of receptor tyrosine kinases induces the formation of cell-filled glandular structures with aberrant phenotypes. All of these alterations are accompanied by growth factor receptor internalization into signaling endosomes and reversed by blocking ARF6 activation or receptor endocytosis. Receptor localization in signaling endosomes results in hyperactive extracellular signal-regulated kinase signaling leading to abnormal cellular alterations. These findings identify a link between ARF6-regulated receptor internalization and events that drive dramatic alterations in epithelial glandular morphogenesis providing new mechanistic insight into the molecular processes that can promote epithelial glandular disruption.

Key Words: ARF6, epithelial morphogenesis, signaling endosomes

---

0192 Structural and signaling functions of sphingomyelinases during inflammation.
M. N. Nikolova-Karakashian*, *University of Kentucky, Lexington.*

Sphingolipids are lipid molecules with structural, signaling, and metabolic functions. Sphingomyelinases (SMases) convert sphingomyelin, a mostly structural lipid, to ceramide, a bioactive metabolite. Two of the five known SMases play distinct roles in inflammation. Neutral sphingomyelinase-2 (nSMase-2) is a plasma membrane-localized enzyme and mediates the hepatocyte response to IL-1b. Our experiments have identified PP2A, IRAK1, JNK, FoxO1, and the insulin-like growth factor binding protein 1 (IGFBP1) as components of a novel pathway in the IL-1b signaling network that are dependent on nSMase-2. Surprisingly, we also found that

conditions associated with chronic, subclinical inflammation (like oxidative stress, hepatic steatosis, and aging), affect the basal activity of nSMase2, causing up-regulation of that specific pathway and IL-1b hyperresponse. Experiments in mice and rats also show that silencing of nSMase-2 in hepatocytes can be achieved in vivo and can help alleviate an exacerbated IL-1b response.

Acid sphingomyelinase (ASMase) is localized in the endo-lysosomal compartment of the cells and impacts the dynamics of lipid raft domains and endosomes. These effects are especially important for the functions of macrophages during the innate immune response. In activated macrophages, ASMase activity modulates the magnitude of LPS-induced secretion of TNFa. The mechanism is complex and involves the regulation of: (1) the activity of TACE, an enzyme that cleaves the inactive TNFa precursor (pro-TNFa) to its active form and (2) the rate of recycling of pro-TNFa between lysosomes and the plasma membrane. Together, these experiments delineate a novel understanding of the bioactive functions of SMases in chronic and acute inflammation.

Key Words: inflammation, liver, macrophage

0193 Practical application of the basic aspects of membrane trafficking and receptor-mediated signaling on issues related to animal agriculture.
S. B. Smith*, *Texas A&M University, College Station.*

Because of the relatively short life spans of beef cattle, membrane trafficking in relation to inflammation is not considered important unless it overtly affects productivity. However, glucose uptake and utilization is important for adipose tissue development in beef cattle, and increasing glucose utilization in intramuscular adipose tissue can increase carcass quality. Research from the 1980s demonstrated a lack of insulin sensitivity in isolated bovine adipocytes and adipose tissue explants incubated in vitro. Insulin did not stimulate glucose or acetate incorporation into fatty acids, nor did it increase concentrations of glycolytic intermediates in bovine adipose tissue incubated with exogenous glucose. Specific binding of [I125] iodoinsulin and insulin degradation in bovine isolated adipocytes was low to non-detectable. These early studies indicated that insulin-dependent receptor-mediated signaling was less important in bovine adipose tissue than in adipose tissues of humans or laboratory species. Recent research demonstrated that GLUT4 expression in muscle and adipose tissue declined markedly after birth in calves, indicating the development of insulin resistance as cattle transitioned from suckling to functional ruminants. Insulin resistance is important in dairy cattle, and causes ketosis and fatty liver. In dairy cattle, s.c. adipose tissue GLUT4 expression decreased 50% following parturition, although insulin responsiveness in s.c. adipose tissue was restored as early as 3 wk postpartum. Expression of genes associated with insulin responsiveness (*IRS1*, *INSIG2*, *SREBF1*, and *ZFP423*) was upregulated in similar fashion. Understanding the underlying mechanisms of insulin resistance and inflammation would increase animal health and thereby improve productivity.

Key Words: adipose tissue, bovine, insulin

ASAS GRADUATE STUDENT SYMPOSIUM

0194 Marketing 101: Learning how to market yourself for a successful career.
R. M. Yamka*, *Blue Buffalo Company Ltd., Wilton, CT.*

The animal science industry can be a competitive marketplace as new graduates begin to look for a new job. Having good grades, the right skill set (laboratory experience, publication experience, good grades, etc.) and work experience (collecting samples, computer experience, working with animals, etc.) is not always enough to secure employment. Especially in a competitive job market. As a result, identifying ways to stand out from the crowd becomes important. Unfortunately, most job candidates do not realize that it is important to learn how to market and sell yourself to your target audience to meet their current and future business goals. How you market and sell yourself will be career and industry dependent (academia vs. consumer goods vs. pharma). Marketing and selling yourself does not end once you get your foot in the door. Marketing and selling yourself continues as you advance in your career. Although it is not as formal as the interview, marketing yourself requires you to network, communicate and engage management inside & outside your department. In addition, looking for new opportunities to build your credentials (board certification, become the "go to" person) and identifying ways to be unique will help set you apart and differentiate you from your peers. In this session, some of these key strategies will be discussed and how they can be applied for a successful career.

Key Words: marketing yourself, target audience, successful career, professional development

---

0195 Personal branding.
M. Calvo-Lorenzo*, *Elanco Animal Health, Greenfield, IN.*

Who you are and how you carry yourself are very important to becoming successful. As a student and professional, your personal brand keeps you current in your own field, opens doors of opportunities for you, and creates a lasting impression. While making an unforgettable first impression in person is important, it is no longer the only way to establish your brand. Personal branding should help individuals define themselves in their workspace, while also incorporating the personal elements that make you who you are. In this session, several strategies will be discussed on creating a successful personal brand, while providing an overview on how to articulate one's

skills, experience, knowledge, and overall aspirations. The world wants to hear what professionals and experts have to say, and given the real-time connectivity of online social media today, learning how to create a powerful personal brand couldn't be more important.

Key Words: personal brand, success, professional development

0196 Bridging the gaps. J. D. Crosswhite*, *North Dakota State University, Fargo.*

The animal science community is constantly changing to meet the needs of the consumer. The same is true for animal science departments striving to meet the three pronged goals of land grant universities. The landscape of research in animal science is always evolving as our knowledge of basic science expands. The competitiveness of research funding is higher than ever, and this puts increased pressure on the researchers vying for these funds. In addition to this, the generation gap between the average consumer and production agriculture is increasing, making extension education as important as ever. These challenges are making split appointment positions within academia harder to accomplish, as the education of students taking animal science classes is still a major focus. This environment has opened up the opportunity for individuals with a completed master's degree to become instructors. Having a 100% teaching appointment allows these lecturers the unique opportunity to focus all of their attention on bridging the gap between a research mindset and production animal science within the classroom. Thus, opening up time and opportunity for research and extension faculty.

Key Words: lecturer, classroom, teaching

0197 Doctoral programs in animal science: Strategies for targeting academic careers. J. S. Caton*, *Department of Animal Sciences, North Dakota State University, Fargo.*

Objectives of this review are to discuss successful doctoral student professional development strategies for targeting academic positions in the animal sciences and related fields. Entry level positions for academic careers are most often 2-way split appointments containing proportions of research, teaching, and extension responsibilities. Occasionally, institutions will offer 1- or 3-way split appointments. Positions will usually range from 9 to 12 mo appointments on a tenure-track, though variations exist. Successfully targeting these types of career positions requires deliberate planning and action by the doctoral student and mentoring team. Carefully selecting an advisor, institution, doctoral training committee, and other mentoring and training structures are essential early components in the process. Research experiences need to contain both discovery and application based aspects, present opportunities for leadership and collaborative team efforts, be solid in experimental design and methodologies, demonstrate focus in targeted areas, and breadth across species, mechanisms, methods, and systems. Data should be published in multiple venues, including refereed manuscripts. Mentoring and training in teaching at the university level needs to be real and relevant. Experience in formal and informal aspects of teaching are needed and should be supported with both student and peer teaching evaluations when possible. Mentoring in extension needs to include significant clientele contact, evidence of proficiency with a breadth of communication techniques, and clear goals and assessments. Effective training in perusing and securing grant funds to support research, teaching, and extension activities should be evident. Leadership, collaborative skills, and professionalism should be developed and effectively demonstrated. Evidence of effectively managing research teams, mentoring undergraduate students, and overseeing undergraduate research projects helps demonstrate preparedness for the transition from doctoral student to assistant professor. Strategically targeting and successfully accomplishing specific professional development activities within research, teaching, and extension will foster excellence and help secure effective and successful academic careers in animal sciences and related fields.

Key Words: academic careers, doctoral programs, professional development strategies

ASAS UNDERGRADUATE STUDENT POSTER COMPETITION

0198 Antimicrobial activity of tropical spice extracts against *Escherichia coli* O157:H7. E. Olasoji[*1], I. M. Ogunade[2], D. Kim[2], and A. T. Adesogan[2], *[1]Department of Food Science, University of Florida, Gainesville, [2]Department of Animal Sciences, IFAS, University of Florida, Gainesville.*

This study examined the antibacterial effects of spices (Alligator Pepper, Yellow Nutmeg, Tumeric, Green Pepper, Nutmeg, Ginger, African Guinea Pepper, Bayleaf, and Rosemary) on *Escherichia coli* O157:H7 (EC). Stock solutions containing 0.2 g of each spice per mL of ethanolic extract were prepared. The antimicrobial activity of each extract was examined using the agar disc diffusion method. Approximately 100 μL of EC culture was surface-plated on MacConkey agar supplemented with cefixime and tellurite. An aliquot (10 μl) of each spice extract was pipetted onto a 6.2-mm sterile paper disc on the agar surface and incubated for 24 h at 35°C. The inhibition zones around the discs were measured in millimeters. The Minimum Inhibition Concentration (MIC) of each of the spice extracts was determined by macrobroth dilution method. The experiment was repeated twice. Results were analyzed using the GLIMMIX procedure of SAS. The inhibition zones

observed for Green Pepper (19.33mm), Alligator Pepper (18.67mm), Rosemary (18.83mm), Tumeric (15.33mm), Nutmeg (16.50mm), African Guinea Pepper (16.67mm), Bayleaf (15.50) and Ginger (15.67mm) were greater ($P = 0.0001$) than that of the Control (11.67mm). African Guinea Pepper had the lowest MIC (2 mg/mL) while others inhibited EC at MIC less than 16 mg/mL. In conclusion, extracts of these tropical spices showed antimicrobial activity against EC.

Key Words: *Escherichia coli* O157:H7, inhibition zone, spices

0199 Effect of low- and high-fat dry distillers grains supplementation on forage intake and digestibility in beef heifers. E. L. Stephenson*[1], A. L. Jones[2], J. S. Luther[1], and A. E. Radunz[1], *[1]University of Wisconsin, River Falls, [2]University of Wisconsin, Madison.*

The objective of this study was to evaluate low-medium quality intake and apparent total tract digestibility supplemented with of low-fat vs. high-fat corn dried distillers grains with solubles (DG) in yearling Angus, Hereford, and Angus-cross beef heifers ($n = 30$; 399 ± 16 kg). Heifers were stratified by BW and breed composition and then assigned to 1 of 3 treatments: (1) no supplementation (CON); (2) supplementation of low-fat DG (LDG; 5.04% EE); (3) supplementation of high-fat DG (HDG; 9.09% EE). Heifers were provided ad libitum intake of low to medium quality chopped grass hay (7.82% CP; 1.14 Mcal NE_m/kg). Both LDG and HDG were supplemented at 0.8% body weight (BW) to provide a similar CP intake of 0.22% of BW. Hay was fed twice a d at 0800 and 1600 and supplement was fed once a d before hay feeding at 0700. Individual feed intake was recorded for 37 d. Two-day BW were collected at the beginning and end of the trial. To determine apparent total tract digestibility feed-offered, feed refusals, and fecal grab samples were collected on d 27 from a subset of 3 heifers per treatment and then DM, OM, CP, ADF, NDF, and EE analysis was performed and ADIN was used an indigestible marker. Heifers supplemented with DG (LDG or HDG) had greater BW gain and ADG ($P < 0.0001$) and lower ($P = 0.002$) total DMI in g/kg of BW compared with CON, however no differences were detected ($P \geq 0.14$) in BW gain, ADG, or total DMI in g/kg of BW between HDG and LDG. Furthermore, a change in BCS was not detected ($P = 0.46$) among treatments. Heifers that were supplemented LDG had lower DM, N, and NDF apparent digestibility than heifers supplemented HDG and heifers with no supplementation ($P \leq 0.004$). Apparent digestibility of OM and ADF did not differ among treatments ($P \geq 0.05$) while heifers supplemented LDG had lower apparent digestibility of EE ($P = 0.001$) and HDG supplementation was intermediate as compared with CON. Supplementation of DG regardless of fat content reduced total DMI and improved BW gain for yearling beef heifers, but supplementing the LDG vs. HDG resulted in lower DM, N, and NDF digestibility fed with low to medium quality grass hay.

Key Words: corn distillers grains, protein supplementation, forage digestibility

0200 Nutritive and digestibility parameters of invasive grasses in northwest Missouri. F. C. Huneke*, M. H. Richardson, A. M. Snyder, and J. D. Allen, *Northwest Missouri State University, Maryville.*

The purpose of this study was to determine nutritive and digestibility parameters of invasive grasses located in improved pastures in northwest Missouri. Samples from 18 grass species were gathered at reproductive maturity in 3 of 6 grazing pastures located at the R. T. Wright farm of Northwest Missouri State University (3 samples/species). Grasses were dried, ground, and subsequently subjected to the following laboratory analyses: NDF, ADF, and ash. Samples were also analyzed for 12-, 24-, and 48-h in situ digestibility using 2 cannulated Holstein dairy cows fed a consistent corn silage based diet. Dry matter was relatively similar (range 23.2 to 33.8 ± 4.78%DM) across species except for Stinkgrass (*Eragrostis cilianensis*; 41.7% DM) and Prairie cordgrass (*Spartina spectinata*; 45.3% DM; $p < 0.01$). Prairie cordgrass also had the greatest ($p < 0.01$) NDF and ADF (64.3 and 30.8%, respectively) when compared with the other species (range 49.1 to 60.7 ± 2.17% NDF and 22.6 to 30.8 ± 1.51% ADF). Ash content also varied (range 7 to 13.1 ± 1.48%; $p < 0.05$). Twelve hour in situ digestion was similar across species ($p > 0.10$), however, species diverged in 24- and 48-h digestion (range 42.2 to 65.4 ± 3.41% and 52.9 to 73.7 ± 3.70%, respectively, $p < 0.01$). In situ digestion developed 3 distinct digestion groups among the species, with Little barley (*Hordueum pusillum*), Foxtail barley (*Hordeum jubatum*), and Prairie cordgrass being the least ($p < 0.01$) digestible over a 48-h period (58.9, 56.4, and 52.9%, respectively). Results indicate that nutritive quality of invasive grasses varies by species, which may disrupt overall forage quality.

Key Words: cattle, digestibilty, invasive species, nutrient composition

---

0201 Poor maternal nutrition during gestation alters mesenchymal stem cell (MSC) metabolism in offspring. N. H. Sereda*[1], S. M. Pillai[1], M. L. Hoffman[1], S. A. Zinn[1], Y. K. Park[2], J. Y. Lee[2], and K. E. Govoni[1], *[1]Department of Animal Science, University of Connecticut, Storrs, [2]Department of Nutritional Sciences, University of Connecticut, Storrs.*

Poor maternal nutrition due to excess or reduced nutrient intake during gestation has negative effects on fetal growth and metabolism including reduced bone and muscle, and increased adipose tissue. There is evidence that poor maternal

diet during gestation impairs the function of MSC, stem cells that contribute to bone, muscle, and adipose development, in the offspring. It was hypothesized that poor maternal nutrition during gestation would negatively alter MSC metabolism in offspring. Eighteen pregnant ewes were individually housed and randomly assigned to one of three diets (100%, 60%, or 140% of NRC requirements for TDN) at d 31 ± 1.3 of gestation. One lamb per ewe was euthanized within 24 h of birth (100% = CON, 60% = RES, 140% = OVER; n = 6/treatment) and MSC were isolated from the bone marrow of left tibia and femur. For analysis of glycolytic and mitochondrial functions, cells were plated at 30,000 cells/well and incubated at 37°C for 48 h. Assays were performed using Glycolysis Stress and Cell Mito Stress Test Kits and analyzed using the Seahorse XF^{e}24 Extracellular Flux Analyzer. Data were normalized for total cellular DNA and analyzed using PROC MIXED in SAS. Basal respiration was reduced in RES and OVER, compared with CON (127.4 ± 7.48, 90.17 ± 9.75, 87.51 ± 8.48 ρmol O_2^{-1}·min^{-1}·μg; CON, RES, OVER, respectively; $P \leq 0.008$). Compared with CON, RES and OVER had reduced ATP production (121.09 ± 6.08, 84.86 ± 11.05, 77.7 ± 6.44 ρmol O_2^{-1}·min^{-1}·μg; CON, RES, OVER, respectively; $P \leq 0.006$) and reduced maximal respiration (149.29 ± 17.05, 90.64 ± 23.81, 67.93 ± 10.15 ρmol O_2^{-1}·min^{-1}·μg; CON, RES, OVER, respectively; $P \leq 0.03$). Spare respiratory capacity was reduced in OVER compared with CON (P = 0.02) while RES were intermediate (21.9 ± 10.8, 0.47 ± 12.3, and −19.56 ± 9.24 ρmol O_2^{-1}·min^{-1}·μg; CON, RES, OVER, respectively; $P \leq$ 0.25). There were no significant differences between groups for proton leak, non-mito-derived OCR, coupling efficiency, MSC glycolysis, glycolytic reserve, non-glucose-derived extracellular acidification rate, and glycolytic reserve capacity ($P \geq 0.18$). In conclusion, maternal over- and under-nutrition during gestation reduced the basal metabolic state of offspring MSC, and the ability of these cells to up-regulate ATP production during energetic deficits. The altered MSC metabolism may contribute to impaired muscle, bone, and adipose growth and maintenance in offspring.

Key Words: mesenchymal stem cells, metabolism, nutrition

0202 The abundance of myosin heavy chain Ilb mRNA in porcine Longissimus dorsi muscle was not affected by dietary lysine level.

M. B. Lewis*[1], S. F. Liao[2], T. Wang[2], and J. M. Feugang[1], *[1]Mississippi State University, Starkville, [2]Mississippi State University, Starkville.*

Successful swine production is about raising leaner pigs, because the lean meat (i.e., the skeletal muscle) is the most desired component of pork. Myosin, the most abundant contractile protein, constitutes approximately 45% of the total myofibrillar proteins, among which myosin heavy chain IIb (MyHC-IIb) isoform appears to be the determining protein contributing to pig muscle growth. This study was conducted to determine how dietary lysine level affects the expression of MyHC-IIb mRNA in pig skeletal muscle, as lysine is the first limiting amino acid in typical swine diets. Nine crossbred barrows (94.4 ± 6.7 kg) were randomly assigned to one of three groups fed either Diet 1 (lysine-deficient), 2 (lysine-adequate), or 3 (lysine-excess), which contained 0.43, 0.71, or 0.98% total lysine, respectively. After 5 wk on the trial, pigs were slaughtered, and approximately 2 g muscle sample was collected from the middle portion of *Longissimus dorsi* of each pig. Real-time RT-PCR technology was employed to determine the abundance of MyHC-IIb mRNA in each sample using the ΔΔCT quantitative method. Results showed that there was no difference ($0.42 < P < 0.90$) in the MyHC-IIb mRNA abundance between the pigs fed Diet 1 and Diet 2, as well as between the pigs fed Diet 3 and Diet 2. These results suggest that changing dietary lysine level to either below or above the adequate requirement level did not affect the abundance of MyHC-IIb mRNA in Longissimus dorsi of finishing pigs. Since our previous study using these pigs showed that the loin eye areas of the pigs fed Diets 2 and 3 were increased by 18 and 9% when compared with Diet 1, respectively, we further hypothesized that the level of dietary lysine has a significant effect on the abundance of MyHC-IIb protein in the Longissimus dorsi of finishing pigs. Therefore, our next study will be conducted to quantify the MyHC-IIb protein in these Longissimus dorsi samples.

Key Words: myosin heavy chain Ilb, lysine, pig

0203 Identification of loci on chromosome 3 associated with susceptibility to bovine paratuberculosis using genotypes imputed to whole genome sequence in Holstein cows.

C. F. Pierce*[1], J. N. Kiser[1], J. L. Hoff[2], M. Neupane[3], S. N. White[4], J. F. Taylor[2], H. L. Neibergs[3], *[1]Department of Animal Science, Washington State University, Pullman, [2]University of Missouri, Columbia, [3]Department of Animal Sciences, Washington State University, Pullman, [4]USDA-ARS, Animal Disease Research Unit, Pullman, WA.*

Bovine paratuberculosis or Johne's disease (JD) is an infectious disease of ruminants caused by Mycobacterium avium paratuberculosis (Map) infection. JD continues to increase in prevalence in dairy cattle resulting in loss of profitability and increased animal suffering and death. Several studies have been conducted to identify loci associated with susceptibility to JD with the goal of using selection to reduce the prevalence of the disease. One study with 219 Holstein cows identified a locus on chromosome 3 (BTA3) associated with risk of JD. The objective of this study was to test the association with this locus, identify new quantitative trait loci (QTL), and better characterize the QTL regions in a new population of dairy cows using genotypes imputed to whole genome sequence.

Ileo-cecal lymph nodes were removed from 205 Holstein dairy cows from an Idaho abattoir at harvest, were PCR tested for the presence of Map and DNA was extracted and genotyped with the Illumina BovineSNP50 BeadChip. Cows with genotype call rates < 90% were removed, leaving 190 cows of which 70 were positive for Map (cases) and 120 were negative for Map (controls). Whole genome sequence-level genotypes were imputed from run 4 data from the 1000 bull genomes project. Indels and SNPs with MAF < 0.01 were removed leaving 708,788 biallelic SNPs for analysis on BTA3 with Efficient Mixed Model Association expedited (EMMAX) additive and allelic models. Little evidence for population stratification was evident as l = 1.01. The additive model identified 10 QTL that were moderately associated ($p < 5.5x10^{-5}$) with JD on BTA3, and the allelic model identified 21 QTL (20 that were moderately associated with JD, and one QTL strongly associated ($p = 5.13 \times 10^{-7}$), but did not include the previously identified locus on BTA3. The use of imputed genotypes aided in identifying new QTL, more narrowly defining the QTL regions and testing if QTL were replicated in new cattle populations.

Key Words: bovine paratuberculosis, genetics, chromosome 3

0204 Effect of the total Western diet via direct or ancestral exposure on estrous cycling in third-generation offspring in mice. K. Contreras*[1], J. Cuthbert[1], S. Phatak[1], D. Larson[2], and A. Benninghoff[1], *[1]Utah State University, Logan, [2]USTAR Applied Nutrition Research, Logan, UT.*

Obesity is a contributing factor to many diseases, such as cancer and diabetes. Moreover, mounting evidence points to a role for obesity as a risk factor for infertility and other reproductive dysfunctions. In a previous study, mice fed a diet containing 60% of energy from fat experienced abnormal estrous cycles, with significant extended time in the diestrus phase (Brothers et al., 2010 *Cell Metab*. 12(3): 295–305). Animal model studies investigating the contribution of obesity to other adverse health outcomes usually do not account for typical Western dietary patterns with respect to macro- and micronutrient content. Previously, our group developed the Total Western Diet (TWD) for rodents, which models the typical American diet with respect to macro- and micronutrient content on an energy density basis, as opposed to other simple high fat diets traditionally used in pre-clinical studies. The primary objective of this study was to determine the impact the TWD on estrous cycling in mice. Based on prior observations with a very high fat diet, we expected mice fed TWD would have abnormal estrous cycles. C57BL/6J mice were bred for three generations, during which they were fed an optimized diet (AIN93G), TWD or a simple high fat diet (45% fat DIO) in the F_0 only, F_0 through F_3 or the F_3 generation only ($n = 14$ to 17 mice all but one group, which had $n = 6$). Vaginal cell smears were obtained over 10 d from individual F_3 offspring at 23 wk of age. Samples were stained, fixed and then examined via light microscopy to assess estrous stage. The percent time in proestrus, estrus, metestrus and diestrus were calculated for each individual, and data were analyzed using a mixed model analysis of variance with cage as a random nested factor. No significant differences were observed among any of the diet treatment groups for any of the estrous cycle stages ($p > 0.18$). These data disagree with prior observations that a high fat diet prolonged time in diestrus, although the current study used diets with fewer calories from fat (35% for TWD and 45% for DIO) compared with the study by Brothers et al. (2010), which employed a 60% fat diet. As part of the present study, other ongoing work will assess impacts of these test diets on other reproductive parameters, including birth rate, cannibalism rate, weaning weight and biomarkers of oocyte quality.

Key Words: Western diet, estrous cycle, obesity

0205 Maternal over-feeding during gestation alters islet size and number in the pancreas of 135-d-old fetuses. M. C. Wynn*, M. L. Hoffman, S. M. Pillai, A. K. Jones, K. K. McFadden, S. A. Reed, S. A. Zinn, and K. E. Govoni, *Department of Animal Science, University of Connecticut, Storrs.*

Maternal over-feeding during gestation can lead to increased circulating insulin concentrations, increased carcass adiposity and reduced insulin sensitivity in the offspring. However, the mechanisms behind these changes are not well known. We hypothesized that maternal over-feeding during gestation would affect structures of the endocrine and exocrine pancreas of fetuses at d 135 of gestation. For this study, ewes were fed either 100% (control-fed; $n = 6$) or 140% (over-fed; $n = 7$) of NRC requirements for TDN starting at d 30 ± 0.02 of gestation. Ewes were euthanized at d 135 of gestation and the pancreas from each fetus ($n = 11$ fetuses per treatment group) were collected. Fetal body weight as well as pancreas weights were recorded and pancreas tissue was embedded in optimal cutting temperature medium for histological analysis. A total of 8 fetuses from control-fed ewes (CON) and 9 fetuses from over-fed ewes (OVER) were used for histological analysis. Three 5 µm thick sections per fetus were stained with Harris Hematoxylin and Eosin Y. Sections were imaged using a Zeiss Axiovert 200M microscope with 3 to 4 images taken per section. Islet and duct size and number were quantified using ImageJ across 5 and 10 images per fetus, respectively. Data were analyzed using a student's *t* test. An effect of maternal diet was not observed for fetal BW or pancreas weight expressed as a percent of BW at d 135 of gestation ($P \geq 0.71$). In OVER lambs, islet size was 63% greater compared with CON (5404 ± 477 µm and 8836 ± 300 µm for CON and OVER, respectively; $P < 0.01$). There was an 18% decrease in islet number in OVER lambs compared with CON (8.8 ± 0.5 and 7.2 ± 0.4 islets for CON and OVER lambs, respectively; $P =$

0.03). No effects of maternal over-feeding were observed for offspring duct size or number ($P > 0.13$). The observed effect of maternal over-feeding on islet size and number could be due to changes in cell function and differentiation as a result of being exposed to excessive nutrients during gestation. In conclusion, maternal over-feeding during gestation alters the fundamental structural aspects of the endocrine pancreas of the fetus, which may contribute to altered pancreas function during gestation and later in life. Further studies are needed to determine the link between changes in pancreas structure and function later in life.

Key Words: maternal nutrition, pancreas, sheep

0206 Comparison of high definition Zenmuse X3 and X5 video cameras onboard unmanned aerial vehicles for future use in precision ranching.

C. F. Solecki* and J. S. Church, *Thompson Rivers University, Kamloops, BC, Canada.*

The use of unmanned aerial vehicles (UAVs) in agriculture to increase the efficiency of management is a new and rapidly advancing field. Being able to locate and identify cattle with UAVs would enable producers to better utilize spatiotemporal data from range livestock to better manage both livestock herds and range. UAVs provide a method of capturing aerial video observation data of cattle on extensive range that is more flexible, affordable, and safer for the pilot than traditional aircraft. In this study we used common industry cattle ear tags of two sizes (large tags = 7.5 × 5 cm, small tags = 5.5 × 3 cm) of varying colors as well as back tags (23 × 14 cm, used in behavioral studies) to assess the visual acuity of two commercially available aerial high definition cameras. The aim of this project was to assess the capabilities and limitations of these aerial cameras specifically designed for UAV use, with the goal of determining their practical use in the field as tools for observing and identifying cattle. A set of images from each camera was obtained using the DJI Inspire 1 Pro flight platform (Da-Jiang Innovations Science and Technology Co. Ltd., Shenzhen, China). Images were captured at an initial height of 5 m and progressing upward at 5 m intervals to 80 m above ground level (ABL). An onboard GPS module on the UAV was used to monitor and record the height of the aircraft at each interval. Recorded images were then assessed on a computer monitor to determine whether identification of numbering and lettering on the tags was possible. Through qualitative visual assessment of these aerial photographs, it was determined that the capabilities of the Zenmuse X5 were significantly superior than that of the Zenmuse X3 and will therefore be of greater use in future identification of animals using UAVs. We concluded that identification by cattle ear tags using a UAV is likely not a practical application due to the maximum ABL that is required to identify numbering and lettering on tags (15 m using the Zenmuse X5); however, identification of numbering on back tags to identify individual animals was possible up to an ABL of 70 m using the Zenmuse X5 camera.

Key Words: cattle, drone, ear tags

0207 Leucine supplementation increases mouse mammary cell proliferation in vitro.

M. M. McGuckin*, R. Manjarin, and D. G. Peterson, *California Polytechnic State University, San Luis Obispo.*

The objective of this study was to determine if leucine supplementation increases mammary epithelial cell proliferation in vitro, and whether this effect is associated with the upregulation of leucine transporters, cell cycle protein regulators, and leucyl-tRNA synthetase, which mediates leucine-induced activation of the mammalian target of rapamycin complex 1. Growth of HC11 mouse mammary epithelial cells in either control (CON; 0.38 mmol/L leucine) or leucine-supplemented HMEM media (LEU; 1.52 mmol/L leucine) was assessed by the MTT proliferation assay over 6-d, followed by RNA extraction and quantification of gene expression. Transcript abundance of leucine transporter LAT1 (*SLC7A5*), cyclin D (*CCND1*), leucyl-tRNA synthetase (*LARS2*), and reference genes hypoxanthine guanine phosphoribosyl transferase (*HPRT*), RNA polymerase 3 (*POL3*) and ribosomal protein L3 (*RPL3*) was determined using reverse transcription quantitative PCR. Data were analyzed using a linear mixed model procedure of SAS that included the fixed effect of treatment and the random effect of replicate. Compared with CON, proliferation of leucine-treated cells tended to increase at d 5 ($P < 0.1$), and was significantly higher at d 6 ($P < 0.01$). Similarly, expression of genes encoding LAT1 and leucyl-tRNA synthetase was increased ($P < 0.05$) in cells exposed to LEU. Messenger RNA abundance of cyclin D did not differ between treatments. Taken together, these results suggest that leucine supplementation increases the proliferation of mouse mammary epithelial cells in vitro, which may be mediated by the upregulation of LAT1 and leucyl-tRNA synthetase at the gene expression level. These results represent a novel contribution to our understanding of how amino acid nutrition regulates mammary gland growth, and to the critically needed tools for development of mechanistic models of nutrient utilization for improving efficiency of milk production.

Key Words: mammary gland, proliferation, leucine, growth

0208 Effects of maternal nutrition during gestation on placental steroid metabolizing enzyme activity in sheep. K. J. McCarty*[1], M. P. T. Coleson[1], S. M. Pillai[2], M. L. Hoffman[2], A. K. Jones[2], K. E. Govoni[2], S. A. Reed[2], S. A. Zinn[2], and C. O. Lemley[1], [1]*Mississippi State University, Starkville,* [2]*Department of Animal Science, University of Connecticut, Storrs.*

Normal pregnancy in sheep relies heavily on placental secretion of steroids during the last half of gestation. Maternal nutrient restriction or over-nutrition has been shown to increase or decrease peripheral concentrations of steroids, respectively. The objective was to determine the effects of maternal nutrition on placental steroid metabolizing enzyme activity in sheep. Pregnant ewes ($n = 60$) were allocated to receive either 100% [control-fed (CON; $n = 20$)], 60% [restricted-fed (RES; $n = 20$)], or 140% [over-fed (OVER; $n = 20$)] of NRC requirements for TDN beginning at d 30.2 ± 0.2 of gestation. Ewes from each nutritional treatment were slaughtered at d 45 ($n = 20$), 90 ($n = 20$), or 135 ($n = 20$) of gestation. At slaughter the maternal (caruncle) portion of the placenta was collected for enzymatic activity analysis. Activity of cytochrome P450 1A (CYP1A), cytochrome P450 3A (CYP3A), and UDP-glucuronosyltransferase (UGT) were determined using specific luminogenic substrates. Activities were expressed relative to mg of tissue protein. Data were analyzed using MIXED procedure of SAS and the model statement included nutritional treatment, day of gestation, and their respective interaction. Main effects are discussed in the absence of nutritional treatment by gestational day interactions. Activity of CYP1A in the caruncle was not different across gestational d ($P = 0.15$) or nutritional treatment ($P = 0.94$). Similarly, activity of CYP3A in the caruncle was not different across gestational d ($P = 0.29$) or nutritional treatment ($P = 0.98$). Activity of UGT was not different across gestational d ($P = 0.26$). Activity of UGT in the caruncle tended ($P = 0.07$) to be different across nutritional treatment, whereby activity was increased ($P = 0.02$) by 170% in OVER compared with CON ewes. In addition, activity of UGT in the caruncle tended ($P = 0.10$) to be increased by 86% in OVER compared with RES ewes, while activity was not different ($P = 0.50$) between RES and CON ewes. In conclusion, over-fed ewes had an increase in activity of UGT in the caruncle compared with control-fed and restricted-fed ewes. Therefore, the increase in caruncle UGT could be involved in stimulating additional steroid metabolism during gestation, thereby contributing to the decrease in peripheral concentrations observed in over-fed animals.

Key Words: cytochrome P450, maternal nutrition, steroid

0209 Relationship between antioxidants and residual feed intake in grazing heifers. J. N. Kidrick*, E. Felton, K. S. Shaffer, and K. M. Barnes, *West Virginia University, Morgantown.*

Residual feed intake (RFI) has been established to be a more accurate measure of feed efficiency; however, questions remain about the specific factors that contribute to individual variation. It has been determined that heat production from metabolic processes, body composition, and physical activity explain a large proportion of the variation but not 100%. Additionally, because RFI is an expensive trait to measure, identification of an easily measured biomarker of RFI would be beneficial in animal selection. Our current objective was to determine if antioxidant status contributes to variation in RFI. Serum was collected from a group of genetically similar heifers that were maintained on the same diet. During the feeding period, feed intake and body weight were recorded and used in the calculation of ADG and RFI. Serum nitric oxide ($n = 48$), glutathione peroxidase ($n = 34$), and total antioxidant capacity ($n = 34$) were measured using colorimetric assay kits. Nitric oxide levels were estimated using a nitrate/nitrite kit. Serum nitric oxide tended ($P = 0.08$) to be positively ($r = 0.26$) correlated with RFI. Glutathione peroxidase and total antioxidant capacity were not correlated with RFI, but total antioxidant capacity did tend ($P = 0.06$) to be negatively ($r = -0.33$) correlated with ADFI. Our data indicate that total antioxidant status may not be an adequate indicator of RFI. Increased intake may require a greater utilization of antioxidants, thus the reduced levels we observed in high intake heifers. The positive correlation we observed between RFI and nitric oxide could indicate less tissue turnover in the more efficient animals (low RFI). Therefore nitric oxide does show some potential as a biomarker of RFI.

Key Words: antioxidants, residual feed intake, nitric oxide

0210 Effects of spices on in vitro enteric methane production. S. Taylor*, I. M. Ogunade, D. Kim, K. G. Arriola, and A. T. Adesogan, *Department of Animal Sciences, IFAS, University of Florida, Gainesville.*

This experiment was conducted to study the effects of spices (*Rosmarinus officinalis*, RO and *Allium cepa*, OP) on in vitro rumen fermentation, methane production and digestibility of corn silage-based ration. A corn silage-based total mixed ration (TMR; 0.5 g/sample) for dairy cows was treated with each of the spices at doses of 0 (Control), 5 (Low), 10 (Med) and 15% (High) of the TMR or with monensin (1.2 mg/g of TMR). Each mixture was incubated in triplicate in 50 mL of a rumen fluid-buffer inoculum (ratio 1:2) in a 120-mL gas-tight culture bottle at 39°C for 24 h in each of two runs. In vitro DM digestibility (DMD), fermentation parameters, gas

and methane production were measured. Data were analyzed using the GLIMMIX procedure of SAS. The high dose of RO decreased DMD and acetate-propionate ratio relative to the Control, whereas, all doses of OP increased DMD and decreased acetate-propionate ratio relative to Control and monensin treatments. Gas volume (mL/g DM) and methane (mL/g DMD) were reduced ($P < 0.05$) by the High dose of RO and monensin, but not by Low and Med doses, relative to the control. Compared with monensin, adding OP at Low, Med and High doses reduced ($P < 0.05$; mL/g DMD) the gas volume (158 vs. 140, 136 vs. 110) and methane production (13.48 vs. 9.98, 9.46, and 10.38), respectively. Ruminal pH was increased by monensin and reduced by the High dose of OP. In conclusion, the High rate of *Rosmarinus officinalis* reduced methane production but decreased TMR digestibility whereas, all doses of of *Allium cepa* reduced methane production and increased TMR digestibility compared with the control and monensin treatments.

Key Words: methane, monensin, spices

0211 An exploratory observational study to quantify ante- and post-mortem complete blood count variables in fed beef cattle. C. L. Rogers*[1], T. J. McEvers[1], J. T. Richeson[1], S. L. Roberts[2], and T. E. Lawrence[1], [1]*West Texas A&M University, Canyon,* [2]*Department of Agricultural Sciences, West Texas A&M University, Canyon.*

Our objective was to quantify changes in complete blood count (CBC) variables before and after terminal marketing of fed beef cattle. Steers ($n = 39$; BW = 622 ± 6.6 kg) were used to obtain individual blood samples the morning before harvest (0600 h; BASAL), the morning of harvest (0600 h; ANTE), and on exsanguination at a nearby commercial abattoir (1500 h; POST). Blood was collected via jugular venipuncture (BASAL and ANTE) or proprietary method (POST) and analyzed within 4 h using an automated hemocytometer. Repeated measures analysis was used to determine changes in the concentration (K/μL) of total white blood cells (WBC), neutrophils (NEUT), lymphocytes (LYMPH), monocytes (MONO), eosinophils (EOS), basophils (BASO), platelets (PLT), and red blood cells (RBC, M/uL), hemoglobin (HGB, g/dL), and mean corpuscular HGB concentration (MCHC, g/dL). The percentage of NEUT (NP), LYMPH (LP), MONO (MP), EOS (EP), and BASO (BP) relative to WBC was also calculated. Moreover, hematocrit (HCT, %), mean corpuscular volume (MCV, fL), mean corpuscular HGB (MCH, pg), and NEUT to LYMPH ratio (N:L) were determined. No differences were detected ($P \geq 0.10$) among CBC variables between BASAL and ANTE except for MONO, MP, MCV, and MCHC ($P \leq 0.01$). However, marked and frequent alterations in CBC variables were observed between BASAL and POST; increased ($P \leq 0.05$) NEUT (1.94 K/uL), BASO (0.003 K/uL), MCV (2.13 fL), NP (24.21%), and N:L (1.04) were coupled with decreased ($P \leq 0.05$) PLT (175.87 K/uL), LYMPH (2.53 K/uL), WBC (1.12 K/uL), MONO (0.37 K/uL), EOS (0.16 K/uL), MCHC (1.67 g/dL), HGB (0.37 g/dL), MCH (0.15 pg), LP (20.07%), MP (2.94%), and EP (1.24%). Likewise, ANTE to POST resulted in increased ($P \leq 0.04$) values for NEUT (1.72 K/uL), BASO (0.004 K/uL), MCV (1.47 fL), NP (22.78%), BP (0.03%), and N:L (0.98) concomitant with decreased PLT (172.66 k/uL), LYMPH (2.38 K/uL), WBC (1.31 K/uL), MONO (0.49 K/uL), EOS (0.16 K/uL), MCHC (1.10 g/dL), HGB (0.32 g/dL), MCH (0.09 pg), LP (17.63%), MP (4.05%), and EP (1.14%). Few variables differed from BASAL to ANTE, yet NEUT and N:L increased and EOS decreased between ante- and post-mortem collection times. This indicates that terminal marketing is stressful, but further research is needed to delineate the specific stressors such as handling, transportation, lairage time or immobilization, that may be most impactful during terminal marketing.

Key Words: cattle, complete blood count, slaughter

0212 Body fat distribution is a determinant of pulmonary arterial and central venous pressures in feedlot cattle. K. M. Freeman*, A. K. Gulick, B. C. Bernhard, R. J. Rathmann, J. O. Sarturi, and J. M. Neary, *Texas Tech University, Lubbock.*

The objective of this study was to determine if adiposity is associated with mean pulmonary arterial and central venous pressures in feedlot cattle during the finishing phase. These pressures are measures of the severity of pulmonary hypertension and venous congestion due to right heart failure, respectively. Pressures were measured in a cohort of crossbred yearling steers ($n = 23$, initial BW = 364 ± 52 kg) at an altitude of 975m, 6 d before slaughter. Steers were fed for 171 d. Measures of body fat evaluated included 12th rib fat thickness, USDA quality grade, KPH fat percentage, and empty body fat percentage (EBFP). These served as proxies for subcutaneous fat, intramuscular fat, visceral fat, and total body fat, respectively. The EBFP was calculated from hot carcass weight, 12th rib fat thickness, USDA quality grade, and longissimus muscle area. KPH fat was evaluated subjectively by a USDA grader. Mean (± SD) pulmonary arterial and central venous pressure were 54 ± 6 mmHg and 28 ± 5 mmHg, respectively, and were positively associated ($P < 0.01$, $r^2 = 0.26$). Cattle with a KPH fat of 2% ($n = 18$) had mean central venous and pulmonary arterial pressure that were 8 ± 2 mmHg ($P < 0.01$, $r^2 = 0.41$) and 8 ± 3 mmHg ($P < 0.01$, $r^2 = 0.26$) greater than cattle with a KPH fat of 1.5% ($n = 5$), respectively. When controlling for mean pulmonary arterial pressure as a covariate ($P = 0.20$), cattle with KPH fat of 2% had a mean central venous pressure that was 7 ± 2 mmHg greater than a KPH fat of 1.5% ($P = 0.01$, $R^2 = 0.43$). This indicates that KPH fat is deleterious to cardiac function independent of its effect on mean pulmonary arterial pressure. None of the other body fat measures evaluated were associated with either central venous or

pulmonary arterial pressures ($P > 0.40$). These findings are in agreement with the many peer-reviewed studies that have reported visceral adiposity to be a strong risk factor for cardiovascular disease in humans. Increasing visceral adiposity may, in part, explain why mean pulmonary arterial and central venous pressures increase in cattle through the feeding period.

Key Words: heart failure, adiposity, visceral, steer

0213 The effects of lavender oil on stalled horses subjected to a stressor. S. R. Adkins*, A. I. Apel, K. D. Vogel, and D. N. Smarsh, *University of Wisconsin, River Falls.*

The use of alternative medicine, such as aromatherapy, has increased in recent years within the equine industry. Lavender oil is commonly thought to have a calming effect, however, there is limited data in horses to confirm these claims. In addition, there are questions regarding the efficacy of such products. Therefore, the two objectives of this research were to conduct a basic chemical analysis of lavender essential oil products, and to assess the potential anti-anxiety effects of lavender essential oil on stalled horses subjected to a stressor. In the first part of this study, gas chromatography analysis was performed on lavender oil products from two companies looking at linalool concentrations. Both oils were of the *Lavendual augstifolia* species, and results were then compared with standards set by the International Standards Organization and published third-party tests. In the second part of this study, 18 horses (12 Quarter Horse geldings and 6 Thoroughbred geldings, aged 10 ± 5 yr) were organized into a Latin Square design with each horse acting as its own control. Horses were individually stalled for a total of 2 h, during which heart rate (HR) and salivary samples were collected at 10, 30, 50, 60, 80, 90, 100, and 110 min. The treatment group was administered lavender oil by aromatic application for 15 min at 40 min and 95 min. The control group did not have an application of lavender oil. The stressor used was a sound recording of sirens played for 10 min. Salivary cortisol and HRs were later analyzed. Gas chromatography results confirmed that both lavender oil products tested did contain linalool. There was an overall effect of time ($p < 0.0001$) on HR, with HR lower at 10, 30, and 50 min as compared with 60 min ($p < 0.0001$), and higher at 80, 90, 100, and 110 min as compared with 60 min ($p < 0.0017$). There was an overall effect of treatment on salivary cortisol ($p = 0.04$), and a trend for an overall effect of treatment on HR ($p = 0.0518$). While the stressor did increase HR, the application of lavender oil did not have a direct effect on HR or cortisol at any specific time point. Further research is needed to identify an effective dose of lavender oil via aromatic application as a means of reducing stress in horses.

Key Words: horse, lavender, anti-anxiety

0214 FSH dependent and IGF-1 independent phosphorylation of β-catenin is similar in bovine and human granulosa cells. C. R. Smith*[1], B. H. Aloqaily[2], C. A. Gifford[3], B. I. Gomez[2], and J. A. Hernandez Gifford[2], *[1]Oklahoma State University, Stillwater, [2]Oklahoma State University, Stillwater, [3]Department of Animal Science, Oklahoma State University, Stillwater.*

Estradiol is a steroid hormone and is required for female fertility. Ovarian granulosa cells (GC) are the major source of estradiol, and synthesis of estradiol relies on the pituitary gonadotropin FSH and local ovarian signaling molecule, insulin-like growth factor 1 (IGF-1). In GC, FSH signals primarily through protein kinase A (PKA), which contributes to β-catenin phosphorylation at Ser^{675} and Ser^{552}. Beta-catenin is a co-transcriptional protein required for the maximal aromatase gene expression and subsequent estradiol production. Ovarian derived IGF-1 signals primarily through protein kinase B (AKT) to regulate steroidogenesis. The objective of the current study was to identify which one of these kinases is responsible for β-catenin activation, and if the phosphorylation has a species specific pattern. Bovine GC and human GC line (KGN) were cultured and treated with IGF-1 (50 ng/mL), FSH (100 ng/mL), or the FSH agonist Forskolin (FSK) (10 μM) for 24 h. At the termination of the treatment period, cells were collected for protein quantification of total and phosphorylated β-catenin abundance via Western blot analysis and protein abundancies were analyzed using densitometry software and the values were analyzed using GLM procedure of SAS. In bovine GC total β-catenin protein increased with FSH, IGF-1, and FSH+IGF-1 ($n = 3$; $P < 0.1$) treatments compared with control. Similarly, in KGN cells FSK increased total β-catenin abundance. However, IGF-1 did not stimulate β-catenin abundance when compared with control. These species differences may be due to a downregulated IGF-1 receptor in the KGN cell line. Phosphorylation of β-catenin Ser^{675} did not differ among treatment groups regardless of cell types. In contrast, phosphorylated Ser^{552} on β-catenin was dramatically increased by FSH or co-treatment of FSH+IGF-1 ($n = 3$; $P < 0.1$), and by FSK and FSK+IGF-1 ($n = 3$; $P < 0.001$) in bovine and KGN cells, respectively. These results suggest that activation β-catenin via phosphorylation at Ser^{552} affected by FSH but not IGF-1 signaling. Follicle stimulating hormone signaling induces β-catenin phosphorylation in cattle and human, indicating that phosphorylated β-catenin is essential in estradiol production regardless of species.

Key Words: β-catenin, FSH, IGF-1

0215 Receptor (chemosensory) transporter protein-4 expression and regulation in bovine granulosa cells. C. N. Horsley[*1], B. H. Aloqaily[1], J. A. Hernandez Gifford[1], and C. A. Gifford[2], *[1]Oklahoma State University, Stillwater, [2]Department of Animal Science, Oklahoma State University, Stillwater.*

In the ovary, the female egg is developed within a follicle, and a follicle is composed of thecal and granulosa cells (GC). These two cell types coordinate development of the oocyte and well as synthesize the steroid hormones progesterone and estrogen. Both FSH and insulin-like growth factor-1 (IGF-1) are known to regulate follicle development and drive steroid hormone production. Receptor (chemosensory) transporter protein-4 (RTP4) belongs to a gene family whose function is to transport G protein coupled receptors. Work in our laboratory suggests that the message for *RTP4* is found in GCs, but the function(s) and regulation of RTP4 is unclear. The objective of current study was to evaluate the effect of FSH and IGF-1 on expression of RTP4 in bovine GC and determine RTP4 localization in bovine ovaries. A rabbit was immunized using 18 AA in an antigenic region of the amino terminus of RTP4. Rabbit serum was collected pre-immunization and at sacrifice (immune serum). Cross-sections from 3 bovine ovaries were incubated with pre-immunized serum and immune serum (1:600) and were developed using biotinylated anti-rabbit IgG for visualization. Primary bovine granulosa cells (n = 3/treatment) were treated with vehicle control, FSH (100 ng/mL; 24 h), IGF-1 (50 ng/mL; 24 h), Forskolin (10 μ M; 24 h) and a combination of the treatments for 24 h and protein lysates collected. Fifty μg of protein was separated by SDS-PAGE. Pre-immunized and immune serum was incubated on separate blots and detected using biotinylated anti-rabbit IgG and horseradish peroxidase development, protein abundancies were analyzed using densitometry software and the values were analyzed using GLM procedure of SAS. Pre-immunized serum displayed no signal in ovarian cross-sections while immunized serum exhibited a robust signal that was ubiquitously expressed in the ovary. Western blot analysis revealed a unique band in immunized serum that showed greater expression ($P < 0.05$) in IGF-1-treated samples compared with controls or FSH-treated samples. However, the unique band was observed at unexpected size; thus, further experiments are necessary to elucidate the size of RTP4 in ovarian tissue. These data suggest that RTP4 is present in the ovary and is regulated by IGF-1 indicating that RTP4 may play a role in steroidogenesis or follicular development.

Key Words: ovary, RTP4, steroidogenesis

0216 Protein expression and localization of receptor (chemosensory) transporter protein 4 in the endometrium during early pregnancy in sheep and cattle. K. S. Wilson[*1], J. A. Hernandez Gifford[1], T. L. Ott[2], and C. A. Gifford[3], *[1]Oklahoma State University, Stillwater, [2]Department of Animal Science, Pennsylvania State University, University Park, [3]Department of Animal Science, Oklahoma State University, Stillwater.*

Reproduction in domestic ruminants continues to challenge efficiency in livestock operations. During early pregnancy, the conceptus produces a unique type I interferon, interferon-tau (IFNT), which acts both locally and systemically to regulate IFN-stimulated genes (ISG) in the maternal uterus and circulating immune cells. Previous work demonstrated that mRNA levels for receptor (chemosensory) transporter protein-4 (*RTP4*) was regulated by pregnancy in peripheral immune cells, the endometrium, and corpus luteum. Receptor transporter protein-4 belongs to a class of G protein coupled receptor transporters, but the function(s) of RTP4 in reproduction remains unclear. Though, mRNA levels for RTP4 are spatially and temporally regulated during early pregnancy in ruminants, there is no information regarding RTP4 protein expression. The objective of the current experiment was to evaluate RTP4 protein expression and localization in the endometrium during early pregnancy in cattle and sheep. A rabbit was immunized using 18 AA in an antigenic region of the amino terminus of RTP4. Rabbit serum was collected pre-immunization and at sacrifice (immune serum). Cross-sections of a D15 pregnant ewe were incubated with pre-immune serum and immune serum (1:600 primary antibody concentration), and protein presence was detected after incubation with biotinylated anti-rabbit IgG and horseradish peroxidase development. No signal was detected for pre-immunized serum, while immune serum exhibited a robust signal in the luminal and glandular epithelium and in the stromal compartments. In the second experiment, cross-sections from D17 pregnant and cyclic Holstein heifers were utilized for immunofluorescence detection of RTP4 protein. Pre-immune serum showed no fluorescence, but immune serum exhibited strong fluorescence in the luminal epithelium, glandular epithelium, and stroma during pregnancy. Interestingly, previous work using in situ hybridization did not detect a presence of *RTP4* mRNA in the luminal epithelium, but the RTP4 protein was clearly expressed in the luminal epithelium in the current experiment. These results demonstrate that RTP4 protein is expressed in the uterus and is regulated by pregnancy. Because RTP4 protein is both expressed in maternal tissues and regulated by pregnancy, it seems likely that RTP4 plays a role in establishment of pregnancy in domestic ruminants.

Key Words: uterus, interferon-tau, RTP4

0217 Follicle-stimulating hormone regulation of proenkephalin in granulosa cells. A. D. Gullic*[1], B. I. Gomez[1], B. Couger[1], C. A. Gifford[2], and J. A. Hernandez Gifford[1], [1]*Oklahoma State University, Stillwater,* [2]*Department of Animal Science, Oklahoma State University, Stillwater.*

Estradiol biosynthesis by ovarian granulosa cells (GC) is crucial for normal female reproductive function and is mediated primarily by FSH. Binding of FSH elicits a multitude of signaling cascades to enhance or inhibit the expression of target genes to regulate estradiol production. The objective of the current experiment was to utilize global expression analysis to identify genes significantly regulated by FSH. Primary rat GC were cultured in the presence or absence of FSH (100 ng/mL) for 24 h and gene expression was analyzed via microarray. Of the 1104 FSH-regulated genes, the opioid precursor proenkephalin *(Penk)* was downregulated ($P < 0.001$) with FSH treatment. Endogenous opioid peptides originate from three protein precursors Penk, proopiomelanocortin (Pomc), and prodynorphin (Pdyn). Stimulation of the μ, δ, and κ opioid receptors in GC downregulate basal estradiol concentrations in cultured GC. Therefore, we hypothesized that Penk blocks FSH-induced estradiol production. Real-time PCR was used to confirm *Penk* regulation in response to FSH treatment. Rat GC were treated with and without FSH for 24 h ($n = 3$) for quantification of *Penk*. Relative fold change values were evaluated using the GLM procedure of SAS and means were separated using the PDIFF function when the model was significant. In agreement with microarray data, FSH downregulated *Penk* 12.81-fold ($P < 0.01$) when compared with control. To determine if the opioid pathway disrupts FSH target genes, KGNGC, a human granulosa tumor cell line, were pre-treated with vehicle or β-endorphin (100 nM), a ligand for the μ opioid receptor, for 5 h followed by treatment with or without 5 μM forskolin (FSK) for 24 h ($n = 3$). Steady state mRNA levels for aromatase (*Cyp19a1)* were quantified via real-time PCR. As expected, FSK increased ($P < 0.01$) *Cyp19a1* 33.5-fold compared with vehicle control whereas treatment with β-endorphin was similar to controls ($P = 0.97$). Co-stimulation of KGN GC with β-endorphin and FSK did not decrease *Cyp19a1* ($P < 0.01$). Results from these experiments indicate that FSH regulates opioid peptides in granulosa cells and work in the literature suggests that opioids regulate steroidogenesis. In the current experiment, stimulation of the μ receptor and subsequent opioid signaling pathway did not inhibit the ability of FSK to increase *Cyp19a1* indicating that opioid regulation of steroidogenesis could be through mechanisms other than disruption of the cAMP signaling pathway or through other opioid receptors.

Key Words: FSH, opioid, aromatase

0218 Optimization of probes and PCR conditions for the correlation between 4 genes and production of high citrate in milk. V. A. Smith*[1], R. Manjarin[1], and R. Jimenez-Flores[2], [1]*California Polytechnic State University, San Luis Obispo,* [2]*Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo.*

We have previously demonstrated the existence of 4 gene products associated to key metabolic pathways that are necessary for the production of citrate in milk, namely isocitrate dehydrogenase 1 (*IDH1*), pyruvate dehydrogenase β (*PDHB*), pyruvate kinase (*PKM2*), and solute carrier family 25 member 1 (*SLC25A1*). Following sequencing of genome of a small sample of cows in the Cal Poly herd, it was shown several single nucleotides (SNP) within these genes that were significantly associated with increased milk citrate content, and therefore that could be potentially selected on to influence the outcome of citrate in milk. We now aimed to design primers for identifying the SNPs in the various genes involved in citrate production, and to optimize the conditions for PCR amplification. Primers for *IDH1*, *PDHB*, *PKM2* and *SLC25A1* were designed based on publicly available bovine cDNA and on expressed sequence tag (EST) sequences deposited in the National Center for Biotechnology database using Primer Express software with default settings. Primer pairs were optimized for concentration using a primer optimization matrix and a relative standard curve was used to determine the efficiency. The standard curve was constructed using cDNA synthesized from a RNA pool made of all samples using the following amounts of cDNA (in duplicate): 40 ng, 4 ng, 0.4 ng, 0.04 ng and 0.004 ng. Specific hybridization of the primers was validated by agarose gel electrophoresis of the PCR products. Non-template controls were included to validate that primers were not amplifying contaminating DNA. Our work demonstrates that each set of primers has singular characteristics that deeply influence the efficiency of PCR conditions. We have also developed accurate PCR conditions for the 4 genes of interest. These results are fundamental for our future studies where SNPs identification will be correlated with citrate levels in milk.

Key Words: milk, citrate, SNPs

ASAS/ASN JOINT SYMPOSIUM: GUT MICROBIOTA, DIET AND HEALTH

0219 Modulation of the gut microbiota: An ecological perspective. J. Walter*, *University of Alberta, Edmonton, Canada.*

Diverse strategies have been used for several decades to improve human and animal health through the modulation of

the gut microbiota, spanning from the administration of defined probiotic strains (or Live Biotherapeutics), whole microbial consortia (e.g., fecal bacteriotherapy), to the provision of bacterial growth substrates (prebiotics and dietary fiber). However, we still lack a conceptual understanding on how the gut microbiota can be modulated. In this presentation I will summarize how ecological theory can provide a framework by which to understand characteristics of the human gut microbiota and the impact of microbiome-modulating strategies. I will present some of our own studies that investigated basic ecological questions regarding how the temporal, spatial, and global patterns of the human microbiome, the factors that shape these patterns, and the ecological constraints within the human microbiome can be manipulated by diet and probiotics. The methodological toolset that is now available (e.g., through next-generation sequencing) provides an unprecedented opportunity to obtain phylogenetic, compositional, and functional information of microbial communities. When analyzed in the light of ecological theory, this has the potential to elucidate the factors and ecological processes that determine and potentially predict the response of the gut microbiota to therapeutic modulations.

Key Words: gut microbiota, probiotic, ecological theory

0220 Effects of early antibiotic exposure on host metabolism. L. M. Cox*, *Harvard Medical School and Brigham and Women's Hospital, Boston, MA; New York University Langone Medical Center, New York.*

The intestinal microbiota, consisting of trillions of bacterial, viral, and fungal cells, can influence growth and development. From infancy through early childhood, the microbial community develops with a succession of key organisms that likely have important roles in shaping metabolic health. Disrupting these ancient patterns of microbe-host maturation may have lasting metabolic consequences. Low-dose antibiotics, especially administered during infancy, can increase weight gain and feed efficiency in a wide variety of host species. To identify key members of the microbiota that may participate, we administered low-dose penicillin (LDP) to mice, measured changes in body composition, and characterized changes in the microbiota by high-throughput sequencing. We found that LDP administered only during the first 4 wk of life increased fat mass later in adulthood, despite the fact that the microbiota recovered, indicating microbiota interactions in infancy may be critical determinants of long-term host metabolic effects. In addition, LDP enhanced the effect of high-fat diet induced obesity. The growth promotion phenotype was transferrable to germ-free hosts by LDP-selected microbiota, showing that the altered microbiota, not antibiotics per se, play a causal role. Four different bacteria were consistently suppressed during infancy in multiple independent experiments, suggesting that they may have beneficial roles in metabolic development. These studies characterize important variables in early-life microbe-host metabolic interaction and identify several bacteria consistently linked with metabolic alterations.

Key Words: antibiotics, microbiome, weight gain

0221 Impact of gut microbiota on brain and behavior. J. F. Cryan*, *University College Cork, Ireland.*

The concept of the gut influencing brain and behavior has existed for almost two centuries. However, a new player has emerged in the past decade: the gut microbiota, which is now seen as a key regulator of the gut-brain axis. The gut is home to a diverse array of trillions of microbes which significantly to outnumber human cells. Advances in sequencing technologies show that the microbiota influences almost all aspects of human biology. Bacterial colonization of the gut plays a major role in postnatal development and maturation of key systems that have the capacity to influence central nervous system (CNS) programming and signaling, including the immune and endocrine systems. Individually, these systems have been implicated in the neuropathology of many CNS disorders and collectively they form an important bidirectional pathway of communication between the microbiota and the brain in health and disease. Evidence of a crucial role for the microbiota in regulating stress-related changes in physiology, behavior, and brain function has emerged mostly from animal studies. Mice that grow up devoid of a microbiome (in a germ-free environment) have an exaggerated hypothalamic-pituitary axis response to stress and altered anxiety-related behaviors. Converse findings have shown that stress (either early in life or in adulthood) changes microbiota composition. Moreover, the concept that bacteria were required for normal brain development has emerged and that the microbiota is regulates many key processes in the adult brain, such as neurogenesis, blood brain barrier function and microglia activation. Thus, the ability to target the brain via the microbiome is viewed as a paradigm shift in neuroscience and psychiatry and has led to the concept of psychobiotics (bacteria with positive effects on mental health) being put forward. Moreover, microbiota is essential for both social cognition and visceral pain. Finally, there are critical time-windows early in life when the effects of microbiota on brain and behavior appear to be more potent. Our data also demonstrates that these effects may be mediated via the vagus nerve, spinal cord, or neuroendocrine systems. Such data offer the enticing proposition that specific modulation of the enteric microbiota by dietary means may be a useful "psychobiotic"-based strategy for brain disorders.

Key Words: stress, neurodevelopment, probiotic

0222 The human milk microbiome and oligosaccharides: What's normal and so what? M. K. McGuire*[1] and M. A. McGuire[2], [1]*Washington State University, Pullman,* [2]*University of Idaho, Moscow.*

Human milk is inarguably the only food "designed" to be consumed exclusively by humans, providing all the essential nutrients (and other bioactive compounds and constituents) needed for growth and development of the human infant. As such, understanding human milk composition and variation therein is critical to optimizing human health during this vulnerable time, particularly in the most at-risk infants. More complete characterization of human milk composition may also lend important insight as to what constitutes optimal nutrition in other phases of the lifecycle, not only for the human host but also for the myriad commensal, mutualistic, and sometimes pathologic microbes with which we coexist. However, our understanding of human milk composition and its impact on host and microbial health is far from complete. For instance, until recent advances in instrumentation allowing the detection and identification of difficult-to-culture bacteria, common dogma was that human milk was sterile unless produced by an infected mammary gland or contaminated after expression. As such, focus on the roles played by complex (an indigestible) human milk oligosaccharides (HMO) has been directed exclusively toward those related to the recipient infant and his/her gastrointestinal microbiota- roles that are without a doubt important for infant health. We now know that human milk contains a diverse population of bacteria. As such, we and others postulate that HMO may impact the microbial communities present in milk and the mammary gland producing it. Here we will briefly describe what is currently known about variation in the human milk microbiome and HMO as well as relationships among maternal diet, milk composition (including microbes and HMO), and the infant gastrointestinal microbiome. In addition, we will introduce an ongoing cross-cutting study funded by the Integrated National Science Foundation Support Promoting Interdisciplinary Research and Education (INSPIRE) mechanism designed to help us better understand what is normal in terms of milk microbes, HMO, and infant fecal microbiome in various locations worldwide. The importance of cooperation and interdisciplinary discussion around methods and vocabulary will be discussed, as will some of the challenges faced in terms of sample collection, storage, transport, and data analysis. Finally, selected preliminary data from the INSPIRE study and a framework for considerations for future studies designed to use big (and interdisciplinary) data to understand variation in global milk composition and how this is related to infant health will be presented.

Key Words: human milk, microbiome, oligosaccharides, HMO, health, development

0223 Dietary fiber and starch, digestive physiology, and metabolic health. R. T. Zijlstra*, J. M. Fouhse, T. Vasanthan, and M. G. Gänzle, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

In monogastric nutrition, analyses of fiber and starch have focused on assessing quantity. However, both have a wide range of functional properties. Fibers ranging from low to high viscous affect digesta flow and from slowly to rapidly fermentable alter production of volatile fatty acid (VFA) serving as energy for the gut or the whole body. Likewise, starches ranging from low to high amylose change from rapidly digestible in the upper gut to poorly digestible but fermentable in the lower gut, thereby changing from glucose source into VFA source. Poorly digestible or resistant starch thus basically acts as dietary fiber. Functionality of these carbohydrates for nutrition or health was studied in lab and pig models. Our hypothesis is that total extent, kinetics, and site of digestion or fermentation of starch and fiber are important for whole body energy utilization and gut health. To elucidate their effects, we developed in vitro, lab-based methodologies to describe kinetics of digestion and fermentation and linked these with in vivo models including: (1) ileal cannulation to collect digesta, (2) portal-vein catheterization to sequentially sample blood, (3) slaughter method to collect site-specific intestine tissue and digesta, and (4) indirect calorimetry. Using these models, kinetics of absorption of glucose was associated with insulin and incretin release into the portal vein, intestinal microbiota, and gene expression in intestinal tissue and microbiota. These studies confirmed that slowly digestible starch is partially degraded in the large intestine and fermented into VFA including butyrate (10-fold increase in net portal appearance), reducing insulin responses by 60% and reducing whole body energy utilization. Starch entering the distal intestine altered mRNA abundance of nutrient transporters, increased portal release of the incretin glucagon-like peptide-1 (GLP-1), and was bifidogenic in the large intestine. Extreme viscous purified fiber dampened glycemic responses and reduced digesta passage rate by 50%, thereby increasing small intestine digestion of dietary nutrients, whereas increased fiber in feed grains reduced nutrient digestibility. Fermentable fiber increased butyrate and insulin production. In whole grains with ranging content of amylose and fermentable fiber, effects of similar direction but less extreme were observed. In summary, fiber and starch characteristics influence digestive physiology and thereby gut health, metabolic health, and whole body nutrient utilization. Functional characteristics of fiber and starch should also be considered is diet formulation.

Key Words: digestive physiology, fiber, starch

0224 Methane matters: From blue tinged moos, to boozy roos, and for the health of humans too.

E. C. Hoedt[1,2], P. OCuiv[3], and M. Morrison[*4], *[1]University of Queensland, School of Chemistry and Molecular Biosciences, St Lucia, Australia, [2]University of Queensland Diamantina Institute, Woolloongabba, Australia, [3]University of Queensland Diamantina Institute, Woolloogabba, Australia, [4]University of Queensland Diamantina Institute, Brisbane, Australia.*

Methane production is a typical occurrence within the digestive tracts of warm blooded animals, including humans. Methanogens and methane emissions however, means something different to each host. Methane emissions from ruminant livestock has been a major focus of research over the last decade because of the attribution of ~10–20% of the annual anthropogenic methane output to these animals. This has led in part to methane emission measurements for a broad range of animal species and breeds, including Australia's native herbivores, to identify "low emitters"; and resulted in comparative studies to define how the gut microbiota in these animals might account for the differences. The presence of methanogens within the human gut has long been recognized via a combination of breath methane measurements and microbiota surveys, and linked to a range of functional gastrointestinal disorders and non-communicable diseases. Historically much of the focus has been directed to the numerically most predominant species, principally assigned to the genus *Methanobrevibacter,* which are canonically involved with the conversion of gaseous substrates (CO_2 and H_2) arising from bacterial fermentation. However, recent studies by our group and others have revealed that, perhaps, the heterotrophic methanogens (i.e., those capable of using small organic molecules such as alcohols and methylated amines) warrant closer attention if "methane matters" in animals and man are to better managed. Here, we provide a brief overview of recent research on these heterotrophic archaea, with a specific focus on the genus *Methanosphaera,* which so far has been found only in the gastrointestinal tracts of animals, by using specific examples of our own and others recently published research with livestock, Australian macropodids (kangaroos and wallabies) and human clinical and nutritional studies. We propose this specific guild of methanogenic archaea not only warrants further attention, but provides new opportunities for the better management of the "animal-methane" axis.

Key Words: methane and methanogens, gut function, human health and animal productivity

0225 Sub-acute ruminal acidosis (SARA): A tale of two microbiomes.

C. A. McCartney[1], R. C. Cernat[2], H. H. C. Koh-Tan[3], H. J. Ferguson[3], E. M. Strachan[4], W. Thomson[4], T. J. Snelling[1], C. M. Harvey[4], I. Andonovic[5], C. Michie[5], N. N. Jonsson[3], G. W. Horgan[6], and R. J. Wallace[*7], *[1]University of Aberdeen, UK, [2]Chr. Hansen A/S, Hoersholm, Denmark, [3]University of Glasgow, UK, [4]Harbro Ltd., Turriff, UK, [5]Strathclyde University, Glasgow, UK, [6]BIOSS, Aberdeen, UK, [7]Rowett Institute of Nutrition and Health, Aberdeen, UK.*

Most mechanistic studies of sub-acute ruminal acidosis (SARA) in cattle involve the experimental induction of SARA by dietary starch or legume. Our aim was to determine how these observations relate to on-farm conditions in northeastern Scotland. In six beef farms, management practices, feed composition/particle size and animal activity using motion sensor collars were monitored using 20 animals per farm. At slaughter, rumen wall condition was assessed under four categories: color, papillae integrity, papillae shape, and post-washing blackness. Ruminal fluid and cecum contents were collected for VFA and soluble lipopolysaccharide (LPS) analysis, and also for microbial community analysis. Eighty-six ss rRNA amplicon libraries were generated by PCR, which were subsequently sequenced in equimolar concentrations using Illumina MiSeq.

Close examination of the feed indicated that the process of mixing grain with forage was critical. Rumen wall damage did not appear to be correlated with the particle size of the total mixed ration, but rather with the dustiness of the barley component of the feed. Motion sensor data showed that the rate of change of movement appeared to be correlated with the condition of the rumen wall across farms. Ruminal LPS concentrations were significantly different ($P < 0.001$) between farms, and caecal LPS concentrations were significantly higher (up to 27-fold) than corresponding ruminal LPS concentrations, and exhibited a stronger relationship with the rumen damage scores. We therefore postulate that the hindgut has a greater effect on ruminal health than previously thought.

Microbial community and subsequent PCA analysis revealed significant ($P < 0.001$) clustering of ruminal fluid and caecal content communities. Within each sample type, there was also significant clustering by farm; however, the clustering was weaker when grouped by damage score. Bacteroidetes, Firmicutes and Proteobacteria were the predominant phyla in the ruminal digesta. In the caecal content, Proteobacteria were barely detected and comprised mainly the Moraxellaceae family (known pathogens, "pink eye" in cattle). This was surprising as LPS from Enterobacteriaceae has been implicated with SARA. It is possible that growth of Proteobacteria is not supported in the cecum and the bacteria therefore lyse, causing the high LPS concentrations. In conclusion, the particle size of the barley component of the feed appears to have a relationship with SARA related pathology. Further-

more, this study has highlighted the role of the hindgut in the pathology of SARA, which warrants further investigation.

Key Words: cecum, rumen, sub-acute ruminal acidosis (SARA)

0226 Dietary manipulation of canine and feline gut microbiome. K. S. Swanson*, *Department of Animal Sciences, University of Illinois, Urbana.*

Dogs and cats evolved as Carnivora and have traditionally relied on high-protein, high-fat diets containing relatively low fiber concentrations. Despite having a simple gastrointestinal tract designed to digest such diets, a rich microbial community exists. Today's pet dogs and cats live in close proximity to humans and have similar environmental exposures, serving as potential vectors for pathogen exposure. Dogs and cats are also afflicted by many of the complex diseases present in humans, including obesity, diabetes, inflammatory bowel diseases, and cancers, all of which may be influenced by diet and the gut microbiota. Given their proximity to humans, similar disease incidence and etiology, and unique metabolism, microbiome research in dogs and cats may not only lead to improved pet nutrition and veterinary care, but may increase our understanding of host-microbe interactions, with relevance to human metabolism and diseases and public health at large. Molecular techniques, including high-throughput sequencing, have dramatically changed the research landscape in regards to gastrointestinal microbiology. These techniques have been used to characterize the phylogeny and functional capacity of the canine and feline gastrointestinal microbiota and identify the effects of diet, age, and disease on these communities. Several hundred bacterial phylotypes, predominated by members of Firmicutes, Fusobacteria, Proteobacteria, Bacteroidetes, and Actinobacteria, are now known to inhabit the dog and cat gastrointestinal tract. Recent studies have revealed that the functional capacity of the gastrointestinal microbiota in dogs and cats is quite broad and similar to that of humans and rodent models. Although these populations are quite stable over time, our laboratory has demonstrated that macronutrient profile (e.g., dietary protein:carbohydrate ratio), dietary fiber amount and type, and the form of food consumed (e.g., raw vs. extruded diets) may have dramatic effects on the gastrointestinal microbiome of these host species. These dietary changes have not only been reported to impact microbial diversity and richness, gene content, and metabolic activity, but to alter host physiology and metabolism as well. Unfortunately, the majority of research has been performed in healthy animals housed in research colonies rather than free-living pets. Continued research on the composition and activity of the canine and feline gastrointestinal microbiomes, and how they are impacted by dietary intervention and other environmental exposures, is needed to increase our understanding of the host-microbe interactions that occur in the gastrointestinal health and their relevance to health and disease.

Key Words: canine nutrition, feline nutrition, gut microbiota

BEEF SPECIES I

0227 Relationship between forage quality parameters and mineral intake in grazing beef cattle. J. D. Rivera*, M. L. Gipson, and R. G. Gipson, *Mississippi State Univ. South Branch Exp. Sta., Poplarville.*

One hundred ninety-two forage samples were collected over a 2-yr winter grazing season from cool-season pastures grazed by beef cattle (avg. BW = 294 kg) to determine the effects of periodicity and forage quality on mineral intake. Beef cattle minerals were offered to each pasture (n = 24 pastures) every 28 d from December through June. Refusals were weighed at the end of each interval, and forage samples were collected at the same time. Mineral refusals were used in conjunction with offered mineral to calculate mineral DMI. Forage samples were weighed and dried for 72 h at 50°C to determine DM; dried samples were analyzed using NIR technology to determine ADF and CP content. Data were analyzed to determine correlation (PROC CORR) of periodicity, CP, ADF, DM and mineral intake. As expected, as the season progressed, sampling period was highly correlated to forage quality ($P <$ 0.01) with decreasing CP ($r^2 = -0.92$), increasing ADF ($r^2 =$ 0.96) and DM ($r^2 = 0.80$) associated with periods later in the grazing season. No effect ($P = 0.25$) of sampling period was observed for DMI of mineral. Average mineral intake through the grazing season was 81.6 g ± 1.7 g. Crude protein averaged 18.7% ± 8.4%; ADF averaged 31.3% ± 11.7%. Crude protein had no effect on mineral intake ($P = 0.34$). Acid detergent fiber tended to negatively correlate ($P < 0.06$; $r^2 = -0.14$) with mineral DMI; greater mineral DMI was associated with lower ADF. Forage DM had a negative impact on mineral DMI ($P = 0.001$; $r^2 = -0.38$); with greater forage DM associated with lower mineral DMI. Results suggest that mineral intake of beef cattle grazing cool-season forages is not affected by forage quality (ADF, CP), nor sampling period, but rather more likely affected by forage DM content.

Key Words: beef cattle grazing mineral intake

0228 Feeding antibodies against interleukin-10 improved gain efficiency in beef steers. M. R. Schaefer*, M. E. Cook, D. M. Schaefer, *University of Wisconsin, Madison.*

Recent studies showed that oral anti-interleukin-10 antibody (aIL-10) is protective against gastrointestinal pathogens. The current objective was to evaluate oral aIL-10

Table 0229.

administration on top of best management practices in newly arrived weaned steers. Laying hens immunized with peptide VMPQAENG-conjugate with Freund's adjuvant (aIL-10 hens) or only Freund's adjuvant (control hens) were used to produce eggs containing aIL-10 and Control antibodies. One hundred thirteen black hided steers (initial BW 297 ± 7 kg) were purchased from a local auction barn (160 km) via 14 lot purchases, and allowed to rest for 4 d before starting the trial. Steers were blocked by initial BW and allotted to 18 pens (6 or 7 steers/pen). Pens (9/treatment) were randomly assigned to either Control antibody (42 g · hd^{-1} · d^{-1} whole liquid egg from control hens) or aIL-10 antibody (42 g · hd^{-1} · d^{-1} whole liquid egg providing 500 µg aIL-10 antibody) mixed in a common diet (70.0% corn silage, 15.9% cracked corn, 5.8% DDGS, 5% wheat midds, and 3.3% supplement, DM basis) for the initial 14 d of the trial. No additional eggs were fed for the remainder of the 64 d trial. Antibiotics were administered to treat bovine respiratory disease based on visual observations and whether rectal temperatures exceeded 39.7°C. Data were analyzed as a randomized complete block design using the PROC MIXED procedure of SAS, with pen as the experimental unit. Average DMI was similar between treatments (8.1 kg, $P = 0.84$), however G:F was greater for steers fed aIL-10 vs. Control (0.193 vs. 0.182, $P = 0.04$) over the 64 d trial. Average daily gain over 64 d was 1.58 and 1.48 kg/d for aIL-10 and Control groups, respectively ($P = 0.13$). Frequency of steers requiring a single antibiotic treatment was similar between treatments (16%, $P = 0.97$), but a greater percentage of steers fed the Control eggs required a second antibiotic treatment relative to steers fed the aIL-10 (7 vs. 0%, $P = 0.09$). Total antibiotic treatments per animal were statistically similar between treatments ($P = 0.15$), but was numerically lower for the aIL-10 vs. Control group (0.16 vs. 0.35, SEM = 0.08, respectively). Feeding aIL-10 increased G:F in newly received feedlot steers possibly by improving cattle health immediately after commingling.

Key Words: interleukin-10, respiratory disease, feedlot cattle

0229 Animal and digestibility marker variation influence predictions of dry matter intake and dry matter digestibility. K. A. Weld*[1], J. R. R. Dorea[1], F. A. P. Santos[2], and D. E. Oliveira[3], *[1]University of Wisconsin, Madison, [2]University of São Paulo, Piracicaba, Brazil, [3]Santa Catarina State University, Lages, Brazil.*

The current literature shows that there is animal and marker variability in digestibility marker recovery, but does not address the effect of this variability on individual animal DMI predictions. The objective of this study was to test the use of various markers and administration methodologies to predict DMI in grazing systems and determine the main contributors to variability. Eight rumen cannulated Nellore steers were randomly assigned to two 4 × 4 Latin squares. Steers had ad libitum access to pasture of *Brachiaria brizantha*. Steers were either not supplemented or individually supplemented with a mixture of fine ground corn and sodium monensin at 0.3, 0.6 or 0.9% of body weight. Steers were each administered 3 external markers via rumen cannula: a C32 controlled release capsule (CRC) on d 3; LIPE® (purified lignin), once daily on d 7 to 15; and Cr_2O_3 once daily on d 1 to 15 of each period. Fecal grab samples were collected twice daily for the last 5 d of the 15-d periods. Intake predictions were calculated using the Large Ruminant Nutrition System (LRNS), C31:C32 ratio, C33:C32 ratio, LIPE®, and Cr_2O_3. Indigestible DM (iDM), indigestible NDF (iNDF) and indigestible ADF (iADF) were used as internal markers. LIPE® was determined by infrared spectroscopy, Cr_2O_3 by inductively coupled plasma optical emission spectroscopy and alkanes by gas chromatography. A 240-h rumen incubation was used for the internal markers. A mixed model with the fixed effect of supplementation level and random effects of Latin square, animal(Latin square), period, and animal x period was used to determine treatment effects. LIPE® and Cr_2O_3 detected a treatment effect on pasture intake ($P < 0.10$) except for the Cr_2O_3/iADF combination ($P = 0.43$). Only LIPE® detected a treatment effect on total intake ($P < 0.03$). The alkanes provided greater and variable intake predictions. The final 4 d in each period demonstrated decreased CRC release rate compared with the previous 8 (mm/d = -0.012*d^2 + 0.091*d + 3.93, R^2

= 0.79). A completely random model containing internal and external markers, and their interactions with animal, period, and supplementation level determined which variables contributed to intake prediction variability. Variability was mainly due to internal and external markers (11–66% of variation), residual error (11–24% of variation), and external marker x animal interactions (5–16% of variation). Digestibility markers should be used cautiously to predict individual intakes in a grazing system due to animal by marker interactions, though markers can detect treatment differences.

Key Words: digestibility marker, intake prediction, steer

0230 Using hair cortisol concentrations to assess the adrenocortical stress response in beef cattle administered corticotrophin-release hormone.

K. M. Schubach*[1], R. F. Cooke[1], A. P. Brandao[1,2], K. Lippolis[1], M. T. Hinchliff[1], D. W. Bohnert[1], and R. L. A. Cerri[3], *[1]Oregon State University-EOARC Burns, Burns, [2]UNESP-FMVZ, Botucatu, Brazil, [3]Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada.*

Our objective was to determine if hair cortisol concentrations can be used to assess the adrenocortical stress response in beef cattle receiving corticotrophin-release hormone (CRH) injections. Eight halter-trained Angus heifers (BW 189 ± 4 kg; age 225 ± 4 d) were ranked by BW and allocated to 2 groups (4 heifers/group), which were randomly assigned to a crossover design containing 2 periods of 35 d (d −7 to 28) and the following treatments: (1) 0.5 μg of CRH/kg of BW twice daily (i.v. at 0600 and 1800h) from d 0 to 13 (CORT), or (2) 5 mL of 0.9% saline (i.v.) concurrently with each treatment administration to CORT heifers (CON). Heifers were maintained in individual pens from d −7 to 13, or as a single group from d 14 to 28 of each period. Between periods, heifers were maintained as a single group and were not exposed to any experimental procedures for 24 d. Blood samples were collected via jugular venipuncture before and 90 min after each treatment administration. On d 0, 13, and 28, hair samples were collected from the tail switch before the first treatment administration of the day. Hair was collected using scissors as close to the skin as possible, and the hair material closest to the skin was stored (2.5 cm of length, 300 mg of weight). Plasma samples were analyzed for cortisol using a chemiluminescent enzyme immunoassay. Hair samples were cleaned with water and isopropanol, and then ground in a ball mill once dry. Cortisol was extracted with methanol before being measured using ELISA. Data were analyzed using the MIXED procedure of SAS, whereas hair cortisol concentration was analyzed using results obtained on d 0 of each period as covariate. A treatment × time interaction was detected for plasma cortisol concentrations ($P < 0.01$), which were less for CORT vs. CON heifers before treatment administration, but greater for CORT vs. CON heifers 90 min after treatment administration (2.1 vs. 4.8 ng/mL and 20.5 vs. 3.9 ng/mL, respectively; SEM = 0.8). Mean hair cortisol concentration was greater ($P = 0.04$) for CORT vs. with CON heifers (20.2 vs. 11.9 pg/mg of hair, respectively; SEM = 3.3). These results indicate that cortisol concentrations in hair samples collected from the tail switch can be used as an indicator of adrenocortical stress response in beef cattle.

Key Words: beef cattle, cortisol, hair, plasma, tail switch

0231 Effects of static or oscillating dietary crude protein levels on fermentation dynamics of beef cattle diets using a dual-flow continuous culture system.

P. Amaral[1,2], L. Mariz[1,2], P. Del Bianco Benedeti[1,2], L. Galoro da Silva[1], E. Marostegan de Paula[1], H. Monteiro[1,3], T. Shenkoru[1], S. A. Santos[4], S. Poulson[1], and A. Faciola*[1], *[1]University of Nevada, Reno, [2]Federal University of Vicosa, Brazil, [3]Maringa State University, Maringa, Brazil, [4]Universidade Federal da Bahia, Salvador, Brazil.*

In nature several animal, microorganism, and plant species experience seasonal periods of undernourishment followed by periods of nutrient abundance. This nutrient oscillation promotes a period of accelerated growth defined as compensatory growth. The objective of this study was to evaluate the effects of increasing dietary crude protein (CP) levels and also comparing the effects of static versus oscillating dietary CP on ruminal nutrient digestibility, ruminal fermentation, nitrogen (N) metabolism, and microbial efficiency in beef cattle diets using a dual-flow continuous culture system. Eight fermenters (1223 ± 21 mL) were used in a replicated 4x4 Latin square design with periods lasting 12 d each (8 d for adaptation and 4 d for sampling). Dietary treatments were: (1) 10% CP, (2) 12% CP, (3) 14% CP, and (4) 10 and 14% CP diets oscillating at 48-h intervals. Experimental diets consisted of 50% orchard hay and 50% concentrate. Fermenters were fed 72 g/d and solid and liquid dilution rates were adjusted to 5.5 and 11%/h, respectively. Data were analyzed using the MIXED procedure in SAS. Partial data are presented in Table 1. Digestibilities of dry matter and organic matter were not affected ($P > 0.05$) by increasing dietary CP, nor by oscillating dietary CP. Total volatile fatty acids concentration and molar proportions of acetate, propionate, butyrate, valerate, iso-butyrate and iso-valerate were not affected ($P > 0.05$) by increasing or oscillating dietary CP. Ruminal NH_3–N concentration increased linearly ($P < 0.01$) in response to increasing dietary CP. Total N, non-ammonia N, and rumen undegraded protein flows did not differ among treatments or between oscillating dietary CP and static 12% CP. Microbial N and NH_3–N flows and microbial efficiency did not differ when comparing oscillating versus static CP ($P > 0.05$). However, there was a quadratic effect ($P < 0.05$) for these variables when dietary CP was increased.

Table 0231.

Table 1. Effects of static or oscillating dietary crude protein levels on fermentation dynamics.

Item	Treatment, CP%				SEM	*P*-value		
	10%	12%	14%	OSC		OSC vs. 12%	Linear	Quadratic
Total N flow, g/d	1.8	2.0	2.1	1.8	0.15	0.27	0.30	0.81
NAN flow, g/d	1.8	1.9	1.8	1.9	0.09	0.70	0.72	0.24
Microbial N flow, g/d	0.9	1.1	1.0	1.1	0.04	0.78	0.06	0.01
Microbial efficiency	31.3	40.5	37.4	36.5	2.20	0.19	0.05	0.02
RDP supply, g of N/d	0.8	1.1	1.2	1.1	0.07	0.84	<0.01	0.34
RUP flow, g of N/d	0.9	0.9	1.0	0.9	0.07	0.95	0.27	0.34
NH_3-N, mg/100 mL	2.9	3.1	8.9	4.8	1.10	0.12	<0.01	<0.01
Total VFA, m*M*	60.5	64.7	64.7	63.0	3.37	0.58	0.17	0.41
Acetate, % total VFA	35.6	34.5	30.9	38.8	2.99	0.29	0.25	0.72
Propionate, % total VFA	28.9	31.2	33.2	28.9	2.38	0.41	0.14	0.95
Butyrate, % total VFA	29.1	29.1	30.5	26.1	3.37	0.51	0.76	0.85
CP digestibility, %	77.5	70.0	67.0	68.4	7.43	0.86	0.30	0.79
DM digestibility, %	41.8	39.0	39.1	43.6	2.21	0.15	0.39	0.61

These results indicate that either ruminal microorganisms do not respond to oscillating CP levels or are capable of coping with 48-h periods of undernourishment. It is possible that other levels of CP, other CP sources, or other oscillating regimes could help elucidating these issues. The diet with 12% CP provided positive effects on microbial N flow and microbial efficiency in the rumen; therefore, it was the best strategy to improve N utilization in the rumen. Beyond that level, there were no further benefits of feeding greater dietary CP.

Key Words: microbial protein, nitrogen metabolism, in vitro fermentation

0232 Reproductive development of rotationally grazed beef heifers when supplemented chelated trace minerals. H. A. Tucker*, S. Bettis, T. Hampton, and M. Vázquez-Añón, *Novus International Inc., St. Charles, MO.*

Supplementation of trace minerals, Zn, Cu, and Mn, impact the health and productivity of ruminants resulting in increased growth and greater reproductive performance. Furthermore, increasing the availability of key trace minerals to the animal through technologies, such as chelation, not only reduces the amount released back into the environment, but may allow for a reduction in the amount of minerals being provided to the animal for optimum performance. Therefore, the objective of this study was to evaluate reproductive development of beef heifers supplemented with chelated trace minerals provided at a reduced inclusion rate. Sixty beef heifers (BW = 264 ± 6 kg; mean ± SEM) were utilized in a randomized complete block design with 2 treatments. Heifers were rotationally grazed and offered pelleted supplements for 91 d. The control (CON) supplement supplied 8.8 ppm Cu, 28.4 ppm Zn, and 31.6 ppm Mn from inorganic sources (133% of NRC requirement). The treatment (MAAC®) supplement contained reduced concentrations of Cu, Zn, and Mn (100% of NRC requirement) achieved through a partial replacement (50%) of inorganic trace minerals with MAAC® chelated trace minerals (Novus International Inc., St Charles, MO). To determine cyclicity of heifers, reproductive tract score (RTS) and plasma progesterone concentrations, along with BW and BCS, were assessed on d −1, 21, 35, 49, 63, 77, and 91 of study. Body weight (P = 0.81), BCS (P = 0.72), and ADG (d 0 to 91; P = 0.34) were not altered by treatment. Heifers supplemented with MAAC® (2.8 ± 0.1) had significantly (P < 0.01) greater RTS than CON (2.5 ± 0.1) throughout the trial. Furthermore, RTS was significantly (P < 0.01) greater on d 91 for MAAC® (3.9 ± 0.2) compared with CON (3.2 ± 0.2). Progesterone levels were significantly (P = 0.02) greater on d 21 (0.56 vs. 0.39 ± 0.06 ng/mL; MAAC® vs. CON) and tended (P = 0.06) to be greater on d 77 for MAAC® (1.05 vs. 0.54 ± 0.19 ng/mL; MAAC® vs. CON). Heifers supplemented MAAC® had 1.66 greater odds of cycling by d 91 of study compared with those supplemented CON. These data suggest that supplementation of MAAC® chelated trace minerals improve reproductive performance of beef heifers. Additionally, current data suggests that a reduction in trace mineral supplementation may benefit reproductive performance while maintaining growth and ADG.

Key Words: chelated trace mineral, reproduction, beef

0233 Comparison of treatment protocols for bovine respiratory disease in high-risk, newly received beef calves. J. J. Ball*[1], E. B. Kegley[1], J. A. Hornsby[1], J. L. Reynolds[1], J. Sarchet[2], and J. G. Powell[1], [1]*Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville,* [2]*Zoetis, Kalamazoo, MI.*

The objective of this study was to evaluate different treatment protocols for bovine respiratory disease (BRD) on performance, morbidity, antibiotic usage, and cost in newly received beef calves. Crossbred male calves (n = 176; BW = 232 ± 1.6 kg) were stratified by bodyweight and assigned randomly to 1 of 2 treatments in a randomized complete block design. Upon

arrival, calves were tagged with an individual identification tag, vaccinated for respiratory and clostridial pathogens, dewormed, castrated (if applicable), branded, tested for persistent infection with BVDV, and administered either 1.1 mL/45 kg BW of tulathromycin with a 7-d post-metaphylactic interval (PMI) or 1.5 mL/45 kg BW of tilmicosin with no PMI. A blinded pen rider observed cattle daily for signs of morbidity and a Clinical Attitude Score (0 [normal] to 5 [morbid]) was recorded. Calves that scored a 1 or greater and were PMI eligible were pulled and rectal temperatures were recorded; if temperature exceeded 40°C, calves on the tulathromycin treatment were given ceftiofur with a 7-d post-treatment interval (PTI) as the initial treatment antibiotic and tilmicosin calves were given enrofloxacin with a 3-d PTI. If the calf was pulled a second time and met the treatment criteria, a final antibiotic was administered, tulathromycin cattle received danofloxacin and tilmicosin cattle received florfenicol + flunixin meglamine. Calves were assigned to 1 of 16 replicated 0.4 ha grass lots with automatic waterers. Calves had ad libitum access to bermudagrass hay and were fed a grain supplement to exceed nutritional requirements. Calves were weighed on d −1, 0, 15, 41, and 42. Performance was similar across treatments throughout the duration of the study ($P \geq 0.10$). Percentage morbidity was greater for first treatment, second treatment, and relapse in the tilmicosin calves compared with the tulathromycin calves ($P < 0.01$). Initial antibiotic cost was greater in tulathromycin calves compared with tilmicosin calves ($P < 0.01$). Both first and second treatment antibiotic cost for cattle were greater in tilmicosin calves compared with tulathromycin calves ($P < 0.01$). However, there were no differences across treatments in terms of overall medical cost ($P = 0.51$), exclusive of labor or chute charges. Metaphylaxis treatment protocols did not affect performance, but differences were found in the percentage of calves treated with antibiotics for BRD and in the number of antibiotics used.

Key Words: bovine respiratory disease, tulathromycin, tilmicosin

0234 Glycerin as alternative energy source for ruminants: In vitro fermentation, total gas and methane production. P. Del Bianco Benedeti[1,2], T. Shenkoru[2], M. Fonseca[3], R. Bittner[2], K. Murphy[2], D. Ivey[2], B. Ribas[2,4], E. Marostegan de Paula[2], L. Galoro da Silva[2], H. Monteiro[2,5], I. Nicolis[2], L. Mariz[1,2], H. Costa[2,6], P. Amaral[1,2], M. I. Marcondes[1], and A. Faciola[*2], *[1]Federal University of Vicosa, Brazil, [2]University of Nevada, Reno, [3]Texas A&M University, College Station, [4]São Paulo State University, Botucatu, Brazil, [5]Maringa State University, Brazil, [6]Federal University of Minas Gerais, Belo Horizonte, Brazil.*

Glycerin has the potential to increase glycogenic potential of beef cattle diets; however, its effects on total gas and CH_4 production have been inconsistent. The objective of this study was to evaluate the effects of glycerin compared with corn and starch on ruminal fermentation, total gas, and CH_4 production using an in vitro system. Twenty-four bottles (620 mL each) equipped with wireless pressure sensors (Ankom[RF] Gas Production System) were used in 4 consecutive 48-h runs. Three ingredients were tested (corn, glycerin, and starch) at 0.5 g per bottle. The experimental design was: 4 incubation runs × 3 ingredients × 7 bottles per treatment, plus 12 blank bottles (3 per run), totaling 96 observations. Rumen fluid was collected from two rumen-cannulated steers and mixed with a buffer solution (1:2 v/v) in water bath at 39°C under anaerobic conditions. Bottles were inoculated with 75 mL of rumen/buffer solution. The data acquisition software was set

Table 0234.

Table 1. Least-square means of *in vitro* fermentation of dietary corn, starch, and glycerin

Item	Corn	Starch	Glycerin	SEM	*P*-value
24h total gas production, mL/g DM	324[a]	324[a]	287[b]	19.1	< 0.01
48h total gas production, mL/g DM	384[a]	344[b]	354[b]	24.1	< 0.01
Final pH	5.89[a]	5.67[b]	5.93[a]	0.13	< 0.01
N-NH_3, mg/100mL	18.9[a]	10.5[b]	16.6[a]	2.11	< 0.01
Total volatile fatty acids, mM/g DM	15.3[ab]	14.4[b]	17.4[a]	3.67	0.01
Acetate, mol/100mol	35.8[a]	35.2[a]	24.8[b]	0.42	< 0.01
Propionate, mol/100mol	24.8[b]	29.5[a]	30.0[a]	1.43	< 0.01
Butyrate, mol/100mol	23.0[b]	21.4[b]	28.9[a]	1.27	< 0.01
Valerate, mol/100mol	6.26[b]	5.67[c]	8.34[a]	0.41	< 0.01
Iso-butyrate, mol/100mol	3.13[a]	2.62[b]	2.40[c]	0.09	< 0.01
CH_4, %	5.22[b]	5.16[b]	8.92[a]	0.42	< 0.01
CH_4, mL/g DM	9.71[b]	8.49[b]	13.6[a]	1.67	< 0.01
CO_2, %	30.9[a]	30.1[a]	26.5[b]	1.29	< 0.01
CO_2, mL/g DM	57.1[a]	48.5[b]	40.8[c]	6.85	< 0.01

[a,b,c] Within a row, different subscripts differ at $P < 0.05$.

to record cumulative pressure every 5 min for 48 h. At the end of the incubation, 10-mL samples were filtered through two layers of cheesecloth, preserved with sulfuric acid and centrifuged for ruminal NH_3 and VFA analyses. The production of CO_2 and CH_4 were determined by chromatography. Data were analyzed using the MIXED procedure of SAS, with ingredients as fixed factors and replicate within ingredient as random. Least-square means are presented in Table 1. Glycerin decreased 24-h total gas production, and acetate concentration ($P < 0.01$). The 48-h total gas production was highest for corn ($P < 0.01$), and similar between glycerin and starch. Compared with glycerin, pH and NH_3–N decreased with feeding starch ($P < 0.01$) but not for corn. Starch had the lowest total VFA concentration ($P = 0.01$), while corn had the lowest propionate concentration ($P < 0.01$). Compared with corn and starch, glycerin had the highest butyrate and valerate concentrations ($P < 0.01$). Glycerin increased CH_4 (% and mL/g) production ($P < 0.01$). CO_2 (mL/g) was higher ($P < 0.01$) for corn, but similar for glycerin and starch. CO_2 (% and mL/g) production was lowest for glycerin ($P < 0.01$). These results suggest that glycerin may change ruminal fermentation relative to corn, increasing propionate, butyrate, and valerate concentrations. Glycerin had higher CH_4 concentration than both corn and starch; therefore, results indicate that glycerin would contribute more to the enhancement of methanogenesis than these carbohydrates.

Key Words: beef cattle, finishing diet, greenhouse gases

0235 The effects of supplementing ruminal bypass unsaturated fatty acids during late gestation on cow and calf serum fatty acids in beef cows.

R. E. Ricks, E. K. Cook, S. K. Duckett, and N. M. Long*, *Clemson University, Clemson, SC.*

The objective of this study was to determine if supplementation with ruminal protected unsaturated fatty acids (FA) increased unsaturated FA in both maternal serum and colostrum during late gestation and in serum from their newborn beef calves. Commercial Angus and Angus crossbred heifers and young cows all bred to a single Angus sire were blocked by breed and parity and randomly assigned to either control (1.5 kg of corn gluten feed, CON $n = 29$) or an isocaloric isonitrogenous supplement containing 200 mg of ESSENTIOM (EFA, $n = 29$) for the last 90 d of gestation. All supplements were individually fed 5 d/wk. All cows had ad libitum access to the same pastures throughout the study. Maternal blood samples were collected at 90 and 45 d before expected parturition. At parturition, blood and colostrum samples were obtained from each cow. Blood samples was collected from calves at parturition and then at 5 d of age. Serum and colostrum FA content were determined. All data were analyzed using PROC MIXED procedure of SAS either as repeated measures or ANOVA depending on parameters. Maternal serum concentrations of C16:0, C18:0 C18:1c9, C18:2, C20:4, and total FA were similar in all cows at start of supplementation but increased (treatment × day interaction $P < 0.01$) in the EFA cows at 45 d before and at parturition compared with CON cows. Colostrum DM was increased ($P = 0.01$) in EFA cows compared with CON cows (30.4 vs. 25.4%, 1.30 SEM). Colostrum concentrations on a DM basis of C18:2, total FA, and total unsaturated FA were increased ($P < 0.05$) in EFA cows compared with CON cows. Serum from calves at birth whose dams were supplemented with EFA had increased ($P \leq 0.01$) concentrations of C16:0, C18:0, C18:1 t9, C18:2, C20:4 and total FA compared with calves whose dams were supplemented CON. At 5 d of age calves from EFA supplemented dams had increased ($P \leq 0.05$) serum concentrations of C18:0, C18:2, C20:4 and total FA compared with serum from calves whose dams were supplemented CON. The results of this study indicate that supplementation of rumen protected unsaturated FA in late gestation beef cows increased circulating and colostrum unsaturated FA, and this resulted in increased unsaturated and total FA at parturition and at 5 d of age in their calves.

Key Words: colostrum fatty acids, ruminal bypass fat, serum fatty acids

---

0236 The effects of supplementing ruminal bypass unsaturated fatty acids during late gestation on transfer of passive immunity and growth in calves.

R. E. Ricks, E. K. Cook, L. K. Lewis, and N. M. Long*, *Clemson University, Clemson, SC.*

The objective of this study was to determine if supplementation with ruminal protected unsaturated fatty acids (FA) increased colostrum and serum concentrations of IgG of calves and subsequent calf growth. Commercial Angus and Angus crossbred heifers and young cows all bred to a single Angus sire were blocked by breed and parity and randomly assigned to either control (1.5 kg of corn gluten feed, CON $n = 29$) or an isocaloric isonitrogenous supplement containing 200 mg of ESSENTIOM (Arm & Hammer Animal Nutrition, Princeton, NJ; EFA, $n = 29$) for the last 90 d of gestation. All supplements were individually fed 5 d/wk. All cows had ad libitum access to the same pastures throughout the study. At parturition a colostrum sample was collected from the dam and a blood sample was collected from calves at 24 h of age. Calf BW was collected every month and adjusted back to every 30 d of age. Serum and colostrum IgG content were determined by ELISA. All data were analyzed using PROC MIXED procedure of SAS either as repeated measures or ANOVA depending on parameters. Dam BW and BCS during late gestation were similar ($P > 0.14$) between treatments. Colostrum concentrations of IgG were increased ($P < 0.01$) in EFA cows compared with CON cows (166 ± 13 vs. 102 ± 18 mg/ml, respectively). Calves from EFA dams had a tendency for a reduced ($P = 0.08$) birth weight compared with calves from CON dams (30.9 ± 0.6 vs. 32.5.6 ± 0.6 kg, respectively). Serum from calves at 24 h of age whose dams were

supplemented with EFA had increased ($P \leq 0.01$) concentrations of IgG compared with calves whose dams were supplemented CON (11.4 ± 0.7 vs. 7.6 ± 0.7 mg/ml, respectively). Calf growth had a treatment X parity X day interaction ($P < 0.01$). Calves from EFA dams that had their second or third calves had increased BW ($P < 0.05$) at 90 to 210 d of age and at 210 d of age respectively compared with calves from CON dams. The results of this study indicate that supplementation of rumen protected unsaturated FA in late gestation beef cows increased colostrum and calf serum IgG and increased calf BW in cows with their second and third calves.

Key Words: calf growth, colostrum IgG, ruminal bypass fat, serum IgG

0237 Effect of OmniGen-AF® dietary supplementation on ultrasound parameters in purebred Angus steers fed a finishing diet.

S. A. Armstrong[*1,2], D. J. McLean[1], G. Bobe[2], M. Bionaz[2], and T. J. Wistuba[1], *[1]Phibro Animal Health Corporation, Quincy, IL, [2]Department of Animal and Rangeland Sciences, Oregon State University, Corvallis.*

Dietary supplementation to aid the immune system of finishing steers is recommended to maintain health and growth; however limited knowledge exists regarding the influence on performance. The objective of this study was to determine the effect of OmniGen-AF® supplementation on ultrasound parameters in steers through the finishing phase. Nine purebred Angus half-sibling steers were divided into one of two treatment groups; Control (CNTL $n = 4$) and OmniGen-AF® (OG; $n = 5$). Cattle were offered 0 g/hd/d (CNTL) or 56 g/hd/d of OG through backgrounding and transition (42d). At the beginning of the finishing phase, cattle were scanned by ultrasound using an Aloka SSD- 500V console with UST-5044–3.5 linear transducer and analyzed using BIA Pro software (Designer Genes Technologies, Harrison, AR). Cattle were subsequently scanned on d 69 and 104 of supplementation to examine the effects of OG supplementation on ultrasound carcass parameters during the finishing phase. Weights, average daily gain (ADG), and dry matter intake (DMI), were collected through the backgrounding and finishing phases. Rib eye area (REA), 12th rib fat thickness (FT), rump fat (RF), REA/cwt and percent intramuscular fat (%IMF) were collected. Predicted yield grade was completed using FT, REA, live weight × 62% dressing percent and 2.5% Kidney Pelvic Heart fat (KPH); predicted quality grade was calculated using %IMF data. Data were analyzed using multiple *t* tests procedure of GraphPad Prism 6.03 with significance declared at $P < 0.05$. No difference between groups was detected for REA, FT, RF, %IMF, predicted yield on d 42 or 69. Predicted quality grade, weight, ADG and DMI did not differ between CNTL or OG. On d104 OG finished cattle had a tendency to have lower FT (CNTL 0.38 ± 0.01, OG 0.32 ± 0.02; mean ± SEM; $P = 0.06$), and higher REA/cwt (CNTL 0.86 ± 0.04; OG 1.01 ± 0.06; $P = 0.07$), and scan with a lower %IMF (CNTL 3.54% ± 0.11 OG 3.03% ± 0.18; $P = 0.06$) compared with controls. Similarly, OG finished cattle scanned with lower RF (CNTL 0.34 ± 0.034 in, OG 0.24 ± 0.02 in; $P = 0.03$) and larger REA (CNTL 11.56 ± 0.44 sq in, OG 13.79 ± 0.67 sq in; $P = 0.04$). Upon evaluation, the OG supplemented cattle had lower predicted numerical yield grades (2.64 ± 0.24) than their control counter parts (3.42 ± 0.16; $P = 0.04$). In this study, supplementing OG during finishing decreased predicted numerical yield grades by increasing REA and decreasing fat deposition.

Key Words: OmniGen-AF, ultrasound, beef cattle

0238 Total gastrointestinal tract digestibility of dry matter, neutral detergent fiber and starch of Nellore and 1/2 Angus x Nellore cattle adapted either for 9 or 14 d to high-concentrate diets.

W. I. Silva Filho[*1], D. H. M. Watanabe[1], A. L. Rigueiro[1], M. C. Pereira[2], G. P. Bertoldi[1], A. C. J. Pinto[1], A. A. Santos[1], M. M. Squizatti[1], L. A. Tomaz[1], O. A. Souza[1], and D. D. Millen[1], *[1]São Paulo State University (UNESP), Dracena, Brazil, [2]São Paulo State University (UNESP), Botucatu, Brazil.*

This study was designed to evaluate the length of the adaptation period to high-concentrate diets on total tract digestibility of DM, NDF and starch of Nellore (NE) and 1/2 Angus x Nellore (AN) cattle. The experiment was designed as completely randomized block with 2 × 2 factorial arrangement, replicated 6 times (3 animals/pen), in which 72 22-mo-old yearling bulls [36 NE (319.2 ± 18.5 kg), and 36 AN (307.9 ± 29.5 kg)] were fed in 24 pens for 89 d according to the treatments: NE adapted for 9 d; NE adapted for 14 d, AN adapted for 9 d, and AN adapted for 14 d. Measures over time were taken on d 10, 15, and 20 of the experimental period. Each of the adaptation diets containing 62%, 70%, and 78% concentrate was fed for 3 d to cattle adapted for 9 d. For cattle adapted for 14 d, the adaptation diets containing 62%, 70%, and 78% concentrate were fed for 5 d, 4 d, and 5 d, respectively. The finishing diet contained: 66.5% cracked corn grain, 14.0% sugarcane bagasse, 16.0% cottonseed meal, 1.5% supplement, 1.2% urea, and 0.8% limestone (DM basis). Diet samples were collected just after morning delivery (0830h) on d 8, 9, 13, 14, 18, and 19 of experimental period, and composite samples were made per pen for d 8 and 9, 13, and 14, and 18 and 19. Samples of orts and feces were collected just before morning (0800h) meals on d 9, 10, 14, 15, 19, and 20 of the experimental period, and a composite samples were made per pen for d 9 and 10, 14, and 15, and 19 and 20. Fecal samples were collected from the same animal in each pen, which was chosen randomly. No significant ($P > 0.10$) biotypes and adaptation length main effects were observed for DM and starch digestibilities. A significant ($P = 0.01$) interaction between biotype, adaptation length, and day of collection was observed for NDF

digestibility, where no differences were detected ($P > 0.10$) across treatments on d 10 and 20; however, on d 15 the NDF digestibility was greater for AN adapted in 14 d (53.9%) and NE adapted in 9 d (53.1%) when compared with AN adapted in 9 d (41.3%) and NE adapted in 14 d (35.1%). Thus, cattle should be adapted for 14 d regardless of biotype, because no differences in digestibility were detected on d 20, and because longer periods of adaptation are safer.

Key Words: adaptation, digestibility, feedlot

0239 Effect of OmniGen-AF® supplementation on the metabolic profile of growing beef cattle.

T. H. Schell*[1,2], S. A. Armstrong[1,2], J. A. Branson[2], M. C. Lewis[2], A. P. Snider[1,2], D. J. McLean[2], and G. Bobe[1], [1]*Department of Animal and Rangeland Sciences, Oregon State University, Corvallis,* [2]*Phibro Animal Health Corporation, Quincy, IL.*

To examine the effect of OmniGen-AF® (OG) supplementation on serum indicators of growth and development in growing beef cattle, healthy 8-mo old purebred Angus cattle were randomly assigned to 0 (control; 4 heifers, 2 bulls, and 2 steers) or 56 g/hd/day OG (OG; 4 heifers, 3 bulls, and 2 steers). Cattle were housed in a freestall barn with straw bedding and fed via Calan Broadbent system a diet including grass hay, alfalfa hay, and ground corn once per day. Blood was collected via jugular puncture on d 0, 3, 5, 7, 10, 14, 21, 28, 35, and 49 of supplementation and 1, 3, 7, 10, 14, and 21 d after supplementation and analyzed for serum concentrations of glucose, insulin, leptin, and haptoglobin. Using a repeated-measures-in-time design in PROC MIXED, we examined changes in serum parameters from baseline during the 49 d of supplementation and separately during the 21 d after supplementation. We hypothesized that OG supplementation alters carbohydrate metabolism during the supplementation period. We observed sex-specific effects of OG supplementation on serum indicators of carbohydrate metabolism and growth. During the supplementation period, serum glucose concentrations increased in control bulls and steers compared with male OG-supplemented cattle ($P = 0.01$), whereas no treatment effects were observed for heifers ($P = 0.80$); those gender-specific treatment group differences were also observed after supplementation. During the supplementation period, serum leptin concentrations decreased in female controls compared with female OG-supplemented cattle ($P < 0.01$). No treatment group differences for serum leptin were observed for bulls and steers combined ($P = 0.54$) or after supplementation irrespective of gender. Changes in insulin concentrations were not different between treatment groups ($P = 0.29$); however, insulin concentrations were lower during but not after supplementation in OG-supplemented cattle compared with controls, when baseline insulin concentrations were used as linear covariate ($P = 0.01$). During but not after the supplementation period, haptoglobin concentrations decreased in OG-supplemented bulls ($P = 0.03$) and increased in OG-supplement steers ($P = 0.06$) compared with their sex-specific controls. No differences in serum haptoglobin between treatment groups were observed in females or during supplementation withdrawal. These data suggest no consistent effects of OG supplementation on the metabolism of growing beef cattle.

Key Words: beef cattle, metabolism, OmniGen-AF

0240 Dietary melatonin and growth responses in feedlot heifers.

M. R. Schaefer* and D. M. Schaefer, *University of Wisconsin, Madison.*

Two trials were conducted to determine if feeding melatonin (MEL) to growing beef heifers altered feedlot performance or carcass composition. Trial 1 was initiated on October 22 while Trial 2 commenced on April 15, and both utilized black-hided, non-implanted heifers ($n = 90$ per trial) which were blocked by initial BW (380 kg, Trial 1; 300 kg, Trial 2). Heifers were assigned to a pen (6 hd/pen) within block and pen was randomly assigned 1 of 3 treatments which provided 0, 20 or 100 mg MEL $\cdot$ hd^{-1} $\cdot$ d^{-1} for Trial 1, while Trial 2 treatments provided 0, 100 or 200 mg MEL $\cdot$ hd^{-1} $\cdot$ d^{-1}. Heifers were fed twice daily at 0700 and 1100 h a basal diet that contained (DM basis) 15% corn silage, 70.9% cracked corn, 5.8% DDG, 5.0% wheat midds, 1% urea, and the residual was micro ingredients which included MGA (NEg = 1.46 Mcal/kg, CP = 12.9%). Melatonin supplements were made monthly for each treatment by diluting MEL powder into finely ground corn and were fed at 0.45 kg as-fed $\cdot$ hd^{-1} $\cdot$ d^{-1} as a replacement for cracked corn at the 1100 h feeding. Slaughter occurred by block, and carcasses were chilled for 48 h before data collection. Pen (experimental unit) data were analyzed using the MIXED procedure of SAS and orthogonal contrasts were used to assess linearity (-0.5345, -0.2673, and 0.8018 for Trial 1, and -1, 0, 1 for Trial 2). In Trial 1, a positive linear effect for G:F (0.156, 0.160, and 0.169) and calculated dietary NEg (1.36, 1.41, and 1.45 Mcal/kg) was observed ($P \leq 0.02$) for the 0, 20, and 100 mg treatments, respectively. Positive linear tendencies ($P \leq 0.09$) were detected for ADG (1.84, 1.88, and 1.95 kg/d) and HCW (354, 355, and 361 kg), while all treatments had similar rib-eye ether extract percentages ($P = 0.41$) in Trial 1. In Trial 2, feeding 200 mg MEL increased HCW vs. 0 mg (348 vs. 342 kg, $P = 0.05$) and 100 mg HCW = 343 kg. No differences in 12th rib fat depth or marbling score were recorded ($P \geq 0.13$) in either trial. Results indicate that feeding MEL to non-implanted feedlot heifers may increase gain efficiency and HCW with no effects on carcass composition.

Key Words: melatonin, feedlot, heifers

0241 Dietary melatonin and growth responses in implanted feedlot steers. M. R. Schaefer* and D. M. Schaefer, *University of Wisconsin, Madison.*

Two trials were conducted to determine if feeding melatonin (MEL) to growing beef steers altered feedlot performance or carcass composition. Trial 1 was initiated on October 23 while Trial 2 started on March 19, both utilized black-hided steers (n = 90 per trial) which were blocked by initial BW (325 kg, Trial 1; 410 kg, Trial 2). Steers were assigned to a pen (6 hd/pen) within block and pen was randomly assigned 1 of 3 treatments which provided 0, 100 or 200 mg MEL per animal/d. All steers received a single implant of 120 mg trenbolone acetate and 24 mg estradiol on d 28 (Trial 1) or d 0 (Trial 2). Steers were fed once daily at 0800 h a basal diet that contained (DM basis) 15% corn silage, 70.9% cracked corn grain, 5.8% dried distillers grains, 5.0% wheat midds, 1.4% limestone, 1% urea, and the residual was micro ingredients (NEg = 1.46 Mcal/kg, CP = 12.9%). Melatonin supplements were made monthly for each treatment by diluting MEL powder into finely ground corn and were fed at 0.45 kg as-fed per animal/d as a replacement for cracked corn. On d 154 in Trial 1, three steers per pen in the lightest 2 blocks were restrained between 1400 and 1600 h to collect blood and urine samples. Data were analyzed using the MIXED procedure of SAS with treatment as a fixed effect while block and trial were recognized as random effects, and an orthogonal contrast was used to compare the 0 vs. 200 mg treatments. No growth responses were different across the treatments ($P \geq 0.19$). Feeding MEL increased ($P \leq 0.01$; 0 vs. 200 mg) 12th rib fat depth (1.2 vs. 1.4 cm) and yield grade (2.9 vs. 3.3), tended ($P = 0.10$) to increase HCW (379 vs. 386 kg); however, it did not alter marbling score (563 vs. 566; $P = 0.74$). Plasma serotonin levels were similar across treatments; however, urine 6-hydroxymelatonin-sulfate increased ($P = 0.01$) in MEL fed steers (5, 217, and 253 ng/ml urine). Dietary MEL may increase HCW in steers; however, the additional weight accumulation might be attributed to more fat gain as implied by the increased rib fat depth.

Key Words: feedlot, melatonin, steers

0242 Use of the residual retained energy as a measure of efficiency in growing Nellore cattle bulls. A. M. Castilhos*[1], A. M. Jorge[1], C. L. Francisco[1], M. E. Z. Mercadante[2], S. F. M. Bonilha[2], C. M. Pariz[1], D. C. M. Silva[1], and R. H. Branco[2], *[1]Universidade Estadual Paulista-FMVZ, Botucatu, Brazil, [2]Centro APTA Bovinos de Corte, Instituto de Zootecnia, Sertãozinho, Brazil.*

This study used 357 Nellore bulls (212 + 38 kg BW; 279 + 29 d of age) to evaluate the effect of a new efficiency measure (residual retained energy) on feedlot performance and economic viability of the cattle production system. GrowSafe automated feeding system (GrowSafe Systems Ltd., Airdrie, AB, Canada) and individual pens were used to record DMI. Residual retained energy (RRE) was calculated as difference between net energy required for gain (NEFG) and the retained energy (RE) for animal. Net energy required for gain was estimated as (DMI– feed required for maintenance) * diet NE_g. Retained energy for animal was predicted by equation of the NRC (2000). Other efficiency measures as residual feed intake (RFI), residual intake and BW gain (RIG), and residual BW gain (RG) were used. Residual feed intake was calculated as the residuals from the regression of total DMI on $BW^{0.75}$ and ADG. Residual gain was calculated as the residuals from the regression of total ADG on $BW^{0.75}$ and DMI. Residual intake and BW gain was determined from linear combination into RFI and RG. Animals were classified for each efficiency measure as Low (< 0.5 SD mean), Medium (within ± 0.5 SD), and High (> 0.5 SD mean) groups. Carcass characteristics [LM area and back fat thickness (BF); 12th–rib] were evaluated using ultrasound measures. Economic value included was profit ($/bull.d^{-1}). Feedlot performance variables were ADG (kg/d), DMI (kg/d), and final BW (kg). Data were analyzed using PROC MIXED in SAS. For feedlot performance, High group had greater ($P < 0.001$) final BW and ADG compared with other groups. No group effects ($P = 0.94$) were detected for DMI. For carcass characteristics, no group effects ($P = 0.50$) were detected for BF. However, High group had greater LM area ($P = 0.001$) than other groups. High group demonstrated better efficiency values for the three measures evaluated (RFI, RIG, RG; $P < 0.001$), and greater profit ($P < 0.001$) compared with other groups. In conclusion, the residual retained energy proved to be a new measure of efficiency able to identify more productive and profitable animals on herd, without detriment to the degree of finish of the carcass.

0243 Effects of rumen-protected PUFA supplementation to late-gestating beef cows on performance and physiological responses of the offspring.

R. Marques[*1], R. F. Cooke[1], K. M. Shubach[1], A. P. Brandao[1,2], M. C. Rodrigues[1,2], K. Lippolis[1], P. Moriel[3], and D. W. Bohnert[1], *[1]Oregon State University-EOARC Burns, Burns, [2]UNESP-FMVZ, Botucatu, Brazil, [3]UF/IFAS, Range Cattle Research and Education Center, Ona, FL.*

Our objective was to evaluate the effects of PUFA supplementation to beef cows during late gestation on performance and physiological responses of the offspring. On d 0 of the experiment, 96 multiparous, non-lactating, pregnant Angus × Hereford cows at the end of their second trimester of gestation were stratified by BW and BCS, and divided into 24 groups of 4 cows/group. Groups were randomly assigned to receive (as-fed basis) 452 g of soybean meal per cow daily in addition to 1) 200 g/cow daily of rumen-protected PUFA mix based on eicosapentaenoic, docosahexaenoic, and linoleic acids (PF) or 2) 200 g/cow daily of rumen-protected fatty acid mix based on palmitic and oleic acids (CON). Groups were maintained in 2 pastures (12 groups/pasture) with ad libitum access to water and alfalfa hay. However, groups were segregated 3 times/wk and offered treatments (Mondays, Wednesdays, and Fridays) from d 0 until calving. Within 12 h after calving, calf BW was recorded. Calves were weaned on d 280, and preconditioned for 45 d. Blood samples were collected from all calves on d 280, 282, 285, 288, and 293 to evaluate plasma haptoglobin concentration. Supplementing beef cows with PF did not ($P \geq 0.24$) impact cow BW change or pre-calving BW, as well as cow BCS change and pre-calving BCS. No treatment effects were detected ($P \geq 0.14$) for calf birth BW, calving rate, percentage of male calves born, and kg of calf born per cow assigned to the experiment. At weaning, no treatment differences were detected ($P \geq 0.24$) for weaning rate, calf weaning BW (205-d adjusted or not), and kg of calf weaned per cow assigned to the experiment. Calves from CON cows were older at weaning ($P = 0.03$) than PF cohorts. No treatment effects were detected ($P \geq 0.22$) for calf preconditioning ADG, BW, and percentage of calves treated for BRD symptoms. Nevertheless, a treatment × day interaction was detected ($P = 0.03$) for plasma haptoglobin concentration, which was greater for calves from CON vs. PF cows on d 282. In summary, PF supplementation to late gestating beef cows did not impact overall cow and offspring productive parameters, but reduced offspring acute-phase protein reaction elicited by weaning.

Key Words: beef cows, offspring, PUFA, supplementation

0244 Effects of injectable trace mineral supplementation on yearling bull growth, carcass characteristics, testicular development and semen quality attributes.

C. P. Blank[*1], P. J. Gunn[2], D. Schrunk[1], S. Ensley[1], D. Madson[1], and S. L. Hansen[1], *[1]Iowa State University, Ames, [2]Department of Animal Science, Iowa State University, Ames.*

The study objective was to evaluate effects of injectable trace mineral supplementation on growth, carcass characteristics, testicular development and semen quality in yearling Angus bulls. Bulls (446 kg ± 35, SD) were blocked by age into 4 pens of 15, and randomly assigned to receive Multimin 90 (MM) or a saline injection (CON; $n = 30$ per treatment) at 1 mL/68 kg BW and fed a common finishing diet for 73d. Breeding soundness exams (BSE) and scrotal circumference measurements were conducted on d 53 on all bulls. Liver and blood mineral concentrations ($n = 14$/treatment) were determined on d 1 and 53, and semen mineral concentrations were also determined on d 53. Bulls were harvested on d 74, and testicles were assessed for testicular density and histology, and carcass data collected after a 48-h chill. Data were analyzed using MIXED or GLIMMIX procedures of SAS with the fixed effect of treatment and bull as the experimental unit. Days of age (BSE, testicular data) and initial mineral concentrations (plasma, liver) were used as covariates. No differences due to treatment were observed in ADG, carcass characteristics, testicular density or histology ($P \geq 0.27$). Results from BSE indicate no differences in scrotal circumference, testicular tone, morphology, or pass/fail percentages ($P \geq 0.30$) between treatments; however, overall motility ($P = 0.07$) tended to be lesser in MM-bulls. Based on reference ranges, d 1 liver mineral concentrations were considered adequate in all bulls. Day 53 liver and plasma mineral concentrations were similar between MM and CON treatments ($P \geq 0.15$). Treatment did not affect whole semen mineral concentrations ($P \geq 0.18$), or Se, Zn, and Mn concentrations ($P \geq 0.48$) of seminal plasma. However, seminal plasma Cu concentrations were greater in MM bulls ($P = 0.04$). Spermatozoa concentrations of Se and Zn ($P \geq 0.27$) did not differ due to treatment; however, spermatozoa Cu tended ($P = 0.07$) to be lesser and spermatozoa Mn concentrations were decreased ($P = 0.03$) in MM-bulls. Interestingly, spermatozoa Mn concentrations were negatively correlated with morphology ($r = -0.41$, $P = 0.04$). These data suggest supplementing bulls adequate in mineral status with MM does not affect growth, carcass characteristics or semen attributes. However, semen mineral concentrations may be related to semen quality and more work is needed to clarify the importance of mineral distribution in semen fractions on semen quality.

Key Words: bulls, semen quality, trace minerals

0245 Effect of α tocopherol acetate and ascorbic acid on performance, carcass traits, and incidence and severity of liver abscesses in finishing cattle.
H. C. Muller*, C. L. Van Bibber-Krueger, and J. S. Drouillard, *Kansas State University, Manhattan.*

Liver abscesses (LA) in cattle negatively affect feedlot performance by decreasing ADG, feed intake, and G:F. Abscessed livers are condemned and abdominal adhesions associated with LA can result in extensive carcass trimming during harvest, further compounding adverse economic impact. Given pending regulatory changes pertaining to the use of in-feed antibiotics in cattle production, there is growing interest in alternatives to antibiotics for LA control. The objective of this study was to evaluate use of a combination of the antioxidants, ascorbate and α tocopherol acetate, for mitigation of LA in feedlot cattle. Yearling crossbred heifers (n = 390; initial BW 481 ± 9.4 kg) were blocked by previous treatment and allocated randomly to 24-dirt surfaced feedlot pens (10 m × 35 m) with 13 to 14 heifers/pen. Heifers were weighed, implanted with TE-200 implants, and placed into feeding pens. Finishing diets consisted of 60% steam-flaked corn, 30% wet corn gluten feed, 8% alfalfa, and 2% supplement (DM basis) and provided 300 mg/d monensin, no tylosin, and either 200 IU/d α tocopherol acetate (CTL) or 2000 IU/d α tocopherol acetate plus 500 mg/day crystalline ascorbate (AOX). Heifers were fed once daily ad libitum for 94 d, then weighed and transported 450 km to a commercial abattoir for harvest. The HCW and incidence/severity of LA were determined the day of harvest, and carcass traits were evaluated following 32 h of refrigeration. Compared with CTL, feeding AOX tended to decrease DMI (10.66 vs. 10.31 kg/d; P = 0.08) and improve G:F (0.1204 and 0.1254; P = 0.12), but did not impact ADG, incidence of LA (25.6 vs. 23.5% for CTL and AOX, respectively), HCW (828.4 vs. 830.5 kg for CTL and AOX, respectively), or other carcass traits (P > 0.20). In conclusion, feeding antioxidants is not a viable alternative to decrease incidence of liver abscesses in finishing cattle.

Key Words: antioxidant, feedlot, liver abscess

0246 Feed intake and production efficiency of beef cows.
H. C. Freetly*, L. A. Kuehn, R. M. Thallman, and W. M. Snelling, *USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

The objective of this study was to determine the relationships between DMI and growth as heifers and cows and calves weaned, weight of calf weaned, and milk production. Cows born in 1999–2001and sired by industry AI bulls (Angus, Hereford, Simmental, Limousin, Charolais, Gelbvieh, and Red Angus) and with Angus, Hereford, and MARC III (composite) dams were randomly mated to F_1 bulls from these same crosses (with the exception of MARCIII dams) resulting in heifers (F_1^2) that were 2-, 3-, and 4-breed crosses. Heifers (F_1^2) born in 4 consecutive years (2004–2007) were retained and bred to produce four successive calf crops, calving first at 2 yr of age. Individual feed intake and BW gain were measured for an 84-d period between weaning and first breeding on F_1^2 heifers born in years 2005–2007 (n = 220, 249, and 218, respectively). At 5 yr of age, F_1^2 cows were not bred. Twenty-one d after weaning, F_1^2 cows (n = 158, 179,154, and 131, respectively, for birth years 2004–2007) were individually offered 120 kcal ME/kg $BW^{0.75}$·d^{-1}in Calan gates for 112 d, and then given ad libitum access for an additional 98 d. Milk production at approximately 100 d after calving was measured using a 16-h weigh-suckle-weigh at 2- and 5-yr of age. Heritability and genetic correlations were estimated with MTDFREML. The heritability estimates were Heifer DMI (0.69) Heifer ADG (0.49), Cow DMI (0.48), Cow ADG (0.46), and 5-yr-old milk production (0.41). There were positive genetic correlations between heifer DMI and heifer ADG (0.89), cow DMI (0.65), cow ADG (0.73), average weaning weight of calves (0.52), and total calf weight weaned (0.23). There were positive genetic correlations between cow DMI and average weaning weight of calves (0.28), and total calf weight weaned (0.21). In conclusion, there are genetic correlations between DMI and total weight of calf weaned; also, heifer intake does offer some opportunity to select for intake in mature cows. Selection for reduced DMI may have a negative effect on total BW of calf weaned. USDA is an equal opportunity provider and employer.

Key Words: cows, feed intake, production efficiency

0247 Effects of concurrent selection for residual feed intake and average daily gain on fertility and longevity in black Angus beef females.
P. J. Gunn*[1] and G. R. Dahlke[2], [1]*Department of Animal Science, Iowa State University, Ames,* [2]*Iowa State University, Ames.*

During an individually fed feed efficiency test, traits including ADG, DMI, G:F, residual feed intake (RFI), and residual gain (RG) are evaluated. Almost invariably, ADG and RFI are the only traits in this list that are not correlated. Previous data would suggest that RFI does not affect fertility; however, a selection index that incorporates RFI and improves fertility has not been well defined. Thus, the objective was to determine if concurrent selection for RFI and ADG may identify beef heifers that have improved fertility and longevity in the beef herd. Yearling feed efficiency testing and subsequent production data were collected on 540 purebred, Black Angus heifers from 14 contemporary groups over 6 yr. These data were unbiased in that heifers were retained based on fertility, irrespective of feed efficiency performance indicators. Cattle that were both above contemporary group average for ADG as well as below contemporary group average for RFI were categorized as PASS, and all other heifers were categorized as FAIL. The MIXED and GLIMMIX procedures of SAS were used to analyze continuous and binary variables, respectively.

The model included heifer category as the main effect and included contemporary group as a random effect. Across the dataset, ADG and RFI were not correlated ($P = 0.64$). Yearling pregnancy rates did not differ ($P = 0.14$) between PASS (87.2%) and FAIL (82.3%), nor did the proportion of heifers that became pregnant in the first 21 d of the breeding season ($P = 0.69$). Pregnancy rate as a 2-yr-old tended to be greater ($P = 0.07$) in PASS (85.7%) compared with FAIL (75%). Moreover, the proportion of females that remained in the herd at 3, 4, and 5 yr of age was greater ($P \leq 0.05$) in PASS than FAIL. It should be noted that PASS did not differ from FAIL for phenotypic birth BW, weaning BW, yearling BW, or yearling height ($P \geq 0.53$). Furthermore, nonparent EPDs for calving ease maternal, scrotal circumference, milk, and rib-eye area did not differ between PASS and FAIL ($P = 0.42$). However, PASS tended to have a greater nonparent marbling EPD than FAIL (0.409 vs. 0.375, respectively). These data indicate that dual selection for ADG and RFI may identify beef heifers that have improved fertility and longevity without impacting growth and maternal EPDs.

Key Words: feed efficiency, fertility, residual feed intake

0248 Efficacy of a novel intranasal Zn solution on health and growth performance of high risk, newly received stocker cattle. M. M. Foster*, E. B. Kegley, J. G. Powell, J. L. Reynolds, J. A. Hornsby, D. L. Galloway, J. J. Ball, and J. Zhao, *Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville.*

The objective of this study was to determine if using an intranasal Zn solution would impact health and growth performance of high-risk stocker cattle. Upon arrival from regional sale barns, male beef calves ($n = 239$; 3 arrival dates [block]; initial BW = 276 ± 2.4 kg) were identified with individual ear tags, vaccinated with clostridial and 5-way modified live bovine respiratory viral vaccines, dewormed, branded, and castrated (if necessary). In addition, nasal swabs were collected from 24 calves (12/treatment) in block 2 and cultured for bacterial pathogens on d 0, 1, 2, and 7. Calves were stratified by arrival gender and BW into 2 treatments: Zn treated, 3 mL of a solution containing 32.4 mg of Zn administered intranasally, or control, in which calves were not treated. Calves were penned without fenceline contact to calves on the other treatment in replicated 0.42-ha grass pastures (24 pens), and cattle had ad libitum access to bermudagrass hay along with receiving a grain supplement to meet or exceed their nutritional requirements. Rectal temperatures were taken on d 0, 1, 7, and 14 after arrival. Calves were observed daily for signs of morbidity and a Clinical Illness Score (CIS 1 [normal] to 5 [morbid]) was recorded. Cattle that scored > 1 on the illness score and had a rectal temperature greater ≥ 40°C were treated with an antibiotic per a preplanned treatment protocol. If rectal temperature ≥ 40°C persisted past first antibiotic post-treatment interval, cattle were re-treated according to pre-planned protocol. Body weights were similar across treatments throughout the duration of the study ($P \geq 0.22$). Calves treated with Zn had a lower ADG from d 7 to 28 and d 14 to 28 compared with the control ($P < 0.01$). Control calves tended to be treated with 3 antibiotics more often than Zn treated calves ($P = 0.06$). Overall treatment antibiotic costs did not differ across treatments ($P = 0.64$). There were no differences ($P \geq 0.10$) for rectal temperature of calves across treatment. The prevalence of bacterial pathogens were not different across treatments ($P \geq 0.24$) except the presence of *P. aeruginosa* which tended to be greater in the control compared with the Zn treated calves ($P = 0.08$). From the results of this study, calves treated intranasally with Zn showed no differences in overall performance and minimal differences in morbidity compared with the control.

Key Words: bovine respiratory disease, morbidity, Zn

0249 Performance and net energy in High and Low RFI beef cattle on restricted intake. K. C. Dykier and R. D. Sainz*, [1]*University of California, Davis.*

To determine how beef cattle with known residual feed intake (RFI) phenotypes would perform under restricted feeding, 36 weaned Angus cross beef calves (24 steers and 12 heifers) were selected from a group of 98 calves that had been previously phenotyped for RFI. High and Low RFI animals (24 steers and 12 heifers) were subjected to a 52-d feeding trial with intake limited to 1.5% of BW. Feed offered and refused were measured daily, BW was taken at 14-d intervals, and ultrasound measures (LM area and subcutaneous fat over the 12th–13th ribs) were taken at the beginning, middle and end of the trial. After 52 d of intake restriction, RFI groups had similar BW, ADG, DMI, RFI and G:F. Fat gain, protein gain, and estimated recovered energy (RE) were similar between groups, although High RFI cattle had 0.26 cm more subcutaneous rib fat than Low RFI ($P = 0.01$). High RFI cattle also had more rib fat at the start of restricted feed trial. RFI groups did not differ in estimated heat energy (HE) or maintenance requirement (NEm; $P > 0.10$). Heifers had lower HE than steers ($P < 0.01$). All cattle had lower ADG, RE, NEm and HE in response to limited feed. Overall HE was reduced from 0.26 Mcal/kg$^{0.75}$ on ad libitum feeding to 0.16 Mcal/kg$^{0.75}$ on the restricted level of intake. The difference in HE from ad libitum to restricted feeding was −47 and −28% in High and Low RFI cattle, respectively ($P < 0.01$). Estimated NEm requirement was reduced from 0.095 to 0.073 Mcal/kg$^{0.75}$ overall, with a difference of −39% and +14% ($P < 0.01$) in High and Low RFI cattle, respectively. Estimated NEm requirement changed by −32% and +7% ($P = 0.004$) in heifers and steers, respectively. These results indicate that when limited, both High and Low RFI cattle lower their maintenance requirement and heat production to similar levels, although High RFI cattle had higher HE and NEm during ad libitum

Table 0249.

Table 1. Performance and net energy of RFI groups in response to diet restriction.

	RFI		Sex			P value		
Trait	High	Low	H	S	SD	RFI	Sex	RFI x Sex
Initial BW, kg	454.4	440.2	443.2	456.2	49.2	0.42	0.31	0.80

feeding. Furthermore, heifers may be better equipped than steers to adapt maintenance requirement and heat production in response to limited feed.

Key Words: efficiency, net energy, residual feed intake

0250 Effects of the EPNIX® beef program on feedlot performance in diets containing no Monensin or Tylosin. V. B. Holder[*1], J. S. Jennings[2], and R. S. Swingle[3], *[1]Alltech Inc., Nicholasville, KY, [2]Texas A&M AgriLife Research and Extension Center, Amarillo, [3]Cactus Feeders, Amarillo, TX.*

This study was conducted to compare growth performance, health and carcass characteristics of beef steers fed diets containing EPNIX® products (Alltech Inc., EPNIX) with steers fed control (CON) diets formulated using conventional sources of trace minerals and common feed additives. One thousand six hundred eighty crossbred steers (Initial BW = 347.9 ± 23.7 kg) were used in a randomized complete block design with 2 treatments (CON and EPNIX) and 12 pens per treatment. Pen was the experimental unit. CON diets contained trace minerals from mostly inorganic sources plus monensin and tylosin. EPNIX diets contained organic trace minerals, yeast and bacterial preparations, but not monensin or tylosin. Both treatments were fed diets containing ractopamine hydrochloride at the end of the feeding period. EPNIX products tended to increase DM intake (9.95 vs. 10.12 kg/d, $P = 0.086$), but there were no differences between treatments in final BW, ADG or feed efficiency ($P \geq 0.145$). Carcasses from steers on the EPNIX treatment were 6.4 kg heavier (409.7 vs. 416.1, $P = 0.015$) than CON steers and dressed yield was 0.5 units higher (64.4 vs. 64.9%, $P < 0.001$). Final BW adjusted to a common dressed yield was higher for EPNIX steers ($P \leq 0.038$), as was carcass-adjusted ADG ($P \leq 0.033$). Carcass adjusted feed efficiency did not differ between treatments. Differences in health parameters between treatments were not remarkable. Marbling score and quality grade distributions were not remarkably different between treatments ($P \geq 0.019$). Calculated yield grade was lower (leaner) for EPNIX than CON carcasses (3.30 vs. 3.15, $P = 0.049$) due to heavier carcass weight and larger LM muscle area (92.5 vs. 96.3 in^2, $P < 0.001$). Liver abscess prevalence was higher for steers on EPNIX relative to CON (13.6 vs. 26.5%, $P < 0.001$), but measures of liver abscess severity did not differ between treatments. Differences in meat quality parameters were not remarkable. These results demonstrate that cattle may be fed successfully with EPNIX® products fed in lieu of monensin and tylosin, although liver abscess prevalence would be a concern. The increased dressed yield and heavier carcass weights for steers on the EPNIX treatment suggests a possible role of EPNIX products to improve carcass weight transfer.

Key Words: antibiotics, carcass

0251 Natural dry matter intake fluctuation impacts performance, feeding behavior and rumen morphometrics of feedlot cattle: 10 yr of data assessment. G. D. Cruz[*1], I. C. Pereira[2], D. D. Millen[3], M. D. Arrigoni[2], C. L. Martins[2], and C. F. Costa[2], *[1]Cargill Animal Nutrition, Elk River, MN, [2]São Paulo State University (UNESP), Botucatu, Brazil, [3]São Paulo State University (UNESP), Dracena, Brazil.*

This study aimed to evaluate the impact of natural DMI fluctuation on performance, carcass characteristics, feeding behavior,

blood metabolic profile and rumen morphometrics of feedlot cattle. All 10 experiments used for this analysis were conducted at the feedlot research station (São Paulo State University, Botucatu, Brazil campus) from 2006 to 2015. Data were collected from 838 yearling bulls fed high-concentrate diets in group pens (3 or 4 animals per pen; $n = 238$ pens). Pens were considered the experimental unit for this study. Daily DMI fluctuation was calculated for each pen as the difference in intake between consecutive days. Daily DMI fluctuation was expressed as variation according to the following formula: DMI fluctuation in kilograms/DMI of the previous day in kilograms × 100. The final data from each pen represented the average daily DMI fluctuation for the entire feeding period. Based on the overall median of DMI fluctuation of 5.62%, cattle were classified into two groups: high- or low-fluctuation. All data analysis was performed in R using a mixed model approach where pens and years were random variables and fluctuation group was considered as fixed. The low and high fluctuation groups presented a DMI fluctuation average of 4.79% and 6.74%, respectively. Low fluctuation group performed better than high fluctuation one, with greater ADG (1.45 kg vs. 1.39 kg; $P = 0.05$), DMI (9.16 kg vs. 8.89 kg; $P = 0.06$), total weight gain (143 kg vs. 137 kg; $P = 0.08$), LM area daily gain (0.18 cm^2 vs. 0.16 cm^2; $P = 0.03$), and lower shear force (4.71 kg vs. 5.41 kg; $P = 0.03$). In terms of feeding behavior, low fluctuation group spent more time ruminating (341 min vs. 322 min; $P = 0.04$), less time resting (893 min vs. 917 min; $P = 0.06$) and visited the water trough less often (6.6 visits vs. 7.4 visits; $P = 0.04$). No effects of DMI fluctuation was observed ($P > 0.10$) on blood metabolic profile, rumenites incidence and rumen morphometrics. This multiannual evaluation illustrates the severe impact of an apparent small DMI intake fluctuation on feedlot performance and raises even more awareness to bunk management and proper nutrition.

Key Words: feedlot, intake fluctuation, performance

0252 Effect of total replacement of trace minerals with Bioplex® proteinated minerals on the health and performance of lightweight, high-risk feedlot cattle.

V. B. Holder*[1], J. S. Jennings[2], and T. L. Covey[3], *[1]Alltech Inc., Nicholasville, KY, [2]Texas A&M AgriLife Research and Extension Center, Amarillo, [3]OT Feedyard and Research Center, Hereford, TX.*

This study was conducted to compare growth performance, health and carcass characteristics of lightweight beef steers fed diets containing traditional trace mineral supplementation (CON) with steers fed diets containing only proteinated forms of Zn, Cu, Co and Mn (BIOPLEX). Eight hundred one lightweight crossbred beef steers (Initial BW = 139 ± 4.3 kg) were used in a randomized complete block design with 2 treatments (CON and BIOPLEX) and 12 pens per treatment. Pen was the experimental unit. CON diets contained trace minerals from mostly inorganic sources. BIOPLEX diets were reformulated to replace all supplementary sources of Zn, Cu, Co, and Mn with proteinated forms of these minerals (Bioplex®, Alltech Inc.). Diets were formulated to provide equal total mineral concentrations in the ration. There were no significant differences between treatments in dry matter intake, gain or feed efficiency. Numerical improvements in both average daily gain and dressing percentage resulted in a tendency for increased hot carcass weight in BIOPLEX diets (357.2 vs. 366.0 kg, $P = 0.10$). Morbidity was not affected by treatment but mortality was reduced by 57% on the BIOPLEX treatment (4.78 vs. 2.05%, $P = 0.03$), driven by a 69% reduction in mortality due to respiratory causes (3.28 vs. 1.02%, $P = 0.016$). Carcass composition, quality and yield grades were unaffected by treatment. In this study, total replacement of the trace minerals Zn, Cu, Co and Mn with proteinated forms reduced mortality from respiratory disease and tended to improve carcass weight. Total replacement with proteinated forms of trace minerals may play a role in supporting the production and health of high risk, light weight feedlot cattle.

Key Words: carcass, chelate, respiratory

0253 The effect of frequency of supplementing rumen protected unsaturated fatty acids on blood serum fatty acid profiles in beef heifers and lactating cows.

E. K. Cook*[1], M. E. Garcia-Ascolani[2], R. E. Ricks[1], S. K. Duckett[1], N. DiLorenzo[2], G. C. Lamb[2], and N. M. Long[1], *[1]Clemson University, Clemson, SC, [2]University of Florida, North Florida Research and Education Center, Marianna.*

The objective of this study was to determine frequency of supplementation of rumen protected fat (RPF; ESSENTIOM) influences circulating serum fatty acids (FA) in beef heifers and lactating cows. In experiment 1, 12 early gestation beef heifers were supplemented 0.5 kg corn gluten feed (CGF) daily during a 2-wk adaptation period. During the last 3 d of adaptation, blood samples were collected immediately before supplementation, then 8 and 16 h post-supplementation daily. Each heifer was then randomly assigned to one of 3 supplementation frequency treatments of RPF (3, 5, or 7 d/wk) for 3 wk in a Latin square design with 3 periods, with each treatment receiving the same amount of RPF and CGF per wk (1 and 2.7 kg respectively). Blood samples were collected during the final 3 d of each supplementation period as in adaptation period. In experiment 2, 18 Angus crossbred cows in early lactation were supplemented 4.54 kg CGF weekly either at 3, 5, or 7 d/wk during a 2-wk adaptation period. Blood samples were collected during the last 3 d of adaptation as in experiment 1. For the subsequent 3 wk, RPF was added to the CGF supplement so that each supplementation frequency received 1.59 kg/wk of RPF. Blood samples were collected during the last 3 d of supplementation as in experiment 1. Serum FA profiles on a random subsample of 8 heifers in experiment 1

and all animals in experiment 2 were determined via GC and values were analyzed using the MIXED procedure of SAS. In experiment 1, serum concentrations of C18:2 and total FA were increased during supplementation compared with during adaptation (trt*time, $P \leq 0.04$). However, there were no differences between supplementation frequencies within a day*time period. In experiment 2, serum concentrations of C18:2 and total FA were increased with RPF supplementation compared with adaptation (trt*time, $P \leq 0.01$). There was a tendency ($P < 0.1$) for the 7 d/wk frequency to have greater concentration of C18:2 and total FA for some of the first 24 h of the sampling period compared with the other 2 frequencies in experiment 2. These results demonstrate that supplementation of RPF during early gestation or lactation increased serum FA profiles of beef heifers and cows. However, these increases in serum FA may be altered dependent on the frequency of RPF supplementation in lactating cows but not heifers.

Key Words: rumen protected fat, serum fatty acids, supplementation frequency

0254 Economic viability of supplementation during the rainy season for growing water buffaloes.

D. C. M. Silva*, F. M. Silva, C. L. Francisco, A. M. Castilhos, P. R. L. Meirelles, and A. M. Jorge, *Universidade Estadual Paulista-FMVZ, Botucatu, Brazil.*

The aim of this study was to evaluate the economic viability of the use of supplementation during rainy season for growing water buffaloes. Twenty buffaloes [Murrah water buffalo, non-castrated males; 10 ± 1 mo of age; 206 ± 29 kg initial body weight (BW)] in growing phase on rotational stocking system (*Urochloa brizantha* cv. Xaraés; 3.36 ha) were used. Animals were randomly assigned by BW and divided into two treatments to receive supplementation (0.6% BW; corn, urea and mineral salt; $n = 10$) or not (control; $n = 10$). Body weight was measured at the beginning and the end of the rainy season (180 d of experiment) to determining total gain (TG) and average daily gain (ADG). Economic viability was demonstrated by the items: cost/steer, cost/kg gain, income/steer, profit/steer, and profitability per hectare. Data were analyzed with PROC MIXED in SAS. No treatment effects ($P = 0.64$) were detected for initial BW (202.45 vs. 208.75 kg for supplement and control treatments, respectively). Supplement treatment had greater final BW ($P = 0.03$), TG ($P < 0.01$), ADG ($P < 0.01$), cost/steer ($P = 0.03$), income/steer ($P < 0.01$) and profit/steer ($P < 0.01$) than control treatment (338.63 vs. 301.86 kg for final BW; 136.18 vs. 93.11 kg for TG; 0.76 vs. 0.52 kg for ADG; \$225.77 vs. \$196.83 for total cost/steer; \$317.42 vs. \$217.03 for income/steer; \$91.65 vs. \$20.20 for profit/steer, for supplement and control treatments, respectively). Supplement treatment showed lower cost/kg gain ($P = 0.01$) than control treatment (\$3.10 vs. \$4.06, respectively). For profitability per ha, supplement treatment had higher value ($P < 0.01$) than control treatment (\$1221.58 vs. \$267.39, respectively). For stocking density, supplement treatment tended ($P = 0.06$) to have higher rate than control treatment [6.77 vs. 5.47 AU/ha (1 AU = 450 kg of BW), respectively]. In conclusion, supplementation strategy during the rainy season is a viable and profitable option for water buffaloes in growing phase. Supported by FAPESP #2014/06446–3.

Key Words: economic viability, supplementation, water buffalo.

0255 Subclinical ketosis prevalence in Nellore beef cows during the breeding season in Brazil did not affect pregnancy rate.

R. C. de Souza*[1], R. C. Souza[1], A. C. B. P. Tavares[1], G. C. V. de Oliveira[1], L. A. M. de Souza[1], C. A. G. Pellegrino[2], M. I. V. Melo[1], J. P. Lustosa[1], and A. B. D. Pereira[3], *[1]Pontificia Universidade Catolica de Minas Gerais, Betim, Brazil, [2]Faculdade Alis de Bom Despacho, Brazil, [3]University of New Hampshire, Durham.*

Ketosis is a metabolic disease that affects the cattle production, therefore causes significant effects on the animal's metabolism and consequently decrease of animal production. Animals with negative energy balance may be committed by ketosis, with the subclinical form as the most common manifestation. The aim of this study was to evaluate the prevalence of subclinical ketosis (SK) in Nellore beef cows during the breeding season. Ninety-six females, 50 multiparous, and 46 primiparous, housed in a rural company in the state of Minas Gerais, Brazil, were evaluated between January and May of 2015. All cows were managed on a pasture system, composed of *Brachiaria brizantha*, with free access to water and mineral supplementation. For all animals, a protocol for estrus synchronization was performed, resulting in all animals being inseminated on the same day. Before insemination, blood levels of β-hydroxybutyrate (BHBA) were recorded by sampling a drop of blood from the tip of the tail, and adding the sample to a Optium Xceed portable device (Abbott Diabetes Care, Doncaster, Australia) for measurement of BHBA. Animals with BHBA concentration above 1200 mmol/L in the blood were classified as with SK. Visual inspection was also done to assess body condition score (BCS), using a scale of 1 to 5 as recommended by Spitzer (1986). After 60 d from the artificial insemination, animals were tested for pregnancy status. Prevalence of subclinical ketosis was on average 34% (33/96), being 32.61% (15/46) in primiparous and 36% (18/50) in multiparous. There was no effect of SK on the pregnancy rate ($P > 0.05$) for both primiparous and multiparous cows. The overall pregnancy rate was 35.41% (34/96), being 36.36% (12/33) in animals with SK and 34.93% (22/63) without SK ($P > 0.05$). In primiparous cows, the pregnancy rate was 10.8% (5/15) in animals with SK and 19.5% (9/31) in animals without SK, but in multiparous, the pregnancy rate was 14.0% (7/18) in animals with SK and 26.0% (13/32) without SK. There was an effect of the BCS on

the occurrence of SK ($P < 0.001$), in which animals with BCS above 3 had 21.42% (6/28) of SK and animals with BCS below 3 had 39.70% (27/68). In conclusion, the prevalence of SK observed in Nellore beef cows in Brazil was high, but did not affect pregnancy rate. As expected, animals with lower BCS had higher prevalence of SK.

Key Words: subclinical ketosis, pregnancy rate, Nellore cows

0256 Effects of breeding system of origin (natural service or artificial insemination) on pregnancy rates, distribution of calving, and calf weaning weights of commercial beef cow herds in North Dakota.

M. R. Crosswhite*[1], D. N. Black[2], S. R. Underdahl[1], T. L. Neville[2], and C. R. Dahlen[2], *[1]North Dakota State University, Fargo, [2]Department of Animal Sciences, North Dakota State University, Fargo.*

Objectives of this study were to compare pregnancy rates, calving distribution, and calf weaning weights of commercial beef cows exposed to two different breeding systems. Producers recruited ($n = 10$) had never implemented estrus synchronization and AI into their reproductive management plan. Within each herd, cows were randomly assigned to one of two breeding system treatments: (1) only exposed to natural service herd bulls (NS; $n = 1{,}122$) or (2) exposed to ovulation synchronization and fixed-time AI followed by natural service bulls (TAI, fixed-time AI; $n = 1284$). Production, performance and profit outcomes were evaluated within/across herds for each breeding system. Females exposed to TAI were exposed to 7-d CO-Synch + CIDR protocol with fixed-time AI at 60–66 h after CIDR removal. Clean-up bulls were placed in breeding pastures 1 d after AI and remained with females until the end of the producer defined breeding season. Presence of a viable fetus was determined at least 45 d after the conclusion of the breeding season. At parturition, birth date was recorded. No differences ($P = 0.54$) were observed in the proportion of females pregnant at the end of the breeding season between NS (93.1%) and TAI (93.2%) treatments. Cows in the TAI treatment calved 7.8 d earlier ($P < 0.001$) in the calving season compared with NS cows. A greater proportion ($P < 0.01$) of TAI cows (44.8%) gave birth in the first 21 d of the calving season compared with NS cows (26.0%). From d 22 to 42 a greater proportion ($P < 0.01$) NS cows (41.6%) gave birth compared with TAI cows (28.2%), and a greater proportion of NS cows (23.7%) gave birth from d 42 to the end of the calving season compared with TAI cows (17.2%). A treatment x calving group interaction was present for weaning weight. Greater ($P < 0.01$) weaning weights were observed for calves born from TAI cows in the first 21 d of the calving season (269.3 ± 1.82 kg) compared with NS born calves (257.6 ± 2.65 kg). Weaning weights of calves born to TAI and NS cows in the second 21 d and from d 42 to the end of the calving season were similar ($P = 0.17$). Use of TAI in commercial beef herds increased the number of calves born earlier in the calving season and increased the weaning weights of calves.

Key Words: AI, beef cattle, breeding systems, natural service

0257 Resynchronization for sequential timed artificial insemination.

K. E. Zechiel*[1], K. G. Pohler[1], S. A. Lockwood[2], M. Backus[3], and J. D. Rhinehart[4], *[1]University of Tennessee, Knoxville, [2]Department of Animal Science, University of Tennessee, Knoxville, [3]University of Tennessee, Knoxville, [4]University of Tennessee, Spring Hill.*

Increasing the number of pregnancies resulting from AI has a positive impact on the profitability of a beef cattle operation. However, subsequent AI after timed insemination is currently limited by distribution of return to estrus for non-pregnant females precluding a second timed insemination. The objective of this study was to determine if resynchronization in beef cattle for a second timed AI, without knowledge of individual female pregnancy status to the first timed insemination, is a viable management tool. Beef cows ($n = 140$) and heifers ($n = 45$) were allotted to 2 study groups: (1) single synchronization and timed AI (SS; $n = 67$ cows, 22 heifers) and (2) consecutive synchronization and timed inseminations (RS; $n = 73$ cows, 23 heifers). Both groups were simultaneously subjected to the 7-d CO-Synch + CIDR protocol for the initial timed insemination. Briefly, CIDR®s were inserted on d −9 with an injection of GnRH. On d −2, CIDRs were removed and an injection of $PGF_2\alpha$ was administered. Timed AI and an injection of GnRH occurred on d 0. For RS, CIDR®s from the first synchronization protocol were re-inserted on d 14. The CIDR®s were removed on d 21 and estrus detection patches were applied. All cattle with activated estrus detection patches were re-inseminated 72 h after CIDR removal (d 24). Pregnancy was determined via trans-rectal ultrasonography on d 54 to identify cows that conceived to the first or second insemination (based on fetal size) or failed to conceive. Interactions of parity, AI technician, or sire with treatment on pregnancy rate were not detected. Pregnancy rate to the first timed AI did not differ ($P = .49$) between SS and RS groups (66% (59/89) and 61% (59/96), respectively). Re-synchronization yielded 15 additional AI pregnancies, resulting in overall RS AI pregnancy rate of 77% (74/96). Overall pregnancy rate to AI tended ($P = 0.10$) to be greater in the RS than SS group (77% vs. 66%, respectively). This method of resynchronization for a second timed AI may be a useful management tool to increase pregnancy rates during a breeding season. Additionally, it would accommodate scheduling AI technicians where they might not otherwise be available to breed on natural return to estrus. Further analysis of the economic viability of this particular

approach is warranted.

Key Words: beef cattle, estrous synchronization, timed AI

0258 Impact of diet on the behavior of limit-fed beef cows in drylots. C. L. Daigle*[1], J. R. Baber[1], J. E. Sawyer[2], and T. A. Wickersham[1], *[1]Texas A&M University, College Station, [2]Department of Animal Science, Texas A&M University, College Station.*

Providing cattle with opportunities to interact with their environment while in feedlots may impact time allocation and influence space use. Mid- to late-gestation cows ($n = 96$) were stratified by body weight, BCS, age, and days in gestation and randomly assigned to one of 12 pens (8 cattle/pen; 4 pens/treatment). Each pen was randomly assigned to one of three treatments: HAY (cattle had ad libitum access to Bermudagrass hay), HC (limit-fed concentrate in the morning and forage 12 h later), and TMR (limit-fed a total mixed ration once in the morning). Limit-fed treatments, HC and TMR, were fed a diet of wheat straw (35%), cracked corn (29%), dried distillers' grains (27%), and premix (9%) formulated to contain 1.58 Mcal NE_m/kg and fed to deliver 80% of NRC predicted NE_m requirements. After cattle had been exposed to these treatments for 105 d, behavioral observations recorded the number of cattle performing each posture (stand, lie, walk) and behavior (feed, drink, ruminate, rest), as well as the number of cattle within 1 m of the feed bunk using 10-min instantaneous scans. A Generalized Linear Mixed model (PROC MIXED) evaluated the impact of treatment on cattle posture and behavior. Least squared means with a Tukey-Kramer adjustment identified differences among the 3 treatments. Treatment did not impact the number of cattle standing, walking, lying, or drinking ($P > 0.05$). More cattle were observed feeding in HAY ($t_9 \leq 13.7$, $P < 0.01$) compared with HC and TMR (2.76 vs. 0.18 and 0.39). More cattle rested in HC and TMR ($t_9 > -12.7$, $P < 0.01$) than HAY (5.72 and 5.63 vs. 3.20). More cattle ruminated in HAY than TMR (1.18 vs. 0.64; $t_9 = 3.2$; $P = 0.03$), and HC tended to ruminate more than TMR (0.98 vs. 0.64; $P = 0.09$). More cattle were observed resting in HC and TMR than in HAY (6.02 and 6.17 vs. 3.45; $t_9 \leq -12.6$, $P < 0.01$), and HAY spent more time less than 1 m of the feeder than cattle in HC or TMR (3.46 vs. 1.23 and 1.05; $t_9 \leq 3.5$, $P < 0.05$). Cattle provided with hay ad libitum rested less and engaged in more feeding and ruminating. By spending more time at the feeder, hay-fed cattle may use pen space more intensely than others which could impact pen management.

Key Words: behavior, diet, drylot

0259 Newborn beef calves benefit from supplementation of vitamins D and E. C. D. Nelson[1], M. Poindexter*[2], J. L. Powell[2], J. V. Yelich[2], S. L. Bird[3], and R. L. Stuart[4], *[1]University of Florida, Gainesville, [2]Department of Animal Sciences, University of Florida, Gainesville, [3]University of Minnesota, Grand Rapids, [4]Stuart Products Inc., Bedford, TX.*

The objective of this study was to determine the effects of injectable vitamins A, D, and E on fat-soluble vitamin status of beef calves. Sixteen Angus calves from a herd in Minnesota and 17 Angus and Brangus calves from a herd in Florida born in March were randomly assigned to receive no treatment or subcutaneous injection of VITAL-E® Newborn (Stuart Products Inc.; 50,000 IU retinyl-palmitate, 50,000 IU vitamin D_3, and 500 IU *RRR*-α-tocopherol/mL of product). Minnesota calves received either no treatment (CON, $n = 8$) or 5 mL subcutaneous injections of VITAL E-Newborn (ADE, $n = 8$) within 24 h of birth and serum samples were collected at 0, 2, 7, 50, and 210 d of age. Florida calves received either no treatment ($n = 7$) or 4 mL of VITAL E-Newborn ($n = 9$) within 24 h of birth and serum samples were collected at 0, 25, 50, and 180 d of age. Serum retinol concentrations were not affected by treatment, but retinyl-palmitate was greater at 2 d of age in the Minnesota ADE vs. CON calves (646 ± 204 vs. 20 ± 1 ng/mL). In contrast, serum 25-hydroxyvitamin D (25(OH)D) concentrations of the Minnesota ADE calves increased from 8.4 ± 1.3 ng/mL at birth to 61.7 ± 3.6 ng/mL at d 7, compared with 5.5 ± 1.3 at birth and 9.8 ± 4.6 at d 7 in CON calves ($P < 0.001$). Serum 25(OH)D of Florida ADE calves increased from 9.9 ± 3.3 ng/mL at birth to 36.2 ± 3.9 ng/mL at d 25, compared with 5.4 ± 3.5 and 19.7 ± 4.8 ng/mL in CON calves ($P < 0.05$). Serum 25(OH)D was still elevated at 50 d of age in ADE calves in both herds ($P < 0.01$; ADE = 38.8 ± 2.3 ng/mL vs. CON = 29.4 ± 2.5 ng/mL), but was the same at weaning near 50 ng/mL. Serum α-tocopherol increased in Minnesota ADE calves from 1.0 ± 0.5 μg/mL at birth to 6.8 ± 0.5 and 5.3 ± 0.5 μg/mL at d 2 and 7, respectively, compared with 0.6 ± 0.5, 1.3 ± 0.5, and 2.4 ± 0.5 μg/mL in Minnesota CON calves at 0, 2, and 7 d of age, respectively ($P < 0.001$). Serum α-tocopherol was similar between Florida ADE and CON calves with averages near 0.8 μg/mL at birth and 2.5 μg/mL at 25 d of age. In conclusion, supplementation of newborn beef calves with VITAL-E Newborn increases serum 25(OH)D and α-tocopherol concentrations and overcomes deficiences in vitamins D and E of the young calf.

Key Words: beef calves, fat-soluble vitamins

0260 Functional SNP in a polygenic disease induced by high-altitude in fattening Angus steers using systems biology approach. A. Cánovas[*1], R. Cockrum[2], D. Brown[3], S. Riddle[3], J. M. Neary[4], T. N. Holt[5], J. F. Medrano[6], A. Islas-Trejo[6], R. M. Enns[7], S. E. Speidel[7], K. Cammack[4], K. R. Stenmark[8], and M. G. Thomas[7], *[1]University of Guelph, ON, Canada, [2]Virginia Polytechnic Institute and State University, Blacksburg, [3]University of Colorado, Denver, [4]Colorado State University, Fort Collins, [5]College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, [6]University of California, Davis, [7]Department of Animal Sciences, Colorado State University, Fort Collins, [8]University of Denver, CO.*

High-altitude (> 1800m) disease is a challenging problem in beef and dairy cattle. The disease is consequential of hypoxia-induced right ventricular (RV) heart failure as per vascular inflammation of the pulmonary artery (PA) and hypertension. The disease has moderate to high heritability ranging from 0.2 to 0.4; however, minimal information exists of the genes involved. The transcriptomes of six tissues (i.e., left and right ventricle, pulmonary artery, aorta, muscle, and lung) were examined in samples harvested from fattening-yearling Angus steers phenotyped to be of low or high pulmonary arterial pressures (LPAP and HPAP; n = 10/group). Tissue specific splice variants were identified in RV (n = 555), aorta (n = 547) and PA (n = 152; $p < 0.01$ FC > 2) between LPAP and HPAP animals. Most of the splice variants are located in key regulators genes with roles in angiogenesis and cardiomyopathy (NFATC1), movement of leukocytes and neutrophils (OLR1, PLAUR), failure of heart (CTGF), hypertrophy of heart ventricle (TREM1, GATA2) and vascularization (SYVN1). Besides, several SNP variants segregated specifically in either the LPAP or HPAP animals. Among them, 139 SNP were located in key regulator genes involved in the adaptation of high altitude disease. These approaches helped identify splice variants corresponding to key regulator genes in a polygenic disease induced by high-altitude in Angus cattle. The identification of functional SNP associated with high-altitude disease by combining structural and functional genomic data will help to develop more robust approaches for genetic selection in beef cattle.

Key Words: beef, health, genomics, systems biology, RNA-sequencing, functional SNP

0261 Factors affecting timing and intensity of calving season of beef cow-calf producers in the Midwest. C. E. Andresen[*1], P. J. Gunn[1], and L. L. Schulz[2], *[1]Department of Animal Science, Iowa State University, Ames, [2]Department of Economics, Iowa State University, Ames.*

Despite demonstrated market incentives to adopt controlled calving seasons, many producers still have herds that calve somewhat broadly throughout the year. We postulate this observed management behavior is related to a variety of factors. Primary data, collected through a coordinated survey effort with U.S. Department of Agriculture's National Agricultural Statistics Service, were used to quantify factors that affect producers' decisions regarding timing and intensity of calving season. Descriptive statistics were generated using the surveymeans procedure of SAS, and the surveyreg procedure was used to conduct a regression analysis. Of the survey respondents, 88% were commercial producers and 12% were seedstock producers or operated a combination seedstock/commercial operation with an overall average of 63 beef cows. Ninety-seven percent, 50%, 33%, and 26% of farms calve in the spring (March, April, May), summer (June, July, August), fall (September, October, November), and winter (December, January, February), respectively. Twenty-two percent observed a calving season exclusively in the spring. Sixty-six percent of respondents indicated calving season was dictated by weather, 34% because of labor availability, and 31% because of tradition. Least often reasons for calving season were market timing (16%), feed availability (8%), and other (4%). Producer-stated reasons for calving season explained 62% of the variation in timing and intensity of calving on an operation, whereas a model of producer demographic and operation characteristics explained 83% of the variation. These results highlight the importance of evaluating producer and operation characteristics in addition to producer input when making recommendations to enhance production efficiency and profitability. Furthermore, understanding the factors which impact calving season provides opportunities for improved Extension and research programming.

Key Words: beef, calving season, survey

0262 Effects of feeding NaturSafe on performance, carcass characteristics, and liver abscesses in finishing beef heifers at a commercial feedlot. M. F. Scott[*1], K. L. Dorton[1], D. L. Henry[1], C. R. Belknap[1], and B. E. Depenbusch[2], *[1]Diamond V, Cedar Rapids, IA, [2]Innovative Livestock Services Inc., Great Bend, KS.*

With the mandatory implementation of VFD on the horizon, as well as retailer and consumer demands for reduced antibiotic usage, cattle feeders are considering other technologies that can mitigate liver abscesses and maintain growth performance

when standard industry technologies are removed from the diet. In this study, cross-bred heifers (N = 1495; 359 ± 3.4 kg) were utilized in a randomized complete block design at a commercial feedlot to determine the effects of a *Saccharomyces cerevisiae* fermentation product (NaturSafe, Diamond V, Cedar Rapids, IA) on performance, carcass characteristics, and liver abscesses when monensin, tylosin, and direct fed microbials (DFM) were not included in the diet. Upon arrival, heifers were allowed ad libitum access to water and long-stemmed hay. During processing, they received a feedlot tag and growth implant, and were vaccinated and treated for parasites. Heifers were then blocked by arrival BW and randomly assigned to one of 2 treatments (10 pens/treatment, approximately 75 heifers/pen). Treatments consisted of a diet containing: (1) monensin, tylosin, and Bovamine Defend (positive control, PC) or (2) NaturSafe at 18 g/head/d without monensin, tylosin, and the DFM. Diets were fed twice daily with heifers receiving half of the daily dose of treatment in the TMR at each feeding. Pen BW were collected on d 0 and at harvest on d 125 and 146 (5 pens per treatment per day). Feed intake, morbidity and mortality were monitored daily. Cattle were vaccinated and implanted a second time approximately 74 d before harvest. Hot carcass weight, dressing percentage, quality grade, yield grade, percent kidney-pelvic-heart fat percentage, rib fat thickness, rib-eye area, marbling score and liver abscess scores were determined. Performance, carcass characteristics and liver abscess scores were analyzed using the MIXED procedure of SAS with pen as the experimental unit. Performance, carcass characteristics, morbidity and mortality were similar (P > 0.05) between treatments. Heifers fed NaturSafe had a numerically lower (P = 0.11) incidence of liver abscesses compared with PC (14.5% vs. 19.3%, respectively) with fewer (P = 0.02) livers condemned that had less severe (i.e., A-) abscesses (3.3% vs. 6.9%, respectively). Results from this study suggest that NaturSafe has the potential to reduce liver abscesses and maintain growth performance when standard industry technologies like monensin, tylosin, and DFM are removed from conventional production diets.

---

0263 Inclusion of exogenous enzymes in creep feeding rations for nursing beef calves. J. M. Lourenço[*1], B. T. Campbell[2], N. DiLorenzo[3], and R. L. Stewart, Jr.[1], *[1]Department of Animal and Dairy Science, University of Georgia, Athens, [2]DSM Nutritional Products, Parsippany, NJ, [3]University of Florida, North Florida Research and Education Center, Marianna.*

An in vitro experiment was performed to investigate if some exogenous enzymes customarily used in rations of monogastric animals would be effective when included in a creep feed (CF) for nursing beef calves. The chosen enzymes were included in experimental treatments both individually and in combination with other enzymes. The treatments consisted of: (1) Bermuda grass (BER); (2) a mixture of 75% Bermuda grass and 25% CF (BERCF); (3) BERCF enhanced with xylanase (XYL); (4) BERCF enhanced with β-1,3-glucanase (BGLUC); (5) BERCF enhanced with α-amylase (AMYL); (6) BERCF enhanced with a combination of xylanase, β-1,3-glucanase and β-1,4-glucanase (COMB1); or (7) BERCF enhanced with a combination of xylanase, β-1,3-glucanase, β-1,4-glucanase and α-amylase (COMB2). Two rates of inclusion of the enzymes were tested: the dose normally used in rations of monogastrics, and a dose 10 times greater (10x). Five replications per treatment were used. Incubations were performed for 24 h using rumen fluid collected by esophageal tubing from 6-mo-old nursing calves. Analysis of variance was conducted as a completely randomized design using fermentation bottle as the experimental unit with treatments and replications as factors. Digestibility of the ADF portion of the diet was lowest for BER, however, it was greater for BERCF, and it was maximal for BGLUC 10x (P = 0.02). Similarly, IVDMD was lowest for BER and highest for XYL 10x (P = 0.02). Production of acetate, propionate, and butyrate were all lowest for BER (P < 0.01). Total production of VFA was also minimal for BER, and it was greatest for COMB2 10x (P < 0.01). The acetate:propionate ratio was greatest for BER (P = 0.01). No differences were detected regarding molar proportion of propionate, however, molar proportion of butyrate was smallest for BER (P < 0.01). Total gas produced per g of incubated DM, and concentration of methane per L of gas were greatest for AMYL 10 (P < 0.01). Overall, the inclusion of the studied enzymes improved important traits such as IVDMD, ADF digestibility, and production of VFA. This indicates that nursing beef calves may benefit from the use of these enzymes, especially if they are included at rates greater than those found in diets of monogastric animals.

Key Words: creep feeding, exogenous enzymes, in vitro

0264 Body temperature and seminal characteristics in double and normally muscled senepol bulls in the tropics. I. Suero[1], E. Sanoguet[1], H. Sánchez[*1], J. Curbelo[1], A. Casas[1], T. Sonstegard[2], and M. Pagán-Morales[1], *[1]Department of Animal Science, University of Puerto Rico, Mayaguez, [2]Recombinetics Inc., St Paul, MN.*

Double muscled cattle present conformational differences in their carcasses that are highly attractive to the beef industry, including a greater yield of valuable muscles and lower adipose tissue accumulation. However, in the Puerto Rican Senepol cattle, which are highly adapted to the tropics, it is not known if such differences may affect thermoregulation or reproductive performance. Therefore, the present study compared rectal (RT) and scrotal [(ST); determined by infrared thermography at the proximal, medial, and distal regions of

the scrotum] temperatures, as well as sperm concentration, motility, and normality between 8 heterozygous double muscled (HM; MSTN NT821/WT) and 8 normally muscled (NM) Senepol bulls. All animals were homozygous SLICK (PRLR; chr20:39136558GC > G). Bulls were electro-ejaculated at d 55 and d 60 after a previous collection at d 1 (activation of spermatogenesis/sperm removal from epididymis) during a hot (HOT) and a cool (COOL) period with daily mean air temperature values of 30.0 and 28.8°C, respectively. Temperatures were recorded three times/d (0800, 1200, and 1500 h) during 5 d after d 1. Semen was analyzed using a Computer Assisted Sperm Analysis System (CASA) and a GLIMMIX procedure in SAS was used for the correspondent statistical analyzes. The HM bulls presented smaller scrotal circumferences ($P < 0.05$; HM: 36.12 cm vs. NM: 37.72 cm) and higher RT ($P < 0.05$; HM: 38.63°C vs. NM: 38.49°C) than the NM bulls. However, no differences in ST were observed between genotypes in any period ($P > 0.05$). Sperm concentration per cc of semen was lower in HM (460.04 x 10^6) than NM (837.32 x 10^6) in HOT ($P < 0.05$); however, no differences were observed in COOL ($P > 0.05$; 321.20 x 10^6 and 295.92 x 10^6 for HM and NM, respectively), with an imminent reduction in sperm concentration in both groups. In HM, the sperm motility was greater in COOL ($P < 0.05$), while total progressive sperm was greater in COOL for both groups ($P < 0.05$). The latter was also observed for normality ($P < 0.05$). The proportion of coil tail sperm was higher in HOT ($P < 0.05$) and HM showed more proximal cytoplasmic droplets overall in HOT (HM-HOT > NM-HOT > HM-COOL = NM-COOL). These results suggest that greater body temperatures could affect slick-double muscled Senepol cattle in terms of sperm concentration, maturation rate and motility, irrespective of the testicular size.

Key Words: motility, normality, sperm, Senepol

0265 Effects of summer and winter feeding of endophyte infected tall fescue seeds on average daily gain and activity of hepatic cytochrome P450 1A, 2C, 3A, aldo-keto reductase 1C, and uridine 5'-diphospho-glucuronosyltransferase in beef steers.

B. J. McClenton*[1], C. Waldrip[1], C. G. Hart[1], A. Theradiyil Sukumaran[1], C. O. Lemley[1], J. R. Blanton[1], and T. T. N. Dinh[2], *[1]Mississippi State University, Starkville, [2]Mississippi State University, Department of Animal and Dairy Sciences, Starkville.*

The objective of this study was to investigate the effects of feeding endophyte-infected tall fescue seeds on ADG (kg/d) and activities of hepatic cytochrome P450 1A, 2C, 3A, aldo-keto reductase 1C, and Uridine 5'-diphospho-glucuronosyltransferase (UGT). Twelve Angus steers of 181 d of age and an average pre-weaning weight of 194.6 kg were blocked by initial BW at weaning. A control (KY32 or E–) and a treatment (KY31 or E+, 20 µg of ergovaline per kg of BW) were randomly assigned to animals within blocks ($n = 6$) by using Calan gates in two trials of 70 (summer 2015) and 56 d (winter 2016). Body weight was recorded on d 0 and every 14 d. Liver biopsies were collected before each trial and on d 3. Proteins in the S9 fractions were extracted into phosphate buffer and diluted to a concentration of 4000 µg/mL. Enzyme activity (RLU/min/mg of protein) was determined by a Promega Multi-Plus plate reader (Madison, WI) after incubation with specific substrates and detection reagents. Statistical analysis was performed by the GLIMMIX and FACTOR procedures of SAS 9.4 (SAS Institute Inc., Cary, NC) with statistical significance being determined at $P \leq 0.05$. In trial 1, E+ steers gained 0.323 kg/d less than E- steers ($P = 0.013$) between d 28 and d 70. Cytochrome 2C activity differed initially ($P = 0.042$) but did not on d 3 ($P = 0.675$). Cytochrome 1A and 3A activities were correlated ($r = 0.621$, $P = 0.042$). In trial 2, no treatment effect on ADG was found ($P = 0.435$). From d 28 to d 56, ADG increased consistently from 0.567 to 1.393 kg/d, whereas ADG remained similar ($P > 0.392$; 0.539 to 0.574 kg/d) in trial 1. Only initial UGT activity was 42% greater in E+ steers in trial 2. Cytochrome 1A and 2C activities were correlated ($r = 0.912$, $P = 0.002$). Other enzyme activities were similar in both trials ($P > 0.180$), and no treatment × d interaction on ADG was found ($P > 0.142$). Principal component analysis indicated that the activities of 1A, 2C, 3A, and 1C explained 65.88 to 66.41% of enzyme activity variances, whereas UGT activities explained the rest of the variances on d 3. Correlation coefficients of these two groups of enzymes with each principal component confirmed that they acted in separate pathways.

Key Words: beef, endophyte, tall fescue

0266 Relationships of neonatal beef calf birth weight and body size measures.

A. M. Meyer*, S. M. Bolen, and J. M. Larson, *Division of Animal Sciences, University of Missouri, Columbia.*

Research investigating the effects of gestational nutrition or management on fetal development often use birth weight as the primary prenatal growth measure. Weight does not take skeletal size or shape into account and thus may not accurately assess many aspects of fetal growth. Our objective was to determine the relationship of weight and body size measures in neonatal beef calves. Calves were weighed within 16 h postnatal during a fall-calving ($n = 42$, Sim-Angus and Hereford) and spring-calving ($n = 47$, Sim-Angus) season. A flexible tape measure was used to record 5 body size measures for each calf. Crown to rump length (CRL) was defined as the length from poll to tailhead, whereas shoulder to rump length (SRL) was defined as the length from the neck-shoulder junction to tailhead, both following the spine. Heart girth was measured immediately posterior of the front legs and abdominal girth was measured at the umbilicus, both perpendicular to the spine. Cannon circumference was taken at the smallest point of 1 cannon bone. Ponderal index is used in human medicine to

assess body shape or tissue growth relative to skeletal growth. Calf ponderal index was calculated as birth weight (kg)/length $(cm)^3$ using either CRL (PI-CRL) or SRL (PI-SRL). Pearson correlations were determined for weight and body size measures. Birth weight had a weak positive correlation ($P \leq 0.06$) with CRL and SRL, moderate positive correlation ($P < 0.0001$) with heart girth and cannon circumference, and strong positive correlation ($P < 0.0001$) with abdominal girth. This suggests that birth weight is less related with body length than girth in neonatal calves. Birth weight had weak positive relationships ($P < 0.005$) with PI-CRL and PI-SRL, whereas CRL and SRL had strong negative relationships ($P < 0.0001$) with their corresponding ponderal index measures. Abdominal girth had a weak positive correlation with PI-CRL and PI-SRL, but heart girth was not correlated with either. Heart girth had a moderate positive correlation ($P < 0.0001$) with abdominal girth, CRL had a weak positive correlation ($P < 0.003$) with SRL, and PI-CRL had a weak positive correlation with PI-SRL. This suggests that length measures have more variation or potential for error. In summary, birth weight is weakly or moderately related to most body size measures in neonatal calves. Length, girth, and ponderal index measures can help to describe calf size and shape at birth, adding valuable information.

Key Words: calving, fetal growth, neonate

0267 Locomotor activity changes in the final 72 h prepartum in multiparous beef cows. S. M. Bolen[1], B. L. Vander Ley[2], K. N. Niederecker[1], and A. M. Meyer*[1], [1]*Division of Animal Sciences, University of Missouri, Columbia,* [2]*Department of Veterinary Medicine and Surgery, University of Missouri, Columbia.*

The objective of this study was to quantify changes in locomotor activity of multiparous beef cows during the final 72 h prepartum. IceQube activity monitors (IceRobotics, Edinburgh, UK) were placed above the left hind fetlock ($\geq$ 4 d prepartum) of 106 multiparous, spring-calving beef cows over 2 yr. Cows that were moved outside of their normal patterns during the 72 h prepartum were removed from the dataset, resulting in 63 cows to be used for analysis. Cows were housed in 18 × 61 m drylots during calving and allowed ad libitum access to hay or haylage in round bale rings placed in the drylots. Each cow's motion index, standing time, lying time, step count, and number of lying bouts were summed per hour using IceManager 2012 software. Motion index was calculated by the software using a proprietary algorithm. Hour 0 was defined as time of parturition (± 30 min). Data were analyzed by day (d −3 to d −1 prepartum), by 6-h period during the final 24 h prepartum, and by hour during the final 6 h prepartum using MIXED procedures of SAS. Motion index, standing time, step count, and number of lying bouts increased ($P < 0.001$), while lying time decreased ($P < 0.001$) on d −1 compared with d −2 or d −3 relative to parturition. In the 24 h immediately prepartum, the 6 h preceding parturition (−6 to 0 h) had greater ($P < 0.05$) motion index, standing time, step count, and number of lying bouts compared with the other 6-h periods before calving. There was no effect ($P = 0.19$) of 6-h period on lying time during the 24 h before parturition. Motion index increased ($P < 0.05$) from −6 to −4 h and remained steady from −4 h to 0 h. Cows had greater ($P < 0.05$) standing time and less ($P < 0.05$) lying time at 0 h compared with −5 and −6 h before parturition. Step count was greater ($P < 0.05$) from −3 to −1 h compared with −6 to −5 h. Number of lying bouts increased ($P < 0.05$) between −3 and −1 h and decreased ($P < 0.001$) from −1 h until calving. In conclusion, multiparous beef cow activity changes 4 to 6 h before parturition. These data suggest that electronic activity monitors can be used to recognize the earliest signs of parturition in beef cattle.

Key Words: activity, movement, parturition

0268 Impact of heifer development system on subsequent ADG and reproduction in two different breeding seasons. S. A. Springman*, H. R. Nielson, and R. N. Funston, *University of Nebraska, West Central Research and Extension Center, North Platte.*

A 4-yr study was conducted to determine the impact of heifer development system on subsequent growth and reproductive performance in 2 breeding seasons. In Exp. 1, March-born, crossbred (5/8 Red Angus, 3/8 Continental; $n = 225$) heifers were stratified by BW and randomly assigned to 1 of 2 post-weaning nutritional treatments (2 pastures·treatment^{-1}·yr^{-1}) from mid-January to mid-April. Heifers were offered ad libitum meadow hay (HAY) and 1.81 kg/d (29% CP, DM) supplement or allowed to graze meadow (MDW) and offered 0.45 kg/d supplement. Heifers were managed as a single herd before and following treatment. Heifers were synchronized with a single PG injection 5 d after being placed with bulls for a 45 d breeding season. HAY heifers had greater ($P = 0.01$) ADG during the treatment period than MDW heifers (0.77 vs. 0.51 ± 0.03 kg/d; HAY, MDW). At pregnancy diagnosis, HAY heifers tended to have greater BW compared with MDW heifers ($P = 0.06$; 377 vs. 367 ± 3 kg; HAY, MDW). Percent of mature BW before the breeding season was greater ($P = 0.02$) for HAY compared with MDW (58% vs. 55% ± 1%; HAY, MDW). Pregnancy rates were similar for HAY and MDW heifers ($P = 0.97$, 88 ± 4%). In Exp. 2, May-born, crossbred (5/8 Red Angus, 3/8 Continental; $n = 258$) heifers were stratified by BW and randomly assigned to HAY or MDW treatments. Similar to Exp. 1, heifers on HAY treatment had greater ($P = 0.01$) ADG during the treatment period (0.63 vs. 0.39 ± 0.03 kg/d; HAY, MDW), resulting in greater pre-breeding BW ($P = 0.02$) for HAY heifers compared with MDW heifers (320 vs. 305 ± 3 kg, respectively). At pregnancy diagnosis, BW was similar ($P = 0.16$) between treatments (368 vs. 356 ± 4 kg; HAY, MDW). Percent of mature BW before

the breeding season was greater ($P = 0.02$) for HAY (58%) compared with MDW (54%). Pregnancy rates were similar ($P = 0.44$) between treatments (72 vs. 68 ± 4%; HAY, MDW). Heifer development system did not impact pregnancy rate in the March or May replacement heifers; however, March heifer pregnancy rate was greater ($P < 0.01$) than May (87 vs. 70 ± 3%). The lower pregnancy rate in May heifers may be due to declining forage quality during the breeding season.

Key Words: beef heifer, calving date, heifer development

0269 Effect of castration method and analgesia on growth performance and carcass traits in feedlot cattle.

S. L. Roberts*[1], H. D. Hughes[1], J. G. Powell[2], and J. T. Richeson[1], [1]*Department of Agricultural Sciences, West Texas A&M University, Canyon,* [2]*Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville.*

Castration is a painful, yet routine management practice within the U.S. that is known to transiently decrease performance but the method of castration, provision of analgesia, or both may impact growth in feedlot cattle. Our objective was to determine the effect of castration timing (birth vs. feedlot entry), method (surgical vs. banding) and use of the analgesic meloxicam (**MEL**) on performance and carcass traits in feedlot cattle. This study was a randomized complete block design conducted over a 3-yr period. Single-source Angus × Hereford steer ($n = 42$) and bull ($n = 152$) calves were randomized at birth to 1 of 5 treatments arranged as a 2 × 2 + 1 factorial: (1) steers castrated near birth (**CON**), (2) bulls surgically castrated without MEL (**SUR**), (3) bulls surgically castrated with MEL (**SUR+MEL**), (4) bulls band castrated without MEL (**BAN**), and (5) bulls band castrated with MEL (**BAN+MEL**). Upon feedlot arrival (d −10), animals were blocked by initial BW (224 ± 4.5 kg) and assigned randomly to treatment pens ($n = 6$ pens/treatment). Oral MEL was administered at 1 mg/kg BW concurrent with castration on d 0. Individual BW was collected at weaning, d 0, 7, 14, 32, re-implant and on finishing to determine interim and overall ADG. Although BW was not affected by castration method or MEL, there was a tendency ($P = 0.10$) for CON animals to be heavier at d 32 and re-implant. From d 0 to 7, ADG was reduced for surgical (−0.42 kg/d) compared with band (0.43 kg/d) castration. Conversely, ADG was increased for surgical (1.74 kg/d) vs. band (1.46 kg/d) castration from d 14 to 32. Daily gain was increased for CON compared with castrated for all interim periods ($P \leq 0.02$) except re-implant to final ($P = 0.90$). There was also an overall improvement in ADG for CON ($P = 0.04$) and MEL ($P < 0.01$), but this was not influenced by method ($P = 0.80$). The CON had increased marbling score ($P = 0.03$) compared with castrated; whereas, backfat thickness was increased ($P < 0.05$) in SUR+M, but did not differ from CON ($P = 0.15$). Administration of MEL tended ($P = 0.08$) to increase yield grade. Castration near birth had long-term performance benefits compared with castration on feedlot arrival. Castration, regardless of method, transiently reduced ADG, but MEL administration improved overall ADG for both methods.

Key Words: analgesia, beef cattle, castration

0270 Evaluation of long-acting eprinomectin and a combination of moxidectin/oxfendazole administration post-weaning on immune status by Angus and Angus × Hereford crossbred replacement heifers over a 274-d grazing period.

E. A. Backes*, J. G. Powell, E. B. Kegley, J. A. Hornsby, and J. L. Reynolds, *Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville.*

Internal parasite burdens have been reported to decrease animal performance and feed efficiency; however, little current research has evaluated the effects of burdens on the immune status in beef cattle. The objective of this study was to evaluate the effects of anthelmintic therapy on the immune status in replacement crossbred beef heifers. Beginning June 2, 2014, 83 fall-born Angus and Angus × Hereford replacement heifers were stratified by d −14 BW and fecal egg counts, and d of age. Heifers were then allocated randomly to 1 of 3 anthelmintic treatments consisting of: (1) control ($n = 28$; no anthelmintic administered; CON); (2) moxidectin/oxfendazole combination ($n = 28$; MO); or (3) long-acting eprinomectin ($n = 27$; LAE) for a 274-d grazing study. Heifers grazed in individual treatment groups on pastures, containing predominantly endophyte-infected tall fescue, for the duration of the project and were supplemented daily at 1% BW with corn gluten. Whole blood was collected via jugular vein on d 0, 14, 28, 84, 154, 168, 182, 234, and 274. On each d complete blood cell differentials were determined using a Cell-Dyn 3700 SL machine. Data were analyzed using the PROC MIXED of SAS for repeated measures. Two orthogonal contrasts were used and included: (1) comparing the mean of CON vs. the mean of treated heifers; and (2) comparing the mean of MO vs. LAE. Concentrations of white blood cells (WBC), lymphocytes, eosinophils, basophils, red blood cells (RBC), and platelets were greater ($P \leq 0.02$) from CON compared with treated heifers. The neutrophil:lymphocyte ratio (NEU:LYM) was greater ($P < 0.01$) from treated heifers compared with CON, and basophils were greater ($P = 0.01$) from MO compared with LAE; however, proportions of neutrophils and monocytes did not differ ($P \geq 0.54$) among treatments. A d effect was detected ($P < 0.01$) for WBC, lymphocytes, and monocytes. A treatment × d interaction ($P \leq 0.01$) was detected for neutrophils, NEU:LYM, eosinophils, basophils, and platelets. A treatment × d tendency ($P = 0.08$) was detected for RBC, with RBC being highest for all cattle on d 0 and lowest on d 234 for LAE. Based on this study, anthelmintic therapy may positively impact immune status in replacement

beef heifers treated with various anthelmintics.

Key Words: immune status, long-acting eprinomectin, moxidectin/oxfendazole combination

0271 Modeling milk yield and calf performance of beef suckler cows on pasture-based systems.

D. Sapkota[*1,2], A. K. Kelly[1], M. McGee[2], and P. Crosson[2], *[1]University College Dublin, Belfield, Ireland, [2]Teagasc Grange, Dunsany Co. Meath, Ireland.*

Milk production of beef suckler cows is the main factor determining live weight of calves at weaning. However, the milk yield of beef suckler cows in Ireland is declining due to a reduction in the proportion of replacements sourced from the dairy herd and an emphasis on breeding for terminal traits. Correspondingly, calf weaning weights are also declining. Additionally, in suckler beef systems where grass, both grazed and conserved, forms a major part of the feeding system, beef suckler cows have to cope with seasonal changes in feed resource availability over the annual production cycle. The aim of current study was to develop a dynamic model to evaluate how the dynamics of milk production effects on the growth performance of beef suckler calves, within a pasture-based production system. A dynamic Grange Suckler Cow-Calf Model (dGSCCM) was developed that simulates energy partitioning, milk production and calf performance of two contrasting beef suckler cow genotypes; Charolais (C) and Charolais x Holstein-Friesian (CF). The parameter coefficients and equations used in the model were derived from published literature and established databases. The performance of cows and calves were determined by the genetic potential, physiological status, and availability of feed. The milk production profile of both beef suckler cow genotypes were generated through Irish data fitted to the lactation curve of Wood. The average daily milk yield for first and second parity was 7.35 and 8.70 kg for C and 11.12, and 13.10 kg for CF, respectively. Corresponding weaning weights at 240 d of age were 282 kg and 301 kg for C and, 332 kg and 355 kg for CF. Sensitivity analysis was performed by changing milk yield ± 20%. It showed that calf weaning weight is highly sensitive to cow milk production; each additional kg in daily milk yield increased weaning weight by 10.2 kg for CF in second parity to 14.3 kg for C in first parity. The model provides a basis for the evaluation of the growth response of beef suckler calves based on dynamics of milk production of their dams.

Key Words: calf live weight, dynamic modeling, lactation curve, pasture-based systems

0272 Dry and wet conditions during the prepartum forage growing season affect offspring feedlot performance and carcass composition in beef cattle.

A. M. Meyer[*1], B. L. Vander Ley[2], G. A. Gatson[1], W. D. Busby[3], and P. J. Gunn[4], *[1]Division of Animal Sciences, University of Missouri, Columbia, [2]College of Veterinary Medicine, University of Missouri, Columbia, [3]Tri-County Steer Carcass Futurity, Lewis, IA, [4]Department of Animal Science, Iowa State University, Ames.*

We hypothesize that dry and wet conditions during the prepartum forage growing season impact cow nutrient availability during pregnancy, resulting in altered fetal growth and development, and affecting subsequent feedlot performance and carcass composition. Steers (n = 7439) and heifers (n = 2380) finished in southwestern Iowa feedlots through the Tri-County Steer Carcass Futurity Cooperative were used for a retrospective analysis. Cattle were born in the Midwest (Iowa, Missouri, Indiana, Illinois, and Minnesota) in February, March, or April of 2002 to 2013. Feedlot performance and carcass data were measured for each animal. Palmer Drought Severity Index (PDSI) values were obtained for each dam during the prepartum forage growing season (April through October) on a monthly basis. Conditions were classified as dry (mean PDSI value ≤ -2.00), normal (mean PDSI value > -2.00 and < 2.00), or wet (mean PDSI value ≥ 2.00) during this period. Data were analyzed using the MIXED procedure of SAS with PDSI drought classification, birth year, feedlot, and calf sex included as fixed effects. Feedlot delivery BW was greatest ($P < 0.01$) for calves born to dams in the wet class, intermediate ($P < 0.01$) for normal, and least ($P < 0.01$) for dry. Feedlot ADG was greater ($P < 0.01$) for calves from cows in the dry class compared with normal and wet, suggesting compensatory growth. Calves born to dams in the normal class had a greater ($P = 0.02$) number of days on feed than wet. Calculated yield grade was improved ($P < 0.01$) for calves from normal and wet classes compared with dry, partially because calves born to cows in the normal class had greater ($P \leq 0.01$) LM area than dry and wet. Calves born to cows in the dry class had the most ($P < 0.01$) 12th rib fat and marbling, normal were intermediate ($P \leq 0.03$), and calves from wet had the least ($P \leq 0.03$). Despite this, drought classification did not affect ($P \geq 0.39$) final pre-slaughter BW, HCW, or dressing percent. In conclusion, prepartum forage growing season precipitation likely impacts offspring post-weaning growth and carcass characteristics by altering nutrient intake of cows throughout gestation due to grazing during the growing season and consumption of stored forage in winter. More research is necessary to investigate the impacts of dry and wet conditions during specific periods of fetal development on subsequent calf performance.

Key Words: developmental programming, drought, post-weaning

0273 Modeling body condition score at calving by past body condition and forage allowance in grazing beef cow on rangelands. M. Claramunt[*1] and P. Soca[2], [1]*Centro Universitario de la Regiãn Este, Universidad de la Repãblica, Treinta y Tres, Uruguay,* [2]*Facultad de Agronomia. Universidad de la Republica, Paysandu, Uruguay.*

Body condition score at calving affects the length of postpartum anoestrus, probability of pregnancy and the response of temporary suckling restriction and flushing on reproductive performance. Body condition score could be manipulated by forage allowance (FA). Therefore, modeling the effect of FA on BCS could provide valuable information for beef cow managers. The objective was to study the relationships between FA and BCS at middle gestation (BCSm) and calving (BCSc) of primiparous beef cow grazing located in native pastures. We used data from an experiment that evaluated the effect of 2 levels of FA on productivity of primiparous beef cows grazing rangelands. The experiment took place in Facultad de Agronomía, Uruguay. Eighty cows were assigned to a completely randomized experiment of 2 FA in spatial replication on 2 blocks during 2 yr. The annual FA averaged 2.5 and 4 kg DM/kg BW for low (L) and high (H) FA, respectively. Cow BW and forage mass were measured monthly and used to adjust FA using the "put and take" method. The experiment started in autumn −150 d postpartum (dpp) and finished 190 dpp. The BCS at −150 dpp (early gestation [BCSe]) was recorded. The BCS was recorded by a visual scale (1–9 points). We used a seasonal value FA before BCS was recorded (FAm and FAc), calving date in Julian days (CD) and the previous BCS and FA to explain BCSm and BCSc. Models were obtained by multiple regressions and variables were selected by Stepwise. An increase in BCSe and FAm improved BCSm (BCSm = 0.16 + (0.66*BCSe) + (0.43*FAm) + (−0.07*(FAm-2.89)^2); r2 = 0.63; $P < 0.01$; Mean = 5; RMSE = 0.43) and BCSc was increased as a result of the increase in BCSe and BCSm (BCSc = 0.28+ (0.18*BCSe) + (0.62*BCSm) + (0.008*CD; r2 = 0.57; $P < 0.01$; Mean = 4.4; RMSE = 0.2). Models have a good explanation capacity and highlight the effect of prepartum BCS and FA on BCSc. Forage allowance indirectly affected BCSc by its positive effect on BCSm. These models could be employed by beef herd managers to control or predict the BCSc and reproductive performance.

Key Words: body condition score, forage allowance, modeling

0274 Growth Potential of Dhanni cattle under rain-fed conditions of Punjab, Pakistan. G. Bilal[*1], M. Moaeen-ud-Din[1], and A. Zurwan[2], [1]*PMAS-Arid Agriculture University, Rawalpindi, Pakistan,* [2]*PMAS-Arid Agriculture University, Rawalpindi, Pakistan.*

The objective of the present study was to investigate growth potential of Dhanni cattle (a local humped cattle used for light draft) for possible utilization as potential beef cattle in arid or rain fed region of Attock, Punjab, Pakistan. Data on live weight of cattle ($N = 185$: 105 male, 80 females; age ranged from 1 to 375 d) were recorded in the field from 30 registered farmers raising purebred Dhanni cattle. The overall production system consisting of grazing (from 0800 to 1700 daily) with little or no supplementation. Mostly farmers weaned the calves between 6 and 8 mo of lactation probably due to low milk yield of Dhanni cows. Age of cattle was divided into 11 monthly classes with the last class having d 301 to 375. Data were analyzed using PROC MIXED of SAS (University Edition). The model included fixed effects of age at of cattle on test-day and sex; random effects of herd and residual. Males had slight higher weights (73.94 ± 1.81) than females (71.77 ± 1.97), but overall effect of sex was statistically nonsignificant ($P = 0.33$). Estimates of herd and residual variances were 18.15 and 206.35, respectively. Live weight of cattle varied with age ($P < 0.0001$). The least squares estimates of means of live body weight (kg) for monthly age classes 1 (1–30 d), 2 (31 to 60 d) and so on to 11 (301–375 d) were 24.86 ± 2.60, 39.31 ± 3.18, 51.68 ± 4.62, 61.86 ± 2.90, 72.27 ± 3.67, 75.49 ± 3.65, 80.19 ± 3.93, 81.97 ± 5.04, 97.45 ± 4.25, 98.80 ± 6.12 and 117.49 ± 5.41, respectively. Overall, cattle showed a daily growth rate of 268.50g from 1 mo to approximately 12 mo of age. The data shows potential of Dhanni cattle for raising as a beef cattle using current genetic and genomic selection tools.

Key Words: Dhanni cattle, growth potential, field condition

BEEF SPECIES SYMPOSIUM: IMPROVING WELFARE OF BEEF CATTLE

0275 Assessing and improving welfare in cow calf systems. C. B. Tucker*, *University of California, Davis.*

To date, animal welfare assessment, particularly independent audits, have focused on intensive animal agriculture. As public and corporate interest in farm-to-plate animal welfare assurance grows, extensive animal agriculture, such as cow-calf operations, may begin to be audited as well. The extensive nature of cow-calf systems presents both opportunities and challenges from an auditing perspective. Cow-calf operations lend

themselves toward animal welfare auditing from two perspectives: direct inspection of animals (animal-based measures) and evaluation of practices or records (management-based measures). Looking at the animals directly during a ranch visit allows assessment of several key welfare concerns, namely stockmanship, animal behavior during handling, long-term effects of forage availability (e.g., body condition), and some health conditions like lameness, pinkeye and injury. An investigative approach to assessing management practices provides information about welfare concerns, including pain management during common procedures, weaning practices, and antibiotic use (a proxy for incidence of health problems such as bovine respiratory disease). When available, direct inspection of ranch records can also provide information about frequency and causes of mortality. The more challenging aspects of animal welfare assessment on cow-calf operations are related to how cattle are kept, or facility-based measures, including: water access and quality, access to dry, protected lying areas, shade and shelter. Assessing the animal welfare implications of transport are also a challenge. These environmental factors are known to be important, yet change on a regular basis, thus are difficult to audit. In addition, there are other logistical challenges including the size of the cow-calf sector (757,000 U.S. ranches) and, in some cases, limited availability of days/year and facilities to directly observe cattle. Despite these challenges, there is tremendous potential to provide valuable feedback to ranchers and their customers and ultimately improve animal welfare in the cow-calf sector.

Key Words: cow-calf, welfare, assessment

0276 Best management practices for weaned calves for improved health and well-being. C. R. Krehbiel*, B. K. Wilson, C. J. Richards, and D. L. Step, *Oklahoma State University, Stillwater.*

Morbidity and mortality from Bovine Respiratory Disease (BRD) in newly weaned calves continues to be the most significant health problem facing the beef cattle industry. BRD accounts for over 50% of all cattle treated for sickness, and several studies have documented the economic impacts of BRD on profit outcomes of calves. Direct costs attributable to BRD include death loss, treatment and labor costs, and prevention costs. BRD has been shown to impact growth performance and feed efficiency, days on feed, carcass merit and market value, and can decrease the returns of individual cattle from $50 to $250. Best management practices for weaned calves vary depending on factors such as season of year calves are purchased, calf genetics, length of time in the marketing/transport process, previous management/vaccination, among other factors. Calves purchased directly from a ranch have fewer health problems. In general, the longer an animal is in the marketing chain, the more health problems will be encountered. Calves that have spent several days in the marketing channel may develop clinical BRD before or very soon after arrival at the feedlot; whereas, cattle with less time in the marketing chain may get sick later (2 to 4 wk), due to the length of time it takes for BRD to develop. On or before arrival, calves should be given a risk score (High, Medium, Low) that relates to the quantity of stress they have encountered and the probability they will develop BRD. High-risk calves normally will have been recently weaned, have received no vaccinations, have not been castrated or dehorned, have been commingled and have moved through at least one auction market. Low-risk calves will come from a single source and will have gone through a value added/preconditioning program that includes vaccination, castration, dehorning, weaning, and adaptation to a feed bunk. Variation exists within risk category, and groups of calves from auction markets can have few health problems, while some groups of preconditioned calves have high incidence of BRD. Cattle managers must be willing and able to make changes in management to meet the needs of the individual loads of cattle. To improve health and well-being, the beef cattle industry should move toward lowering the risk of receiving calves. This presentation will review the best management practices for weaned calves based on risk category for improved health and well-being.

Key Words: bovine respiratory disease, health and well-being, weaned calves

277 Dairy cow culling: Best practices and industry trends. J. Walker*, *Dean Foods, Dallas, TX*

We all know that the best time to find a new career is while you still have your current one. And every dairy farmer should know that every dairy cow should have two careers, a MILK cow and a BEEF cow. While the proportion of animals sent to slaughter unfit for transport is extremely low, considering the number of cows slaughtered every year, the number of cows shipped that are unfit for transport becomes a significant welfare concern. There have been significant efforts on the part of the beef industry in the form of the Beef Quality Assurance programs to address the issue, yet there seems to remain a gap in performance in the dairy sector when it comes to dairy cattle condition at slaughter. The underlying cause of this gap is multifactorial, and the key to the solution is understanding the fundamental disconnect between dairy farmers and the beef supply chain. If progress is going to be made, we must first understand the drivers at the farm level. Milk price, milk production, feed cost and cull cow prices appear to be the primary drivers. Additional drivers include an apparent disconnect between the processor and the supplier and language barriers. Stakeholder engagement from farm to plant is essential to bridge the gap and improve the welfare of cattle sent to slaughter. Once the bridge is built, education, training and accountability will be the necessary drivers to secure change needed to demonstrate to consumers and customers alike that the welfare of cattle continues to be an industry priority.

Key Words: dairy, cull, welfare

0278 Welfare assessments of low stress handling in finishing feedlot cattle. K. S. Schwartzkopf-Genswein*, *Agriculture and Agri-Food Canada, Lethbridge, AB.*

Over the past 10–15 yr low stress handling for beef cattle and the techniques used to achieve it have gradually increased in use and understanding. The goal of low stress handling is to facilitate ease of animal movement as well as improve animal and handler safety. Its use is particularly important when handling finishing feedlot cattle that are heavy (> 300 kg) and more prone to injury, exhaustion, heat stress and lameness particularly at marketing when cattle are sorted, loaded/unloaded. Much excellent information is written and available on websites regarding specific techniques. The goal of this talk is to provide a brief over view of relevant low stress handing techniques for finishing cattle with a main focus on how and if these techniques reduce stress both physiologically and behaviorally. Studies assessing the effects of noise, light, visibility of the handler, facility design and prod use on indicators of cattle stress, as well as performance and meat quality have shown significant relationships between these variables. Overall, these studies help to validate the use of low stress techniques. Continued research is required to document the effects that low stress handling has on animal health, welfare and economics in the feedlot industry.

Key Words: low stress, handling, feedlot, finishing cattle

279 Evolution of animal welfare at packing plants. L. N. Edwards-Callaway*, *JBS USA, Greeley, CO.*

Animal welfare and humane handling have become integral components of slaughter plant operations over the past several decades. In the early nineties, Dr. Temple Grandin, a world-renowned animal scientist who revolutionized animal handling within the livestock industry, worked with the North American Meat Institute (NAMI) to publish the *Recommended Animal Handling Guidelines for the Meat Packing Industry*, which since its inception has served as the gold standard for animal handling at packing plants. Many commercial slaughter facilities address the proper treatment of animals through standard operating procedures, verification and monitoring programs, founded on the NAMI guidelines, in addition to applicable federal regulations. In the mid-1990s, Dr. Grandin was commissioned by the USDA to develop an objective system to evaluate the critical control points of animal handling at packing facilities. A HAACP-type (Hazard Analysis Critical Control Point) approach to evaluating animal handling was developed and adopted by NAMI and ultimately the meat industry as the voluntary standards for proper humane handling at slaughter facilities. By the end of the ’90s, major corporations such as McDonald’s began requiring animal handling audits at beef and pork supplier slaughter plants. With their purchasing power, these major food companies were able to drive improvement in animal handling performance at the packing facilities that supplied them. Within the past several years, many federally inspected plants have implemented a “systematic approach” to humane handling, which is a voluntary HAACP-based program described by the USDA Food Safety Inspection Service (FSIS) as a program that assesses critical control points of animal handling, develops appropriate programs and facilities to minimize stress and discomfort to animals and monitors performance continually. The meat industry has professionalized animal handling by supporting additional training and certifications specific to working with and processing animals, building a strong culture of animal care with the animal handlers at their facilities. As the number of plants reaching “excellent” levels on animal handling audits have continued to increase, the meat industry looks for novel ways to continually make progress (e.g., implementing the use of remote video auditing to monitor and train employees). There has been more focus in recent years on the condition of animals arriving at facilities and the impacts that has on how they must subsequently be handled. Animal handling continues to be a priority for all segments of the value chain.

Key Words: animal handling, auditing, slaughter

BIOETHICS SYMPOSIUM

0280 How was that chicken raised? Ethics and deliberating conscientiously about animal welfare standards. R. X. Anthony*, *University of Alaska, Anchorage.*

How was that chicken raised? Ethics and deliberating conscientiously about animal welfare standards

Whose or which animal welfare standards should be framing and guiding deliberations and practices so that they actually contribute to higher level of animal welfare? Animal welfare standards should first and foremost produce positive outcomes for the health and welfare of farm animals. However, the development and implementation of these standards do not always meet this mark. Global trade and commercial factors and the lack of governance structures and local science can result in less than desirable outcomes for animals. Farmers must contend with governmental regulations that are legally binding and a variety of private standards ranging from assurance and certification schemes and programs, voluntary codes of practice and standards of excellence from advocacy organizations. The plethora of standards can lead to “psychic numbing” and the moral psychology of denial among both farmers and consumers and can impede the discharge of good animal husbandry practices. Here, I explore the promise and shortcomings of employing wide reflective equilibrium (WRE, Daniels, 1996) to address these conditions. WRE can

help to produce coherence among conflicting sets of beliefs and values held by a moral agent or groups of moral agents, such as farmers and consumers who must consider "wicked problems," i.e., problems that are seemingly intractable in nature and which breed error, ignorance, confusion, transference of responsibility and learned helplessness. The development and implementation of animal welfare standards produce "wicked problems" that are complicated by social, economic and environmental constraints, empirical deficits and political struggle among different stakeholders in the food system. Implications of WRE for personal morality and public policy will be discussed.

Key Words: animal welfare, bioethics, ethics and deliberation

0281 Farm animal welfare: Three essential ingredients from an international context. A. De Paula Vieira*, *Positivo University, Curitiba, Brazil.*

The animal food chain is characterized by an array of values that represent the interests of different stakeholders. These values are reflected in policies, practices, branding, and media. They highlight market share and profitability, food safety, quality assurance, traceability, sustainability, good governance, and trustworthiness. Animal welfare value is informed by animal welfare science, which brings the perspective of the animal into focus. This presentation will highlight (1) the centrality of animal welfare science and technology in innovating for animals' needs; (2) the importance of local contexts and engaging stakeholders in discussions when implementing substantial changes; and (3) the roles of shared value, well-informed communication and development of tools for monitoring, e-government and education, respectively.

(1) Animal welfare science is central in ensuring that policymakers, producers, consumers, retailers and industry agents continue to make the interests of farm animals a priority as the global system anticipates new challenges. Animal welfare scientists are essential in multidisciplinary teams to design new apparatuses, articulate the proper role of care for farm animals, and in transferring knowledge to producers.

(2) Engaging with all interested parties at the local level is key to contextualize the needs and challenges faced by animal producers in their home countries as they strive to be responsible custodians of their animals, promote respectable livelihoods and enhance food security and efficient use of resources, and minimize food loss and waste. Local producers and professionals such as animal welfare scientists should be given training and greater visibility as strategic collaborators for their significance in promoting animal welfare and "co-branding."

(3) There is increasing aspiration by consumers that animal production reflects common goals such as greater transparency and reflexivity by all in the food system, humaneness and social justice. Here, it is paramount that animal welfare scientists become conduits of innovation. Technology such as e-government platforms together with public policies will be crucial as the production sector embraces robust sustainability pathways and produces "responsible commodities" in the information age.

To sustain financial success and promote social benefit, animal value chains must consider the structure of their respective operations, be open to perform structural changes that is informed by the best science available and have strong ethical grounding, adopt new practices, design and model business and production processes that are personalized to their customers, and innovate their products and services to meet contextualized local and global expectations.

Key Words: farm animal welfare, sustainability, food chain

0282 Breaking down communication barriers to connect with stakeholders. R. Beck*, *The Center for Food Integrity, Gladstone, MO.*

The science is clear on antibiotics, animal housing, GMO feed, the global demand for protein, etc.—so why does it seem consumers don't understand or agree with any of it? The gap between consumer expectations and perceived industry performance presents grand challenges for those trying to stick to the science, but presenter Roxi Beck will lay the foundation for a big solution that serves to decrease that gap. In this session, attendees will:

(1) Gain an understanding of what U.S. consumers believe about animal agriculture and associated issues (animal care, antibiotics, GMOs, etc.)

(2) Expand awareness of why consumers distrust agriculture and the food system

(3) Review the Center for Food Integrity's peer-reviewed and published model to build consumer trust

(4) Learn effective approaches that allow stakeholders (including consumers) to consider complex and controversial science in their decision-making process

(5) Walk away with a toolbox of approaches and methods that complement CFI research to have meaningful stakeholder conversations

Key Words: consumers, industry performance, trust

ADVANCES IN BOVINE RESPIRATORY DISEASE

283 Genetic approaches to selection for resistance to bovine respiratory disease. J. E. Womack*, *Texas A&M University, College Station.*

Advances in genomics, molecular genetics and genotyping technology offer unique opportunities to identify genetic

variation associated with complex traits, including host resistance to infectious diseases. The Bovine Respiratory Disease Consortium is a team of scientists and educators who are exploiting these technologies to identify genomic elements underlying resistance to the bovine respiratory disease complex and translating research findings for application by the beef and dairy industries. Genome-wide association studies (GWAS) in both dairy calves and beef feedlot cattle have been conducted, and numerous associated loci have been identified. Promise for successful translation to genomic selection and effective breeding of resistant animals comes from our discovery of higher than expected heritabilities and some loci with reasonably large effects. Challenge of animals with single BRD associated pathogens and subsequent RNA-seq and pathway analyses complement the GWAS studies and helps provide candidate genes for causal variation underlying susceptibility. Work is underway to identify optimal clinical criteria to identify BRD for use in EPDs and translation into predicted transmitting abilities for susceptibility. This program also includes development of educational courses and a study of economic impact of BRD to both beef and dairy industries. A comprehensive extension component of the project includes outreach at every level as evidenced through the project website (http://www.brdcomplex.org).

0284 Differential gene expression in cattle challenged with single pathogens of the bovine respiratory disease complex.

L. J. Gershwin[*1], A. Vaneenennaam[1], J. F. Taylor[2], J. Kim[2], R. L. Toaff-Rosenstein[3], H. L. Neibergs[4], and J. E. Womack[5], *[1]University of California, Davis, [2]University of Missouri, Columbia, [3]University of California, Berkeley, [4]Department of Animal Sciences, Washington State University, Pullman, [5]Texas A&M University, College Station.*

Bovine respiratory disease complex (BRDC) is an important infectious cause of mortality and morbidity in cattle. BRDC develops when stressed cattle are infected with one of several viruses followed by one or more bacterial pathogens. To evaluate the host response to each of these pathogens, we measured global transcript abundance using RNA sequence analysis, comparing infected steers with normal controls after single pathogen infections. At maximum clinical signs, steers were euthanized for necropsy and collection of lung, bronchial, nasopharyngeal, and retropharyngeal lymph nodes, and pharyngeal tonsils for RNA sequencing. Viral agents used for the challenge were: bovine respiratory syncytial virus (BRSV), infectious bovine rhinotracheitis (IBR), and bovine viral diarrhea virus (BVDV). Bacteria used to challenge included: *Mannheimnia hemolytica*, *Pasteurella multocida,* and *Mycoplasma bovis*. Differential expression of genes coding for non-specific defense innate immunity and the acute phase response was found among all pathogen infections. These included pattern recognition receptors, mucins, and host defense peptides; more specific immune response genes were differentially expressed in individual pathogen infections. Adaptive immune system pathways for both T and B cells were activated in BRSV infection. In general viral infections elicited a greater number of differentially expressed genes than bacterial pathogens. Tissues were compared and found to contain both differentially expressed genes shared among all tissues examined and specific to tissue type. Overall data obtained will have important implications for design of better therapeutic modalities; and will help further elucidate the complex pathogenesis of BRDC.

Key Words: BRDC, infection, RNA

0285 Genome-wide association study of bovine respiratory disease complex in U.S. feedlot cattle.

C. M. Seabury[*1], H. L. Neibergs[2], J. F. Taylor[3], and J. E. Womack[4], *[1]College of Veterinary Medicine, Texas A&M University, College Station, [2]Department of Animal Sciences, Washington State University, Pullman, [3]University of Missouri, Columbia, [4]Texas A&M University, College Station.*

Bovine respiratory disease complex (BRDC) is the leading natural cause of morbidity and mortality among feedlot cattle, and is responsible for substantial economic losses during commercial beef production. The primary objective of the present study was to estimate the heritability of two related BRDC traits in U.S. feedlot cattle (binary case-control; clinical severity scores), and identify quantitative trait loci (QTL) associated with differential susceptibility to BRDC. All beef cattle (Angus, Red Angus, Taurine Crossbreds, Charolais, Hereford) were sampled from commercial feedlots in Colorado (CO) and Washington (WA), with BRDC phenotypes assigned using the McGuirk diagnostic scoring system. Similar numbers of heifers (928) and steers (934) were genotyped using the Illumina BovineHD BeadChip, which included 932 BRDC cases, and 930 controls. Genome-wide association analyses were performed using a linear mixed model (EMMAX) with genomic relationship matrix (G), and accounted for the effects of month, season, breed, lot-pen, days-to-pull, sex, year sampled, and location in the combined cohort (CO+WA). Heritability estimates for the BRDC binary case-control and clinical score phenotypes ranged from 0.13–0.14 in CO, 0.25–0.20 in WA, and 0.20–0.22 in the combined cohort, respectively; thereby suggesting that a common set of susceptibility loci were likely to exist. QTL estimated to explain $\geq$ 2% of the variance in either of the BRDC phenotypes were detected in each individual population (CO, WA), whereas the most significant QTL detected for the combined cohort were estimated to explain $\geq$ 1% of the variance in both BRDC phenotypes. The genomic positions of several binary and clinical scores BRDC QTL

were found to overlap in all analyses (i.e., CO, WA, CO+WA); with the combined cohort producing overlapping QTL intervals (i.e., binary, clinical scores) on BTA1, BTA5, BTA8, BTA10, BTA13, and BTA27 thereby suggesting that genomic selection for reduced BRDC susceptibility in beef feedlot cattle is likely to help mitigate economic and production losses.

0286 Identification of causal variants underlying pathogen susceptibility and translation to genetic improvement.
J. F. Taylor*[1], H. L. Neibergs[2], C. M. Seabury[3], A. Vaneenennaam[4], J. E. Decker[1], J. L. Hoff[5], P. C. Tizioto[6], J. E. Womack[7], and R. D. Schnabel[1], *[1]University of Missouri, Columbia, [2]Department of Animal Sciences, Washington State University, Pullman, [3]College of Veterinary Medicine, Texas A&M University, College Station, [4]University of California, Davis, [5]Division of Animal Sciences, University of Missouri, Columbia, [6]Embrapa Southeast Livestock, São Carlos, Brazil, [7]Texas A&M University, College Station.*

We have developed populations of 2781 preweaned Holstein calves (CA and NM) and 1862 Angus, Red Angus, Taurine Crossbred, Charolais and Hereford heifers and steers (WA and CO) that are approximately equally represented as cases or controls that are being used to train models for the prediction of additive genetic risk of Bovine Respiratory Disease (BRD). Analyzing BovineHD genotypes for these populations revealed heritabilities for BRD risk in the range from 20–23% and revealed numerous large effect QTL, many of which are located in genomic regions that also harbor genes that are differentially expressed between Angus × Hereford controls and animals challenged with single pathogens of the BRD Complex. To enable selection for increased resistance to the pathogens responsible for BRD, we seek to develop estimates of genetic merit that are robust to the breed composition of the tested animals and to the extent of their relatedness to these training populations. To accomplish this requires the identification of the causal variants that have a large effect on risk of BRD that were detected in Genome-Wide Association Analyses (GWAA). The strategy that we have followed involves the development of a functional variant assay known as the GGP-F250 that includes variants likely to alter the function of proteins through frameshifts, amino acid substitutions or altering the sequences of 5' and 3' untranslated regions. Variant discovery was performed using whole genome sequences (WGSs) for 262 taurines and RNA sequence data for 153 taurine animals. Variants were validated using 1000 Bull Genomes project data for 1147 sequenced animals and WGS data on 35 indicine or indicine × taurine composite animals. Holstein training population animals have been genotyped with this assay and the combined data have been imputed to WGS variation (~11M variants with minor allele frequency > 5%) for the purpose of performing GWAA. The beef populations are likewise being imputed to WGS, and we seek to identify variants that are consistently associated with risk of BRD across populations for which the direction of allele effects is conserved across populations. These variants will be migrated to assays commercialized by Zoetis and GeneSeek that are routinely utilized by the beef and dairy industries to enable the translation of project results.

This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2011–68004–30367 from the USDA National Institute of Food and Agriculture.

Key Words: BRD, GWAS, causal variants, estimated breeding values

0287 Gene set enrichment analysis of bovine respiratory disease complex SNP data in feedlot cattle.
M. Neupane[1], J. F. Taylor[2], C. M. Seabury[3], J. E. Womack[3], and H. L. Neibergs*[1], *[1]Department of Animal Sciences, Washington State University, Pullman, [2]University of Missouri, Columbia, [3]Texas A&M University, College Station.*

Bovine Respiratory Disease Complex (BRDC) is responsible for annual deaths of more than 350,000 feedlot cattle and estimated losses of over $1 billion in the U.S. The objective of this study was to use gene set enrichment analysis of SNP data (GSEA-SNP) to identify pathways associated with susceptibility to BRDC in *Bos taurus* feedlot cattle. Cattle were sampled from commercial feedlots in Colorado and Washington, and cases were determined using the McGuirk diagnostic system. Approximately equal numbers of steers (933) and heifers (935) and cases (936) and controls (932) were genotyped with the Illumina BovineHD BeadChip and analyzed using an additive model with breed (Angus, Red Angus, Crossbred, Charolais and Hereford), days to pen removal, month and location as covariates in the genome-wide association analysis (GWAA). EIGENSTRAT principal component (PC) analysis was used to correct for population stratification using the first 10 PC resulting in $\lambda = 1.03$. GWAA was followed by GSEA-SNP utilizing 4388 pathways from Gene Ontology (GO), Kyoto Encyclopedia of Genes and Genomes, Reactome, Biocarta and Panther. Haplotype block size was estimated and averaged across breeds to determine the size of the interval harboring each gene in which to search for a SNP that would serve as the proxy for the gene. The most significant SNP from the GWAA that was located within 7 kb of each gene was used as the proxy for each of the 19,723 genes mapped in the UMD 3.1 assembly. For each gene set, the significance value was calculated using the null distribution generated from 10,000 phenotype-based

permutations. Enrichment scores (ES) were calculated using running sum statistics. Five GO gene sets had normalized ES > 3 and were found to be associated with susceptibility to BRDC: GO:0005887 Integral Component of Plasma Membrane, GO:0031324 Negative Regulation of Cellular Protein Metabolic Process, GO:0005496 Steroid Binding, GO:0030162 Regulation of Proteolysis and GO:0008277 Regulation of G Protein Coupled Receptor Protein Signaling Pathway. No other gene sets were found to be associated with BRDC susceptibility. Of the 228 leading edge genes, 79 were differentially expressed between cases and controls and represent putative BRDC functional candidate genes which will be further investigated to determine how they may be best used in the selection of feedlot cattle that are more resistant to BRDC.

Key Words: GSEA-SNP, bovine respiratory disease complex

0288 Calculation of genomic predicted transmitting abilities for bovine respiratory disease complex in Holsteins. C. P. VanTassell*[1], G. Spangler[2], D. M. Bickhart[3], G. R. Wiggans[4], J. B. Cole[5], J. F. Taylor[6], H. L. Neibergs[7], C. M. Seabury[8], A. L. Van Eenennaam[9], and J. E. Womack[10], *[1]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [2]USDA-ARS, Beltsville, MD, [3]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [4]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [5]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [6]University of Missouri, Columbia, [7]Department of Animal Sciences, Washington State University, Pullman, [8]College of Veterinary Medicine, Texas A&M University, College Station, [9]University of California, Davis, [10]Texas A&M University, College Station.*

Bovine Respiratory Disease Complex is a disease that is very costly to the dairy industry. Genomic selection may be an effective tool to improve host resistance to the pathogens that cause this disease. Use of genomic predicted transmitting abilities (GPTA) for selection has had a dramatic effect on rates of genetic improvement in Holsteins, particularly for lowly heritable traits. Data were collected on 2682 calves located in California (n = 1978) and New Mexico (n = 705). DNA was extracted and animals were genotyped using the BovineHD BeadChip. A total of 22 individuals were excluded based on genotype call rate and breed designation other than Holstein. Of the remaining animals, 708 had unidentified sires, the remaining 1952 animals were the offspring of 578 sires which were identified by genotype matching. There were 38 bulls with at least 10 offspring, 343 with at least 2 progeny, and 235 bulls with a single offspring in the data set. A standardized scoring system considering animal body temperature, cough severity, nasal discharge, and eye discharge or ear scores was used to characterize the disease status of all calves according to the McGuirk classification system. Currently, GPTA are being calculated from these data using a heritability value of 0.20, which will be validated from the data. Estimated genetic marker effects will be compared with results from previous genome-wide association studies.

0289 The value of genetic selection in reducing economic losses from bovine respiratory disease complex in beef cattle feedlots. J. S. Neibergs*[1] and H. L. Neibergs[2], *[1]Washington State University, Pullman, [2]Department of Animal Sciences, Washington State University, Pullman.*

The U.S. inventory of beef cattle has declined since its peak in the 1980s to levels present in the early 1960s. Low cattle inventories have contributed to record high prices since 2009. The increased cattle values have also resulted in a subsequent increase in economic losses from disease. Reducing losses due to disease has become increasingly important in managing thin profit margins at feedlots. The objective of this study was to develop a bio-economic model to evaluate the economic cost of bovine respiratory disease complex (BRDC) in beef feedlots and estimate the potential net economic gain from using selection approaches to reduce BRDC prevalence. Treatment cost, mortality, and harvest data from approximately 1000 heifers and 1000 steers with similar numbers of cases and controls were taken from two commercial feedlots and two commercial processing facilities at harvest. These data were used to develop a Reed-Frost epidemiological model that simulated BRDC prevalence in a population of cattle on feed. Treatment cost was computed as a function of days on feed and the prevalence of cases. Losses due to mortality, and carcass quality discounts were also included to estimate total economic losses. Based on market prices, and carcass discounts, the average economic loss per BRDC case was estimated. To estimate the potential net economic gain from selection, the rate of genetic gain was estimated using a 16.2% national BRDC prevalence rate obtained over a 15-yr period and an estimated heritability for BRDC susceptibility of 21% from the 2000 cattle evaluated in this study. An @ Risk model was used to estimate a 20-yr time frame of genetic selection with stochastic BRDC prevalence rates using historical USDA data. The model compared net economic gains for cattle feedlots that used selection to reduce BRDC and feedlots that approached reducing BRDC without selection. This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2011–68004–30367 from the

USDA National Institute of Food and Agriculture.

0290 How might genomic information get translated into industry outcomes? A. L. Van Eenennaam*, *University of California, Davis.*

The 5-yr USDA-funded Bovine Respiratory Disease Complex Coordinated Agricultural Project (BRD CAP; USDA-AFRI 2011–68004–30367) aims to develop genetic markers associated with bovine respiratory disease (BRD) to enable the genetic identification of cattle that are less susceptible to BRD. Ultimately the aim of this project is to integrate predictive markers for BRD susceptibility into genetic tests and national cattle genetic evaluations. The research team is activity working to identify regions of the genome associated with BRD susceptibility in both dairy and beef cattle. Initial results have identified multiple genomic regions that were significantly associated with BRD susceptibility. Genomic selection has been introduced into dairy cattle breeding programs globally and within breed genomic estimated breeding values (GEBV) are published in a number of countries. Work is ongoing to integrate BRD information into dairy cattle evaluations at the appropriate economic weighting. However the incorporation of genomic information into beef cattle evaluations has been more problematic due to the presence of numerous breeds and the importance of crossbreeding in the commercial cattle population. Linkage disequilibrium between markers and quantitative trait loci (QTL) is not consistent across breeds, and so markers that were identified in one breed were frequently uninformative in other breeds. However, the sequencing of a large number of animals has opened up the possibility of identifying the actual SNP variations that are causing genetic variation. It is envisioned that by imputing the genotypes of reference animals collected by the BRD CAP up to full sequence and further fine mapping and analyses, the causative genetic variants associated with BRD susceptibility will be identified, and that inclusion of these markers on genotyping platforms will provide a reliable selection criterion to enable for the selection of both beef and dairy cattle that are less susceptible to BRD. There are several advantages associated with using causative SNP makers in selection panels including persistence of the marker effect across generations, and an increased likelihood that causative polymorphisms will be similarly associated with variation across multiple breeds. Ultimately, prospective marker panels will need to be tested in independent cattle populations to ensure they are predictive of BRD phenotype. Toward this end the BRD CAP is working in collaboration both breed associations and commercial feedlots to develop populations of BRD phenotyped animals. Ultimately selection against BRD susceptibility will depend on breeder inclusion of this disease trait in their breeding objective and selection decisions. See http://www.brdcomplex.org for more information.

BREEDING AND GENETICS

0291 APY inverse of genomic relationship matrix–theory, analyses and questions. I. Misztal*, I. Pocrnic, D. Lourenco, and Y. Masuda, *University of Georgia, Athens.*

Genomic relationship matrix (GRM) can be inverted by Algorithm for Proven and Young (APY) based on recursion on a random subset of animals. While a regular inverse has a cubic cost, the cost of the APY inverse can be close to linear, allowing inexpensive computations with millions of genotyped animals. Theory proposed for APY assumes that optimal size of the subset (maximizing accuracy of genomic predictions) is due to a limited rank of GRM, which is a function of independent chromosome segments (Me) and subsequently of effective populations size (Ne). Simulation studies have shown that (1) the dimensionality is almost a linear function of Ne but for large Ne can be depressed by limited number of genotyped animals and SNP markers, (2) accuracy of predictions with APY inverse is higher than with a regular inverse, and (3) the distribution of independent chromosome segments is skewed. Tests using commercial data sets confirmed results by simulation. Comparisons of eigenvalue plots between simulated and commercial populations indicated an effective population size of 157 for Holsteins, 115 for Angus, 107 for Jerseys, 41 for broiler chicken and 30 for pigs. Experiences with the APY inverse raise a few questions. Can the rank provide information on the minimum SNP chip size that eliminates the polygenic component (or missing heritability)? Is the rank of GRM for a large two-breed population twice that of a single population? In simulation studies where QTL are on SNP markers, the best correlation of a simulated QTL effect is not with the actual SNP effect but with an average of adjacent SNPs. Is the optimum number (window size) of adjacent SNP a function of Ne and dictates the maximum resolution in GWAS? With all causative SNP are identified and their variances known, and appropriate weighted GRM (with APY inverse applicable) has the rank of the number of causative SNPs. Is the rank of weighted GRM with incomplete identification of QTLs (e.g., via GWAS or BayesB) smaller than that of a regular GRM? The APY inverse solves the problem of large-scale genomic computations and provides new insight into the genomic information.

Key Words: genomic selection, single-step GBLUP, APY inversion

0292 Dimensionality of genomic information and APY inverse of genomic relationship matrix. I. Pocrnic*[1], D. A. L. Lourenco[1], Y. Masuda[1], A. Legarra[2], and I. Misztal[1], [1]*University of Georgia, Athens,* [2]*INRA, UMR 1388 GenPhySE, Castanet-Tolosan, France.*

The objective of this study was to evaluate by simulation the dimensionality of genomic information in closed populations and its effect on genomic predictions using regular or sparse inverses of the genomic relationship matrices (GRM). Six datasets were simulated, representing populations with effective population sizes (Ne) approximately 20, 40, 80, 120, 160, and 200. Each population consisted of 10 non-overlapping generations, with 25,000 animals per generation and phenotypes available for generations 1 to 9. The last three generations were fully genotyped assuming genome length L = 30 Morgan, with 49,980 evenly allocated biallelic SNP markers and a total of 4980 biallelic and randomly distributed QTL affected the trait. The GRM was constructed for each population and analyzed for distribution of eigenvalues. The number of the largest eigenvalues explaining 90, 95, 98 or 99% of variation in GRM ranged from 814, 1611, 3701, 6253 (Ne≈20) to 5512, 9245, 15483, 20786 (Ne≈200), respectively. Genomic EBV (GEBV) were computed by single-step genomic BLUP (ssGBLUP) using either a direct inverse of GRM or a sparse inverse with the algorithm for proven and young (APY) that is based on recursion on a random subset of animals, where subset sizes were set to number of the largest eigenvalues explaining 90, 95, 98 or 99% of variation in GRM. APY inverse has approximately a linear cost as opposed to cubic for the regular inverse. Accuracies of GEBV for the last generation with APY inverse peaked at EIG98 and were slightly lower with EIG95, EIG99 or the direct inverse. In a situation with large number of SNP markers and genotyped animals, dimensionality of the SNP genomic information defined by the eigenvalues of GRM is approximately a linear function of effective population size, where most information is contained in about NeL largest eigenvalues, with no information beyond 4NeL. Genomic predictions with APY sparse inverse of GRM are more accurate and computationally inexpensive compared with regular inverse.

Key Words: genomic relationship matrix, genomic recursion, single-step genomic BLUP

0293 Accounting for discovery bias in genomic prediction. R. M. Thallman*[1], J. T. Parham[2], L. A. Kuehn[1], and J. P. Cassady[2], [1]*USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE,* [2]*South Dakota State University, Brookings.*

Our objective was to evaluate an approach to mitigating discovery bias in genomic prediction. Accuracy may be improved by placing greater emphasis on regions of the genome expected to be more influential on a trait. Methods emphasizing regions result in a phenomenon known as "discovery bias" if information used to determine influential regions is also used to predict genetic merit. Discovery bias causes genomic predictions to appear to be more accurate than they actually are. Generally, EBV of a population are conditional on as much information as possible and individual EBV are each conditional on exactly the same information. An analysis of simulated data (105 replicates) was conducted to test whether discovery bias could be reduced and true accuracy of prediction could be improved by relaxing the constraint that all EBV are conditional on the same information. In the default analysis, molecular breeding values (MBV) were computed from 2487 random SNP effects whose variances were estimated by REML. The 2600 phenotypes were simulated for non-parent animals only, which were progeny of 107 sires with number of paternal half-sibs per group ranging from one to 107. Corrected MBV (CMBV) were computed for each paternal half sib group by repeating the REML analysis on a data set that excluded records within that paternal half-sib group in an attempt to reduce discovery bias. True accuracy (correlation of MBV or CMBV with simulated breeding value) was lower for CMBV than for MBV. To recover the lost information without reintroducing discovery bias, a two-trait pedigree-based post-analysis was performed in which all 2600 phenotypes were fit as the first trait and the MBV (CMBV) were fit as the second trait. The solutions for the first trait are referred to as EBV and CEBV, respectively. True accuracy was greater for EBV than for MBV, suggesting the pedigree captured some genetic variance not accounted for by SNP. True accuracy was greater for CEBV than for EBV. Model derived accuracies were computed from prediction error variances of animals or functions of marker effects in the respective models. All model derived accuracies were greater than the corresponding true accuracies, indicating that discovery bias was present. Model

Table 0293.

	Model Derived Accuracy		True Accuracy		Discovery Bias
	Mean	SE	Mean	SE	Mean
MBV	0.960	7.11e-5	0.687	0.006	0.273
CMBV	0.954	7.59e-5	0.620	0.007	0.334
EBV	0.942	6.85e-5	0.716	0.006	0.226
CEBV	0.865	5.84e-5	0.721	0.007	0.144

MBV = Uncorrected molecular breeding value; CMBV = Corrected MBV; EBV = Uncorrected estimated breeding value; CEBV = Corrected EBV; Discovery bias = Model derived accuracy – True accuracy

derived accuracy was closer to true accuracy for CEBV than for EBV, indicating that the proposed correction was successful in reducing discovery bias, although it did not completely remove it. USDA is an equal opportunity employer.

Key Words: accuracy, discovery bias, genomic prediction

294 Assessing genomic prediction accuracy for Holstein sires using bootstrap aggregation sampling and leave-one-out cross validation. A. Mikshowsky[1], K. A. Weigel[*2], and D. Gianola[3], *[1]University of Wisconsin, Madison, [2]Department of Dairy Science, University of Wisconsin, Madison, [3]University of Wisconsin, Madison.*

Since the introduction of genomic prediction for dairy cattle in 2009, genomic selection has dramatically changed many aspects of the dairy genetics industry and enhanced the rate of response to selection for most economically important traits. Young dairy bulls are genotyped to obtain their genomic predicted transmitting ability (GPTA) and reliability (REL) values. These GPTA are the main factor in most purchasing, marketing, and culling decisions until the bulls reach 5 yr of age and their milk-recorded offspring become available. At that time, daughter yield deviations (DYD) can be compared with the GPTA computed several years earlier. For most bulls, the DYD are similar to the initial predictions. However, for some bulls, the difference between DYD and corresponding GPTA is quite large, and published REL are of limited value in identifying such bulls. A method of bootstrap aggregation sampling (bagging) using genomic BLUP (GBLUP) was applied to predict the GPTA of 2963, 2963, and 2803 young Holstein bulls for protein yield, somatic cell score (SCS), and daughter pregnancy rate (DPR), respectively. For each trait, 50 bootstrap samples from a reference population comprised of 2011 DYD of 8610, 8405, and 7945 older Holstein bulls were used. Leave-one-out cross validation was also performed to assess the prediction accuracy when removing specific bulls from the reference population. The main objectives of this study were: (1) to assess the extent to which current REL values and alternative measures of variability, such as the bootstrap standard deviation (SD) of predictions, could detect bulls whose daughter performance will deviate significantly from early genomic predictions and (2) to identify factors associated with the reference population that can cause inaccurate genomic predictions. Correlations between bagged GBLUP predictions and 2014 DYD were lower than GBLUP predictions from the full reference population. The SD of bootstrap predictions was a useful metric for identifying bulls whose future daughter performance may deviate significantly from early GPTA for protein and DPR. Use of bootstrap predictions could prevent up to 50% of type I errors and roughly 10% of type II errors in sire selection decisions. The removal of certain reference population bulls indicated that testing set predictions for protein were robust overall, but some bulls negatively affecting prediction accuracy were identified.

0295 The impact of call rate on genotype accuracy. D. C. Purfield[*1], M. C. McClure[2], and D. P. Berry[3], *[1]Animal & Grassland Research and Innovation Centre, Teagasc, Moorepark, Fermoy, Co. Cork, Ireland, [2]Irish Cattle Breeding Federation, Bandon, Ireland, [3]Teagasc, Moorepark, Fermoy, Co. Cork, Ireland.*

Data quality of single nucleotide polymorphism (SNP) arrays plays a key role in the accuracy and precision of downstream data analyses. The use of low quality genotypes can lead to false-positive results and impair the accuracy of genomic predictions. One such quality control measure commonly used is individual animal call rate, defined as the proportion of SNPs per individual where a genotype was called. Currently, no consensus exits on the minimum individual call rate that should be imposed, with threshold call rates per individual varying from 0.80 to 0.95 across studies. The objective of the present study was to determine the minimum individual call rate that could be applied without jeopardizing data quality. A total of 144,672 samples genotyped on a custom Illumina genotype panel on 143,827 dairy and beef cattle were available. The genotyping panel includes 14,371 SNPs on either the Illumina Bovine SNP50 or high density genotyping panels. All genotypes were called using the Illumina GenCall method. Lab-dates ($n = 4$) where > 15% of the samples genotyped had a call rate < 90% were not considered further. Of the remaining 142,433 samples, 493 animals had both a poor call rate (< 90%) and a subsequent high call rate (> 99%) after re-sampling and re-genotyping. The mean call rate for all samples was 98.77% (range: 15.81%-99.97%). The genotype and allele concordance rate among the genotypes available for all 493 animals with both a low and subsequent high call rate was estimated. Genotype and allelic concordance between low- and high-call genotypes increased as call rate increased (Table 1.). Low minor allele variants (i.e., variants with a minor allele frequency < 0.05) were imputed with greatest accuracy for samples with a mean genotype and allelic concordance of 99.24% and 99.55%. Imputation algorithms often correct for genotyping error, therefore to test if imputation improved concordance, all 493 low call rate samples were imputed using FImpute. A reference population of 140,268 animals with call rates > 90%, excluding the 493 high-call rate samples, was used. Imputation marginally increased concordance rates for all SNPs with a called genotype, but overall genotype concordance per class slightly decreased because missing genotypes were often incorrectly imputed as heterozygous genotypes. However, if a direct relative (i.e., sire, dam or progeny) was included in the imputation reference population, mean genotype

Table 0295.

Table 1. Genotype and allele concordance rates (CR) prior and post imputation for all 493 animals with a poor (<90%) and subsequent high call rate (>99%).

	Pre Imputation		Post Imputation			
Call rate class	Genotype CR	Allele CR	Genotype CR Called SNPs	Allele CR Called SNPs	Genotype CR All SNPs	Allele CR All SNPs
<40	38.36	62.35	38.61	62.38	39.42	63.22
40-50	47.08	68.57	47.33	68.62	44.74	67.15
50-60	58.59	76.59	58.89	76.67	53.68	73.54
60-70	79.31	89.51	79.66	89.65	73.21	85.92
70-75	86.06	93.01	86.29	93.08	81.71	90.51
75-80	93.47	96.73	93.64	96.79	90.77	95.26
80-85	96.83	98.41	96.93	98.46	95.56	97.72
85-90	98.44	99.22	98.47	99.22	98.08	99.01

and allele concordance for samples with a call rate between 85 and 90% increased to 98.13% and 99.04%, respectively.

Key Words: call rate, quality-control, genotype panels

296 Strategy for incorporating newly discovered causative genetic variants into genomic evaluations. G. R. Wiggans*[1], P. M. VanRaden[1], D. M. Bickhart[2], and M. E. Tooker[1], *[1]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [2]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD.*

With sequence data available for an increasing number of dairy cattle, discovery of causative genetic variants is expected to be frequent. Current genomic evaluation systems require genotypes for all markers that contribute to an evaluation. A minimum number of animals with an observation for a new marker is required for accurate imputation. The SNP calls derived from sequence data from the 1000 Bull Genomes Project for 444 Holsteins were combined with SNP genotypes from bulls in the predictor population for U.S. national genetic evaluations to impute candidate variants from the full sequence. From this imputed data, the set of SNP used in genomic evaluation along with the newly discovered causative variants were selected and stored. Those genotypes replaced the original genotypes for the bulls when extracting genotypes for genomic evaluation. The time required for imputation is substantially reduced in routine evaluation by using the haplotype library and assignments from the previous evaluation. To create suitable prior information for the expanded SNP set, genotypes for approximately 100,000 animals (including the predictor bulls and many cows with genotyped progeny) were imputed without priors. This step took about 1 d; if the full set of animals had been used, it would have taken over a week. The accuracy of this approximation was tested using the December 2015 Holstein genomic evaluation of nearly 1 million animals. Genotypes from 978,987 bulls and cows were used to create the priors, which were used to impute the December 2015 Holstein genotypes. Of the nearly 60 billion comparisons, 97.7% were identical, 1% differed by 1 allele, and 1.2% differed by a missing allele. Efficient methods that result in higher concordance may be possible. Adding new highly informative markers to the evaluation process is expected to improve prediction accuracy. In addition, excluding other markers may further increase accuracy if they contribute more noise than value when highly informative markers are included. The procedure developed enables newly discovered causative variants to be added to genomic evaluation almost immediately, which saves the time previously required for a marker to be added to a new genotyping chip as well as the time required for sufficient animals to be genotyped with the new chip to achieve adequate imputation accuracy. With this strategy, the benefits from adding new markers to genomic evaluation can be realized sooner.

Key Words: causative variant, sequence data, genomic evaluation

0297 High density marker panels, SNPs prioritizing and accuracy of genomic selection. L. Y. Chang*[1], S. Toghiani[1], S. E. Aggrey[2,3], and R. Rekaya[1,3], *[1]Department of Animal and Dairy Science, University of Georgia, Athens, [2]NutriGenomics Laboratory, Department of Poultry Science, University of Georgia, Athens, [3]Institute of Bioinformatics, University of Georgia, Athens.*

Availability of high density (HD) SNP marker panels, genome wide variants and even sequence data create an unprecedented opportunity of dissect the genetic basis of complex traits and to enhance selection in livestock and plant species. The disproportional increase in the number of parameters in the genetic association model compared with the number of phenotypes has led to further deterioration in the statistical power, and increase in co-linearity and false positive rates. HD panels do not improve the accuracy of GS in any significant manner and could even lead to reduction in accuracy using both regression and variance component methods. As a result, HD panels at best they did not improve significantly the accuracy of genomic selection and at worst they led to a reduction in accuracy. This is true for both regression and

variance component approaches. To remedy this situation, either some form of SNP filtering or external information is needed. Current methods for prioritizing SNP markers (i.e., BayesB, BayesC) are sensitive to the increased co-linearity in HD panels which could limit their performance. In this study, the usefulness of F_{st}, a measure of allele frequency variation among populations, as an external source of information in genomic selection was evaluated. A simulation was performed for a trait with heritability of 0.4. Data was divided into three subpopulations based on trait distribution (top 5%, bottom 5% and in between). Marker data was simulated to mimic 770K SNP marker panel. A ten chromosome genome with 200K SNPs was simulated. Several scenarios with varying number of QTLs and their associated effects were simulated. F_{st} empirical cutoff values of 0.004, 0.008, 0.01, and 0.02 were used to prioritize markers resulting in 4579, 2288, 1745, and 650 selected SNPs, respectively. Using all 200K markers and no filtering, the accuracy of genomic prediction (correlation between true and predicted breeding values) was 0.48. When SNPs were pre-selected based on F_{st}, accuracy was 0.41, 0.48, 0.49, and 0.53 for F_{st} cutoff values of 0.004, 0.008, 0.01, and 0.02, respectively. It is clear that the accuracy obtained using all SNPs can be easily achieved using only 0.5 to 1% of all markers. These results indicated that SNP filtering using already available external information could increase the accuracy of genomic selection. This is especially important as next generation sequencing technology is becoming more affordable and accessible to animal and plant applications.

298 Selection of sequence variants to improve dairy cattle genomic predictions. M. E. Tooker*[1], P. M. VanRaden[1], D. M. Bickhart[1], and J. O'Connell[2], *[1]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [2]University of Maryland School of Medicine, Baltimore.*

Genomic prediction reliabilities improved when adding selected sequence variants from run 5 (July 2015) of the 1000 bull genomes project. High density (HD) imputed genotypes for 26,970 progeny tested Holstein bulls were combined with candidate sequence variants within or near genes for 444 Holstein animals. Variants with minor allele frequency (MAF) < 0.01, incorrect map locations, excess heterozygotes, or low correlations of sequence and HD genotypes for the same variant were removed. Individual genotype probabilities < 0.98 from Beagle and Mendelian conflicts between parents and progeny were set to missing. Test 1 included 481,904 candidate sequence SNP consisting of 107,471 exonic, 9422 splice, 35,242 untranslated regions at the beginning and end of genes, 329,769 SNP upstream or downstream of genes. Test 2 also included 249,966 insertions and deletions (indels). After merging sequence variants with 312,614 HD SNP and editing, Test 1 included 762,588 variants and Test 2 included 1003,453. Imputation quality was assessed by keeping 404 of the sequenced animals in the reference population and randomly choosing 40 animals as a test set. Their sequence genotypes were reduced to the subset in common with HD genotypes and then imputed back to sequence. Percentage of correctly imputed variants averaged 97.3% across all chromosomes in Test 1 and 97.2% in Test 2. Total time required to prepare, edit, and impute the sequence variants for 27,235 animals was about 5 d using < 20 processors. Computation of genomic predictions using deregressed evaluations from August 2011 for 33 traits and 19,575 bulls required about 3 d with 33 processors. Predictions were tested using 2015 data of 3983 U.S. bulls whose daughters were first phenotyped after August 2011. Many sequence variants had larger estimated effects than nearby HD markers, but prediction reliability improved only 0.6% points in Test 1 when sequence SNP were added to HD SNP, and only 0.4 higher than HD SNP in Test 2 when sequence SNP and indels were included. However, selecting the 17,000 candidate SNP with largest estimated effects and adding those to the 60,671 SNP used in routine evaluations improved reliabilities by 2.7% points (67.4% vs. 64.7%) on average across traits, compared with 35.2% parent average reliability. Accuracy of prediction can improve by adding selected sequence SNP to marker sets.

0299 Genomic prediction of crossbred performance. B. Harlizius*[1], M. S. Lopes[1], J. Vandenplas[2], C. A. Sevillano[2], and J. W. M. Bastiaansen[3], *[1]Topigs Norsvin Research Center, Beuningen, Netherlands, [2]Wageningen University, Netherlands, [3]Animal Breeding and Genomics Centre, Wageningen University, Netherlands.*

The majority of the commercial slaughter pigs are crossbred animals. However, breeding efforts have been mainly focused on increasing genetic progress of purebred populations. The aim of this work is to evaluate different strategies to improve genomic prediction of crossbred performance taking into account the breed origin of alleles in crossbred populations (breed-specific effects). Previous work showed that marker effects estimated in one breed cannot predict performance in another breed (across-breed prediction). This might be due to breed-specific effects caused by differences in linkage disequilibrium between the marker and the QTL, as well as differences in allele frequencies and in genetic background of the breeds. For prediction of crossbred performance, marker effects estimated in single-breed data showed some predictive value but training on crossbred data achieved higher accuracies, although the breed origin of alleles was ignored. In this study, prediction accuracies of breeding values from a traditional genomic selection model (GS) were compared

with prediction accuracies of breeding values from a model that accounts for breed-specific effects (BS). The population evaluated consisted of a two-way (Large White and Landrace) crossbred population. As both parents of all crossbred animals were known, the breed origin of alleles was easily determined after phasing of the data. The trait evaluated was gestation length (GL), for which a genetic correlation between purebred and crossbred performance (r_{pc}) of 0.90 was estimated. Prediction accuracy of BS breeding values was slightly greater than prediction accuracy of GS breeding values (0.53 and 0.52, respectively). Additional benefits of BS over GS are expected for traits with lower r_{pc} and when crosses of more distant purebred populations are evaluated. As a step further, a method based on long-range phasing for determining the breed origin of alleles in three-way crossbred data was developed. In a simulation study, the accuracy of breed of origin assignment was determined for 400 three-way crossbred animals with 95% correct assignments, 3% unassigned and < 2% incorrect assignments. Application of this method to real data, including 14,000 genotyped purebred animals and 1700 genotyped three-way crossbred animals, achieved 93% assignments of breed of origin of alleles without using pedigree information. Genotypic data from purebred animals was required to define the haplotypes of the three breeds contributing to the crossbreds. Currently, analyses are underway to use this breed origin information of the three-way crossbred population to estimate breed-specific effects for genomic prediction.

Key Words: pigs, crossbred performance, breed-specific effects

0300 SNP filtering using Fst and implications for genome wide association and phenotype prediction. S. Toghiani[*1], L. Y. Chang[1], S. E. Aggrey[2,3], and R. Rekaya[1,3],[1]*Department of Animal and Dairy Science, University of Georgia, Athens,* [2]*NutriGenomics Laboratory, Department of Poultry Science, University of Georgia, Athens,* [3]*Institute of Bioinformatics, University of Georgia, Athens.*

Although genome-wide association studies (GWAS) detect single nucleotide polymorphism (SNP)-trait association, these SNPs explain only a small fraction of the variation. Genomic selection (GS), through the use of all available genetic information, tends to have a better dissection of the phenotypic variation, but its performance is still far from optimum. GWAS and GS are affected by lack of power is due to small sample size, large number of highly correlated markers, and the moderate to small effects of most QTLs. This situation could get even more complex with the continuous increase in marker density. Methods that internally try to prioritize SNPs (i.e., BayesB) tend to provide a certain relief when low to medium density panels are used but their advantages degrade with the increase of the number of markers. Thus, it is becoming a necessity to either perform a SNP filtering before conducting the association analysis or to enlist additional external sources of information. Knowledge of genetic diversity based on evolutionary forces is beneficial for tracking loci influenced by selection. F_{ST}, as measure of allele frequency variation among populations, provides a tool to reveal genomic regions under selection pressure. To evaluate its usefulness as an external source of information in association studies, a simulation was performed. A trait with heritability of 0.4 was simulated and three sub-populations were created based on the empirical phenotypic distribution (< 5% quantile; > 95% quantile and between 5 and 95% quantiles). Marker data was simulated to mimic 600K and 1 million SNP panels. Genetic complexity of the trait was modeled by the number of QTLs, their distribution, and magnitude of their effects. Using different empirical cut off values for F_{ST}, most QTLs were correctly detected using as little as 0.8% of SNP markers in the panels. Furthermore, the genomic similarity base on the selected SNPs was very high (> 0.80) for individuals with similar genetic and phenotypic values even that they have limited to no blood relationship. These results indicate that filtering SNPs using F_{ST}could be beneficial to GWAS and GS by focusing on genome regions under selection pressure. This could be relevant with the availability of next-generation-sequencing data. High functional genomic similarity based on selected markers indicates similarity in SNP signatures, regardless of blood relationships, and translates into high phenotypic correlation that could be used in decision making.

Key Words: GWAS, F_{ST}, genetic and phenotypic prediction

0301 A combined coalescence forward in time simulator software for pedigreed populations undergoing selection for complex traits. J. T. Howard[*1], F. Tiezzi[1], J. E. Pryce[2], and C. Maltecca[1], [1]*North Carolina State University, Raleigh,* [2]*Department of Economic Development, Jobs, Transport and Resources, Bundoora, Australia.*

The use of marker information in animal breeding has recently been an active area of research and has been incorporated in selection decisions and as a tool to control inbreeding across a variety of species. There is yet still much to be learned on the optimal way to use marker information to select animals and manage the genome of a population that is undergoing selection for complex traits that have a traditional quantitative basis (i.e., yield) and/or fitness basis (i.e., number of progeny). We have developed a combined coalescence and forward-in-time simulator for complex traits and populations. The simulator is performed in two stages. In the first stage whole-genome SNP data is read in ms format and is utilized to generate founder individuals and associated SNP marker panels ranging in size from thousands to millions of SNP. During this stage a wide variety of trait architectures can be generated with additive

and dominance effects for both a traditional quantitative trait and fitness along with genomic covariance among traits. The second stage generates new individuals across generations based on a variety of selection scenarios. The selection stage can be performed using a wide variety of relationship matrices including pedigree, independent markers, haplotypes, or run of homozygosity based haplotypes. Relationship matrices and their associated inverse are generated using computationally efficient algorithms based on updating matrices from previous generations. Complex population structures can be generated that allow for a differential contribution of gametes to the next generation as well as mating constraints. To demonstrate the program, we present a small application that mimics a dairy cattle and swine population to describe some of the metrics that are generated. Scenarios were generated based on a 12,000 SNP marker panel spread across 3 chromosomes and a population size of 650 animals (sires = 50; dams = 600) per generation. A scenario with selection on a quantitative trait occurring for 5 generations and breeding values estimated from pedigree or independent SNP had a running time for the dairy cattle scenario of 4.85 and 5.82 min, respectively. GenoDriver allows for a wide range of selection strategies to be evaluated in the presence of a fitness trait and is available at https://github.com/jeremyhoward/GenoDriver.

0302 Identifying and calling insertions, deletions, and single-base mutations efficiently from sequence data. P. M. VanRaden[*1], D. M. Bickhart[2], and J. R. O'Connell[3], *[1]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [2]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [3]University of Maryland School of Medicine, Baltimore.*

Whole-genome sequencing studies can identify causative mutations for subsequent use in genomic evaluations, but sequence alignment and variant identification are lengthy and sometimes inaccurate processes. Speed and accuracy of identifying small insertions and deletions (indels) of sequence can be improved by calling variants while aligning sequence reads. Previous algorithms separated alignment and calling steps, whereas program findmap stores previously known variants in memory, calls alleles for those variants, and identifies other potential new variants during alignment. The algorithm uses a string-pattern hash to store the reference genome in a rapidly accessed table. If both ends of a paired-end read do not align fully, the length of a potential indel within the read is calculated from the map location difference for two partial matches. The algorithm then finds the indel location and checks if the full read matches after accounting for the indel. Potential variants detected by findmap are checked and edited by program findvar for consistency across reads. New variants from findvar were compared with those from the Genome Analysis Toolkit (GATK) UnifiedGenotyper and from SamTools after Burrows-Wheeler Aligner (BWA) alignment. Detection accuracy was examined using reads simulated for 10 animals at 10X coverage from cattle reference map UMD3.1 with variants derived from run 5 (July 2015) of the 1000 bull genomes project that included 38,062,190 SNP, 532,179 insertions, and 1127,620 deletions. Half of variants were simulated as heterozygous, one-fourth as homozygous alternate, and one-fourth as homozygous reference. For homozygous alternate variants, findvar found 99.8% of SNP, 79% of insertions, and 67% of deletions; GATK found 99.4, 90, and 89%; and SamTools found 99.8, 12, and 18%, respectively. For heterozygotes, findvar found 99.1, 75, and 62%; GATK found 99.0, 90, and 88%; and SamTools found 98.2, 9, and 11%, respectively. False positives as percentages of true variants were 14, 0.4, and 0.3% from findvar; 12, 8.4, and 2.9% from GATK; and 37, 1.3, and 0.4% from SamTools, respectively. Read depth was 85.9 from findmap/findvar, 96.1 from BWA/GATK, and 84.4 from BWA/SamTools. With 10 processors, clock times were 106 h for BWA, 25 h for GATK, 11 h for SamTools, 3 h for findmap, and 1 h for findvar. The new software is freely available, with algorithms 10 to 30 times faster than current strategies for calling known and identifying new variants. Accuracy is improved by accounting for DNA variants while aligning sequence data.

Key Words: sequence alignment, variant calling, indel

0303 Issues in commercial application of single-step genomic BLUP for genetic evaluation in American Angus. D. A. L. Lourenco[*1], S. Tsuruta[1], B. D. Fragomeni[1], Y. Masuda[1], I. Pocrnic[1], I. Aguilar[2], J. K. Bertrand[1], D. W. Moser[3], and I. Misztal[1], *[1]University of Georgia, Athens, [2]INIA, Las Brujas, Uruguay, [3]Angus Genetics Inc., St. Joseph, MO.*

American Angus Association (AAA) has been using genomic information for genetic evaluations in a multistep approach since 2009. To improve accuracy while simplifying procedures, AAA is transitioning to single-step genomic BLUP (ssGBLUP) in the middle of 2016. Initial tests with ssGBLUP showed an increase in prediction accuracy of 25% for growth traits compared with traditional evaluations. Besides evaluation for growth traits, the goal of this study was to update the full pipeline for genetic evaluation with ssGBLUP methodology. The pipeline includes multi-trait models with linear and categorical traits, maternal effects, multibreed evaluations with external information, and a large number of genotyped animals but most of them with low EBV accuracy. Data included 9.7 M animals in the pedigree, 184,354 genotyped animals, and at most 8.2 M phenotypes for growth traits, calving ease (categorical), and carcass traits. The first issue during the implementation was the increasing number of genotyped animals. Single-step GBLUP requires the inverse of the genomic

relationship matrix (GRM), which had a high computing cost and required around 1 Tb of memory for this dataset. The algorithm for proven and young animals (APY) was used to approximate the inverse of the GRM. The number of core animals was set to 15,000, which was calculated as the number of eigenvalues of GRM explaining 99% of the variation. This algorithm reduced the memory usage to 40 Gb and required 10% of the computing time while slightly improving the accuracy. Another issue was the increase in computing time for calving ease evaluation, which uses a threshold model, from 12 h to 4.5 d. Resetting the preconditioned conjugate gradient iteration to solve the mixed model equations every 40 to 200 rounds helped decrease the time to 19 h. The inclusion of external EBV for Red Angus was required for evaluation of growth traits. We developed software to support genomic and external information, and the implementation of a genomic multibreed model increased the computing time only by 2.5 h. Current algorithm for approximation of accuracy of genomic EBV (GEBV) was too expensive for > 100,000 animals. A new algorithm was developed that does not require inverse of large GRM and accounts for multiple sources of information while avoiding double-counting. Correlations between accuracy from the new algorithm and true accuracy from PEV were higher than 0.85 for growth traits. Single-step GBLUP can be considered a mature methodology for commercial genomic selection in beef cattle.

Key Words: beef cattle, genomic selection

0304 Single-step GBLUP using APY inverse for protein yield in U.S. Holstein with a large number of genotyped animals. Y. Masuda*[1], I. Misztal[1], and P. M. VanRaden[2], [1]*University of Georgia, Athens,* [2]*Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD.*

The objective of this study was to provide initial results in an application of single-step genomic BLUP with a genomic relationship matrix (G^{-1}_{APY}) calculated using the Algorithm of Proven and Young (APY) to 305-d protein yield for U.S. Holsteins. Two G^{-1}_{APY} were tested; one was from 139,057 genotyped bulls with 12,895 core animals (APY140K) and the other one was from 764,029 genotyped animals with 12,913 core animals (APY760K). The predictor data set consisted of phenotypes recorded after 1989 and pedigrees limited to 3 generations back from recorded or genotyped animals. Genomic predictions (GPTA2011) were calculated for predicted bulls that had no recorded-daughters in 2011 but had at least 50 such daughters in 2015. We used the official daughter yield deviations published in 2015 (DYD2015) for the predicted bulls (N = 3797). We also used the official GPTA published in 2011 with a multistep method as a comparison, although official methods have improved since then. Coefficient of determination (R^2) and slope (b_1) were calculated from a linear regression of DYD2015 on GPTA2011. Using APY140K, the R^2 was 0.50 compared with 0.51 from the official GPTA. The b_1 was much better (0.98) compared with 0.81 from the official GPTA. With APY760K, the R^2 was 0.46 and b_1 was 1.08. Incorporating effect of a SNP related to DGAT1 increased R^2 to 0.51 for APY140K and 0.48 for APY760K. The decrease in R^2 with APY760K compared with APY140K could be due to inclusion of lower quality genotypes, or biases caused with the use of all genotypes with incomplete phenotypes. All the computations finished within 11 h including 4.2 h to set up APY-inverse with APY760K. Based on the linearity of the computation cost, using 1 million genotyped animals with the same model would require 14 h of computations. Single-step GBLUP can provide genomic predictions for all genotyped bulls and cows while accounting for pre-selection. Further research will determine the impact of various factors affecting the reliability such as validation methodology, weighting SNP markers, and quality of genotyped data.

Key Words: genomic evaluation, Holstein, ssGBLUP

0305 Heteroskedastic extensions for genome-wide association studies. Z. Ou*[1], R. J. Tempelman[2], J. P. Steibel[3,4], C. W. Ernst[3], R. O. Bates[3], C. Chen[3], and N. M. Bello[1], [1]*Department of Statistics, Kansas State University, Manhattan,* [2]*Michigan State University, East Lansing,* [3]*Department of Animal Science, Michigan State University, East Lansing,* [4]*Department of Fisheries and Wildlife, Michigan State University, East Lansing.*

Bayesian multiple regression models based on genomic marker information are commonly used for genomic prediction and selection and are being increasingly utilized in genome-wide association (GWA) analyses to search for genomic regions associated with economical important traits in agriculture. These models jointly fit all markers, thereby circumventing the limitations of "one-marker-at-a-time" of traditional GWA inference. We have recently validated and tested extensions of genomic prediction models to account for residual heteroskedasticity, which is prevalent in livestock field data. Our objective was to evaluate the impact of not accounting for potential residual heteroskedasticity in GWA inference. Using simulated data scenarios that reflected a gradient of increasing residual heteroskedasticity, we fitted homoscedastic and heteroskedastic error versions of hierarchical Bayesian genomic prediction models assuming either normal (RR-BLUP) or heavy-tailed (BayesA) prior specifications on the effects of genomic markers. For each marker, we then constructed a posterior z-score using prediction error variance of the estimated marker effect to detect associations between genomic regions and phenotypes of interest. Under conditions of extreme heterogeneity of residual variances, heteroskedastic models showed an increase in power of up to 10% points for GWA discovery with little impact on false positive rate (i.e., change of 0 to 3% points), compared with the homoscedastic model counterparts.

Further, when heteroskedasticity was high, the absolute magnitude of the estimated signal for the most prominent QTL expressed as a posterior *z*-score was enhanced by 20% and 34% for heteroskedastic RR-BLUP and BayesA, respectively. The inferential advantages of heteroskedastic models over homoscedastic ones were particularly apparent under a BayesA specification. A data application involving three quantitative carcass and meat quality traits from a swine resource population representing high, mild and low levels of heteroskedasticity yielded proportionally enhanced differential detection signal for the heteroskedastic models relative to the homoscedastic ones, consistent with results from the simulation study. In conclusion, accounting for residual heteroskedasticity can be expected to enhance power in the identification of important genomic regions for traits of interest.

Key Words: genome-wide association, residual heteroskedasticity, genomic prediction model

0306 Exploring the feasibility of using copy number variants as genetic markers through large-scale whole genome sequencing experiments.

D. M. Bickhart*[1], L. Xu[2], J. L. Hutchison[3], J. B. Cole[4], D. J. Null[4], S. G. Schroeder[5], J. Song[6], J. F. Garcia[7], T. Sonstegard[8], C. P. VanTassell[5], R. D. Schnabel[9], J. F. Taylor[9], and G. E. Liu[5], *[1]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [2]Department of Animal and Avian Sciences, University of Maryland, College Park, [3]Animal Improvement Programs Laboratory, USDA-ARS, Beltsville, MD, [4]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [5]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [6]University of Maryland, Animal Science and Avian, College Park, [7]UNESP Univ Estadual Paulista, Araçatuba, Brazil, [8]Recombinetics Inc., St Paul, MN, [9]University of Missouri, Columbia.*

Copy number variants (CNV) are large scale duplications or deletions of genomic sequence that are caused by a diverse set of molecular phenomena that are distinct from single nucleotide polymorphism (SNP) formation. Due to their different mechanisms of formation, CNVs are often difficult to track using SNP-based linkage disequilibrium inference. This can result in decreased reliabilities of prediction for CNV causal mutations tracked by SNP genotyping arrays. To test if CNVs can serve as suitable genetic markers, we sequenced 75 individual bulls from eight different breeds and two subspecies of cattle (*Bos taurus taurus*: Angus, Holstein, Jersey, Limousin, Romagnola; *Bos taurus indicus*: Brahman, Gir, Nellore) to 11X coverage. We identified 1853 non-redundant CNV regions (CNVR) that comprise ~3.1% (87.5 Megabases) of the cattle genome, which represents an increase over previous cattle genome variability estimates (~2%). With the discrete genome copy number values identified in our analysis, we selected the top 1% (n = 80) of CNV sites found to be variable among the sequenced breeds by a modified F statistical measure to perform population structure analyses. We were able to distinctly separate breeds of cattle based on genomic copy number, suggesting that CNVs may have utility as genetic markers. Further analysis revealed that 77.5% (62/80) of our selected CNV windows could reliably be assessed for variability and that 54 of these loci were, in turn, located near tandem duplications. CNV genotyping remains a difficult endeavor and suffers from several obstacles related to their detection and mechanisms of formation; however, these initial results suggest that our current methods can be refined and may provide suitable utility for genomic evaluation in the future.

0307 Use of marker × environment interaction whole genome regression model to incorporate genetic heterogeneity for residual feed intake, dry matter intake, net energy in milk, and metabolic body weight in dairy cattle.

C. Yao[1], G. de los Campos[2], M. J. VandeHaar[2], D. M. Spurlock[3], L. E. Armentano[4], M. P. Coffey[5], Y. de Haas[6], R. F. Veerkamp[7], C. R. Staples[8], E. E. Connor[9], Z. Wang[10], R. J. Tempelman[2], and K. A. Weigel*[1], *[1]University of Wisconsin, Madison, [2]Michigan State University, East Lansing, [3]Iowa State University, Ames, [4]University of Wisconsin, Madison, [5]SRUC, Edinburgh, UK, [6]Animal Breeding and Genomics Centre, Wageningen UR Livestock Research, Netherlands, [7]Animal Breeding and Genomics Centre, Wageningen University, Netherlands, [8]Department of Animal Sciences, University of Florida, Gainesville, [9]USDA-ARS, Animal Genomics and Improvement Laboratory, Beltsville, MD, [10]University of Alberta, Edmonton, Canada.*

Feed efficiency in dairy cattle has gained much attention recently. Due to the cost prohibitive measurement of individual feed intakes, combining data from multiple countries is usually necessary to ensure a large enough reference population. It may then be essential to model genetic heterogeneity when making inferences about feed efficiency or selecting efficient cattle using genomic information. In this study, we constructed a marker × environment interaction model that decomposed marker effects into main effects and interaction components that were specific to each environment. We compared environment-specific variance component estimates and prediction accuracies of the interaction model analysis, an across-environment analysis ignoring population stratification, and a within-environment analysis on the feed efficiency data set. Phenotype traits included residual feed intake (RFI), dry matter intake (DMI), net energy in milk (MilkE), and metabolic body weight (MBW) from 3656 cows measured

in 3 broadly defined environments: North America (NAM), the Netherlands (NLD), and Scotland (SAC). Genotypic data included 57,574 single nucleotide polymorphisms per animal. The interaction model gave the highest prediction accuracy for MBW, which had the largest estimated heritabilities ranging from 0.37 to 0.55. The within-environment model performed the best when predicting the trait of RFI which had the lowest estimated heritabilities, ranging from 0.13 to 0.41. For traits (DMI and MilkE) which had intermediate estimated heritabilities (0.21 to 0.50 and 0.17 to 0.53), performance of the 3 models was comparable. Genomic correlations between environments were also computed using the variance component estimates from the interaction model. Averaged across all traits, genomic correlation was the highest between NAM and NLD, and was the lowest between NAM and SAC. In conclusion, the interaction model provided a novel way to evaluate traits measured in multiple environments in which genetic heterogeneity may exist. It offered the capability of estimating environment-specific parameters and performed either the best or nearly the best in the genomic prediction.

Key Words: genomic selection, interaction model, feed efficiency

0308 Imputation of medium density genotypes from custom low density genotype panel in sheep.

D. P. Berry*[1], A. O'Brien[2], S. Randles[3], K. McDermott[3], E. Wall[3], and N. McHugh[4], *[1]Teagasc, Moorepark, Fermoy, Co. Cork, Ireland, [2]Teagasc, Fermoy, Ireland, [3]Sheep Ireland, Bandon, [4]Teagasc Moorepark, Fermoy, Ireland.*

A custom low density genotype panel has been developed with 16,351 single nucleotide polymorphisms (SNPs), 12,118 of which are on the medium density Illumina Ovine50 Beadchip which has 51,135 SNPs. The objective of the present study was to quantify the accuracy of imputation from the low density to medium density panel in five different sheep breeds. Medium density genotypes were available on 2375 sheep from the breeds Suffolk (n = 566), Texel (n = 318), Vendeen (n = 461), Charollais (n = 559) and Belclare (n = 471). The youngest 75 animals per breed were used as the validation population; the 37,278 autosomal SNPs on the medium density panel that are not on the low density panel were masked for the validation population. Imputation was undertaken across the entire genome simultaneously using both family and population wide linkage (disequilibrium) information. Concordance rates and the correlation between the true and imputed genotypes were estimated for the validation animals which included the low density SNPs in the calculation. Across all genotypes, the correlation between the actual and imputed genotype was 0.983; the mean genotype (allele) concordance rate was 0.979 (0.989). The mean genotype and allele concordance rate per individual varied from 0.864 to 0.997 and from 0.929 to 0.999, respectively. The individual with the poor concordance rate was an outlier and the minimum genotype (allele) concordance rate excluding this individual was 0.920 (0.958). Mean genotype concordance rate per breed was 0.984, 0.972, 0.982, 0.969 and 0.989 for Belclare, Charollais, Suffolk, Texel and Vendeen, respectively. Imputation accuracy not accounting for pedigree was marginally better than when pedigree was accounted for in the imputation process. Imputation accuracy with a reference population of only the breed of animal to be imputed was also marginally better than when multiple breeds were included in the reference population; imputation accuracy of breeds not represented in the reference population were considerably worse. The low density panel is therefore a useful, lower cost, strategy to achieve genomics evaluations in these sheep breeds.

Key Words: imputation, sheep, genomic, low density

0309 Systematic profiling of short tandem repeats in the cattle genome.

G. E. Liu*[1], L. Xu[1], R. Haasl[2], J. Sun[3], Y. Zhou[1], D. M. Bickhart[4], J. Li[5], J. Song[6], T. Sonstegard[7], C. P. VanTassell[1], and H. Lewin[8], *[1]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [2]University of Wisconsin, Platteville, [3]South China Agricultural University, Guangzhou, [4]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [5]Institute of Animal Science of Chinese Academy of Agricultural Sciences, Beijing, China, [6]University of Maryland, Animal Science and Avian, College Park, [7]Recombinetics Inc., St Paul, MN, [8]University of California, Department of Evolution and Ecology, Davis.*

Short tandem repeats (STRs), or microsatellites (MS), are genetic variants with repetitive 2–6 base pair motifs in many genomes. Using high-throughput sequencing and experimental validations, we systematically profiled STRs in five Holsteins. We identified a total of 60,106 microsatellites and generated the first high-resolution STR map, representing a substantial pool of polymorphism in cattle. We observed significant STR overlaps with RefSeq genes and quantitative trait loci (QTL). We performed evolutionary and population genetic analyses using over 20,000 common dinucleotide STRs. Besides corroborating the well-established positive correlation between allele size and variance in allele size, these analyses also identified dozens of outlier STRs based on two anomalous relationships that counter expected characteristics of neutral evolution. And one STR locus overlaps with a significant region of a summary statistic designed to detect STR-related selection. Additionally, we showed that only 57.1% of STRs are located within SNP-based linkage disequilibrium (LD) blocks while the other 42.9% are not. Therefore, a substantial number of STRs are not tagged by SNPs in the cattle genome, likely due to STR's distinct mutation mechanism and elevated polymorphism. This study provides the foundation for future

STR-based studies of cattle genome evolution and selection.

Key Words: cattle genome, short tandem repeat (STR), whole genome sequencing (WGS)

0310 Assessing genetic diversity in Canadian beef cattle populations using Illumina BovineSNP50 chip.

M. K. Abo-Ismail*[1,2], E. C. Akanno[1], R. Khorshidi[1], J. Crowley[1,3], L. Chen[1], B. K. Karisa[4], X. Li[1], Z. Wang[1], J. Basarab[1,5], C. Li[1,6], P. Stothard[1], and G. Plastow[1], *[1]Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]Animal and Poultry Production, Damanhour University, Egypt, [3]Canadian Beef Breeds Council, Calgary, AB, [4]Alberta Livestock and Meat Agency Ltd, Edmonton, Canada, [5]Lacombe Research Centre, Alberta Agriculture and Forestry, Lacombe, Canada, [6]Lacombe Research and Development Centre, Agriculture and Agri-Food Canada, Edmonton, AB, Canada.*

The main objective of this study was to utilize genomic profiles to assess genetic diversity within and between Canadian beef cattle populations to gain insights on population admixture and dynamics. Individuals (n = 2831) were genotyped for Illumina BovineSNP50 for 9 populations (Gelbvieh (GVH, n = 488), Charolais (CHA, n = 396), Angus (AAN, n = 492), Simmental (SIM, n = 404), Limousin (LIM, n = 205), Hereford (HER, n = 591), Hays Converter (HC, n = 208), Kinsella composites (KC, n = 15) and Lacombe Research Centre (LRC, n = 33). A total of 2828 individuals with 43,172 SNPs across 29 autosomes passed quality control and were used for further analyses. To study population structure between populations, a principal component analysis (PCA) was performed using SNP1101 software. Genomic inbreeding coefficients for each individual were estimated using 4 methods; VanRaden 2008 (F_v), Leutenegger 2003 (F_l), excess of homozygosity (F_h) and GCTA software (F_g) method implemented in SNP1101 software. The PCA analysis reported clear divergence between GVH, CH, AAN, SIM, LIM, HER and HC populations where 7 clusters were well defined, illustrated in Fig. 1. The KC and LRC populations are distributed between the other clusters confirming their genetic architectures as crossbred. The most genomically divergent breeds were CHA, AAN, GVH and HER. The correlations between inbreeding coefficients F_v with F_l and F_g were strong; 0.98 and 0.93, respectively. The average estimate of genomic inbreeding coefficients (F_v, Fl, and Fg) were highest for the HER ranged from 12.8 ± 0.1to 18.5 ± 0.2% followed by AAN ranged from 10 ± 0.1 to 12.7 ± 0.1%. In addition, the genomic inbreeding coefficients for composites/crossbreds ranged from 2.0 ± 1.0 to 4.0 ± 1.0% and from 1.0 ± 0.7 to 7.0 ± 1.0% for KC and LRC, respectively, where these inbreeding levels were low across all methods compared with purebred cattle. In conclusion, the genomic assessment of inbreeding using different methods indicated that HER and AAN breeds had the highest inbreeding level and thus inbreeding depression should be assessed for their traits at the genome level. Information on specific regions that are fixed for deleterious alleles allows directed introgres-

Fig 0310.

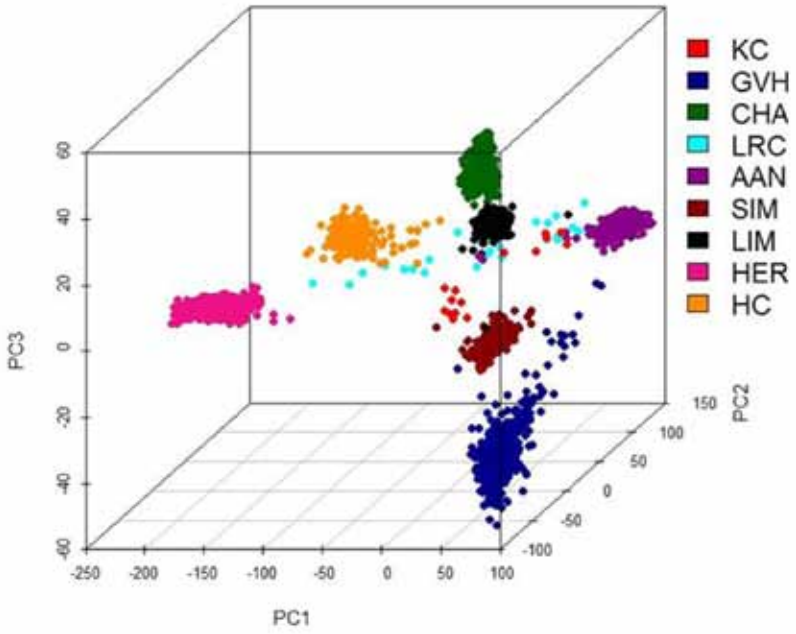

Figure 1. Population structures identified by principal component analysis. The plot shows the first three principal components (PCs) using Illumina BovineSNP50 (43,172 SNPs) across the 29 autosomes. KC is Kinsella composites, LRC is Lacombe Research Centre, GVH is Gelbvieh, CHA is Charolais, ANG is Angus, SIM is Simmental, LIM is Limousin, HER is Hereford, HC is Hays Converter.

sion between breeds to help address performance.

0311 Joint association analysis of additive and non-additive genomic effects for growth and carcass traits of beef cattle. E. C. Akanno*[1], M. K. Abo-Ismail[1,2], L. Chen[1], C. Li[1,3], J. Basarab[1,4], and G. Plastow[1], *[1]Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]Animal and Poultry Production, Damanhour University, Egypt, [3]Lacombe Research and Development Centre, Agriculture and Agri-Food Canada, Edmonton, AB, Canada, [4]Lacombe Research Centre, Alberta Agriculture and Forestry, Lacombe, Canada.*

The biological dominance effects of genes have been suggested as one of the genetic mechanism explaining heterosis. We performed a joint association analysis using genotypes from Illumina BovineSNP50 (50K) BeadChip to evaluate the contributions of additive and dominance genomic effects to the variance of growth and carcass traits in beef cattle and to identify genomic regions that potentially harbor genes or quantitative trait loci underlying the variation. A total of 6794 multi-breed and crossbred beef cattle with phenotype and 50K genotypes were used. Traits studied included birth weight (BWT), weaning weight (WWT), pre-weaning daily gain (PDG), average daily gain (ADG), yearling weight (YWT), hot carcass weight (HCW), back fat thickness (BFT), rib-eye area (REA), marbling score (MS), lean meat yield (LMY) and yield grade (YG). Additive and dominance genomic relationships were created based on 42,610 single nucleotide polymorphism (SNP) markers that passed the quality control. The model used accounted for fixed contemporary group effects (herd, year, data source, and sex), covariates of genomic breed composition, age of dam, weaning age, age at start of feedlot test, and slaughter age, and random maternal and maternal permanent effect depending on the trait analyzed. A single SNP analysis that partitions the SNP effects into additive and dominance components was used for genome-wide association. The proportions of total phenotypic variance explained by additive and dominance effects for the studied traits are presented in Table 1. After applying a false discovery rate at a 5% significance level, a total of 66, 20, 2, 36, 66, 22, 9, 15, 10, and 3 SNPs were significantly associated with BWT, WWT, PDG, ADG, YWT, HCW, BFT, REA, LMY, and YG, respectively, for the additive component. For the dominance component, three SNPs (rs110564527, rs110361335, and rs41663796) and one SNP (rs43624164) were significantly associated with MS and WWT, respectively. The SNP rs110361335 located on chromosome 4 was found to be within *islet cell autoantigen 1* (*ICA1*) gene which is involved in insulin regulation. In addition, SNP rs43624164 on chromosome 10 found to be near the gene *ribosomal protein L10-like* (*RPL10L*) had significant additive and dominance effects on WWT. Although, the proportions of phenotypic variance explained by dominance were moderate for growth traits with known heterosis effects, the results of this study suggest that dominance effects are polygenic.

Key Words: beef cattle, dominance genetic effect, genomic prediction

0312 Investigation of genomic imprinting through allelic expression analysis of mRNA in chicken embryonic brain and liver. Z. Zhuo[1], S. J. Lamont[2], and B. Abasht*[1], *[1]Department of Animal and Food Sciences, University of Delaware, Newark, [2]Department of Animal Science, Iowa State University, Ames.*

Genomic imprinting refers to the epigenetic phenomenon that some autosomal genes are exclusively expressed from either the maternal or paternal allele whereas, based on Mendelian inheritance, expression of alleles are expected to be in

Table 0311.

Table 1. Proportions of phenotypic variance explained by additive and dominance effects in purebreds, crossbreds and overall populations[1]

	Purebreds (n = 2060)		Crossbreds (n = 4734)		Overall (n = 6794)

[1]Purebred individuals have > 90% of their representative breeds (Angus, Hereford and Charolais); Crossbred individuals included beef-dairy hybrids, Beefbooster composite (www.beefbooster.com), and two and three way crossbreds involving Angus, Hereford, Charolais, Gelbvieh, Simmental, Limousine, and Piedmontese

equal amount and independent of their parental origin. DNA methylation in *cis*-acting manner is the major mechanism for genomic imprinting. Imprinted genes have been identified in several animal species and are frequently associated with embryonic growth and survival functions. Yet whether genomic imprinting exists in chickens is still debatable, as previous studies reported conflicting evidence regarding the topic. Albeit no genomic imprinting has been found in the chicken embryo as a whole, we investigated whether certain embryonic tissues exhibit genomic imprinting. In this study we interrogated the existence or absence of genomic imprinting in chicken embryonic brain and liver by examining the mRNA expression of parental alleles in an F1 generation. Eggs from two highly inbred chicken lines (Fayoumi and Leghorn) and their reciprocal crosses were collected and incubated for 12 d; then brain and liver were harvested from embryos for cDNA library preparation. To establish the genotypes of the inbred lines and the F1 hybrids and to minimize reference bias of RNA-seq sequence alignment, genomic DNA from inbred Fayoumi and Leghorn chickens was pooled separately and each pool was sequenced at 20X coverage. The SNP loci identified from DNA-Seq data were masked to create a customized reference genome (based on Ensembl Galgal4) for RNA-seq reads mapping. Of 65 million RNA-seq reads per sample generated using the Illumina HiSeq 2000 sequencer, 88% were mapped to the customized reference genome. The genome-wide ratio of mapped reads containing reference allele was reduced by 1.5% when comparing with the results from the original reference genome. Our analyses indicated that genomic imprinting is absent in chicken 12-d embryonic brain and liver. In genome-wide and chromosome-wide scales, we observed a balanced expression of maternal and paternal alleles. About 9.2% of the heterozygous loci showed allele specific expression independent of their parental origin (binominal test, p value $\leq$ 0.05). Certain alleles showed consistent expression pattern across all 8 F1 individuals indicating possible presence of *cis*-acting regulatory mutations or epigenetic modifications influencing expression of these alleles.

Key Words: genomic imprinting, chicken, RNA-seq

0313 Identification of causative genomic region for carcass weights of cattle. H. Chung*, *National Institute of Animal Science, Wanju, Korea (The Republic of)*.

The present analysis was designed to find causative genomic regions for carcass weights according to the recent requirements of farms. A total of 5000 Hanwoo cattle, which were registered in the national database, were slaughtered to measure carcass weights and extract DNA samples. Animals were genotyped with customized 56K Affymetrix SNP chips to identify genomic regions regarding carcass weight. The chip contained previously reported genetic variants, including QTL analyses from the literature reviews for meat quality traits from various cattle breeds in the world. Genome-wide association studies (GWAS) found significant genotypic effects for carcass weights in the genomic region (26254142 to 26274142 Mb) on the bovine chromosome 14 based on UMD3.1. To confirm significance for the identified SNP, 3700 animals were additionally slaughtered and genotyped, and as results, the 20 SNP presented extreme significant associations for carcass weights. The identified genomic regions with SNP may be used in marker-assisted selection programs to improve carcass weights in beef cattle.

Key Words: SNP, carcass weight, QTL

0314 Introgression of the Belgian Blue Myostatin variant into Nellore cattle: Effects of double muscling on birth weight and calving ease. G. Nogueira*[1], K. S. Paulussi[2], A. T. H. Utsunomiya[3], Y. T. Utsunomiya[3], A. Almeida[4], A. Tanuri[5], T. Santos[4], and R. Alonso[6], *[1]UNESP, Aracatuba-SP, Brazil, [2]UNESP, Araçatuba, Brazil, [3]UNESP Univ. Estadual Paulista, Jaboticabal, Brazil, [4]Deoxi, Aracatuba-SP, Brazil, [5]UFRRJ, Rio de Janeiro-RJ, Brazil, [6]Deoxi, Aracatuba-SP, Brazil.*

Introgression and backcrossing are powerful strategies to insert a specific segment of the genome expressing a desirable trait from a population to another and recover the original genetic background, respectively. The aim of this work is to present the effect of introgression of myostatin mutation on birth weight in Nellore cattle (*Bos indicus*). We evaluated 92 calves 15/16 Nellore, offspring of one purebred Nellore and two 7/8 crossbred (Nellore x Belgian Blue) bulls. All animals were genotyped to identify the ones carrying the myostatin mutation (BN– heterozygous for the mutation, NN– homozygous for the absence of mutation). The birth weight was analyzed in a mixed model framework, fitted by restricted maximum likelihood (REML) using lme4 package in R, including sex, biotechnology of reproduction (FTAI-fixed-time artificial insemination x FTET-fixed-time embryo transfer) and myostatin mutation as fixed effect and sire as random effect. Thirty-nine calves were identified as heterozigous for the mutation (BN) and 53 as homozygous for absence of mutation (NN). Heterozygous calves were born 4.92 ± 0.998 kg heavier (p-value = 1.6e-6) compared with the homozygous. No differences were found comparing FTAI (34.12 kg) and FTET (35.50 kg) (p-value = 0.126). Although not significant, males were born 1.76 ± 1.01 kg heavier than females (p-value = 0.083). Considering the random term of the mixed model, only 0.34% of the phenotypic variance was explained by sire effect. In summary, these results show that the effect of the myostatin mutation is the main factor regulating differences in birth weight. Despite to be expected, dystocia was not an issue in this study. Future analysis will comprise homozygous individuals for the presence of myostatin mutation (BB) and

its impact on birth weight and parturition.

Key Words: Nellore, double muscling, birth weight

0315 Genomic-polygenic and polygenic parameters and prediction trends for growth and reproduction traits in an Angus-Brahman multibreed population. M. A. Elzo*[1], R. Mateescu[1], M. G. Thomas[2], D. D. Johnson[1], D. O. Rae[1], J. D. Wasdin[1], M. D. Driver[1], and J. D. Driver[1], *[1]University of Florida, Gainesville, [2]Department of Animal Sciences, Colorado State University, Fort Collins.*

The objectives of this research were to estimate genomic-polygenic and polygenic parameters and to evaluate prediction trends as Brahman fraction increased from 0% to 100% in an Angus-Brahman multibreed population for 305-d yearling weight (YW), yearling reproductive tract score (RTS), age at first calving (AFC), and first calving interval (FCI) using single-step genomic-polygenic (GPM) and polygenic models (PM). Phenotype records were 1758 for YW, 381 for RTS, 1385 for AFC, and 985 for FCI. The pedigree file had 6845 calves, sires, and dams, and the genotype file contained 115,711 actual and imputed Illumina150k SNP markers from 1547 animals. The 4-trait GPM and PM included contemporary group, age of dam (YW only), sex of calf (YW only), direct heterosis, maternal heterosis (YW only) as fixed effects, and animal and residual as random effects. Genetic parameters were estimated using REML procedures and computed using AIREMLF90. Heritabilities were somewhat higher for GPM than for PM (0.47 vs. 0.45 for YW, 0.31 vs. 0.30 for RTS, 0.14 vs. 0.12 for AFC, and 0.31 vs. 0.29 for FCI). Genetic correlations were positive between YW and RTS (GPM: 0.55; PM: 0.60), negative between RTS and AFC (GPM: −0.22; PM: −0.55) and between AFC and FCI (GPM: −0.68; PM: −0.67), and near zero for all other trait pairs. The similarity between GPM and PM heritabilities and genetic correlations indicated that the 115,711 Illumina150k SNP markers added little additional information to that contained in the pedigree. Regression coefficients of breed group EBV means on Brahman fraction were negative ($P < 0.0005$) for YW, RTS, and FCI, and positive ($P < 0.0001$) for AFC as Brahman fraction increased. This indicated that heifers with higher Brahman percentages tended to be lighter and less mature as yearlings, older at first calving, and have shorter FCI than heifers with higher Angus percentages in this population. Regression coefficients of individual animal EBV on Brahman fraction showed similar trends, but were smaller, guaranteeing the existence of animals with high, medium, and low EBV across all Brahman percentages.

Key Words: cattle, genomic, reproduction

0316 Genome-enabled prediction of genetic values of growth traits using artificial neural networks. S. O. Peters*[1], M. Sinecen[2], M. G. Thomas[3], I. G. Imumorin[4], and K. Kizilkaya[2], *[1]Department of Animal Science, Berry College, Mount Berry, GA, [2]Adnan Menderes University, Aydin, Turkey, [3]Department of Animal Sciences, Colorado State University, Fort Collins, [4]Animal Genetics and Genomics Laboratory, Cornell University, Ithaca, NY.*

Data from Brangus heifers (3/8 Brahman-*Bos indicus* × 5/8 Angus-*Bos taurus;* n ≈ 743) registered with International Brangus Breeders Association were analyzed to predict genetic parameters of growth traits. Phenotypes included body weights collected at birth (birth weight), ~205 (weaning) and 365 (yearling) days of age. Genotypes were from BovineSNP50 (Infinium BeadChip, Illumina, San Diego, CA; 53,692 SNP). Artificial neural networks (ANN) have been used for marker-based genomic predictions of complex traits in animal and plant breeding. In this study, ANN was used to estimate the genetic values of growth traits of birth weight, weaning weight and yearling weight of Brangus heifers with all genome-wide marker data set and chromosome-base genome-wide marker data set. ANN provide nonlinear relationships between inputs and outputs with the interplay among variables learned adaptively. For the ANN model, 95% of the animals were randomly allocated to a training set, 5% to a test set. In the training phase of ANN with the scaled conjugate gradient method, 52,640 SNP as the genomic covariates of 706 individuals are linearly combined with a vector of weights. The resulting linear score were then transformed using an activation function to produce the output of ANN. Different ANN architectures were examined to assess the best predictive ANN. Up to 30 neurons in the hidden layer were tested for their influence on predictive quality. ANN models with 13, 15, and 1 neurons in the hidden layer were used for birth weight, weaning weight and yearling weight of Brangus heifers. ANN model including chromosome-base genome-wide markers achieved predictive correlations of $r = 0.96$ for birth weight using chromosome 23, $r = 0.94$ for weaning weight using chromosome 17 and $r = 0.92$ for yearling weight using chromosome 1. ANN model including all genome-wide markers achieved predictive correlations of $r = 0.93$ for birth weight, $r = 0.91$ for weaning weight and $r = 0.91$ for yearling weight. Results suggest that neural networks may be useful for predicting complex traits using high-dimensional genomic information.

Key Words: artificial neural network, genomic prediction, growth traits, SNP

0317 Molecular breeding values distribution in slick male and female Senepol cattle differing in musculature. C. L. González-Berríos*[1], A. Rivera-Serrano[1], A. Casas-Guérnica[1], T. Sonstegard[2], and M. Pagán-Morales[1], [1]*Department of Animal Science, University of Puerto Rico, Mayaguez, Puerto Rico,* [2]*Recombinetics Inc., St. Paul, MN.*

Recently, the polymorphisms responsible for double muscling [MSTN: exon 3 11bp indel (NT821)] and slick coat phenotype (PRLR: exon 10 cytosine indel) in Senepol cattle were described. However, the genomic implications of segregating animals according to PRLR and MSTN genotypes have not been elucidated for economically relevant traits (ERTs), especially in tropically adapted beef cattle. Thus, purebred Senepol cattle (males/females) were genotyped for both indel and molecular breeding values (MBV) were obtained through a commercially available marker panel (Igenity, Neogen Corp.). Three MBV categories were established: low (L), intermediate (I) and high (H) based on standard deviations of +1 (L), +2 (I) or +3 (H) from the average MBV for 12 ERTs. Statistical differences were determined using the Chi^2 test [sex, genotype (MSTN; PRLR) and double and triple combinations]. Genotypic proportions observed were: double muscle (DM): 6/NT821-NT821, 95/NT821-WT, and normal musculature (NM): 273 WT-WT ($P < 0.0001$) and slick coat (SC): 256/BB, 99/BA, and normal coat (NC): 4 = AA ($P < 0.0001$). Proportional differences were observed within BB for MBV-average daily gain between MSTN genotypes: NT821/WT: (11.76 H, 72.06 I, 16.18 L) and NM: (26.06 H, 53.72 I, 20.21 L) ($P < 0.05$). Also, within BB, differences in MBV categories distribution were: males: (20.90 H, 79.10 I, 0.00 L)/females: (33.33 H, 56.08 I, 10.58 L) and females: (16.93 H, 68.78 I, 14.29 L)/males: (4.48 H, 77.61 I, 17.91 L) for average daily gain and calving ease, respectively ($P < 0.05$). Significant differences in MBV-tenderness were observed within females for: NT821/WT (7.46% H, 68.66% I, 23.88% L) and NM: (14.22% H, 73.04% I, 12.75% L) ($P < 0.05$). Moreover, females BB ($n = 189$) significantly differed in MBV category distribution depending on musculature for: residual feed intake [NT821/WT: (26.83 H, 68.29 I, 4.88 L)/NM: (18.92 H, 60.14 I, 20.95 L), yield grade [NT821/WT: (24.39 H, 70.73 I, 4.88 L)/NM: (14.19 H, 66.89 I, 18.92 L)], backfat thickness [NT821/WT: (57.14 H, 38.10 I, 4.76 L)/NM: (27.70 H, 50.0 I, 22.30 L)], pregnancy rate [NT821/WT: (4.88 H, 78.05 I, 17.07 L)/NM:(25.00 H, 66.22 I, 8.78 L)] and Stayability [NT821/WT: (9.76 H, 63.41 I, 26.83 L)/NM: (18.24 H, 70.27 I, 11.49 L)] ($P < 0.05$). In the present study, a higher proportion of Senepol cattle with SC and NM were observed and intermediate MBV for all ERTs were predominant, with the exception of backfat thickness (NT821/WT-BB-Females). Therefore, genomic selection in slick Senepols segregating MSTN alleles are needed to improve their ERTs-MBV.

Key Words: slick, myostatin, Senepol

0318 PRUNE2 gene has a potential effect on residual feed intake in Nellore cattle. A. O. D. Lima[1], P. S. N. Oliveira*[2], P. C. Tizioto[2], A. L. Somavilla[3], W. J. S. Diniz[1], J. V. D. Silva[1], S. C. S. Andrade[4], C. Boschiero[5], A. S. M. Cesar[6], M. M. Souza[7], M. I. P. Rocha[1], J. Afonso[1], C. E. Buss[1], M. A. Mudadu[8], G. B. Mourao[5], L. L. Coutinho[6], and L. C. A. Regitano[9], [1]*Federal University of São Carlos, São Carlos, Brazil,* [2]*Embrapa Southeast Livestock, São Carlos, Brazil,* [3]*Universidade Estadual Paulista "Júlio de Mesquita Filho," Jaboticabal, Brazil,* [4]*Genetics and Evolutionary Biology Department-IB, University of São Paulo, Brazil,* [5]*Department of Animal Science, University of São Paulo/ESALQ, Piracicaba, Brazil,* [6]*Animal Biotechnology Laboratory-ESALQ, University of São Paulo, Piracicaba, Brazil,* [7]*Federal University of São Carlos, Brazil,* [8]*Embrapa Pecuária Sudeste, São Carlos, Brazil,* [9]*Embrapa Southeast Livestock, São Carlos, Brazil.*

Residual feed intake (RFI) can increase the profitability of producers, reduce methane emission and land allocation to livestock production. However, this trait has late and costly measurements. Identifying gene expression changes combined with polymorphisms that affect residual feed intake variation is important for identify target regulatory polymorphisms that can be used in animal breeding programs. Diverse studies performed by our research group in a Nellore population, such as genome-wide association (GWA), association weight matrix (AWM) and RNA-seq analysis of liver tissue have been pointed *Prune homolog 2 (Drosophila) (PRUNE2*) as a potential candidate gene influencing feed efficiency. For this reason, we select this gene for a more detailed analysis considering haplotypes consisting of SNPs presented in the *Illumina Bovine HD Bead Chip.* For this, we used a population consisted of 591 steers with genotypes and RFI estimates available. After quality control filtering, performed by PLINK and Bioconductor/R, we used a total of 449.203 SNPs in our haplotype analysis. Genotype phasing and missing genotype imputation were performed using BEAGLE and the LDexplorer software was used for haplotype block recognition. After adjust the RFI estimates for fixed effects of contemporary group, which included type of pen, birth place, feedlot location and age of the animal effect as covariate, the genetic effects of haplotypes in *PRUNE2* gene was estimated by PLINK using a linear regression method. We identified 1 haplotype constituted of 4 SNPs: rs136298898 (C/T); rs133593644 (C/T); rs137799737 (A/C); rs132675549 (C/T), for which two out of 4 haplotype combinations had significant effect ($P \leq 0.05$) on RFI. Haplotype variation (1111) (p-value

= 0.0345) with 35.29% frequency was associated to lower RFI ($\beta = -0.0776$). On the other hand, haplotype variation (1112) (p-value = 0.0351) presenting 11.13% frequency was associated with high RFI ($\beta = 0.0846$). The *PRUNE2*gene has a potential role in biological processes, such as oxidation–reduction, metal ion and polyphosphate catabolic. Our findings indicated that this gene influence genetic variation of RFI, it is a strong candidate gene to be incorporated in Nellore breeding programs, nevertheless more studies considering this gene should be realized to understand better its biological role on feed efficiency in beef cattle.

Key Words: haplotype, feed efficiency, functional gene enrichment

---

0319 A genome-wide association study for changes in dry matter intake due to temperature variation in an admixed beef cattle population. R. Ghebrewold[*1] and M. L. Spangler[2], *[1]University of Nebraska, Lincoln, [2]University of Nebraska, Lincoln.*

Environmental conditions, such as changes in ambient temperature, can cause changes in animal behavior and performance. In general it is believed that as ambient temperature increases, dry matter intake (DMI) of beef cattle decreases. However, our hypothesis was that the degree to which animals adjust their daily DMI due to changes in ambient temperature is partially controlled by underlying genetic effects. Consequently, the objective of this study was to estimate the genetic component of the regression of DMI on ambient temperature using an admixed beef cattle population consisting of various crosses of Angus, Simmental, and Piedmontese (n = 207). Ambient temperatures were received from a local weather station and DMI was collected via Calen gates. The feeding period averaged 155 d with a range of 114 d to 189 d depending on the management group. Individual animal regressions of DMI on ambient temperature were performed using either daily high or low temperatures over the entirety of the feeding period. Daily high temperatures (°C) averaged 15.07 with a range of −17.21 to 38.25. Daily low temperatures (°C) averaged 2.37 with a range of −28.33 to 15.26. The corresponding intercept and regression coefficient for each animal were used as phenotypes for a genome-wide association study (GWAS). Animals were genotyped with the BovineSNP50 Beadchip. Data were analyzed using GenSel software and a BayesC model fitting contemporary group (n = 4) and initial body weight (IBW) as fixed effects. A MCMC chain of 100,000 iterations was used with the first 40,000 samples discarded as burn-in. The proportion of SNPs having null effect (π) was set to 0.995. Posterior mean heritability estimates (SD) for the analysis when daily high temperature was considered in the regression were 0.64 (0.07) and 0.46 (0.08), for the intercept and slope, respectively. Similarly, posterior mean heritability estimates (SD) for the intercept and slope when the daily low temperature was considered in the regression were 0.69 (0.06) and 0.52 (0.07), respectively. These results suggest that changes in DMI due to changes in ambient temperature are under genetic control. Admittedly the population under study is small and admixed, suggesting that the genomic heritability estimates contained herein are potentially biased upward. However, the concept of applying this same procedure in larger populations warrants further investigation as a means of identifying animals that are less sensitive to environmental extremes.

Key Words: beef cattle, GWAS, feed intake

0320 An international effort to improve feed efficiency and reduce methane emissions in dairy cows through genomics. A. M. Wilson[*1], A. M. Butty[1], C. Baes[1], A. Cánovas[1], M. P. Coffey[2], E. E. Connor[3], M. De Pauw[4], B. Gredler[5], E. Goddard[4], G. Hailu[6], V. R. Osborne[7], J. E. Pryce[8], M. Sargolzaei[1,9], F. S. Schenkel[1], P. Stothard[10], E. Wall[2], Z. Wang[4], T. C. Wright[7,11], and F. Miglior[1,12], *[1]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [2]SRUC, Edinburgh, UK, [3]USDA-ARS, Animal Genomics and Improvement Laboratory, Beltsville, MD, [4]University of Alberta, Edmonton, Canada, [5]Qualitas AG, Zug, Switzerland, [6]Department of Food, Agricultural and Resource Economics, University of Guelph, ON, Canada, [7]University of Guelph, ON, Canada, [8]Department of Economic Development, Jobs, Transport and Resources, Bundoora, Australia, [9]Semex Alliance, Guelph, ON, Canada, [10]Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [11]Ontario Ministry of Agriculture, Food and Rural Affairs, Guelph, ON, Canada, [12]Canadian Dairy Network, Guelph, ON.*

Increasing international demand for high quality dairy and meat products as well as greater awareness of climate change has put pressure on the livestock industry to deliver quality products while reducing its environmental impact. Enteric methane from cattle is a major contributor to greenhouse gas emissions and is a target of reduction through improving cow feed efficiency (FE) and reducing methane emissions (ME). The overall goal of this project is to produce genomic predictions for FE and ME that are ready for breeding application in the dairy cattle industry. Breeding for improved FE and less methane emitted will lower feed costs and reduce the industry's environmental footprint. Collecting phenotypes required for genetic improvement is presently very difficult and expensive, and to date, there has been limited to no direct selection for these traits in dairy cattle breeding. Recent genomic approaches provide the opportunity to finally select for these traits, but require a large reference population with accurate phenotypes. Data of individual feed intake and ME are being

collected from dairy cows and heifers, and whole DNA (Genome) and RNA (Transcriptome) sequence information will be used to identify new markers or mutations that influence the traits. The expanded Canadian database will be combined with international data from the United States, UK, Australia and Switzerland to create the world's first database to routinely validate genomic predictions for FE and ME. Milk spectral records will also be used to further develop predictions of FE and ME. In addition, research will be conducted to analyze the economic, environmental and social costs and benefits of the two traits, as well as the economic and social factors affecting the adoption of the technology at farm, industry and national levels.

Key Words: feed efficiency, methane emissions, dairy cattle

0321 Effect of diet energy level and genomic residual feed intake on dairy heifer performance.

K. Williams*[1], K. A. Weigel[2], W. K. Coblentz[3], N. M. Esser[4], H. Schlesser[5], P. Hoffman[1,6], H. Su[1], and M. Akins[1], *[1]University of Wisconsin, Madison, [2]Department of Dairy Science, University of Wisconsin, Madison, [3]U.S. Dairy Forage Research Center, Marshfield, WI, [4]University of Wisconsin, Marshfield, [5]University of Wisconsin-Extension, Marathon County, Wausau, [6]Vita Plus Corporation, Madison, WI.*

The objective of this study was to determine growth, feed intake, and feed efficiency of dairy heifers with different genomic residual feed intake (RFI) predicted as a lactating cow and offered diets differing in energy density. Post-bred Holstein heifers (128, ages 14–20 mo), were blocked by initial weight (high, medium-high, medium-low, and low weight) with 32 heifers per block. Each weight block was sorted by RFI (high, low) to obtain 2 pens of high and 2 pens of low predicted RFI for each block (8 heifers per pen). Low RFI heifers were expected to have greater feed efficiency than high RFI heifers. Dietary treatments were (1) a control diet with corn silage and alfalfa haylage (CON; 62.7% TDN, 11.8% CP, and 45.6% NDF, DM basis), and (2) a similar diet diluted with straw to reduce energy density (STR; 55.9% TDN, 11.7% CP, and 50.1% NDF, DM basis). Each treatment was randomly allocated to blocks to obtain a 2x2 factorial treatment arrangement of 2 RFI levels and 2 dietary energy levels. Diets were offered in a 120-d trial. Statistical analyses were performed using a MIXED procedure in SAS 9.3 with pen as experimental unit. Dry matter intake was affected by diet (11.0 vs. 10.0 kg/d for CON and STR, respectively; $P < 0.01$) but not RFI or the interaction of main effects ($P > 0.10$). Average daily gain was affected by the interaction of RFI and diet with low RFI heifers having higher gains than high RFI when fed STR (0.94 vs. 0.84 kg/d for low and high RFI, respectively, $P = 0.02$), but no difference for RFI groups when fed CON ($P = 0.25$). Feed efficiency was better for low RFI than high RFI heifers when fed STR (10.6 vs. 11.8 kg feed/kg gain for high and low RFI, respectively; $P < 0.01$), but no effect of RFI found when fed CON ($P > 0.10$). Body condition score increased when fed CON (3.8 vs. 3.5 for CON and STR, respectively; $P = 0.02$). Diet digestibility was greater for CON (58.4 vs. 50.8% DM digestibility for CON and STR, respectively; $P = 0.01$), which likely caused greater intake and gains for heifers fed CON. Based on these results, feed efficiency of heifers having different RFI is dependent on diet energy level with heifers having low RFI using the moderate energy (STR) diet more efficiently. The straw diet reduced intake and also maintained more desirable heifer weight gains.

Key Words: dairy heifer, residual feed intake, diet energy

0322 Genomic prediction for feed efficiency traits based on 50K and imputed high density SNP genotypes in multiple breed populations of Canadian beef cattle.

C. Li*[1,2], L. Chen[1], M. Vinsky[2], J. Crowley[1], S. P. Miller[3,4], G. Plastow[1], J. Basarab[5], and P. Stothard[1], *[1]Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]Lacombe Research and Development Centre, Agriculture and Agri-Food Canada, Lacombe, AB, [3]Invermay Agricultural Centre, AgResearch Ltd., Mosgiel, New Zealand, [4]Centre for the Genetic Improvement of Livestock, University of Guelph, ON, Canada, [5]Lacombe Research Centre, Alberta Agriculture and Forestry, Lacombe, AB, Canada*

Phenotypic data of difficult and/or costly to measure traits, such as feed efficiency, are usually available for a small number of beef cattle in each breed/population, resulting in low accuracy when within-breed/population genomic selection is attempted. Investigation of different strategies to combine data has the potential to improve the genomic prediction accuracy. In this study, we consolidated data of residual feed intake (RFI), average daily gain (ADG) and daily feed intake (DMI) from 7479 animals. These animals consisted of Canadian Angus ($N = 1158$), Charolais ($N = 707$), and four crossbred populations including Kinsella (UofAlberta, $N = 1487$), Elora (UofGuelph, $N = 746$), commercial animals PG1 ($N = 1885$) and TX ($N = 1496$). SNPs from the Illumina Bovine SNP50 Beadchip (50K SNP chip) and imputed Affymetrix high density (HD) (~428K SNPs) were employed to evaluate the genomic prediction accuracy at five-fold cross-validation using single-task Bayesian, simple data pooling Bayesian, and multitask Bayesian methods. The single-task Bayesian method estimates the SNP effects within a breed/population. The simple data pooling Bayesian method assumes the same SNP effect across breeds/populations and estimates the SNP effects based on the training data set that are simply combined from

all breeds/populations. The multitask Bayesian method estimates the SNP effects for each breed/population by also utilizing SNP effect information from other breeds/populations. The results showed that realized prediction accuracy of the single-task Bayesian method with the 50K SNP chip for RFI ranged from 0.22 ± 0.04 for Elora to 0.65 ± 0.03 for Angus. For ADG and DMI, the realized prediction accuracy of the single-task Bayesian ranged from 0.21 ± 0.03 for ADG in the Kinsella and TX populations to 0.57 ± 0.03 for DMI in Angus. The genomic prediction accuracies were improved by 0.02 to 0.17 with the simple data pooling Bayesian method except for RFI, in which the prediction accuracies were similar or slightly reduced by 0.02 to 0.07. The multitask Bayesian method yielded better prediction accuracy than the single-task Bayesian for most of the traits but did not perform better than the simple data pooling Bayesian method. Genomic prediction based on the imputed HD SNPs resulted in similar accuracies to that of the 50K SNP chip under all three methods. Further studies that include SNP functional information and/or intermediate phenotypes are underway to improve the genomic prediction accuracy for feed efficiency traits in Canadian beef cattle.

Key Words: beef cattle, genomic prediction, feed efficiency

0323 Use of multivariate statistical analyses to preselect SNP markers for GWAS on residual feed intake in dairy cattle. C. Dimauro[*1], E. Manca[2], A. Rossoni[3], E. Santus[3], M. Cellesi[4], and G. Gaspa[5], *[1]Università di , Italy, [2]Università di Sassari, Italy, [3]ANARB, Italian Brown Cattle Breeders' Association, Bussolengo (VR), Italy, [4]Università di Sassari, Italy, [5]Dipartimento di Agraria, University of Sassari, Italy.*

An index currently used to evaluate feed efficiency in cattle is the residual feed intake (RFI) whose heritability is around 0.20–0.40. Genome wide association studies (GWAS) can contribute to breeding programs aimed at improving RFI by detecting genomic regions and candidate genes that regulate it. However, the detection of significant SNP in GWAS with high density SNP platforms is often hampered by the severity of Bonferroni's *p*-value correction for multiple testing, due to huge number of tests. The pre-selection of markers could be an option to mitigate this problem. In the present research, a multivariate approach was used to select a pool of markers that could have any chances to be associated with RFI. Data consisted of 1092 Brown Swiss young bulls genotyped with the Illumina's 50K BeadChip. Animals were divided into two groups, according to RFI: high RFI (HRFI) for RFI > 0.5 standard deviations from the mean RFI; low RFI (LRFI) for animals with RFI < – 0.5 standard deviations from the mean. The two groups consisted of 266 and 280 animals, for LRFI and HRFI, respectively. Individuals that did not belong to the two groups were discarded.Three multivariate discriminant techniques were applied to data. The stepwise discriminant analysis was used to select 152 genome-wide most discriminant markers that were retained for the further analyses. The canonical discriminant analysis significantly separated the LRFI from the HRFI group, and the extracted canonical function was able to correctly assign 92% of animals to the correct group. Canonical coefficients associated to the 152 SNP in the canonical function were useful to rank markers according to their discriminant power. The ability of the selected SNP in depicting the RFI profile of calves was tested by developing a k-means cluster analysis that correctly classified 84% of individuals. For instance, a GWAS was also developed by regressing RFI phenotypes on SNP covariates. After *p*-values were corrected for multiple testing, no significant marker was obtained by using all original variables (41,183). When only the selected 152 SNP were used, 5 significant markers were obtained.

Key Words: SNP preselection, discriminant analysis, RFI

0324 Breed base representation in dairy animals of five breeds. H. D. Norman[*1], P. M. VanRaden[2], J. H. Megonigal[1], J. W. Dürr[1], and T. A. Cooper[2], *[1]Council on Dairy Cattle Breeding, Bowie, MD, [2]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD.*

Inheritance of DNA from different dairy breeds can be determined by genotyping, just as individual ancestors such as parents, grandparents, or even great grandparents can be identified correctly in a high percentage of cases by genotyping even if not reported or reported incorrectly in pedigrees. Numbers of crossbreds in the U.S. dairy herd have increased by about 400% in the last decade. A procedure developed to determine the extent that alleles of various breeds appear in these crossbreds and in apparent purebreds was used to document breed composition in animals genotyped. The procedure constructed purebred reference groups (PRG) containing registered AI bulls (with milking daughters) chosen to represent 5 different breeds: Ayrshire (AY), Brown Swiss (BS), Guernsey (GU), Holstein (HO), and Jersey (JE). Any bull with an ancestor of another breed in his recorded 5-generation pedigree was excluded from the PRG. An exception was made for AY, for which other red breeds were permitted. The procedure was termed breed base representation (BBR) and estimated the similarity of alleles present in the 5 PRG to those of genotyped individuals. To measure BBR, the percentages of DNA contributed to a genotyped animal by each of the 5 breeds were calculated, summed, and then restricted to be between 0 and 100%. The more an animal's alleles resembled those in a PRG, the higher its BBR for that breed. The BBR help reveal the presence of either outcross bloodlines or crossbreeding, which are difficult to separate. Because animals vary even within breeds, the true source of the various breed alleles differs somewhat from BBR. Numbers of AI bulls in the reference populations in March 2016 were 442 AY, 5464

BS, 550 GU, 19,209 HO, and 3147 JE. Primary-breed BBR for those bulls were 97.2, 97.6, 97.8, 99.2, and 98.0%, respectively, which implies that they are purebreds; SD were 1.9, 1.2, 2.7, 1.2, and 1.0%, respectively. Mean primary-breed BBR were 94.8 for AY, 97.0 for BS, 97.8 for GU, 99.0 for HO, and 96.5% for JE for all genotyped males (201,283) and 95.0, 97.1, 96.9, 98.9, and 96.5%, respectively, for all genotyped females (994,949); SD ranged from 1.2 for males and 1.5% for females (HO) to 5.6 and 4.4% (AY), respectively. Genetic predictions for animals with crossbred genetics in their pedigrees could be obtained in the future by weighting marker effects from each breed by BBR.

Key Words: allele, genomics, purebred

0325 Estimation of the composition of four U.S. swine breeds using genomic data. S. A. Funkhouser[*1], R. O. Bates[2], C. W. Ernst[2], D. W. Newcom[3], and J. P. Steibel[2,4], *[1]Genetics Program, Michigan State University, East Lansing, [2]Department of Animal Science, Michigan State University, East Lansing, [3]National Swine Registry, West Lafayette, IN, [4]Department of Fisheries and Wildlife, Michigan State University, East Lansing.*

Lines of purebred pigs are essential for use in crossbreeding systems within the commercial industry. However, verification of breed purity can be challenging, and using color test matings to confirm white color in the Yorkshire or Landrace breeds is time-consuming and costly. Alternatively, advances in the availability and analysis of genomic data may enable rapid and precise determination of breed composition. Here, we have refined methods for determination of breed composition in U.S. populations of four swine breeds, and white color in Yorkshire or Landrace breeds using SNPs present on the GeneSeek Genomic Profiler for Porcine LD platform. These methods use a linear model in which unknown animal genotypes are regressed on a panel of allele frequencies, derived from reference Duroc, Landrace, Hampshire and Yorkshire purebred animals. Only SNPs that are not fixed across all reference animals and have a genotyping call rate of 90% or greater were used in the model. Model coefficients were constrained to be non-negative and to sum to 1.0, facilitating their interpretation as breed composition coefficients. By simulating 1000 admixed animals of known composition, a strong correlation was observed between the actual and estimated breed proportion of the simulated animals ($R^2 = 0.94$) so long as the actual breed of the simulated animals was reflected in the reference panel. Among a real dataset consisting of 920 Yorkshire sires, 95% of the animals were evaluated to have a Yorkshire breed proportion of 0.825 or greater. Determining that an animal may be highly purebred genome-wide does not preclude from failing a color test mating, in which alleles at particular genes such as *KIT* play a major role in color segregation patterns. Using seven SNPs flanking *KIT* (spanning chr8:43Mb– 44Mb), we have demonstrated that SNP haplotypes derived from the reference animals may be used to compute breed composition probabilities for a genomic segment flanking *KIT* of an unknown test animal. From the real Yorkshire sire dataset, 95% of the animals were estimated to have at least a 0.439 KIT-based breed composition probability of being a white breed. Dual use of genome-wide breed proportions and gene-based breed probabilities has great potential to inform swine breeders of the overall purity of an animal, as well as breed characteristics around particular key genes. Such knowledge may reduce the need to perform color test matings or other time-consuming and expensive procedures for breed verification.

Key Words: breed composition, swine, SNPs

0326 Genome-wide association study and accuracy of genomic prediction for teat number in Duroc pigs using genotyping by sequencing. C. Tan[*1,2], Y. Da[2], Z. Wu[3], D. Liu[3], X. He[2,3], N. Li[1], and X. Hu[1], *[1]State Key Laboratory for Agrobiotechnology, China Agricultural University, Beijing, [2]Department of Animal Science, University of Minnesota, St. Paul, [3]College of Animal Science, South China Agricultural University, Guangzhou.*

Swine teat number is related to a sow's ability to rear piglets to weaning age. The objective of this study was to identify genetic factors affecting swine teat number, evaluate the accuracy of genomic prediction, and evaluate the contribution of significant genes and genomic regions to the total genomic heritability and prediction accuracy using 84,151 autosome single nucleotide polymorphism (SNP) markers from genotyping-by-sequencing on 2936 Duroc boars. Heritability of teat number estimated using genomic restricted maximum likelihood estimation was 0.397 ± 0.033 for additive heritability and was 0.055 ± 0.027 for dominance heritability. Observed prediction accuracy calculated as the average correlation between the genomic best linear unbiased prediction and the phenotypic observations of validation individuals in a 10-fold validation study was 0.44 ± 0.04. Genome-wide association study (GWAS) and heritability estimates of individual SNPs identified a cluster of SNPs in or near the *PTGR2*, *FAM161B*, *VRTN* and *AREL1*genes in the 102.5–104.3 Mb region of chromosome 7 to have highly significant SNP effects on teat number. Fitting 10 SNPs in or near these four genes as fixed non-genetic effects in the model eliminated the significant effects in this region, reduced the additive heritability by 5.9% and reduced the prediction accuracy by 6.88%. Chromosomes 1, 2, 11, 12, 14, and 17 also had significant effects on teat number or substantial SNP heritabilities, and removal of those significant effects by fitting them as fixed non-genetic effects in the model reduced the prediction accuracy by 0.74–2.59% and reduced the total SNP additive heritability by 0–2.69%. The results indicated that swine teat number was

affected by genes with relatively large effects and that many more genes were also relevant to the accuracy in predicting teat numbers using the approach of genomic prediction.

Key Words: teat number, GWAS, genomic prediction, heritability

0327 Genome-wide association study for supernumerary teats in Swiss Brown Swiss Cattle reveals LGR5 as a major gene on chromosome 5.

A. M. Butty[1,2], M. Frischknecht[2,3], B. Gredler[2], C. Baes[*4], S. Neuenschwander[5], J. Moll[2], A. Bieber[6], and F. Seefried[2], *[1]Centre for Genetic Improvement of Livestock, University of Guelph, ON, Canada, [2]Qualitas AG, Zug, Switzerland, [3]School of Agricultural, Forest and Food Sciences, Bern University of Applied Sciences, Zollikofen, Switzerland, [4]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [5]Unit of Animal Genetics, Institute of Agricultural Sciences, Swiss Federal Institute of Technology, Zurich, [6]Department of Animal Science, Research Institute of Organic Agriculture (FiBL), Frick, Switzerland.*

Supernumerary teats (SNT) are any teats present on a cow's udder other than the regular four. In Swiss Brown Swiss cows, 19.9% carry SNT. Different stages of development of SNT are observed from rudimentary appendices to functional and possibly lactating teats. SNT may promote mastitis, impeach good placement of the milking machine and lower the market price of the animals. No genetic analysis of the trait has been done in this cattle population, although SNT have been routinely recorded with other conformation traits since 1995 in Switzerland. This study aimed to investigate the genetic architecture of this trait through genome-wide association studies (GWAS) performed with imputed whole-genome sequence.

Two trait definitions were used: Udder Clearance (UCT) considering whether a cow is carrier of any SNT or has a clear udder and Presence of Supernumerary Mammary Gland (PMG) opposing animal carrier of completely developed and possibly functional SNT with animals with a clear udder or carrier of a rudimentary SNT. Breeding values were estimated for Brown Swiss sires of at least 20 daughters with SNT records using an animal model including the random effects expert-by-year, farm-by-year and animal. The animal's dam life stage—heifer or cow—during its parity was fitted as a fixed effect in the same model. Single SNP regression using deregressed proofs of 1519 bulls with genotypes imputed to the variant list of the 5thRun of the 1000 Bulls Genome Project permitted discovery of three important regions on BTA5, BTA17 and BTA20 associated with the presence or the development of SNT.

Regions on BTA17 and BTA20 reached clearly lower *p*-values (10^{-7} vs. 10^{-4}) when associated to PMG than UCT, while variants on BTA5 were significantly linked to both trait definitions. No candidate genes on BTA 17 and BTA20 were found after functional analysis. On BTA5, however, the *leucine-rich repeat-containing G protein coupled receptor 5* (*LGR5*) can be considered as the major gene for our trait. Encoding a protein known as an up-regulator of the Wnt pathway and having an expression level impacting the mammary gland development, *LGR5* also carries a synonymous mutation that is highly associated to SNT.

To conclude, GWAS in the Swiss Brown Swiss population revealed *LGR5* on BTA5 as a candidate gene influencing the presence and development stage of supernumerary teats.

Key Words: dairy cattle, genome-wide association, supernumerary teats

0328 Genomic and polygenic evaluations for milk and fat yields in Holstein upgraded Thai dairy cattle.

D. Jattawa[1], M. A. Elzo[*1], S. Koonawootrittriron[2], and T. Suwanasopee[2], *[1]University of Florida, Gainesville, [2]Kasetsart University, Bangkok, Thailand.*

The objectives of this study were to compare variance components, genetic parameters, prediction accuracies, and ranking of animals for 305-d milk yield (MY) and 305-d fat yield (FY) in a Holstein upgraded Thai dairy population using two genomic models and a polygenic model (PM). One genomic model utilized 7656 SNP (GM7K) and the other one used 74,144 actual and imputed 80K SNP (GM80K). Phenotypic and pedigree data were from 8361 first-lactation cows located in 810 farms that had their first calving between 1989 and 2014. Variance components and genetic parameters were estimated using REML procedures. Fixed effects were contemporary group (herd-year-season), calving age and heterosis. Random effects were animal additive genetic and residual. Estimates of variance components and heritabilities for MY and FY from GM80K were the highest, followed by those from GM7K, and PM had the lowest values. Correlations estimates between MY and FY were similar across models. The GM80K yielded higher prediction accuracies (38.8% for MY and 31.9% for FY) than GM7K (36.7% for MY, and 31.4% for FY) and PM (31.5% for MY, and 24.4% for FY). Different MY and FY EBV rankings existed across models. The highest rank correlations were between GM80K and GM7K (0.90 for MY, and 0.91 for FY), followed by those between GM80K and PM (0.84 for MY, and 0.83 for FY), and the lowest ones were between GM7K and PM (0.80 for MY, and 0.80 for FY). Animal rankings from GM80K should be preferred because its EBV had higher accuracy than EBV from GM7K and PM. Faster selection responses for MY and FY would be expected from GM80K than from GM7K and PM in this Holstein upgraded population.

Key Words: dairy cattle, genomic evaluation, imputation

0329 Genome-wide association study for loci associated with digital dermatitis and pododermatitis circumscripta in Holstein cattle. A. M. Oberbauer*[1], A. L. Danner[1], J. M. Belanger[1], T. R. Famula[1], and J. M. Heguy[2], [1]*Department of Animal Science, University of California, Davis,* [2]*UCCE Stanislaus and San Joaquin Counties, Modesto, CA.*

Estimates of dairy cattle lameness range up to 50% of individuals in a herd being lame at any one time. The economic costs associated with lameness include premature culling, treatment, reduced reproductive fertility, and decreased milk while there are welfare concerns associated with the pain caused by lesions. Two of the most common lameness disorders are digital dermatitis and sole ulcers (pododermatitis circumscripta). Though the etiology of the two conditions differs greatly, heritability estimates for digital dermatitis and sole ulcers have been determined to be 0.4 and 0.3, respectively, signifying moderate heritability and amenable to genetic selection programs designed to reduce prevalence. To determine loci associated with each condition, genome wide association studies (GWAS) were conducted. Using diagnostic hoof trimming records, as well as digital dermatitis and sole ulcer sire EBVs from two commercial dairy farms in California, blood samples were taken from 150 selected Holstein cows representing 56 cases and 94 controls. DNA extracted from each cow was genotyped with the Illumina BovineHD BeadChip. Derived SNP genotypes were filtered such that only SNPs having call rates ≥ 0.8, minor allele frequencies < 0.5, Hardy-Weinberg equilibria (HWE) p < 0.05, and Fisher's HWE p < 0.05 were included in the GWAS using Golden Helix SNP and Variation suite. Association testing using an additive, recessive, and dominant model for inheritance for each condition was performed using a correlation/trend test. Population stratification was corrected for using a principle component analysis. Haplotype block detection with linkage disequilibrium and association testing were also performed. Significant associations ($P <$ sup > genome < /sub > ≤ 0.05;-log 10≥ 1.3) were noted on chromosomes 3, 8, and 29 for digital dermatitis and a highly significant haplotype (Χ < sup > 2 < /sup > -log10 P ≥ 7.00, 95% CI) was noted on chromosome 29. Genome wide significance was reached on chromosomes 3 and 5 for sole ulcers though significant haplotype blocks were located on chromosomes 17, 25, and 28. An immune mediating candidate gene, *TIRAP*, on chromosome 29 was sequenced in three digital dermatitis cases and three controls, but no significant variations were noted. Future work will focus on further exploring the associated regions with the objective of identifying potential markers to aid in selecting breeding stock to reduce the incidence of both conditions.

Key Words: digital dermatitis, dairy cattle, genome-wide association

0330 Genome-wide associations study for somatic cell score in Russian Holstein cattle population. A. A. Sermyagin*, E. A. Gladyr', and N. A. Zinovieva, *L. K. Ernst Institute of Animal Husbandry, Moscow, Russian Federation.*

The cattle health traits are one of the most important selection features but their improvement in short term is limited by low heritability. For the Russian Holsteins the utilization of fitness traits such as metabolic disorders, genetic diseases and especially udder health became the main goals. The developing new methods in dairy cattle have prompted us to find out associations between SNPs and sires' genomic enhanced breeding values (GEBV) for somatic cell score (SCS) to understand the additive genetic contribution to potential mastitis resistance. According to the first step for implementation of genomic selection in Russia we genotyped 256 bulls using Illumina BovineSNP50 BeadChip. The field records for somatic cell count (SCC) in the milk of 3419 first-calving daughters of 141 Holstein sires from 26 herds were included in the dataset. For sires with daughters' records we calculated the deregressed estimated breeding values (EBV) using BLUP AM. For the sires without SCC daughters' records we got the direct genomic values (DGV) calculated through GBLUP. The DGVs with the EBVs or parents' averages were combined using weight 0.8 to get GEBV as pseudo-phenotypes for common dataset. After quality check in Plink 1.9, the 41383 SNPs were taken for further analysis. The heritability coefficients for SCC and SCS were 0.202 and 0.142, respectively. We detected 10, 67, and 289 significant SNPs using Bonferroni ($P < 1.21 \times 10^{-6}$), permutation procedure (1×10^6 numbers per SNP) and FDR ($P < 0.05$) tests, respectively. The most of the closest and functional related genes involved for cellular, metabolic and immune functions were signed to SNPs: rs41981595 (*TRNAC-ACA*, $P = 2.7 \times 10^{-10}$), rs109696042 (*TCIRG1*, $P = 1.3 \times 10^{-7}$), rs109799695 (*ACO1*, $P = 1.6 \times 10^{-7}$), rs29026486 (*UQCC*, $P = 7.5 \times 10^{-7}$) and rs43298370 (*CERS6*, $P = 1.2 \times 10^{-6}$). Additive genetic variances for these genes ranged from 9.0 to 14.9%. The most of considerable polymorphisms were identified on chromosomes 2, 4, 8, 9, 13, 20, 21, and 29. Some SNPs without a clear causal mutation for SCS were identified (rs109186647, rs110041812, rs41633009, rs110507090 and rs41589293). Our knowledges of gene distribution and quantitative trait loci for SCC combined with the bulls' mating strategy allow decreasing the incidence of mammary gland infection in Russian Holstein population. Supported by the Russian Scientific Foundation, project number 15–16–00020.

Key Words: genome-wide associations, Russian Holstein cattle, somatic cell score

0331 Genome-wide association study of milk coagulation properties in dairy sheep. G. Gaspa[1], J. Serdino[1], M. G. Manca[1], S. Sorbolini[1], R. Negrini[2], C. Dimauro[3], and N. P. P. Macciotta[*1], *[1]Dipartimento di Agraria, University of Sassari, Italy, [2]Associazione Italiana Allevatori, Roma, Italy, [3]University of Sassari, Italy.*

The objective of this work was to seek genomic regions associated with milk coagulation (MCP) properties of ovine milk. A total 478 Sardadairy breed ewes were genotyped with the 60K SNP ovine beadchip (Illumina Inc., San Diego, CA). Individuals and SNPs with > 2.5% missing data were discharged. The remaining missing genotypes were imputed using BEAGLE 4.1 and checked for quality control (QC): SNPs that did not map on any chromosome, with minor allele frequency < 0.1% or statistically deviating from the Hardy-Weimberg equilibrium ($P < 0.01$) were removed. Individual milk samples from mid-late lactating ewes (45–249 d postpartum) added with preservatives (bronopol, 62,5 μL/100 mL) were analyzed to determine MCP by using Formagraph Instrument (Foss Electric A/S, Hillerød, Denmark) The three classical MCP were measured: rennet coagulation time (RCT), curd firming time (k_{20}) and curd firmness (a_{30}). Individual laboratory cheese yield (ILCY, % w/v) was also measured. A GWAS was performed with the GRAMMARgenomic control (GC) approach, that accounts for genetic substructure in the population, as implemented in the Genabel R package. MCP were pre-corrected for the systematic effects of flock-test date, days in milk, parity, lambing month, rack position and the random polygenic additive effect. The genetic (co)variance between animals was structured using the genomic relationship matrix. Environmental residual of the model were analyzed with a linear model including SNP genotype as covariate and statistical significance of the SNP effects were adjusted using the Bonferroni correction on the effective number of independent tests estimated on haplotype blocks bases. A total of 474 individuals and 47,202 SNPs pass the QC. Ten SNP passed the significance threshold in chromosomes 3, 7 10, 12, 13, and 25. Of interest s69172.1 (90,362,719 bp) in OAR7 was close to a QTL affecting fat and protein yield in Sheep. In chromosome 12 one SNP was both associated with RCT and k_{20} (OAR12_80896495.1) and another SNP (OAR12_39255725.1) affected significantly ILCY. Unexpectedly, no significant association were found on OAR6 where casein cluster maps.

Key Words: milk coagulation, GWAS, sheep milk

0332 Genetic markers identification and genotyping for resistance to internal parasites in sheep and goat infected with *Haemonchus contortus*. Z. M. Estrada Reyes[*1], A. L. Goetsch[2], T. A. Gipson[3], Z. Wang[4], M. Rolf[5], T. Sahlu[3], R. Puchala[3], S. Zeng[4], and R. Mateescu[1], *[1]University of Florida, Gainesville, [2]American Institute for Goat Research, Langston University, Langston, OK, [3]American Institute for Goat Research, Langston University, Langston, OK, [4]Langston University, Langston, OK, [5]Oklahoma State University, Stillwater.*

Gastrointestinal nematode infections (GNI) have a great economic impact for small ruminant production in humid areas. In these regions, *Haemonchus contortus* is the most important gastroenteric nematode. Unfortunately, the indiscriminate use of anthelmintic drugs to control GNI has generated resistance to these chemical compounds. Among the alternative strategies proposed, the genotypic and phenotypic variability of the small ruminants have encouraged the identification of the most resistant animals. To identify genetic markers associated with the control of nematode populations within the host, the detection of single nucleotide polymorphisms (SNPs) OLA-DRA20 gene was performed in sheep and goats experimentally infected with *H. contortus*. Animals from 3 different breeds of sheep and goat were used for the study during 3 yr of evaluation. Individuals were selected by using positive assortative mating of the most resistant individuals each year and received a complete diet (15% Crude Protein) ad libitum for the duration of the trial. Animals were treated with levamisole (7.5 mg/kg of live weight) 3 wk before the start of the trial. After deworming,

each experimental animal was infected with 10,000 L_3 of *H. contortus* per kg of body weight per oral route. Fecal samples were obtained to determine fecal egg count using the modified McMaster technique. Blood samples were collected from the jugular vein with sterile vacuum tubes with sodium heparin to evaluate blood package cell volume (PCV) and levels of IgA, IgM and IgG. DNA was purified from blood samples using DNeasy Blood & Tissue Kit (Qiagen). One SNP in the OLA-DRA20 segregating in this population was analyzed using High Resolution Melting assays and three genotypes were observed (AA, GA, GG). A GLM was fitted with MPCV, DMI, ADG, RFI, IgM, IgG, IgA levels and genotype as predictors and the square root of the mean of FEC as the response variable. According the results, the best significant predictors to fit the model were Genotype, Breed (Species), MPCV, DMI, ADG and genotype ($p < 0.05$). In conclusion, the polymorphism in the OLA-DRA20 gene could have an important role in the immune mechanisms against *H. contortus* infections in sheep and goats. Indeed, these results provided evidence that there is a significant effect among the square root of the mean of FEC and production traits between breeds within species.

Key Words: *Haemonchus contortus*, small ruminants, OLA-DRA20 gene

0333 Genomic analysis of lactation persistency in four breeds of dairy cattle.

J. B. Cole[1], D. J. Null[*1], and K. L. Parker Gaddis[2], [1]*Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD,* [2]*Department of Animal Sciences, University of Florida, Gainesville.*

The objectives of this study were to determine gains in reliability from the addition of genomic information to genetic evaluations for best predictions of lactation persistency in U.S. Ayrshire (AY), Brown Swiss (BS), Holstein (HO), and Jersey (JE) cattle, and to identify genomic regions with large effects on those traits. Data consisted of lactations initiated by calvings on or after January 1, 1997, stored in the national dairy database (NDDB) at the Council on Dairy Cattle Breeding (Bowie, MD). Persistencies were computed by multiple-trait best prediction for milk (PM), fat (PF), and protein (PP) yields. Genetic analyses were conducted on a within-breed basis using identical repeatability animal models and breed-specific (co)variance components. Traditional and genomic PTA and reliabilities were computed by GBLUP using the national genomic evaluation system. Gain in reliability from the addition of genomic information was calculated as the difference between the realized genomic reliability and the reliability of traditional PA using a cutoff study. Predictor populations consisted of animals with traditional genetic evaluations in April 2014, and validation sets included animals with traditional genetic evaluations in August 2009. Allele effects were converted to additive genetic standard deviations, and closestBed 2.17.0 was used to obtain a list of genes that contained SNP or were within 25 kbp of a genotyped SNP. Gene names and coordinates were those published in Cow Ensembl Release 79. Reliability gains averaged 8% in AY, 5% in BS, 12% in HO, and 12% in JE. The SNP ARS-BFGL-NGS-4939 at 1801,116 bp on BTA14, downstream of the *DGAT1* gene, had the largest effects on PM and PF in HO and PM in JE of any marker in the analysis. BovineHD1600000386 at 1554,597 bp on BTA16 had largest effect on PF and PP in JE, in a region previously reported to effect fat and protein yields and percentages. The SNP with the largest effects in AY were located on the X chromosome in regions reported to affect fat and protein yields and percentages in HO. The largest effect for PM in BS was in a region of BTA19 associated with MY in Chinese Holsteins, while the largest PF and PP effects were in regions of the X chromosome reported to affect fat and protein yield in U.S. Holsteins. Genetic correlations of yield with persistency range from −0.32 to 0.26, so loci with large effects on yield also can affect persistency.

Key Words: association analysis, best prediction, reliability

0334 Genome-wide association study for tick count and infection level of *Babesia bovis* traits in Angus cattle.

L. Cavani[*1], C. H. Santana[1], R. Giglioti[1], T. B. Bilhassi[1], M. C. D. S. Oliveira[2], R. Carvalheiro[1], and H. N. Oliveira[1], [1]*State University of São Paulo, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, Brazil,* [2]*Embrapa Southeast Livestock, São Carlos, Brazil.*

Tick and tick-borne diseases, including babesia (*B. bovis*), constitutes a major drawback to improve productivity of beef cattle in the tropics, especially for systems where *Bos taurus* cattle animals and their crosses are used. To identify highlight regions highly associated with the studied traits, genome-wide association studies (GWAS) were performed. Tick counts and blood sample were taken in two occasions from each of 355 Angus cattle at a farm located at Rio Grande do Sul State, Brazil. Blood samples were collected, in tubes containing EDTA for DNA extraction. *B. bovis* quantification was performed using both qPCR technique from genomic DNA of each animal with specific primers for this protozoary and the absolute quantification method. Animals were genotyped by using Illumina GeneSeek GGP Bovine 150K. Quality control criteria were: MAF < 2%, call rate < 92%, and animal call rate (with less than 90% of SNPs called). After edits, 144,924 SNPs and 350 animals were available. Fixed effects in the model included contemporary groups and effect of data collection period, as well as additive genetic direct and permanent environmental effects as random. Variance components and genetic parameters were estimated by Bayesian inference in a bivariate analysis using GIBBS2F90 software, and the effect of each SNP was estimated using methods Bayes C as implemented in the GS3 software. Also, it was

used de-regressed EBV. The mean h^2 were 0.207 and 0.059 for tick count (TC), and infection level of *Babesia bovis* (IB), respectively. The genetic correlations were 0.079 between TC and IB. Variances were calculated for windows of 1-Mb SNP. The results showed that the top 10 SNP windows for each trait explained a total of 51.45%, and 3.09% of genetic variance for TC, and IB, respectively. The 10 most significant markers for TC were located on chromosomes 4, 5, 6, 10, 12, 16, 19, 22, 29, and 30. The 10 most significant markers for IB were located on chromosomes 3, 5, 7, 8, 14, 20, and 24. There are others studies that indentified QTLs located in regions of top SNP associated with TC. Therefore, genomic regions identified may be important for the variation of tick count, but less important for infection level of *Babesia bovis* traits in Angus cattle. Acknowledgment: Grant provided by São Paulo State Foundation (FAPESP), São Paulo, Brazil.

Key Words: *Bos taurus,* GWAS

0335 Identification of loci associated with susceptibility to bovine paratuberculosis using imputed genotypes based on whole genome sequencing.

J. N. Kiser*[1], J. L. Hoff[2], S. N. White[3], J. F. Taylor[2], and H. L. Neibergs[4], *[1]Department of Animal Science, Washington State University, Pullman, [2]University of Missouri, Columbia, [3]USDA-ARS, Animal Disease Research Unit, Pullman, WA, [4]Department of Animal Sciences, Washington State University, Pullman.*

Johne's disease or bovine paratuberculosis is a contagious bacterial infection in cattle caused by *Mycobacterium avium* ssp. *paratuberculosis* (*Map*). Previous genome wide association studies (GWAS) to identify loci associated with susceptibility to *Map* infection in Holstein and Jersey cattle have been performed using the Illumina BovineSNP50 BeadChip which consisted of approximately 54,000 SNPs in three released BeadChip versions. Although uniform SNP spacing was a design objective, a number of genomic regions were under-represented by markers. The objective of this study was to determine if there were loci associated with susceptibility to *Map* tissue infection located within these under-represented areas of the Bovine SNP50 BeadChip that would be identified using genotypes imputed to whole genome sequence (WGS). To do this, BovineSNP50 genotypes of 409 Holstein cows (162 cases and 247 controls) were first imputed using Beagle 4.1 to the density of the Illumina BovineHD BeadChip using 2703 previously genotyped Holstein cattle as a reference. The imputed BovineHD data were then imputed to WGS level (35,431,201 indels and SNPs) with FImpute using phased Run 4 WGS data for 1147 previously sequenced cattle from the 1000 Bull Genomes Project as a reference. Genotype quality control was performed using the same parameters as for the BovineSNP50 data and any SNP with a call rate < 90% or MAF < 1% was removed. After quality control, 16,063,342 indels and SNPs remained for analysis. A GWAS was performed with Efficient Mixed Model Association expedited (EMMAX) additive and allelic models and the most highly significant 500 loci were compared with the BovineSNP50 GWAS results. With the imputed genotypes, 13 and 5 new QTL were identified with the allelic and additive models, respectively, and 14 new QTL were identified by both models ($p = 4.17\text{x}10^{-6}$ to $p = 4.45\text{x}10^{-5}$). In addition, 81, 18, and 67 previously identified QTL were identified under the allelic, additive or by both models and were more precisely finely mapped using the imputed genotypes. In conclusion, imputation of BovineSNP50 data to WGS was effective for identifying new QTL and fine-mapping previously identified QTL.

Key Words: paratuberculosis, imputation, GWAS

0336 Joint SNP-haplotype analysis for genomic selection based on the invariance property of GBLUP and GREML to duplicate SNPs.

Y. Da*[1], C. Tan[1,2], and D. Parakapenka[1], *[1]Department of Animal Science, University of Minnesota, St. Paul, [2]State Key Laboratory for Agrobiotechnology, China Agricultural University, Beijing.*

Haplotype analysis of SNP markers in genomic prediction and estimation may utilize haplotype effects unaccounted for by single-SNP analysis, whereas haplotype analysis alone may not account for all single-SNP effects. The objective of this study was to establish a theoretical model by mathematical derivation and validation studies to show why haplotype analysis and the joint SNP-haplotype analysis may improve the accuracy of genomic prediction. We first modeled the genotypic value of a two-haplotype genotype as the summation of the single-SNP effects and the haplotype effects unaccounted for by the single SNPs within the haplotype block plus a potential loss of single-SNP effects of the haplotypes. Then we established an invariance property to duplicate SNPs. Assume that a set of SNP markers is duplicated r times in the mixed model. Genomic best linear unbiased prediction (GBLUP) of genetic values (additive, dominance and genotypic values) of individuals and SNP genetic variance components as well as the associated heritability estimates by genomic restricted maximum likelihood estimation (GREML) are invariant to the duplication of SNPs, and GBLUP of SNP additive, dominance and genotypic effects differ from those without duplicate SNPs by the square root of r. Based on this invariance property, adding single SNPs to the haplotype analysis would recover any loss of single-SNP effects of haplotype-only analysis and maintain the haplotype effects not utilized by single-SNP analysis without overestimating single-SNP effects. Validation studies using 6000 individuals with 423,131 SNPs from the Framingham Heart Study showed that heritability estimates under the joint SNP-haplotype model were lower than those from the haplotype-only model, confirming that adding SNPs to the haplotype model did not result in overestimation

of the total genetic contribution. In most validation samples, haplotype analysis was at least as accurate as single-SNP analysis, and the joint SNP-haplotype analysis had further improvement in prediction accuracy over the SNP-only or haplotype-only models. These validation results provided a confirmation of the benefit predicted by our theoretical model for the joint SNP-haplotype analysis of genomic prediction based on the invariance property of duplicate SNPs.

Key Words: genomic selection, haplotype, GBLUP, GREML, SNP

0337 Practical approximation of accuracy in genomic breeding values for a large number of genotyped animals. S. Tsuruta[*1], D. Lourenco[1], Y. Masuda[1], D. W. Moser[2], and I. Misztal[1], *[1]University of Georgia, Athens, [2]Angus Genetics Inc., St. Joseph, MO.*

Accuracy defined as the squared correlation between true and genomic EBV (GEBV) is required in genomic evaluations and it can be approximated by contributions from phenotypes, pedigrees, and genotypes. In single-step genomic BLUP, contribution from genotypes is based on inverses of genomic (G) and pedigree (A22) relationship matrices for genotyped animals. The objective of this study was to develop a less expensive formula to calculate accuracy in GEBV for a large number of genotyped animals. As alternative contributions from genotypes, we considered the mean square difference between off-diagonals for G and A22 (GmA22) and the number of genotyped animals or the number of effective SNP markers (ESM) as well as parent average accuracy (ACCPA). The ESM was calculated as the number of the largest eigenvalues of G explaining 99% of variation. The following three formulas were proposed: F1 = heritability × ESM × GmA22 × (1 + ACCPA); F2 = 1 + heritability × ESM × ACCPA × GmA22; and F3 = 1 + ACCPA. Phenotypes for birth weight (BW) and post weaning gain (PWG), pedigrees, and genotypes were provided by American Angus Association. The BW dataset consisted of 20K records and 91K animals with 20K genotyped animals. Two PWG datasets consisted of 30K records and 122K animals with 30K genotyped animals, and 35K records and 202K animals with 60K genotyped animals, respectively. The three formulas were compared with the accuracy calculated from prediction error variances (PEV) obtained from the inverse of the left-hand side of the mixed model equations. For direct GEBV on BW, correlations of PEV with F1 and F2 were the highest (0.86), but F1 was overestimated and the MSE was larger. For maternal GEBV on BW, correlations between PEV and F1 and F2 were the highest (0.85). For GEBV on PWG with 30K genotyped animals, correlations of PEV with F1 and F2 were the highest (0.82), but the MSE for F2 was larger. With 60K genotyped animals, correlations between PEV and F1 and F2 were also high (0.79 and 0.78, respectively), but F2 was underestimated and the MSE was larger. Both F1 and F2 gave reliable approximations of accuracy in GEBV. For each data set, the mean accuracy can be adjusted to reduce the bias. The new formula can calculate approximations of accuracy in GEBV for a large number of genotyped animals at a low cost.

0338 Comparison of transcriptome profiles in longissimus dorsi muscle between bulls and steers of Korean cattle. M. Baik, S. J. Park*, and N. Sang Weon, *Department of Agricultural Biotechnology, College of Agriculture and Life Sciences, Seoul National University, Korea (The Republic of).*

Castration of bulls improves beef quality including intramuscular fat (IMF) content and tenderness. Studies have revealed that castration changes expression of many genes associated with beef quality and IMF deposition in longissimus muscle (LM). Limited information is available for global gene expression changes in the LM following castration. Objectives of this study were to understand global transcriptome changes following castration in the LM of beef cattle and to identify new genes associated with beef quality. By using RNA-sequencing (RNA-seq) technique, transcriptome profiles were compared in the LM between bulls and steer of Korean cattle. LM tissues samples of ten bulls and ten steers were prepared, and LM RNA samples from three bulls and three steers were used for the RNA-seq. Among total 18,027 genes identified by RNA-seq and subsequent read mapping analysis with TopHat software, total 1146 transcriptomes (521 upregulated and 625 downregulated genes following castration) were differentially expressed genes (DEGs) in the LM between bulls and steers with false discovery rate at < 0.05 and log fold change above 1.5. Pathway analysis with the 1146 DEGs showed significant ($P < 0.05$) changes in 9 KEGG pathways, including complement and coagulation cascade and peroxisome proliferator-activated receptor signaling. We conducted quantitative PCR (qPCR) with ten genes of the complement and coagulation cascades using LM tissue samples of ten bulls and ten steers. The qPCR data were analyzed using GLM of SAS. The qPCR analysis confirmed differential ($P < 0.05$) expression patterns of all genes including coagulation factor III and mannan-binding lectin serine peptidase 1. In conclusion, global transcriptome analysis using RNA-seq reveals for the first time that castration changes expression of many genes involved in complement and coagulation cascade pathway, which may be linked to beef quality.

Key Words: castration, complement and coagulation cascade, beef cattle

0339 Gene network regulated by microRNAs suggests modulation of fat deposition in cattle.
G. B. Oliveira*[1], A. S. M. Cesar[1], A. M. Felício[1], M. D. Poleti[1], L. C. A. Regitano[2], and L. L. Coutinho[1],[1]*Animal Biotechnology Laboratory-ESALQ, University of São Paulo, Piracicaba, Brazil,* [2]*Embrapa Southeast Livestock, São Carlos, Brazil.*

Meat quality depends on many factors such as nutrition, management system and genetic. The mainly attributes of meat quality besides tenderness are juiciness and flavor, which are associated with intramuscular fat (IMF) content. In this study microRNAs expressed in Longissimus dorsi muscle from *Bos indicus* were identified to better understand the biological processes related to IMF deposition in skeletal muscle. MicroRNAs are small non-coding regulatory RNAs that play an important role in post-transcriptional gene regulation in many tissues and are associated with numerous biological processes. Total RNA was extracted from Longissimus dorsi muscle of 30 steers with extreme values of genomic estimated values (GEBV) for IMF content, classified into High (H) and Low (L) IMF content groups. MicroRNA libraries were constructed and sequenced using NGS technology (MiSeq-Illumina) generating 1 million reads/sample. MicroRNAs were filtered by FastX, annotated by miRDeep2 and, differentially expressed (DE) microRNAs were identified by DESeq2 package. A total of 463 known microRNAs were identified and six of them were DE (FDR < 0.1). MicroRNAs bta-let-7f, bta-let-7a-5p and bta-miR-423 were downregulated, while bta-miR-100, bta-miR-143 and bta-miR-146b were upregulated in the L group. MicroRNAs target genes were identified by Ingenuity Pathways Analysis (IPA®) MicroRNA Target Filter tool and filtered by muscle RNA-Seq data obtained in previous studies, creating a list with 2520 target genes. The metabolic pathways and gene networks were constructed and analyzed by IPA® software, to identify enriched biological processes and genes regulated by microRNAs that were associated with lipid metabolism. Important genes for fatty acid metabolism were related in three gene networks: "Gene Expression, Cell Cycle, Cancer," involving 32 target genes; "Drug Metabolism, Lipid Metabolism, Molecular Transport," with 32 target genes and "Lipid Metabolism, Small Molecule Biochemistry, Vitamin and Mineral Metabolism," with 30 target genes. This last network involved genes such as PPARGC1A, MYCN, ESR2 and ARL4D, targets of downregulated microRNAs; MED1, SMAD4, NEDD4 and MBOAT2, targets of upregulated microRNAs in the L group. These results indicate that gene regulation by microRNAs in this gene network influences lipid homeostasis, principally by PPARα signaling pathway activation and can modulate fat deposition in muscle.

Key Words: smallRNA, functional enrichment, lipid metabolism

0340 Differentially expressed miRNAs in skeletal muscle related to feed efficiency in Nellore cattle.
P. S. N. Oliveira*[1], P. C. Tizioto[1], G. B. Oliveira[2], A. S. M. Cesar[2], W. J. S. Diniz[3], A. O. D. Lima[3], J. M. Reecy[4], L. L. Coutinho[2], and L. C. A. Regitano[5], [1]*Embrapa Southeast Livestock, São Carlos, Brazil,* [2]*Animal Biotechnology Laboratory-ESALQ, University of São Paulo, Piracicaba, Brazil,* [3]*Federal University of São Carlos, Brazil,* [4]*Iowa State University, Ames,* [5]*Embrapa Southeast Livestock, São Carlos, Brazil.*

Feed efficiency (FE), also referred as residual feed intake (RFI), is a production trait that can have a major impact on production costs, reduction of pasture area, and pollutants. Bovine transcriptomic studies have shown that the expression of many miRNAs are tissue specific and have potential roles in some biological mechanisms. In this study, Nellore steers genetically divergent for RFI (kg/d) were selected based on BLUP (Best Linear Unbiased Prediction) estimates and ranked to select the most extreme values for additive genetic merit. Sequencing of small RNA libraries from Longissimus dorsi (LD) muscle tissue of eight Nellore steers (N = 4 High RFI, N = 4 Low RFI) was conducted on a MiSeq using the Miseq Reagent Kit V3 150 cycles. After quality control, the miRDeep2 software was used to identify and quantify novel and known miRNAs using *Bos taurus* UMD3.1 as reference genome. Differentially expressed (DE) miRNAs (FDR = 10%) were identified by DESeq2 R package and potential regulatory target transcripts were predicted by TargetScan software. The bta-miR-486 (padj = 0.0072) was DE in LD muscle tissue. This miRNA was also identified as DE in a transcriptome analysis in skeletal muscle for differential RFI in pigs. The genes *PKHD1L1, ENAH, ATF3, GAS7, LIMK1, MPZ, C3* and *SLC26A2,* related to ion transport, glucose and pyruvate metabolic process and glycosylation, were identified as target genes of this DE miRNA. Supporting our findings, these genes were previously identified as DE in RNaseq study performed using liver and muscle tissues of this same set of samples. This study provides a better understanding of the role of miRNAs in biological mechanisms related to feed efficiency in Nellore beef cattle.

Key Words: *Bos indicus*, residual feed intake, gene regulation

0341 miRNAs related to fatty acids composition in Nellore cattle. P. S. N. Oliveira*[1], A. S. M. Cesar[2], G. B. Oliveira[2], P. C. Tizioto[1], M. D. Poleti[2], W. J. S. Diniz[3], A. O. D. Lima[3], J. M. Reecy[4], L. L. Coutinho[2], and L. C. A. Regitano[5], *[1]Embrapa Southeast Livestock, São Carlos, Brazil, [2]Animal Biotechnology Laboratory-ESALQ, University of São Paulo, Piracicaba, Brazil, [3]Federal University of São Carlos, Brazil, [4]Iowa State University, Ames, [5]Embrapa Southeast Livestock, São Carlos, Brazil.*

Fatty acid (FAs) content is an important trait that can influence the sensorial and nutritional value of meat and play a significant role in biological processes such as adipogenesis. In beef cattle, adipogenesis as well as several other biological processes have been reported that could be regulated by miRNAs. The goal of this study was identify differentially expressed (DE) miRNAs and biological processes associated with FA content between the groups Nellore steers that showed extreme genomic breeding values (GEBV) for oleic acid (OA) and conjugated linoleic acid cis9 trans11 (CLAc9t11). In this study, small RNA libraries from Longissimus dorsi (LD) muscle tissue from a group of 28 (top 14 animals with highest GEBV distribution (H) and bottom 14 with lowest GEBV distribution (L) for OA and CLAc9t11 content) were sequenced on a MiSeq using the Miseq Reagent Kit V3 150 cycles. After quality control, the miRDeep2 software was used to identify and quantify novel and known miRNAs using *Bos taurus* UMD3.1 as reference genome. Differentially expressed (FDR = 10%) miRNAs were identified by DESeq2 R package and potential regulatory target transcripts were predicted by TargetScan software. The bta-miR-126–5p (padj = 0.0987) and bta-miR-2419–5p (padj = 0.0041) were DE for OA and CLA, respectively. The genes *CDS2, FAR2, DIP2B, NAB1, EPT1, UBE2E3*, *PRKAG2* and *CAV3* were identified as target genes of these DE miRNAs, which were identified as DE in a previously RNaseq study. These genes are related to some biological process for fatty acids composition; like phospholipid and lipid metabolism, skeletal system development, proteolysis and insulin signaling pathway. This study helps to better understand of the biological mechanisms that control intramuscular fat deposition and composition, and could positively benefit beef production by supplying the product that the consumer wants.

Key Words: *Bos indicus*, adipogenesis, gene regulation

0342 Expression levels of the bovine SCD gene are significantly associated with fatty acid composition of cattle. H. Chung*, *National Institute of Animal Science, Wanju, Korea (The Republic of).*

The experiment shows that a long-term administration of low and high-energy diets may not functionally either increase or decrease SFA and UFA. The interesting finding was that variation for proportions of all FAC in the low-energy diet group were higher than that of the high-energy diet group except Linoleic acid (18:2n6) and PUFA. According to the variance analysis, the proportions of FAC in the low group tended to have an approximate normal distribution while the high group showed a skewed pattern. Expression analysis of stearoyl-CoA desaturase (SCD) revealed at least twofold high expression levels in the high-diet group, and especially, the SCD4 and SCD6 segments detected more than 10 folds high expressions, whereas none of the SCD segments had high expression values in the low-diet group. The results indicate that long-term feeding with high energy levels of diets lead high expression levels of the SCD gene. However, excessive proportions of nutritional materials limited metabolic availabilities or restricted functional systems for the ruminal bio hydrogenation between FA. Therefore, the present results deliver a critical issue to the public that manipulations of FAC with high nutritional levels in diets may be oriented toward increases of expression levels of SCD, but not activities of other genes that functional elongate and desaturase FA.

Key Words: expression, SCD, FAC

0343 Profiling microRNA expression in longissimus dorsi muscle of F2 pigs from the Michigan State University Duroc x Pietrain resource population. K. R. Perry*[1], J. P. Steibel[1,2], D. Velez-Irizarry[1], S. A. Funkhouser[3], N. E. Raney[1], R. O. Bates[1], and C. W. Ernst[1], *[1]Department of Animal Science, Michigan State University, East Lansing, [2]Department of Fisheries and Wildlife, Michigan State University, East Lansing, [3]Genetics Program, Michigan State University, East Lansing.*

MicroRNAs (miRNAs) are a class of small, non-coding RNAs shown to regulate gene expression post-transcriptionally through complementary binding with an approximately 7 nt "seed" sequence in the 3'UTR of target mRNAs. MiRNAs have been shown to regulate numerous complex biological processes across tissue types, including fetal and postnatal skeletal muscle in pigs. While miRNAs have been characterized for these developmental stages, a more comprehensive understanding of the effects of miRNA regulation in market-age pigs is needed. The objective of this study was to profile the expression of miRNAs in the Longissimus dorsi (LD) muscle of 174 F2 pigs (~5.5 mo of age) from the MSU Duroc x Pietrain Resource Population. Total RNA was extracted from LD samples using the QIAGEN miRNeasy Mini Kit, and library preparation for sequencing was conducted utilizing the Bioo Scientific NEXTflex Small RNA Sequencing Kit (v2) with one cDNA library prepared per sample. The 174 libraries were multiplexed and sequenced on an Illumina HiSeq 2500 platform in 1x50 bp format. Raw sequence reads (fastq format) were trimmed for adaptor sequences, size- and quality-filtered, and PCR duplicates were removed. After processing, 232,826,977

total reads (mean 1338,086 reads per library) were aligned to the *Sus scrofa* reference genome (10.2.79) using miRDeep2. In total, 74.8% of reads were successfully mapped to the reference genome (median = 76.4% of reads per library). The miRDeep2 software package was then utilized to quantify annotated *Sus scrofa* mature miRNAs from miRBase (Release 21). The mature miRNA expression profiles were then filtered for abundance across samples; miRNAs expressing less than 1 read count per million (cpm) in less than 44 samples were removed from the analysis. The remaining 295 profiles were normalized relative to quantified library size (cpm) utilizing the *cpm* function of the *edgeR* package of R. Among the expressed miRNAs ssc-miR-1, ssc-miR-133a-3p, ssc-miR-378, ssc-miR-206, and ssc-miR-10b were the most abundant, all of which have previously been shown to be expressed in pig skeletal muscle. The expression of these five miRNAs represented 47.85% of the total read cpm in the dataset. Further characterization of miRNA expression profiles in adult pig skeletal muscle tissue will help to elucidate the role of miRNA regulation on production efficiency-related phenotypes including skeletal muscle accretion and meat quality.

Key Words: microRNA, skeletal muscle, pig

0344 Scan for allele frequency differences from pooled samples in lines of pigs selected for components of litter size. B. A. Freking*, J. W. Keele, and G. A. Rohrer, *USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Direct single trait selection within two seasonal replicates for 11 generations resulted in a 1.6 pig advantage for uterine capacity (UC) and a 3.0 advantage for ovulation rate (OR) compared with an unselected control (CO) population. Our objective was to gain insight and identify genetic loci impacted by quantitative selection for these component traits. We utilized historical DNA samples from all three lines obtained five and six generations after selection had ceased. A total of 402 gilts contributed to pooled samples; 8 unique pools per line with an average of 16.6 gilts per pool with paternal-half-sibs kept in the same pool. These 24 DNA pools were applied to Neogen GGP Porcine HD BeadChips. Bead-level normalized X and Y values were analyzed rather than allele calls. Analyses to compare the populations were conducted on individual SNP frequency estimates using REML and also using a sliding 25-SNP window with Wright's fixation index (F_{ST}). Pedigree relationships of all gilts back to the common base population 18 generations prior were utilized to compare to the genomic relationships. The overall relationship between pedigree and genomic information was highly predictive (r^2 = 97.5%); however, OR and UC selected lines differed from CO line with above average genomic relationships observed for the same degree of pedigree relationship. This would be consistent with the idea that selection increased the average within line relationships beyond what was accounted for by drift. Sixteen SNPs had allele frequency differences that exceeded a modest false discovery rate ($P < 0.05$) with none exceeding a genome-wide level of significance. However, three SNP were closely linked on SSC 13 near 203 Mb, while two SNP each were identified on SSC 5 at 63–65 Mb and on SSC 14 at 22–24 Mb offering additional support to those locations. F_{ST}values marked similar chromosomal regions but, again, did not by themselves identify regions that exceeded genome-wide significance. In conclusion, the pooling strategy reduced the cost to initially scan the genome but estimates of allele frequency differences needed to be extreme to exceed differences expected from modeling genetic drift in these populations. Additional samples need to be added to supplement this initial scan.

Key Words: pigs, selection, pooling

0345 Construction and functional analysis of expression vector and miRNA interference vectors of Gsdma of Tibetan sheep. C. Li[1], L. Ren[1], Y. Wang[1], J. Zhong[2], L. Huang[1], Y. Lin[1], X. Zi[1], and Y. Zheng[*1], [1]*Southwest University for Nationalities, Chengdu, China,* [2]*Auburn University, Auburn, AL.*

Gsdm(*gsdermin*) is a newly reported gene family. The human *Gsdma* and mouse *Gsdma3* were demonstrated to regulate the formation and development of hair follicle through signaling pathways such as Wnt and TNF-α. However the functions of *Gsdm* family members from other animal species are poorly studied. The objective of this study was to explore possible functions of *Gsdma* of Tibetan sheep (*Ovis aries*) at cellular level. RNA were extracted from skin tissues of Tibetan sheep (n = 5), and the cDNA sequence of *Gsdma* was cloned by PCR. Tissue expression profile analysis and sequence alignments showed that Tibetan sheep *Gsdma* is skin-specific and shows 99.9% coding sequence similarity to that of predicted sheep *Gsdma* (XM_004012853.1). The deduced protein sequences of Tibetan sheep and human *Gsdma* have high similarity (approximately 90%). An eukaryotic expression vector (pCDsRed2-KG) containing skin-specific KAP6.1 promoter and four interference vectors (pcDNA6.2-GW/EmGFP-miR 1 to 4) for Tibetan sheep *Gsdma* were constructed. The pCDsRed2-KG vector was transfected into human hair inner root sheath cells in vitro, and the positive transfected cells were sorted by flow cytometry. Quantitative real time PCR using *GAPDH* and β-actin as reference genes proved that the expression vector was highly expressed in human hair inner root sheath cells after transfection. In addition, two of the four interference vectors exhibited significant silencing effect on pCDsRed2-KG expression (interference efficiency > 50%). Further analysis showed that the significantly increased *Gsdma* mRNA level was correlated with elevated caspase-3 mRNA level ($P < 0.05$) in the transfected human hair inner root sheath cells. However, the β-catenin showed no significant changes at both mRNA and protein levels. Since caspase-3 is involved in apoptotic pathway, our data suggest that

Gsdma gene may play an important role in regulating hair follicle development through this signaling mechanism.

Key Words: *Gsdma* gene, Tibetan sheep, hair follicle

0346 Genetic characteristics of semi-domesticated reindeer populations from different regions of Russia based on SNP analysis. V. R. Kharzinova*[1], A. V. Dotsev[1], I. M. Okhlopkov[2], K. A. Layshev[3], V. I. Fedorov[4], L. D. Shimit[5], G. Brem[1,6], K. Wimmers[7], H. Reyer[7], and N. A. Zinovieva[8], *[1]L. K. Ernst Institute of Animal Husbandry, Moscow, Russian Federation, [2]Science Institute of Biological Problems Cryolithozone, Yakutsk, Russian Federation, [3]North-West Center of Interdisciplinary Researches of Food Maintenance Problems, Federal Agency of Scientific Organizations, St. Petersburg, Russian Federation, [4]Federal Government Budget Scientific Institutions Yakut Scientific Research Institute of the Agriculture Federal Agency Scientific Institutions, Yakutsk, Russian Federation, [5]Tuva State University, Tyva Republic, Russian Federation, [6]Institute of Animal Breeding and Genetics, VMU, Vienna, Austria, [7]Genome Biology, Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [8]L. K. Ernst Institute of Animal Husbandry, Moscow, Russian Federation.*

Semi-domesticated reindeer are herded on the entire territory of Russian Far North and are represented by several populations which vary in exterior and morphological features. In the present work we considered the following populations: Nenets-NEN (the largest, with 800,000 individuals), Evenk-EVN (100.000 individuals) and Todzha-TOD (the smallest with around 1000 individuals). Genetic characteristics and structure of Russian reindeer populations are insufficiently studied and research in this field is undoubtedly necessary.

Our study aimed at evaluating genetic diversity and structure of NEN (n = 11), EVN (n = 29) and TOD (n = 11). Wild reindeer from Yakutia region (n = 14) were used as outgroup for cluster analysis. DNA was extracted from tissue samples using the Nexttec column (Nexttec Biotechnology GmbH, Germany) according to the manufacturer's recommendations and genotyped using the Bovine SNP50 v2 BeadChip. After quality control (MAF = 0.01) 544 polymorphic SNPs were selected for further analysis. Statistical analysis was performed with PLINK 1.07, Arlequin 3.5.2.2, HP-Rare 1.1, GENETIX 4.05 and STRUCTURE 2.3.4 software.

Greater values of unbiased expected heterozygosity were observed for NEN (0.214 ± 0.008) and EVN (0.211 ± 0.008) populations, while for TOD this was only 0.195 ± 0.008. Inbreeding coefficient (F_{is}) showed heterozygote deficiency in the TOD population (0.049) while NEN and EVN were in H-W equilibrium (0.003 and −0,004, respectively). Allelic richness was significantly higher for EVN (1.74 ± 0.02) and NEN (1.70 ± 0.02) in comparison with TOD (1.65 ± 0.02). AMOVA revealed that most of the variation was within populations (91.8%) and less (8.2%) among populations. The genetic differentiation (pairwise F_{ST}) among populations ranged from 0.05 between EVN and NEN to 0.11 between TOD and NEN. F_{ST}value between EVN and TOD was 0.10 ($p < 0.01$).

Since wild populations coexist with semi-domesticated populations and gene exchange may occur between them, the SNP profiles of wild reindeers were included in dataset for cluster analysis. At k = 4 all animals belonging to the EVN and NEN were distinctly differentiated, while admixture of wild reindeer was observed in three samples belonging to the TOD population.

The genome scan approach in reindeer used in our study revealed that every population was characterized by unique gene pool. Subsequent studies in this field will provide further information for investigating population structure along with a better understanding of biological features of reindeer. The study was supported by the Russian Science Foundation within Project no. 14–36–00039

Key Words: semi-domesticated reindeer, SNPs, genetic diversity, population structure

0347 Candidate gene and marker for equine metabolic syndrome. S. Lewis*, H. Holl, M. T. Long, M. Mallicote, and S. Brooks*, University of Florida, Gainesville.*

Equine obesity gives rise to life-threatening secondary chronic conditions, similar to those in humans, livestock and other companion animal species, leading to loss of use or euthanasia. Elevated circulating insulin levels often characterize the primary disease associated with equine obesity, Equine Metabolic Syndrome (EMS). Due to clinical similarities with other conditions like Pituitary Pars Intermedia Dysfunction (PPID, formerly Equine Cushing's Disease) and hypothyroidism, conclusive diagnosis of EMS often proves challenging. Aside from changes in diet and exercise, few targeted treatments are available for EMS, emphasizing the need for genetic testing to identify at-risk individuals and implement preventative measures. A previous genome-wide association study, using horses with EMS and/or PPID and exhibiting severe laminitis, revealed statistically significant markers for the condition near a single candidate gene, *FAM174A*. A single study describing the function of this gene suggests it may play a role in cholesterol homeostasis. Sequencing of the *FAM174A* gene in EMS affected Arabian horses identified at least five polymorphic haplotypes. In this study, additional samples from a larger population of horses, consisting of 56 individuals, diagnosed with EMS disease were genotyped by Sanger sequencing for polymorphisms in the *FAM174A* gene and the results assessed for association with indicators of the EMS condition. Additionally, we genotyped the most significant intergenic marker

SNP from the previous GWAS, BIEC2–263524, by High Resolution Melt (HRM). An allele in a 3' untranslated region (UTR) of *FAM174A* correlated with both elevated insulin values ($p = 0.0082$) and BCS > 6.5 ($p = 0.0116$). The BIEC2–263524 marker SNP displayed similar associations to elevated insulin values ($p = 0.0060$) and BCS > 6.5 ($p = 0.0049$). The risk allele at both BIEC-263524 and the *FAM174A* 3'UTR correlated at a 95% frequency, indicating strong LD across this haplotype. Confirmation of the association between these markers and the EMS condition will enable genetic tests for the horse as a helpful tool in diagnosing and preventing EMS. In addition to improving our understanding of the etiology of this troubling condition in the horse, the *FAM174A* locus may prove an interesting candidate gene for human obesity.

Key Words: equine, obesity, metabolic

0348 The polymorphisms of Toll-like receptor 4 gene influences milk production traits in Chinese Holstein cows. X. Zhu, M. Wang, S. Xing, Z. Yang, and Y. Mao*, *College of Animal Science and Technology, Yangzhou, China.*

Toll-like receptor 4 (*TLR4*) is an important member of the Toll-like receptor gene family that is widely found in various organisms. *TLR4* can identify molecular patterns from various pathogenic microorganisms, and induce natural immunity and acquired immunity. Two single nucleotide polymorphisms (SNPs) of *TLR4* (c.-226 G > C and c.9788 C > T) were genotyped using Sequenom MassARRAY (Sequenom Inc., San Diego, CA) for Chinese Holstein cows ($n = 866$), and the EBV for each individual cow of milk production traits and somatic cell score (SCS) were analyzed by the multiple-traits multiple-lactation random regression test-day model, and then the associations between SNPs or haplotype and the EBV of milk production traits and SCS were analyzed by PLINK software. The c.-226 G > C and c.9788 C > T showed low linkage disequilibrium ($r^2 = 0.192$). There was no association between these two SNPs and SCS, but significant effects were found for SNP c.-226 G > C on fat content ($P < 0.025$), and SNP c.9788 C > T and haplotype CT on fat content and total solids ($P < 0.005$). The software MatInspector revealed that c.-226 G > C was located within several potential transcription factor binding sites, including transcription factor AP-2, and may alter gene expression, but further investigation will be required to elucidate the biological and practical relevance of these SNPs.

Key Words: milk production traits, SNP, Toll-like receptor 4

0349 A polymorphism within the *PAPPA2* gene is associated with postpartum fertility traits in Holstein dairy cattle located in southern Sonora Mexico. P. Luna-Nevarez*[1], J. C. Leyva-Corona[1], M. A. Sanchez-Castro[1], R. Zamorano-Algandar[1], J. F. Medrano[2], G. Rincon[3], R. M. Enns[4], S. E. Speidel[4], and M. G. Thomas[4], *[1]Instituto Tecnologico de Sonora, Ciudad Obregon Sonora, Mexico, [2]University of California, Davis, [3]Zoetis Inc., Kalamazoo, MI, [4]Department of Animal Sciences, Colorado State University, Fort Collins.*

Postpartum fertility in Holstein cattle is challenging for dairy production systems in southern Sonora Mexico as lactating cows need to get pregnant early in spring to avoid the negative impacts of summer heat stress. The GH-IGF1 signaling

pathway is known as important mediator of physiological mechanisms that regulate fertility in dairy cattle. The PAPPA2 gene is one component of this pathway, which codes for a protease responsible to increase IGF1 bioavailability for reproduction. The objective was to study the associative relationship between a SNP polymorphism in the *PAPPA2* gene (rs109952914-A/T within intron 10) with fertility traits such as first-service pregnancy (FSP), services per conception (SPC), and days open (DO) in postpartum Holstein cows. This SNP had a minor allele frequency of 18% and did not deviate from Hardy-Weinberg equilibrium (X^2 = 1.00, P > 0.42) in 676 Holstein cows. Reproductive records were collected from these cows that were located in three dairy herds in southern Sonora. A blood sample from each cow was spotted on FTA cards and used to genotype a 179 tag SNP panel within 45 genes in the GH-IGF1 pathway. The associative analyses among SNP genotypes and reproductive phenotypes were performed using a mixed effects model for categorical traits (i.e., FSP) and continuous traits (i.e., SPC and DO). The model included phenotype as the response variable, genotype and herd as fixed terms, sire as a random term, and days in milk as a covariate. Frequencies of FSP among genotypes AA, AT, and TT were 38.8 ± 2.6, 54.1 ± 1.9, and 66.7 ± 1.8%, respectively. Least square means among genotypes AA, AT, and TT were 2.3 ± 0.12, 2.0 ± 0.08, and 1.9 ± 0.06 services for SPC, and 159.8 ± 6.4, 153.9 ± 5.9, and 131.2 ± 3.9 d for DO, respectively. The most favorable allele from the SNP was the T allele (P < 0.001) as it increased FSP (12.6 ± 1.3%), and reduced SPC (−0.16 ± 0.05) and DO (−19.5 ± 5.6 d). In conclusion, a SNP within the *PAPPA2* gene appears to be a predictor of postpartum fertility, as it was positively associated to FSP, SPC and DO in postpartum dairy cows. These results provide evidence to propose the *PAPPA2* gene as candidate gene associated with fertility traits in postpartum Holstein cows and that it could be useful in DNA-based genetic selection tools.

Key Words: fertility, Holstein, *PAPPA2*, polymorphism.

0350 Using LD structure of several populations to optimize an SNP panel for conservation and selection. C. Díaz*[1], L. Varona[2], M. J. Carabaño[1], E. Nicolazzi[3], M. Bichard[4], J. Baro[5], A. Molina[6], J. Piedrafita[7], A. Rossoni[8], H. Schwarzenbacher[9], F. Seyfried[10], T. R. Solberg[11], D. Vicario[12], J. Altarriba[2], and K. J. Abraham[13], *[1]INIA, Madrid, Spain, [2]Universidad de Zaragoza, Spain, [3]Fondazione Parco Tecnologico Padano, Lodi, Italy, [4]English Guernsey Cattle Society, Launceston, UK, [5]Universidad de Valladolid, Palencia, Spain, [6]Universidad de Córdoba, Spain, [7]Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain, [8]ANARB, Italian Brown Cattle Breeders' Association, Bussolengo (VR), Italy, [9]ZuchtData EDV-Dienstleistungen GmbH, Vienna, Austria, [10]Qualitas AG, Zug, Switzerland, [11]Geno Breeding and A.I. Association, Hamar, Norway, [12]National Simmental Cattle Breeders Association, ANAPRI, Udine, Italy, [13]Estacio-Uniseb, Ribeirão Preto, Brazil.*

The success of conservation of genetic variability and/or prediction of breeding values by genomic selection is based on the existence of LD between SNP markers and the QTVs. The existing LD is the result of several driving forces acting in each population along their history. Commercial SNP panels have been designed based on the genomic information of a reduced number of breeds. Within the Gen2Farm project framework, communalities and singularities of LD of 12 breeds from 8 countries were used to improve the design of existing SNP panels to fulfill the conservations and/or breeding needs in a breed and/or multibreed context. We analyzed the genomic information provided by the Illumina's BovineHD Beadchip of a total of 1534 individuals from: Asturiana de los Valles (AST, N = 75), Avileña-Negra Ibérica (ANI, N = 72), Brown Swiss (BS, N = 418), Bruna del Pirineus (BP, N = 75), Fleckvieh (Fl,N = 317), Guersey (GUE, N = 28), Morucha (Mo, N = 75), Norwegian Red (NR, N = 100), Pirenaica (Pi, N = 72), Retinta (Re, N = 72), Rubia Gallega (RG, N = 72) and Simmental (Si, N = 158). After editing, 604,551 phased SNP markers per animal were available for the analysis. LD matrices were obtained for each breed-chromosome (348 in total). TagSNPs defined in terms of independency and representativeness, were obtained by a graphical clustering algorithm. After setting aside singletons in each chromosome-breed, a minimum set of TagSNPs along the genome was obtained by maximizing the distance between TagSNPs and minimizing the distance between TagSNPs (centers of clusters) and markers of the same LD block. This was so provided some threshold values obtained from the empirical distribution of the LD values. Communalities and connectivity as a measure of the ratio of the number of tight links present to the maximum number possible were calculated. Connectivity varied between 0.00018 and 0.0013 for the first chromosome in

AST and the chromosome 21 in RE, respectively. All breeds shared a total of 17,720 TagSNPs, with values ranging from 421 TagSNPs in chromosome 25 to 1130 in chromosome 19. Moreover, there was also a high number of private TagSNPs present only in one breed, ranging from 1225 in chromosome 21 to 5827 in chromosome 1. Finally singletons were incorporated to the set of identified TagSNPs. Singletons represented more than 50% of TagSNPs in most cases. However, as the LD between singletons and QTVs is unknown, the maintenance of singletons in the SNP array may be considered as a choice to prevent loosing information.

Key Words: linkage disequilibrium, tags, selection, multibreed

0351 Meiotic recombination differences in ruminant livestock species. K. M. Davenport* and B. M. Murdoch, *University of Idaho, Moscow.*

Homologous recombination or crossovers (CO) ensures proper chromosome segregation while contributing to genetic variation. It is clear from previous studies that at least one CO per chromosome arm is necessary to avoid mis-segregation. Furthermore, it has been well documented that the locations of CO are not random, with some genomic regions exhibiting preferences, called hotspots. Global meiotic recombination rates determined from offspring studies underestimates the total number of meiotic recombination events due to independent assortment. Despite the importance of meiotic recombination in the production of viable gametes and toward predicting or estimating genetic breeding values, we know very little about meiotic recombination rates in livestock species. In this study we have used a cytological approach to quantify the number of recombination events in male sheep and cattle. Characterizing recombination events using a cytological approach allows us to accurately identify all recombination events during meiosis without the need for a large number of offspring and independent of an accurate reference genome that does not exist. Testicular tissue samples were taken from mature rams and bulls, and spermatocytes were spread and fixed on slides. Immunofluorescent staining was used to identify the synaptonemal complexes (SYCP3) and CO events (MLH1) of pachytene stage prophase cells. The total number of CO per meiocyte was quantified for different livestock species. Interestingly, the average number of CO per meiocyte in sheep is approximately 20% higher than in cattle despite having a similar number of chromosome arms and genome size. More specifically, sheep have on average a greater number of recombination events per chromosome arm (~ 2.8 CO per arm) in comparison to cattle (~ 1.7 CO per arm). This research provides important information regarding differences in recombination rates in sheep and cattle spermatocytes, and has a direct impact on the genetic predictions in these species. Moreover, this research contributes valuable information toward a greater understanding of the factors that control meiotic recombination in different species to enhance reproduction, improve accuracy of genetic prediction, and advance selection strategies that support the sustainability of the livestock industry.

Key Words: meiosis, recombination, selection

0352 Genetics of heat stress in purebred and crossbred pigs from different states using BLUP or ssGBLUP. B. D. Fragomeni*[1], D. Lourenco[1], S. Tsuruta[1], K. A. Gray[2], Y. Huang[2], and I. Misztal[1], *[1]University of Georgia, Athens, [2]Smithfield Premium Genetics, Rose Hill.*

The objective of this study was to evaluate potential of regular and genomic selection to mitigate impacts of heat stress in swine populations. Phenotypes of body weight were available for purebred Duroc nucleus animals from farms in North Carolina (n = 151,336) and Texas (n = 55,897); and for commercial crossbred animals (Duroc x Landrace-Large White), hot carcass weight was available from North Carolina (n = 141,756) and Missouri (n = 86,435). Pedigree file combined the two populations and included 553,442 animals. Genotypic information was available for 8232 Duroc animals, for 60k SNP. Analyses were done with an animal model as either single- or two-trait model using phenotypes measured in different states as separate traits. Additionally, reaction norm models were fitted for one or two traits using heat load index as covariable. Heat load was calculated as temperature humidity index above 70 degrees (equivalent to 21°C and 100% relative humidity) and was averaged over 30 d before data collection. Variance components were estimated by AIREML and (genomic) estimated breeding values ((G)EBV) by BLUP or single-step GBLUP (ssGBLUP). Validation was assessed for 146 genotyped sires with progeny in last generation. Accuracy was calculated as correlation of (G)EBV from reduced data (all animals, except the last generation) and (G)EBV with complete data. Heritabilities for purebred animals were similar across states (varying from 0.23 to 0.26), and reaction norm models did not show evidence of heat stress effect. Genetic correlations between states and heat loads were always high (> 0.91). For crossbred animals, no difference in heritabilities were found in single- or two-trait analysis (from 0.17 to 0.18), and genetic correlations between states were moderate (0.43). In the reaction norm for crossbreds, heritabilities ranged from 0.15 to 0.30 and genetic correlation between heat loads were as low as 0.36. Accuracies with genomic information by ssGBLUP were on average 25% higher than by BLUP. Accuracies were higher in two-trait reaction norm models and at extreme heat load values. Impacts of seasonality are evident only for crossbred animals. Genomic information can help mitigating heat stress in swine by identifying superior sires more resistance to heat stress.

Key Words: genotype-by-environment interaction, heat stress, single-step GBLUP

0353 Genetic evaluation for heat tolerance in growing Angus cattle. H. L. Bradford[*1], B. D. Fragomeni[2], D. Lourenco[2], and I. Misztal[2], *[1]University of Georgia, Athens, [2]University of Georgia, Athens.*

The purpose was to investigate the existence of heat stress on preweaning growth in Angus cattle and to develop a genetic evaluation to improve heat tolerance. The American Angus Association provided weight data, and records from the southern United States (n = 82,669) were used because of the hot, humid summer months. Heat stress was measured using heat load, defined as the average degrees of temperature-humidity index greater than 24°C for 30 d before the weigh date. Forty-five percent of cattle experienced heat loads greater than 0. Heat load was used in a reaction norm to assess phenotypic plasticity, and the results were compared with a univariate analysis. For both models, random effects included direct genetic, maternal genetic, maternal permanent environment, and residual; and fixed effects included a linear age covariate, age of dam class, sex, herd, and year. Moderate differences in heat load resulted in strong direct genetic correlations (r > 0.80), but large heat load differences had weaker direct genetic correlations. The same pattern occurred for Spearman rank correlations for proven bulls (n = 1048) with r = 0.30 between no heat load and extreme heat load. Selection decisions should differ depending on heat load, and producers could benefit from environment-specific selection tools. As heat load increased, the maternal genetic effect remained consistent even though heat stress decreased milk production in dairy cows. To compensate for the expected reduction in dam milk production during heat stress, calves may have consumed creep feed or other forages to maintain growth. In addition to comparing results, accuracy was assessed by the ability to predict phenotypes for young animals. Predictivity did not improve when using the reaction norm (r = 0.31) instead of the univariate model (r = 0.30). Thus, the univariate analysis performed as well as the reaction norm and sufficiently evaluated genetic differences in growth despite heat stress. Additional research is needed on methods for assessing heat tolerance in national cattle evaluations. Researchers implemented heat load successfully in species raised in confinement including dairy and swine, but heat load was confounded with contemporary group, calving season, seasonal fluctuations in forage quality and quantity, and fescue toxicity for beef cattle. A more robust measure of heat load would aid in understanding the effect of heat stress on preweaning growth and creating selection tools for improving beef cattle heat tolerance.

Key Words: beef cattle, heat stress, weaning weight

0354 Angus cattle at high elevation: Comparison of models to estimate breeding values of yearling pulmonary arterial pressure. X. Zeng[*1], T. N. Holt[2], S. E. Speidel[1], R. M. Enns[1], and M. G. Thomas[1], *[1]Department of Animal Sciences, Colorado State University, Fort Collins, [2]College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins.*

As an indicator of pulmonary hypertension, pulmonary arterial pressure (PAP) is widely used in the selection of cattle to reduce the incidence of high altitude disease (HAD). In initial analyses of yearling PAP data, a violation of normal distribution of residuals (i.e., skewed right tail) was observed. To remedy, alterative expressions of yearling PAP were investigated in this study with a goal of determining the effect of alternative expressions on genetic evaluation outcomes. Yearling PAP records (42.46 ± 0.58mmHg) were collected from 5296 Angus cattle from 280 sires from Colorado State University Beef Improvement Center (2150m elevation). The alternative phenotypes included power-transformed (PT) PAP records, an ordinal three-category phenotype (CAT3), an ordinal two-category phenotype (CAT2) and the non-transformed PAP observations (RAW). The CAT3 observations were defined as low risk (PAP < 41mmHg), moderate risk (41mmHg ≤ PAP ≤ 49mmHg) and high risk (PAP > 49mmHg) for HAD. The CAT2 observations were constructed by combining low and moderate risk categories of CAT3. Univariate linear and threshold animal models were applied in analyses of RAW and PT; CAT3 and CAT2, respectively. The fixed effects for PAP phenotypes included sex, age of dam, date and age (covariate) of PAP measurement. All fixed effects were significantly (P < *0.05*) associated with each PAP phenotype. The estimated heritabilities were 0.24, 0.24, 0.26, and 0.31 for RAW, PT, CAT3 and CAT2, respectively. Sire EBV accuracies from univariate models of RAW, PT, CAT3 and CAT2 ranged from 0.03 to 0.67, 0.03 to 0.68, 0.01 to 0.65 and 0.01 to 0.58 with means of 0.31, 0.31, 0.28 and 0.21, respectively (pooled sd = 0.13). The Rank correlations between EBV from RAW and PT, CAT3 or CAT2 were 0.92, 0.84 and 0.77, respectively. The lowest Rank correlation (0.69) was identified between PT and CAT2, while Rank correlation of 0.91 was obtained between PT and CAT3. All phenotypes resulted in decreasing genetic trends. Results suggested similar heritability, accuracy and rank of animals based on EBV from RAW and PT, yet losses in EBV accuracy and some re-ranking of sires was observed in ordinal categorical phenotypes compared with continuous PAP scores. In conclusion, violation of normality had limited influences on the genetic evaluation of yearling PAP measurements. Ordinal categorical phenotypes can be alternative dependent variables in studying susceptibility of HAD, however, they would cause some re-ranking of sires relative

to non-transformed PAP scores.

Key Words: cattle, pulmonary arterial pressure, genetic evaluation

0355 The effect of heterosis on pulmonary arterial pressure on beef cattle. M. M. Culbertson[*1], M. G. Thomas[2], L. L. Leachman[3], R. M. Enns[2], and S. E. Speidel[2], *[1]Colorado State University, Department of Animal Sciences, Fort Collins, [2]Department of Animal Sciences, Colorado State University, Fort Collins, [3]Leachman Cattle of Colorado, Fort Collins.*

Pulmonary hypertension can develop due to hypoxia-induced pulmonary vascular remodeling leading to right ventricular hypertrophy and edema, a condition known as brisket or high altitude disease (HAD). Pulmonary arterial pressure (PAP) is used at high altitude regions (> 1500 m) as an indicator of an animal's susceptibility to pulmonary hypertension and HAD. Cattle located at altitudes greater than 1500 m with PAP measurements between 31 and 43 mm Hg are considered to have a low risk of developing HAD at most elevations. To date, there has been no reported research for the effects of heterosis on PAP and therefore, the objective of this study were to examine the effect of heterosis on PAP measurements. Classically, heterosis is most beneficial for survival and fertility related traits; therefore, we hypothesized that increased heterozygosity would decrease an animal's PAP phenotype. Data collected from 2009 to 2015, was obtained from a multibreed seedstock database with an average PAP measurement of 44.56 ± 11.58, and a minimum and maximum of 32 and 149 mm Hg. Data included PAP records (n = 2001), PAP testing date, yearling management code, date of birth, sex and breed. A mixed animal model was used to estimate the effect of heterosis on PAP with the model containing degree of outcross and PAP age as covariates; and contemporary group (i.e., combination of PAP date and yearling management code) and sex as categorical fixed effects. Animal was included as a random effect. A 3-generational pedigree consisting of 9353 animals was used to estimate genetic parameters for PAP (h^2 = 0.29 ± 0.07). Breed effects were included as covariates of breed percentages for Angus, Red Angus, Charolais, South Devon, Gelbvieh, Simmental and "Other" breeds. The effect of breed on PAP had a range of 8.75 mm Hg. The estimated regression coefficient for PAP on heterosis was −0.02 ± 1.31 mm Hg/percent outcross ($P < 0.155$). These results indicate that heterozygosity has no effect on PAP measurements, although other multibreed populations should be examined. As a result we would reject our hypothesis that an increase in heterosis would decrease PAP.

Key Words: pulmonary arterial pressure, heterosis, regression

0356 Genetic and phenotypic analysis of Israeli Holstein milk, fat, and protein production as determined by the Afilab real-time milk analyzer. J. I. Weller[*1] and E. Ezra[2], *[1]ARO, The Volcani Center, Bet Dagan, Israel, [2]Israel Cattle Breeders Association, Caesaria, Israel.*

Given the day-to-day variation in milk components, especially fat, the standard DHIA procedure of measuring milk components in just 1 milking per month, may not be very representative of total production. The combination of much more frequently, but less accurately analyzed milk components, may be more representative of a cow's longer-term milk composition. The AfiLab system (Afimilk, Kibbutz Afikim, Israel) is a real-time individual cow milk analyzer that uses near-infrared spectroscopy for on-line milk analysis. AfiLab records for milk production and fat and protein concentration collected from January 2014 through January 2016 from 47 large Kibbutz (communal) herds distributed throughout Israel with a total of 37,486 Israeli Holstein cows were compared with the same statistics derived from monthly test day records derived by Bentley and Foss milk analyzers at the central laboratory of the Israel Cattle Breeders Association (ICBA). The SD for first and second parity daily records scored by the ICBA and AfiLab system were very similar for all traits, except for fat percentage. The SD for complete lactation production were slightly lower for the AfiLab results for all traits, except protein production. The lactation means for all traits were quite similar by the two methods in both parities, except for fat production, which was higher for the ICBA records. This corresponds to the fat lactation curves, which show that the ICBA results were higher with low DIM, but nearly equal to the AfiLab results after 125 DIM. AfiLab overestimated protein percentage before 150 DIM, and underestimated protein percentage in the second half of the lactation. First parity heritabilities (see table) were higher for AfiLab lactations for all traits, except for protein percentage. For AfiLab records, coefficients of determination to predict future lactation production from truncated lactations were greatest and root mean squared errors were smallest if the mean production from the last 2 wk before the truncation date were used to estimate future production. AfiLab first parity partial lactations with < 150 DIM predicted future lactation more accurately than the corresponding ICBA partial lactations. With only 30 DIM, genetic correlations between predicated and actual lactations ranged from 0.73 to 0.79 for the 3 traits. Further study is required to compare results of individual cows on multiple lactations, and to determine the optimum interval between calibrations for AfiLab meters.

Key Words: dairy cattle breeding, genetic evaluation, milk analysis

0357 ADSA®-EAAP speaker exchange presentation: Genetic analysis of multivariate indices of detailed fatty acid profile determined by gas chromatography in bovine milk.

N. P. P. Macciotta*[1], M. Mele[2], A. Cecchinato[3], G. Conte[4], S. Schiavon[5], and G. Bittante[6], *[1]Dipartimento di Agraria, University of Sassari, Italy, [2]University of Pisa, Italy, [3]University of Padova, Legnaro PD, Italy, [4]Department of Agriculture, Food and Environment, Universitã di Pisa, Italy, [5]Department of Agronomy, Food, Natural resources, Animals and Environment (DAFNAE), University of Padova, Italy, [6]Department of Agronomy, Food, Natural Resources, Animals and Environment (DAFNAE), University of Padova, Italy.*

The genetic improvement of fatty acid (FA) composition is a crucial point for enhancing milk dietary and nutritive properties. However the development of an appropriate breeding goal for this trait is hampered by the large number of FA and the complex correlation pattern among them. Multivariate factor analysis (MFA) is able to derive synthetic variables that can describe efficiently a multivariate system with a complex covariance structure. This study was aimed at: (1) elucidating the structure of relationships between milk yield, composition and detailed FA composition by using the MFA, and (2) estimating genetic parameters for the new-derived synthetic variables. Individual milk samples were collected from 1158 Brown Swisscows and gas chromatography was used to obtain detailed milk FA compositions. MFA was performed on 53 variables (i.e., 47FA and 6 milk production and composition traits). A total of 12 factors were extracted, able to explain about the 75% of the total variance. Factor scores were then used as new phenotypes for estimating (co)variance components using a Bayesian linear animal model via Gibbs Sampling. The model accounted for the effect of days in milk, parity, herd and animal additive genetic effect. Factor scores exhibited a clear structure in term of relationship with the original variables and they were classified, from a biological point of view, as: 'de novo FA,' 'milk yield-branched FA,' 'biohydrogenation,' 'long chain FA,' 'short chain FA,' 'milk-fat-protein,' 'odd FA,' 'conjugated linoleic acid,' 'linoleic,' 'udder health,' and 'vaccelenic,' respectively. Marginal posterior means (SD) of heritabilitiesfor the aforementioned factor scores ranged from 0.048(0.02) for 'vaccelenic' to 0.310(0.09) for 'desaturation.' Moderate heritability estimates were observed for 'milk yield-branched FA' (0.214 ± 0.07), 'linoleic' (0.201 ± 0.08), 'biohydrogenation' (0.193 ± 0.08), and 'short chain FA' (0.157 ± 0.07), respectively. Results highlight the existence of important and exploitable genetic variation in these derived phenotypes. In particular factors strongly associated with variables related to mammary neo-synthesis and desaturation, may offer interesting perspectives for improving

milkfat nutritional properties by selective breeding.

Key Words: fatty acid profile, multivariate factor analysis, heritability

0358 Effectiveness of genomic prediction of boar taint components in Pietrain sired breeding populations. C. Große-Brinkhaus[*1], E. Heuß[1], J. Trautmann[2], D. Mörlein[2,3], K. Schellander[1], C. Looft[1], J. Dodenhoff[4], K. U. Götz[4], and E. Tholen[1], *[1]Institute of Animal Science, University of Bonn, Germany, [2]Department of Animal Science, University of Göttingen, Germany, [3]Isi GmbH & Co. KG, Rosdorf, Germany, [4]Bavarian State Research Centre for Agriculture, Institute of Animal Breeding, Poing, Germany.*

Systematic concern for animal welfare with regard to piglet castration without anesthesia is one challenge in European pig production. For instance, in 2013 the German Federal Council passed the law that non-anesthetized surgical castration will be prohibited by 2019. One alternative is the fattening of entire boars which is controversially discussed, because the risk of tainted meat has to be minimized. One possibility is to include selection for a low incidence of boar taint in breeding programs.

In this study, beside androstenone (And) and skatole (Ska), boar taint perception was recorded by a 10-member trained sensory panel (SENS) established by Mörlein and colleagues. Compiling data from four research projects, in total 4,000 records for And and Ska, and 1,016 records for SENS were available.

Genetic marker effects of 45,645 SNPs on And, Ska and SENS scores were estimated for 1,240 crossbred boars and 976 purebred Pietrain boars. These crosses and purebred boars reflect the heterogeneous population-structure of the Pietrain breed in Germany. Genomic BLUP was used to estimate genomic breeding values for animals in calibration and validation sets. Reliability of genomic prediction was assessed as correlation between genomic breeding value and conventional breeding values. Several scenarios were investigated to evaluate the effectiveness of genomic prediction.

Heritabilities for And, Ska and SENS were 0.64, 0.48 and 0.36, respectively. In a first scenario genomic prediction was evaluated using a five-fold cross validation within all crossbred animals and showed reliabilities ranging from 0.33 to 0.49. Based on a forward prediction, using crossbred boars as calibration set and Pietrain boars as validation set, reliabilities between 0.15 and 0.50 for all boar taint traits were observed.

Our analysis showed that genomic selection against boar taint is promising. It was possible to reach adequately high reliabilities, even in small populations.

The project is supported by funds of the Federal Ministry of Food and Agriculture (BMEL) based on a decision of the Parliament of the Federal Republic of Germany via the Federal Office for Agriculture and Food (BLE) under the innovation support program. Grant no.: 313–06.01–28–1-68.024–11.

Key Words: swine, boar taint, genomic selection

0359 Understanding the genetic archticture of Hays Converter Cattle. M. K. Abo-Ismail[*1,2], R. Khorshidi[1], E. C. Akanno[1], J. Crowley[1,3], S. P. Miller[4,5,6], A. Fleming[7], J. Basarab[1,8], C. Li[1,9], P. Stothard[1], and G. Plastow[1], *[1]Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]Animal and Poultry Production, Damanhour University, Egypt, [3]Canadian Beef Breeds Council, Calgary, AB, [4]AgResearch Limited, Mosgiel, New Zealand, [5]Centre for Genetic Improvement of Livestock, University of Guelph, ON, Canada, [6]University of Queensland, Centre for Animal Science, QAAFI, St. Lucia, Australia, [7]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [8]Lacombe Research Centre, Alberta Agriculture and Forestry, Lacombe, Canada, [9]Lacombe Research and Development Centre, Agriculture and Agri-Food Canada, Edmonton, AB, Canada.*

The Hays Converter (HC) was the first Canadian breed to be recognized in terms of the Canadian Livestock Pedigree Act and combines the genetics of the Hereford, Holstein and Brown Swiss breeds. Although, the improvement program has continued there is now a risk to its sustainability. The objective of this study is to utilize genomic tools to assess genetic diversity and inbreeding within the HC population. Historical samples for 265, 238, and 208 animals born between 1973 and 2015 have been genotyped for 19K (19,792 SNPs,), 6K (6829 SNPs) and Illumina BovineSNP50 (50K, 49,100 SNPs), respectively. A total of 49,100 SNPs across 29 autosomes that passed all quality control criteria were considered for imputation of the target populations with 19k (7496 SNPs) and with 6k (6253 SNPs) using FImpute. The actual and imputed genotypes were filtered for 702 animals and 41,734 SNPs across 29 autosomes passed quality control. Using only actual 50K genotypes of 208 animals, the genetic structure of the HC population was assessed in conjunction with individuals genotyped for Illumina BovineSNP50 from Angus (AN, $n = 486$), Hereford (HE, $n = 591$) and Holstein (HO, $n = 32$) breeds using principal component analysis (PCA). The genomic inbreeding coefficients for individuals within HC were estimated using pedigree information and 4 genomic methods. The genetic distances between animals within each population were calculated based on their genomic profile using Prevosti Distance. Although, the PCA indicated that the HC breed is genetically divergent from Holstein, Hereford and Angus, it was more closely related to Holstein cattle than the other breeds. Genomic inbreeding coefficients using imputed or actual genotypes indicated that the HC is inbred over years,

particularly from 1993 till 2005. Thus, this indicates a smaller effective population size for the HC population at that time. The result from genetic distance and phylogeny of the HC population indicated existence of sub populations within the HC. In conclusion, the study showed an increase of inbreeding within HC breeds so that managing inbreeding and maximizing diversity is required to avoid inbreeding depression. The observed diversity will influence HC design for future mate allocation using genomic information.

Key Words: genetic structure, Inbreeding, Illumina BovineSNP50 chip, Hays Converter beef cattle

0360 Genetic parameters and trends for length of productive life and lifetime production efficiency traits in Thai Landrace and Yorkshire sows.

U. Noppibool[1], M. A. Elzo*[1], S. Koonawootrittriron[2], and T. Suwanasopee[2], *[1]University of Florida, Gainesville, [2]Kasetsart University, Bangkok, Thailand.*

Data from a commercial swine population in Northern Thailand were used to estimate genetic parameters and trends for length of productive life (LPL), lifetime number of piglets born alive per year (LBAY), lifetime number of piglets weaned per year (LPWY), lifetime litter birth weight per year (LBWY), and lifetime litter weaning weight per year (LWWY). Phenotypic records were from 2259 Landrace and 826 Yorkshire sows that had their first farrowing between 1989 and 2013. An average information restricted maximum likelihood procedure was used to estimate variance and covariance components, heritabilities and correlations. The 5-trait animal model included first farrowing year-season, breed group, and age at first farrowing as fixed effects, and sow and residual as random effects. Heritability estimates were 0.17 ± 0.04 for LPL, 0.07 ± 0.03 for LBAY, 0.13 ± 0.03 for LPWY, 0.04 ± 0.02 for LBWY and 0.13 ± 0.03 for LWWY. Genetic correlations between LPL and all lifetime production efficiency traits (LBAY, LPWY, LBWY and LWWY) were all positive ranging from 0.66 ± 0.14 (LPL-LBAY) to 0.95 ± 0.02 (LPL-LBWY). Rank correlations between EBV for LPL and lifetime production efficiency traits were, on the average, higher for boars than for sows in the top 5% (0.51 vs. 0.19), 25% (0.68 vs. 0.42) and 50% (0.86 vs. 0.58). Sire genetic trends were negative for LPL (−2.41 ± 0.59 d/yr; $P < 0.001$) and LWWY (−0.14 ± 0.06 kg/yr; $P < 0.04$) and near zero for LBAY, LPWY, and LBWY. Conversely, dam genetic trends were positive for LPL (1.10 ± 0.39 d/yr; $P < 0.01$), LPWY (0.12 ± 0.01 piglets/yr; $P < 0.0001$), and LWWY (0.26 ± 0.04 kg/yr; $P < 0.0001$) and near zero for LBAY and LBWY. Sow genetic trends were near zero for all traits. Improvement for LPL and lifetime production efficiency traits in this commercial swine population will require these traits to be included in the selection indexes used to identify replacement boars and gilts.

Key Words: swine, length of productive life, lifetime production efficiency

0361 Estimation of genetic parameters on carcass traits and body type measurements in Hanwoo.

Y. S. Choi*[1], S. W. Kim[1], K. S. Kim[1], D. J. Yu[1], M. J. Ku[1], G. H. Lee[1], S. G. Park[1], and J. W. Lee[2], *[1]Livestock Research Institute, Jeollanamdo Agricultural Research & Extension Service (JARES), Jeollanamdo, Korea (The Republic of), [2]Chonnam National University, Gwangju, Korea (The Republic of).*

The objective of this study is to estimate genetic parameters on carcass traits and body type measurements in Hanwoo cows (Korean native cattle). The data for this study were obtained from local rearing farms in Jeonnam province, South Korea from 2003 to 2014. Two hundred seventy-seven head of reproductive cattle were measured for withers height, rump height, body length, chest depth, chest width, rump length, pelvic width, rump width, hipbone width, chest girth, and shank girth. Of the 277 head of cattle, 151 were randomly selected for investigation of carcass traits. Birth year, birth location, and sex were considered as fixed factors.

Genetic correlation coefficients of live weight with chest depth, chest width, rump width, and chest girth were 0.67, 1.00, 0.97, and 0.99, respectively. Genetic correlation coefficients of rump length with withers height, rump height, chest width, and pelvic width were 0.85, 0.92, 0.85, and 0.98, respectively.

Positive selection for chest girth, chest width, chest depth, and rump width resulted in increased live weight. Correlation coefficients of rump length with withers height and rump height were highly positive, which suggests that rump length and rump width are informative indicators for selection of body type measurements.

Heritabilities of body type measurement and carcass traits ranged from 0.19 to 0.83. Estimates of heritability on marbling score, body length, and rump height were 0.18, 0.19, and 0.24, respectively. Estimates of heritability on eye muscle area, shank girth, and withers height were 0.30, 0.36, and 0.48, respectively. Heritabilities of carcass weight, chest width, live weight, hipbone width, rump length, and chest depth were 0.51, 0.67, 0.68, 0.71, 0.76, and 0.77, respectively.

The genetic correlation between carcass weight and chest depth was a negative value of −0.98. The genetic correlation between carcass weight and chest width was 0.68. Genetic correlation coefficients of eye muscle area with rump length, chest depth, hipbone width, and shank girth were 0.67, 0.84, 0.66, and 0.94, respectively. Genetic correlation coefficients of marbling score with withers height, rump length, and hipbone width were −0.54, −0.74, and −0.83, respectively.

Improvement in both quality and quantity traits of Hanwoo cows is difficult due to the negative correlation between the two traits. To develop an optimal breeding scheme for Hanwoo cows, rearing farms need to establish breeding goals for Hanwoo cows individually and obtain informative data, including

pedigree information and reproductive records, from each cow.

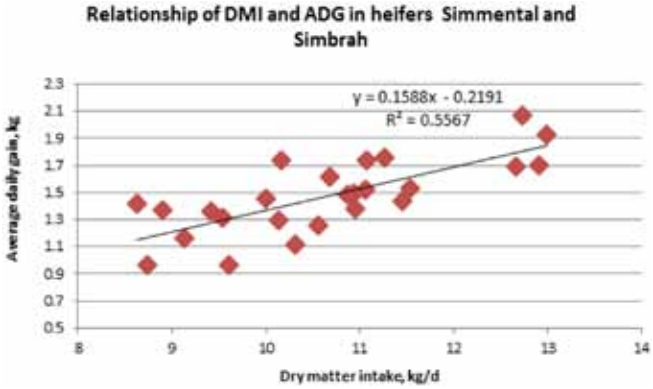
Key Words: Korean native cattle, genetic parameters, body measurement, genetic correlation

0362 Residual feed intake (RFI) for genetic selection of Simmental and Simbrah cattle. N. Manzanares-Miranda*[1], J. R. Kawas[2], H. Villalon-Mendoza[2], and G. Moreno-Degollado[2], *[1]Universidad Autonoma de Nuevo Leon, Posgrado Conjunto de las Facultades de Agronomia y Medicina Veterinaria y Zootecnia, San Nicolas de los Garza, Mexico, [2]Universidad Autonoma de Nuevo Leon, San Nicolas de los Garza, Mexico.*

Since two-thirds of the cost of cattle production is directly related to feed costs, strategies that improve the efficiency of feed utilization will increase the economic viability of livestock operations. An alternative measurement for feed efficiency is the residual feed intake (RFI). The objective of this study was to determine the possibility of using RFI as an indicator for genetic selection of males and females of Simmental and Simbrah cattle breeds. Thirty-one Simmental and 26 Simbrah, males (32) and females (25), were randomly assigned to a 2 × 2 factorial design (breeds and gender). Variables measured were dry matter intake (DMI), average daily gain (ADG) and RFI. There was no correlation between RFI, DMI and ADG. Individuals with negative RFI were detected in the test group among both breeds. ADG was greater ($P < 0.05$) for males (1.81 kg/d) than females (1.47 kg/d). A significant association ($P < 0.05$) between the different variables studied. No statistical differences in RFI were observed for breed ($p = 0.44$) or gender ($p = 0.52$). It was not possible to use RFI as an indicator for genetic selection for Simmental and Simbrah cattle.

Key Words: Simmental, Simbrah, residual feed intake

Table 0362.



0363 Multivariate analysis of reproductive and productive traits in Sindhi breed females (*Bos indicus*). R. R. C. Mello[1], L. D. P. Sinedino*[2], S. L. G. Sousa[1], and M. R. B. Mello[1], *[1]Federal Rural University of Rio de Janeiro, Seropedica, Brazil, [2]University of Florida, Gainesville.*

The aim of this study was to investigate the possibility to generate different productive groups in Sindhi breed through multivariate techniques, to give directions to genetic improvement programs in this breed. For this goal, performance data provided by the Brazilian Association of Zebu Breeders related to 560 Sindhi breed females from 28 different herds in Brazil, born in the period from 1987 to 2011, were used. The traits age at first calving, calving interval, reproductive efficiency, total milk yield and lactation period were analyzed, being submitted to the principal components and cluster analysis, with the GENES® statistical program. By the principal components analysis, these five components were estimated, and the first three explained 90.79% of the data's total variation. The traits considered most relevant to the discrimination of the data set, in decreasing order of importance, were: calving interval, lactation period, age at first calving, total milk yield, and reproductive efficiency. By cluster analysis, 12 different groups were generated from the pool of Sindhi herds analyzed, with a great homogeneity among females for the traits evaluated, and only few females generating separate groups. Four hundred twenty-nine females were clustered in one group, representing 76.60% of the genotypes. This indicates that, although there are genotypes with large genetic diversity, more than two thirds of the animals are similar to the traits evaluated, showing a high degree of relationship between them. The traits for total milk yield showed 71.92% of the total variation, and age at first calving contributed with 23.06% of the variation, being the two most important traits for the variability of the data. Thus, there is evidence of divergence between the groups regarding total milk yield, indicating that this trait stands out in the differentiation of groups, and these groups could be benchmarks for the use of genetic improvement programs whose focus is the increase in milk yield. In conclusion, the multivariate procedures were effective to summarize the evaluated information and to discriminate the most important traits, providing better identification of the most appropriate females to certain herds or milk production systems. The analysis of the relative contribution was effective in identifying total milk yield and age at first calving as the most relevant traits for the differentiation of groups, and they can be useful targets for genetic improvement programs that focus on milk yield and reproductive precocity.

Key Words: cluster analysis, reproductive efficiency, milk yield

0364 Repeatability of egg weight in Japanese quail. O. T. Abanikannda, O. N. Ottun*, and A. O. Leigh, *Lagos State University, Ojo-Lagos, Nigeria.*

Knowledge of genetic parameters is useful in designing efficient breeding systems, and accurate estimates of genetic parameters are essential for construction of applied breeding. Repeatability, the ability of individual animal to repeat its performance and maintain its ranking in a population in successive records is of immense benefit in predicting the expected rate of annual genetic gain in the trait. The objective of the study was to evaluate and assess changes in measurements of eggs by quail hens over a period of time and estimate its repeatability. The study was conducted at the Poultry Breeding Research Laboratory of the Lagos State University, Ojo-Lagos, lying at 06.48N and 003.20E in the humid tropics of Nigeria. The hens studied were brooded and raised from hatch to 6 wk before being separated and raised in individual compartments for ease of egg collection, identification and measurements. In all, 70 hens were studied over a period of 34 d, with each hen laying between 17 and 33 eggs during the study period. The eggs were picked as soon as it was laid and properly tagged to reflect the hen's identification and day of lay. Measurements taken include, hen weight (HenWt), feed consumed (FeedCon), egg weight (EggWt), egg length (EggLt) and egg width (EggWd). The statistical model describing each of the three (egg weight, egg length and egg width) variables studied is given as $Y_{ijklm} = D_i + H_j + C_k + F_l + e_{ijklm}$, where day of lay (D) and Hen (H) are fixed factors and HenWt (C) and FeedCon (F) are covariates to adjust for differences among hens, and it accounted for 62.67%, 49.40% and 71.94% of the total variation, respectively. With the exception of feed consumed which was not significant ($P > 0.05$) on any of the three responses and day of lay which was not significant ($P > 0.05$) on egg weight, all other factors/covariates were highly ($P < 0.01$) significant. Repeatability estimates for the three variables studied were estimated using the one way ANOVA of Hen effect on each of the three variables by $r = [(MS_b – MS_w)/n_0]/\{MS_w + [(MSb\text{-}MS_w)/n_0]\}$ and repeatability values obtained were 0.56, 0.15 and 0.12 respectively for egg weight, egg length and egg width. The repeatability estimate for egg weight, the most desirable trait in successful poultry business is moderate (0.56) and can be employed early in lay to select hens with potentials for bigger eggs.

Key Words: repeatability estimates, quail, Nigeria

365 Genetic parameters of cyclicity and other fertility indicators in dairy cattle. D. Gonzalez-Pena[*1], H. Jeong[2], P. J. Pinedo[3], J. E. P. Santos[4], G. M. Schuenemann[5], G. J. M. Rosa[6], R. O. Gilbert[7], R. C. Bicalho[7], R. Chebel[4], K. N. Galvão[8], C. M. Seabury[9], W. W. Thatcher[10], and S. L. Rodriguez Zas[2], *[1]Zoetis, Kalamazoo, MI, [2]University of Illinois, Urbana-Champaign, [3]Colorado State University, Fort Collins, [4]University of Florida, Gainesville, [5]Department of Veterinary Preventive Medicine, The Ohio State University, Columbus, [6]University of Wisconsin, Madison, [7]Cornell University, Ithaca, NY, [8]Department of Large Animal Clinical Sciences, University of Florida, Gainesville, [9]Texas A&M University, College Station, [10]Department of Animal Sciences, University of Florida, Gainesville.*

Resumption of ovarian cyclicity after calving is crucial to achieving reproductive efficiency in cattle. Early onset of ovulation after calving can decrease veterinary costs and calving interval while augmenting the length of lactation, total milk yield, and genetic improvement of the herd. Four fertility indicators are frequently used: probability of cycling at 45 d post-calving (Pr_Cyc), probability of disease diagnosis at 45 d post-calving (Pr_Sck), probability of pregnancy after 2 AIs (Pr_Prg), and days open (DO). The goal of this study was to identify significant covariables that affect these fertility indicators and to estimate their genetic parameters in dairy cattle. Measurements from approximately 5000 cows from 4 U.S. states (CA, FL, MN, TX) across two calving years were analyzed and relevant covariables were identified by stepwise selection. The three indicator probabilities were described using a logistic model including the explanatory variables: dystocia, retained placenta, stillbirth, body condition score at 7 d and 35 d post-calving (BCS7 and BCS35, respectively), score of vaginal mucous (0 = no mucus to 5 = brownish fetid discharge) at 7 d, 12 d, and 35 d post-calving, and blood β-hydroxybutyrate (BHBA), an indicator of subclinical ketosis. A univariate sire model including the effects of contemporary group and lactation number was used to estimate the genetic parameters of four fertility indicators: Pr_Cyc, Pr_Sck, Pr_Prg, and DO. The percentage of cows cycling, diagnosed with a disease, and pregnant after 2 AIs were 75.5%, 16.6%, and 62.5%, respectively. The marginal probabilities of the significant covariables indicated that Pr_Cyc was 4.8%, 1.5%, and 1.2% lower per unit increase in BHBA, and mucus score at 7 d and 35 d post-calving, respectively. Also, Pr_Cyc was 7.0% higher per unit increase in BCS35. Similarly, the Pr_Prg was 3.2% and 3.0% lower per unit increase in BHBA and mucus score at 35 d post-calving, respectively. The Pr_Sck increased 33.8% per unit increase in BHBA and 2.3% with stillbirth. The heritability estimates for Pr_Cyc, Pr_Sck, Pr_Prg, and DO were 0.12, 0.03, 0.07, and 0.06, respectively. Our findings

corroborate that early resumption of cyclicity postpartum is an important indicator of cow reproduction performance and has substantial genetic variability that can be exploited in selection practices. Improved accuracy of pregnancy predictions is maybe one of the potential benefits of including this indicator in fertility indices. These findings contribute to a long-term multistate project database (USDA-NIFA-AFRI-003542) for direct measures of fertility.

Key Words: reproduction, cattle, pregnancy

0366 Genetic parameters of early lactation diseases in dairy cattle. D. Gonzalez-Pena[*1], T. M. Goncalves[2], P. J. Pinedo[3], J. E. P. Santos[4], G. M. Schuenemann[5], G. J. M. Rosa[6], R. O. Gilbert[7], R. C. Bicalho[7], R. Chebel[4], K. N. Galvão[8], C. M. Seabury[9], W. W. Thatcher[10], and S. L. Rodriguez Zas[2], *[1]Zoetis, Kalamazoo, MI, [2]University of Illinois, Champaign-Urbana, [3]Colorado State University, Fort Collins, [4]University of Florida, Gainesville, [5]Department of Veterinary Preventive Medicine, The Ohio State University, Columbus, [6]University of Wisconsin, Madison, [7]Cornell University, Ithaca, NY, [8]Department of Large Animal Clinical Sciences, University of Florida, Gainesville, [9]Texas A&M University, College Station, [10]Department of Animal Sciences, University of Florida, Gainesville.*

Early lactation diseases impact herd profitability, compromise animal welfare, increase antibiotic use, and affect consumer preferences. Therefore, genetic improvement of disease resistance is becoming an increasingly important goal in dairy cattle breeding. The objectives of this study were to estimate the genetic parameters of major diseases and to identify variables that affect the incidence of these diseases. The probabilities of a cow to develop metritis (Pr_Met), clinical endometritis (Pr_End), ketosis (Pr_Sck), and clinical mastitis (Pr_Mas) were evaluated. Disease records from approximately 5000 cows across U.S. regions (West, Midwest, South, and Southwest) and two calving years were analyzed. Univariate logistic sire models including the effects of contemporary group and lactation number and additional covariates were used to estimate genetic parameters. Additional explanatory variables included: dystocia, retained placenta, stillbirth, body condition score at 7 d and 35 d post-calving (BCS7 and BCS35, respectively), vaginal mucous score at 7 d, 12 d, and 35 d post-calving (on scale of 0 = no mucus to 5 = brownish fetid discharge), and blood β-hydroxybutyrate (BHBA) as indicator of subclinical ketosis. Stepwise selection enabled the identification of the explanatory variables significantly associated with the probability of each disease. The percentage of cows with metritis, endometritis, ketosis, and mastitis were 28.8%, 22.4%, 16.6%, and 7.6%, respectively. Among the significant explanatory variables, Pr_Met increased 5.1% per unit increase in BHBA. Also, Pr_Met increased 35.9% and 7.6% in cows diagnosed with retained placenta and dystocia, respectively. On the other hand, Pr_Met decreased 6% per unit increase of BCS7. The heritability estimates (and standard errors) for Pr_Met, Pr_End, Pr_Sck, and Pr_Mas were 0.06 (0.01), 0.07 (0.02), 0.03 (0.02), and 0.02 (0.007), respectively. The association between explanatory variables and early postpartum disease probabilities and low heritability estimates identified in this study confirm that reliable prediction of disease incidence in dairy herds requires comprehensive accounting for health and management information. These findings contribute to a long-term multistate project database (USDA-NIFA-AFRI-003542) for direct measures of fertility.

Key Words: resistance, genetic parameters, indicators

0367 Genetic evaluation of mastitis, metritis, and ketosis in Holstein cattle using producer recorded data. G. C. Márquez*, Y. Zare, K. L. Stephan, and K. Olson, *ABS Global, DeForest, WI.*

The objective of this study was to develop a genetic evaluation of mastitis (MAST), metritis (MET), and ketosis (KET) from producer recorded data. The period from calving to 60 d postpartum is one of the most challenging times in a cow's lactation when up to 75% of diseases occur. Dairy producers routinely collect health data for management purposes, and these data are also valuable for genetic evaluation. Limited genetic evaluation of these traits exists. Data from on farm management systems was mined by finding keywords that would indicate that a cow had a case of one of the diseases. Only cases within the first 60 d of a cow's first lactation were used. A total of 3264,415, 2822,312, and 2035,174 observations from first lactation Holsteins coming from 776, 593, and 421 farms were used in the evaluations of MAST, MET, and KET, respectively. ASReml was used to fit a linear sire model with an eight-generation pedigree. For each trait a mean as well as herd-year-season of calving and age at first calving were fitted as fixed effects. The random genetic effect of sire was used for all traits. The mean first lactation disease incidence was 16%, 10%, and 3% for MAST, MET, and KET, respectively. The heritability of MAST, MET, and KET was 2%, 4%, and 3%, respectively. There was genetic variation between the best 10% and the worst 10% of sires by EBV. On average the disease incidences of the bottom 10% of sires was higher than the incidences of the top 10% of sires by 5%, 8%, 4% for MAST, MET, and KET, respectively. MAST, MET, and KET have a large economic impact on dairies, and selecting sires whose daughters have lower disease incidence is a cost effective way to make cumulative and permanent change in the population. Given the low heritability of these traits and the wide array of economically relevant traits in dairy, these should be incorporated into a selection index to achieve healthier transition cows.

Key Words: dairy cattle, genetic evaluation, transition period

0368 Genetic evaluation of dairy cow livability.

J. R. Wright* and P. M. VanRaden, *Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD.*

Predicted transmitting abilities (PTA) for cow livability (LIV) were developed to measure a cow's ability to stay alive while on the farm, whereas PTA for productive life (PL) measures a cow's ability to avoid dying on the farm or being culled. About 20% of dairy cows died instead of being sold over the last decade, averaging 7% per lactation. LIV has been recorded since 1970. Records for 69,710,392 lactations of 25,514,760 cows were evaluated with an all-breed animal model, using edits similar to a 2008 study. The scale reports cow livability instead of mortality so that positive PTAs are favorable (0 = died; 100 = lived for each lactation) and reports PTA on lifetime instead of per lactation basis to express LIV differences as a percentage of all cows exiting the herd. The model used individual lactation records for culling as a correlated trait to increase reliability of LIV. Heritability was 1.3% on the observed scale for LIV per lactation vs. 3.0% for overall culling per lactation. The SD of true transmitting ability for LIV was 0.82% per lactation or 2.3% per lifetime using an average of 2.8 lactations per cow. For recent bulls with > 80% reliability, PTA LIV were correlated favorably to PTA for PL (0.70), daughter pregnancy rate (0.45), and somatic cell score (−0.25); correlations with PTA for yield traits were low. The 0.70 correlation with PL was sufficiently below 1 to add value from selecting for both LIV and PL in an index. Genomic PTA (GPTA) for young bulls computed from 4-yr truncated LIV data had squared correlations with future data about twice as high as parent averages (PA) for LIV. Genomic reliability was 56% compared with 30% for PA, but lower than 70% for GPTA PL. Economic values for LIV and PL were estimated assuming $1,200 less income for cows that die than for those sold for beef. Relative emphasis on LIV was 7% of total emphasis, but relative emphasis on PL declined to 14% from 19% currently used in net merit. Thus, total emphasis on PL and LIV could increase to 21% using 2 correlated traits instead of 19% with just 1 trait. The United States in 1994 was the first country to evaluate longevity, and can also become the first country to evaluate cow mortality or livability as a specific economic trait.

Key Words: mortality, productive life, economic value

0369 Genetic associations between milk production and growth traits in Guzerat breed.

M. P. M. Gama*[1], H. T. Ventura[2], M. Alencar Pereira[3], L. El Faro[4], and C. C. P. Paz[5], *[1]Departamento de Genetica, FMRP-USP, Ribeirao Preto, Brazil, [2]Associação Brasileira de Criadores de Zebu, Uberaba, Brazil, [3]Associação Brasileira de Criadores de Zebu-ABCZ, Uberaba, Brazil, [4]SAA/APTA/Instituto de Zootecnia-Centro de Bovinos de Corte, Sertãozinho-SP, Brazil, [5]Universidade de São Paulo, Faculdade de Medicina de Ribeirao Preto-Departamento de Genetica (USP/FMRP), Ribeirao Preto-SP, Brazil.*

In Brazil, the Guzerat breed is used for beef, milk production or as dual purpose breed. Progeny tests of dairy bulls are available for the breed (Programa Nacional de Melhoramento Genético do Guzerá para Leite–National Breeding Program of Dairy Guzerat Cattle), in addition to genetic evaluations of growth traits performed by the Brazilian Association of Zebu Breeders (Associação Brasileira de Criadores de Zebu-ABCZ). For this reason, beef bulls are used in dual purpose herds. To identify differences in the growth and milk production patterns of bulls of this breed, two-trait analyses were performed between cumulative milk production at 305 d (P305) and weight at 120 d (W120), weaning weight (WW), yearling weight (YW), post-weaning weight (PWW), and weight at 24 mo of age (W24). The data files contained 97,394, 65,181, 50,443, 40,425, and 31,279 records, respectively, obtained from the database maintained by ABCZ. The model used included the fixed effects of contemporary group and age of cow at calving (linear and quadratic covariate), and direct additive genetic, permanent environmental (maternal for weights; direct for milk) and residual effects as random effects. The variance components were estimated by the restricted maximum likelihood method using the WOMBAT program. The heritabilities estimated in the two-trait analyses were 0.24 (0.003), 0.14 (0.009), 0.16 (0.0012), 0.18 (0.0014), 0.21 (0.0017) and 0.22 (0.020) for P305, W120, WW, YW, PWW and W24, respectively. The genetic correlations between weights at different ages and P305 were positive but low, ranging from 0.27 (0.111) to 0.38 (0.099), indicating a low association between the breeding values of the traits. Selection for P305 resulted in a low correlated response to increase weights at the ages studied. Based on the breeding values estimated, bulls with a high milk production potential and bulls with a high beef production potential were identified by cluster analysis. The separation of bulls for each selection objective will potentiate the result of genetic selection of the breed.

Key Words: production traits, selection criteria, dual purpose, genetic parameters, Zebu

0370 Production, reproduction, and health of Holstein, Jersey, and crossbred cattle in a seasonal calving pasture-based dairy.
K. A. E. Mullen* and S. P. Washburn, *North Carolina State University, Raleigh.*

Crossbreeding of dairy cattle has received increasing interest among researchers and farmers over the past several years. In a seasonal calving herd, crossbreeding could improve reproductive performance to ensure that more cows become pregnant during the relatively short breeding season. In the current study, we examined data from 14 yr of Holstein–Jersey crossbreeding in a seasonal calving, pasture-based dairy herd in Goldsboro, NC. Approximately 125 calves were produced each year, maintaining populations of pure Holsteins (HH, n = 286), pure Jerseys (JJ, n = 335), reciprocal F1 crosses (HJ, n = 182; JH, n = 233); F1 crosses were backcrossed to either H or J sires on alternate years, and crosses that were > 50% of one breed were always mated to the other breed (HX, n = 571; JX, n = 501). HJ, HX, JH, and HH cows had greater milk, fat, and protein yields per lactation than JX and JJ cows ($P <$ 0.05), whereas JJ and JX cows had greater fat and protein percentage in their milk than HH and HX cows. Milk production and fat percentage for the various breed crosses were 8042 ± 121 kg and 4.15 ± 0.06% for HH, 7828 ± 86 kg and 4.70 ± 0.04% for HX, 8063 ± 144 kg and 4.77 ± 0.07% for HJ, 7439 ± 124 kg and 4.85 ± 0.06% for JH, 6776 ± 94 kg and 4.91 ± 0.04% for JX, and 6180 ± 108 kg and 4.64 ± 0.05% for JJ. Crossbreds had some reproduction advantages, including younger age at first service, age at conception, fewer days to first service, and a greater percentage of cows pregnant during the breeding season. Holstein heifers were less likely than other breed groups to survive to 26 mo of age, but those that survived had reproductive success similar to Jerseys and crosses for subsequent lactations. HH were significantly more likely than JJ to have mastitis (16.4 ± 3.0% vs. 9.3 ± 1.9%, $P < 0.05$). Incidences of retained placenta, metritis, cystic ovaries, udder edema, lameness, milk fever, and the need for hormonal intervention for reproduction were no different among breed groups. Within a seasonal calving pasture-based system, Holstein-Jersey crossbred cattle have some production and reproduction advantages over their purebred contemporaries.

Key Words: dairy crossbreeding, pasture system, lifetime performance

0371 Between and within-lactation repeatabilities for hoof lesions in Canadian Holsteins.
F. Malchiodi[*1], A. M. Christen[2], D. F. Kelton[3], F. S. Schenkel[1], and F. Miglior[1,4], *[1]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [2]Valacta, Ste.-Anne-De-Bellevue, QC, Canada, [3]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Canada, [4]Canadian Dairy Network, Guelph, ON, Canada.*

This study aimed to estimate genetic parameters and between and within-lactation repeatabilities for hoof lesions, considering the hoof lesions as binary traits or as categorical traits, using a severity score. Hoof lesions were recorded by 23 hoof trimmers during the routine trimming activity in 365 herds located in Alberta, British Columbia, and Ontario from 2009 to 2012. The hoof trimmers were trained to use a rugged touchscreen computerized lesion recording system. The lesions included in the analysis were: digital dermatitis, interdigital dermatitis, interdigital hyperplasia, sole hemorrhage, sole ulcer, toe ulcer, and white line lesion. Hoof lesions were coded as binary traits (0; 1), where 1 was assigned to the presence of a lesion in any claw or leg or as categorical traits, using a severity score from 0 to 3, where 0 was assigned to the absence of a lesion, 1 to less severe lesions, 2 to moderately severe lesions, and 3 to more severe lesions. The edited dataset contained 107,933 observations from 53,654 animals. The final pedigree file contained 196,899 animals and included 7 past generations. Hoof lesions were analyzed with univariate animal models using the average information-restricted maximum likelihood procedure in the DMU package. Two different permanent environmental effects were included to separate between-lactation permanent environmental effects from within-lactation permanent environmental effects when multiple lactations per cow occurred. For most lesions, affected cows showed higher proportion of moderate severe cases. Sole hemorrhage and white line diseases had very similar proportion of less severe and moderate severe cases (45.8% and 41.1%; 43.4% and 40.7%, respectively). Most of the cows affected by interdigital dermatitis showed less severe lesions (75.6%), and only 1.2% of affected cows showed more severe cases of interdigital dermatitis. Heritabilities ranged from 0.005 (for toe ulcer) to 0.07 (for digital dermatitis). Heritabilities estimated considering the presence or absence of the lesion, or using a severity scale, were very similar. Repeatabilities were low to moderate, both between and within-lactation. However, they were 3- to 90-fold larger than the heritabilities. The most repeatable lesion was toe ulcer, which showed a within-lactation repeatability coefficient of 0.45, and a between-lactation repeatability coefficient of 0.36. Sole hemorrhage showed the lowest coefficients (0.10, for both within and between-lactation repeatabilities). Results suggested that all the repeated observations might be valuable

for increasing accuracy of estimated breeding values.

Key Words: hoof lesions, repeatability, severity

0372 Sexed-semen usage for Holstein AI in the United States. J. L. Hutchison*[1] and D. M. Bickhart[2], *[1]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [2]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD.*

The dairy industry has used sexed-semen to increase the number of heifer calves born on the farm for over a decade. While the efficacy of sexed-semen has been determined experimentally, we sought to tabulate statistics on the generalized use of the technology in the U.S. dairy herd and determine its effectiveness in the field. Sexed-semen breeding status was determined by a National Association of Animal Breeders' 500-series marketing code or by individual breeding information in a cow or heifer reproduction record from a dairy records processing center. Only breedings from 2007 through 2015 with confirmed outcomes (pregnant or not pregnant) were included: 5,963,876 heifer breedings (1,323,721 to sexed semen) and 42,232,502 cow breedings (253,586 to sexed semen). Sexed-semen breedings resulted in 87 and 89% female offspring, for cows and heifers, respectively. This was a notable improvement over conventional Artificial Insemination (AI), which results in 48% female births, on average. Usage of sexed-semen in heifers has increased from 9% in 2007 to 31% in 2015. Furthermore, mean conception rates for heifer sexed-semen breedings has recently increased due to improved technology (42% in 2007 compared with 49% in 2015). Comparable conception rates for heifer conventional breedings were 56, and 59% for 2007, and 2015, respectively. Smaller increases were seen in sexed-semen breedings to cows where 0.2% of all breedings used sexed semen in 2007, and 1% in 2015. Conception rates for sexed-semen breedings to cows were 26% in 2007, and 30% in 2015 compared with 30, and 32% for conventional breedings during the same years, respectively. Usage of sexed-semen for both heifers and cows has increased, with a bigger increase seen in heifers. Mean conception rates for sexed-semen breedings have also increased for both heifers and cows.

Key Words: sexed semen, conception rate, breeding

0373 Effect of semen type (cooled-fresh vs. frozen-thawed) on fertility of lactating dairy cows. A. H. Souza*[1], H. J. Bessoff[2], and E. Danzeisen[3], *[1]Ceva Animal Health, Libourne, France, [2]Dairy Management Solutions, Tulare, CA, [3]Global AG Alliance, Tulare, CA.*

The objective of this retrospective data analysis was to compare pregnancy per AI (P/AI) in dairy cows inseminated with cooled-fresh semen or frozen-thawed semen. Lactating Holstein cows from 11 confined dairies in CA were detected in estrus or synchronized with a Ovsynch-like timed AI protocol and received an AI with a single dose of either fresh (15 to 40 x 10^6 sptz/straw) or frozen semen (15 x 10^6 sptz/straw) once/day in the mornings. Both types of semen from multiple service-sires were used within all herds throughout a period of 10 mo (Jan 2015 to October 2015). Transcervical AI procedure was performed regularly with deposition of semen in the body of the uterus with the assistance of an AI applicator. Fresh semen was delivered to all farms on a daily basis and kept at 2° to 7°C until AI, which was performed within 24 h after fresh semen delivery to the farm. Pregnancy diagnosis was performed at 30 to 40 d post AI across all participating herds. The final database comprised 37,281 breeding records with confirmed AI outcomes (Fresh = 18,042 and Frozen 19,239). Statistical analysis was performed with the proc GLIMMIX of SAS (version 9.3), considering main effects and meaningful one-way interactions with service-sire and cow included in the model as random effects. At 30–40 d after AI, P/AI was greater for cows bred with fresh semen compared with frozen-thawed semen [Fresh = 36.6% (6603/18,042) vs. Frozen = 30.8% (5926/19,239); $P = 0.02$]. In addition, the amount of sperm cells in the fresh semen straw did not influence P/AI ($P > 0.10$). Interestingly, there were no significant interactions ($P > 0.10$) between type of semen (fresh vs. frozen) and month-of-AI, herd, cow parity, days in milk at AI, or even AI breeding-code (natural estrus vs. synchronization programs), suggesting that positive effects of fresh semen in relation to frozen semen was independent from the above mentioned variables. We conclude that the use of cooled-fresh semen improved P/AI in lactating dairy cows compared with the standard AI utilizing frozen-thawed semen.

Key Words: fresh semen, dairy cow, fertility

0374 Subclinical ketosis in the oocyte donors of Holstein × Gir cows. R. C. de Souza*[1], R. C. Souza[1], B. C. M. V. Reginaldo[1], G. C. M. V. da Silva[1], C. A. G. Pellegrino[2], M. I. V. Melo[1], J. P. Lustosa[1], and A. B. D. Pereira[3], *[1]Pontificia Universidade Catolica de Minas Gerais, Betim, Brazil, [2]Faculdade Alis de Bom Despacho, Brazil, [3]University of New Hampshire, Durham.*

In Brazil, the prevalence of subclinical ketosis in F1 *Holstein* × *Gir* oocyte donors has never been assessed in published literature. The aim of this study was to evaluate the prevalence of subclinical ketosis (SK) in F1 Holstein × Gir embryo donors and the effects of this syndrome on reproductive and economic efficiency. Data was collected from several farms in Minas Gerais, Brazil, from May to August 2015. Twenty-eight lactating F1 Holstein × Gir cows were used as oocyte donors. The dosage of ketone bodies was performed using the handset Ketovet (Ketovet Brazil, TaiDoc technology, Taiwan). Cows with blood β-hydroxybutyrate (BHBA) above 1.2 mmol/dL in

the blood were considered as with SK. Donor cows were aspirated for follicules, which were then taken to the laboratory and classified into viable, non-viable and irregular, according to the methodology recommended by the International Embryo Transfer Society (IETS, 2010). Economic analysis was performed considering the following: average price of one follicular aspiration ($75.00), in vitro production of one embryo ($17.75) and cost of each embryo transfer ($12.75). The experiment was analyzed as a complete randomized block design, and means were compared by the Tukey test with significance declared as $P < 0.05$. Results show that each cow produced an average of 20 oocytes, with only 6 oocytes converted into embryos with a final ratio of 3.5: 1 (oocytes:embryos). Two embryos were required to result in 1 pregnancy. Of the 28 donors evaluated, 17 were healthy and 11 had SK, resulting in a disease prevalence of 39.3%. Specifically, the prevalence of SK was higher in primiparous cows (71.4%) compared with multiparous cows (28.6%, $P < 0.05$). Cows with SK produced less total oocytes (11.5 vs. 26.1; $P = 0.014$); less non-viable oocytes (2.09 vs. 10.65; $P = 0.004$), less viable oocytes (6.45 vs. 15.41; $P = 0.005$) and fewer embryos (1.82 vs. 5.41; $P = 0.038$) when compared with healthy cows. The total cost of pregnancy in cows with SK was $142.41, whereas, for healthy cows, was $87.25. In summary, oocyte donors with SK were less efficient as embryo donors. High prevalence of SK observed in this study had a negative effect in the economic efficiency of embryo transfer, causing this technology to be 60% more costly when compared with the same technology used in healthy cows.

Key Words: subclinical ketosis, economic efficiency, embryo transfer

---

0375 Clinical signs associated with bovine respiratory disease diagnosis and high heritability in beef and dairy cattle.

J. N. Kiser*[1], C. M. Seabury[2], J. F. Taylor[3], J. E. Womack[2], R. Hagevoort[4], T. W. Lehenbauer[5], S. S. Aly[6], A. L. Van Eenennaam[7], and H. L. Neibergs[8], *[1]Department of Animal Science, Washington State University, Pullman, [2]Texas A&M University, College Station, [3]University of Missouri, Columbia, [4]New Mexico State University, Dairy Extension, Clovis, [5]University of California, Davis, [6]VMTRC, University of California, Tulare, [7]University of California, Davis, [8]Department of Animal Sciences, Washington State University, Pullman.*

Bovine respiratory disease (BRD) is an infectious multifactorial disease in cattle. To facilitate industry selection of cattle that are less susceptible to BRD, a uniform diagnosis of the disease that maximizes heritability (h^2) estimates, and is easy to measure is needed. Therefore, the objective of this study was to evaluate the effect of different clinical signs used to diagnose BRD on heritability estimates of BRD in dairy and beef cattle. This study was conducted on two pre-weaned dairy calf populations (California-CA, $n = 2000$; New Mexico-NM, $n = 798$) and two beef feedlot populations (Colorado-CO, $n = 1000$; Washington-WA, $n = 1000$). Cattle within each population were initially diagnosed with BRD using the McGuirk scoring system, which evaluates five clinical signs (CS): cough, temperature, nasal discharge and either eye discharge or ear droop (McGuirk, 2008). Heritability was calculated using EMMAX in each population for 15 different CS combinations, including the original combination used by the McGuirk scoring system. The CS that explained the most h^2 varied by population. In dairy cattle, the h^2 in the different CS combinations ranged from 0.12–0.24 for CA and 0.07–0.2 for NM and in beef cattle ranged from 0.04–0.24 in CO to 0.2–0.25 in WA. Identification of cattle using cough alone as the CS resulted in the highest h^2 estimates in CA ($h^2 = 0.23$) and CO ($h^2 = 0.22$), whereas eye or ear CS resulted in the highest h^2 estimates in NM ($h^2 = 0.17$) and WA ($h^2 = 0.19$). Two CS explained the most h^2 (mean $h^2 = 0.17$) across all populations: temperature, cough and nasal and the McGuirk scoring system. In each population, the CS explaining the least h^2 also differed (CA = nasal, NM = cough, CO = temperature, WA = nasal) although collectively, the nasal CS was ranked lowest (mean $h^2 = 0.14$). Multiple factors (age, pathogens and location) contributed to the differences in importance of CS between the different populations. These results determined that diagnosing BRD based on temperature, cough and nasal CS would facilitate a uniform diagnosis of BRD that could be used for development of breeding values to select beef and dairy cattle that are less susceptible to BRD. This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2011–68004–30367 from the USDA National Institute of Food and Agriculture.

Key Words: BRD, cattle, heritability

0376 Estimating enteric methane and carbon dioxide emission from lactating dairy cows using GreenFeed system.

D. Hailemariam*[1], G. Manafiazar[1], J. Basarab[1,2], F. Miglior[3,4], G. Plastow[1], and Z. Wang[1], *[1]Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]Lacombe Research Centre, Alberta Agriculture and Forestry, Lacombe, Canada, [3]Canadian Dairy Network, Guelph, ON, Canada, [4]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada.*

Enteric methane (CH_4) and carbon dioxide (CO_2) emissions from lactating dairy cows vary over time depending on various factors that include feed intake, feeding strategy, diet composition, and the time of day. GreenFeed system (C-Lock Inc., Rapid City, SD) is an on-farm "bait station" that captures the breath of cattle when they visit and quantitatively analyzes

the emitted gasses for CH_4 and CO_2 flux. The objective of this study was to determine the correlation between measurements of CH_4 and CO_2 at 2 selected time points of the day vs. 8 equally spaced time points over the 24 h in the diurnal cycle. A GreenFeed system was placed at the University of Alberta-Dairy Research and Technology Center in an open area and cows were moved from their stalls to the unit during measurement time. Individual average daily CH_4 and CO_2 emissions were estimated from lactating dairy cows (N = 29) varying from 32–76 average days in milk (DIM). Individual daily CH_4 and CO_2 emissions were estimated 2 times a day (09:00–12:00; 18:00–20:30 h) for 14 consecutive days and then emissions were measured on the same cows at 8 equally spaced time points (0200, 0500, 0800, 1100, 1400, 1700, 2000, and 2300 h) in the diurnal cycle within 2–3 d. The two time points during the day included the higher and the lower peaks in the diurnal pattern of CH_4 and CO_2 emissions. The number of visits during the 2 times a day and over 24 h measurement ranged from 11–31 and 2–8, respectively. Daily individual CH_4 and CO_2 emissions were estimated by averaging visit fluxes and extrapolating over a day. The result showed a strong correlation of dry matter intake (r = 0.73; P < 0.001), CH_4 g/d (r = 0.74; P < 0.001) and CO_2 g/d (r = 0.72; P < 0.001) production between 2 times vs. 8 time-point measurements. The Pearson correlation coefficient for CH_4 yield (g/kg of DMI) also showed moderate correlation (r = 0.41; P < 0.05) between the two measurements. Taken together, daily CH_4 and CO_2 emissions can be estimated with lower frequency of sampling per day as long as the minimum and maximum emission points in the diurnal cycle are included with an adequate number of visits.

Key Words: methane, carbon dioxide, GreenFeed

0377 Evaluation of factors affecting NaCl content the evolution in ewes milk and of its effect on technological properties.

J. Serdino, F. Correddu, M. G. Manca, A. Nudda, P. Urgeghe, and N. P. P. Macciotta*, *Dipartimento di Agraria, University of Sassari, Italy.*

The work was aimed at investigating factors affecting variation of NaCl content in sheep milk and at evaluating its relationships with (MCP) and cheese yield. A total of 2778 individual milk samples were collected from 607 Sarda dairy ewes farmed in 34 flocks. MCP (rennet coagulation time = RCT, curd firming time = k20, curd firmness = a30) were measured by Formagraph. Individual laboratory cheese yield (ILCY) were determined by micro-manufacturing experiments. NaCl content (mg NaCl/100 mL milk) was measured by MilkoScanTM. NaCl content was analyzed with a mixed linear model that included the fixed effects of parity, season of lambing, birth type, altitude, and the random effects of flock-test-date and of the animal. Moreover effects of NaCl on MCP were investigated with a similar model, that included also the fixed effect of NaCl class. Four classes were considered according to the 25th, 50th, 75th and 100th percentiles of the NaCl distribution: A = 57–113.3, B = 113.4–132.9, C = 133–157.8 and D = 157.9–259.6. The average content of NaCl was 137.55 ± 34.44 mg/100 mL, ranging from 57.60 to 259.60. NaCl content increased with days in milk, and it was lowest in secondiparous ewes compared with older parities. The season of lambing influenced NaCl concentration, which was higher in milk of ewes lambing in late winter and early spring (from February to April) compared with ewes lambed in early winter (October and November), with values for December and January being intermediate. Birth type at lambing and altitude of location of flocks did show significant effects on NaCl content. MCP were affected by NaCl concentration. In particular, RCT and k20 tended to increase moving from A to D NaCl classes, whereas a30 exhibited the opposite pattern. ILCY showed the highest value for in the class of the highest content of NaCl. Results of the present study highlight the influence of factors related to the physiological status of the animal on the NaCl variation. The results on milk coagulation properties found in this work seems to suggest a relationship between NaCl and cheese making attitude of sheep milk.

Key Words: NaCl, milk coagulation properties, sheep milk

0378 A survey on breeding strategies and selection objectives for increased feed efficiency and decreased methane emission.

C. Richardson*[1], F. Malchiodi[1], A. M. Wilson[1], A. M. Butty[1], C. Baes[1], A. Cánovas[1], M. P. Coffey[2], E. E. Connor[3], M. De Pauw[4], B. Gredler[5], E. Goddard[6], G. Hailu[7], V. R. Osborne[8], J. E. Pryce[9], M. Sargolzaei[1,10], F. S. Schenkel[1], P. Stothard[11], E. Wall[2], Z. Wang[11], T. Wright[12], and F. Miglioràt[1,13] *[1]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [2]SRUC, Edinburgh, UK, [3]USDA-ARS, Animal Genomics and Improvement Laboratory, Beltsville, MD, [4]University of Alberta, Edmonton, AB, Canada, [5]Qualitas AG, Zug, Switzerland, [6]Department of Resource Economics and Environmental Sociology, University of Alberta, Edmonton, Canada, [7]Department of Food, Agricultural and Resource Economics, University of Guelph, ON, Canada, [8]University of Guelph, ON, Canada, [9]Department of Economic Development, Jobs, Transport and Resources, Bundoora, Australia, [10]Semex Alliance, Guelph, ON, Canada, [11]Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [12]University of Guelph, OMAFRA, ON, Canada, [13]Canadian Dairy Network, Guelph, ON, Canada.*

The combined effects of world population growth, rising incomes and dietary changes have resulted in an increasing

international demand for dairy and meat products. However, livestock can have negative impacts on the environment and the greater awareness of climate change has placed pressure on the dairy industry to reduce its environmental impact. Enteric methane from cattle has been recognized as one of the major contributor to greenhouse gas emissions. In addition, methane resulting from digestive processes in ruminants represents important dietary energy losses. Therefore, reducing methane emissions (ME) will not only improve the environmental impact of livestock but also increase cows feed efficiency (FE). Collecting phenotypes for FE and ME is difficult and expensive. The increased use of genomic data in dairy cattle breeding programs has provided an opportunity to investigate the selection of more complex traits requiring fewer phenotypic observations. However, a sizeable genotyped and phenotyped reference population is required to accurately predict genomic breeding values. Combining international data sets will help to achieve the overall goal of producing genomic predictions for FE and ME to be used for breeding application in the dairy cattle industry. However, this could be quite challenging, as different traits that describe FA and Me have been proposed, and different methods are used for measuring the same trait. The International Committee for Animal Recording (ICAR) recently approved the creation of a Feed & Gas working group. This group aims to provide an overview of the current data available, to facilitate the standardization of recording dry matter intake and methane output in cattle around the world, and to enhance international collaboration by providing technical and methodological tools for data sharing and merging. A survey to collect information about current and future measurements of FA and ME has been developed. The survey will be sent to research centers and to industry organizations in member countries of ICAR and it contains some specific questions regarding the breeding strategies for these two novel traits. Results of the survey will allow assessment of a better understanding of the breeding strategies planned in different country once routine genomic evaluations will be available for the two novel traits.

Key Words: feed efficiency, methane emission, survey

0379 Genetic analysis of superovulation and embryo transfer traits in Holstein cattle. K. L. Parker Gaddis*[1], S. Dikmen[2], J. B. Cole[3], and P. J. Hansen[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]Uludag University, Faculty of Veterinary Medicine, Department of Animal Science, Bursa, Turkey, [3]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD.*

The objectives of this study were to estimate variance components and investigate genomic regions of interest associated with superovulation and embryo transfer in dairy cattle. Superovulation and embryo transfer are methods commonly used by dairy producers to increase the rate of genetic gain achievable from superior females. A limiting factor of these reproductive technologies remains the variability of animal response to treatment. If some of this variability is attributable to genetics, selection for traits related to superovulation and embryo transfer may allow for further improvement. Data were collected from a Holstein dairy operation in Florida from 2008 through 2015, including 926 superovulation records (total number of structures recovered, total number of good embryos), 628 in vitro fertilization records (number of ooctyes recovered, number of cleaved embryos, number of high- and low-quality embryos, number of transferred embryos), and 12,399 embryo transfer records (pregnancy success). Two transformations of count data were compared: Anscombe and logarithmic. Univariate repeatability animal models were fitted for each trait of interest, with the exception of pregnancy success, for which a threshold liability model was used. For traits where a significant genetic component was estimated (total structures collected and number of good embryos), single-step genomic BLUP analyses were conducted using AIREMLF90 (version 1.116). PostGSf90 (version 1.35) was used to calculate SNP effects and 10-SNP window variances. The two transformation methods produced very similar results. Significant genetic components were estimated for total number of structures recovered and number of good embryos in the superovulation dataset, with heritabilities of 0.31 ± 0.07 and 0.21 ± 0.06, respectively. Genetic components estimated from the in vitro fertilization dataset were not significantly different from zero. Heritability of recipient pregnancy success after embryo transfer was estimated to be 0.024 (SD = 0.01). The region explaining the largest proportion of variance for total structures collected in the superovulation data was located on chromosome 8, at 55,663,248 basepairs with additional peaks located on chromosomes 5, 13, 14, and 21. Similar regions were identified for total number of good embryos, with the largest proportion of variance explained by a region on chromosome 14 at 26,713,734 basepairs. Results indicate that these traits have a genetic component. Significant genomic regions can be further investigated for genes putatively associated with these traits.

Key Words: embryo transfer, genetic analysis, superovulation

0380 Genetic correlations of hoof lesions and trimming status with feet and leg conformation traits in Canadian Holsteins.

F. Malchiodi[*1], A. M. Christen[2], D. F. Kelton[3], F. S. Schenkel[1], and F. Miglior[1,4], *[1]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [2]Valacta, Ste.-Anne-De-Bellevue, QC, Canada, [3]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Canada, [4]Canadian Dairy Network, Guelph, ON, Canada.*

The objectives of this study were to estimate genetic correlations between hoof lesions and feet and legs conformation traits and to evaluate the association between those latter traits and the pre-selection process that leads a cow to be presented or not to the hoof trimmer. Hoof lesions were recorded by 23 hoof trimmers in 365 Canadian herds from 2009 to 2012. Hoof lesions included in the analysis were digital dermatitis, interdigital dermatitis, interdigital hyperplasia, sole hemorrhage, sole ulcer, toe ulcer, and white line lesion. Hoof lesions recorded during the first parity and hoof lesions recorded in second or later parities were considered as different traits. Conformation traits considered were bone quality (BQ), foot angle (FA), heel depth, rear leg side view, rear leg rear view (RLRV), locomotion (LOC) and the overall score for feet and legs (FL). In total, 37,158 cows that had a trim record in first and/or later parities also had conformation traits records. A second series of analyses considered all cows that were in a given herd during the trimming period, including cows that did not have any hoof data during the lactation. An additional trait, the trimming status, was defined as follows; a value of 1 was assigned to cows that had been visited at least once by the trimmer during the lactation, and a value of 0 to cows that did not have a hoof trim recorded during the lactation but were in the herd during the trimming session. Approximately 30% of cows were not presented to the trimmers during the lactation. Digital dermatitis, interdigital dermatitis and interdigital hyperplasia detected in first and later parities were negatively correlated to RLRV, FL, and LOC, with genetic correlations ranging from -0.24 ± 0.11 to -0.62 ± 0.15. With the exception of white line lesions, all of the horn lesions recorded in parities ≥ 2 showed moderate positive correlations with FA (from 0.29 ± 0.12 to 0.55 ± 0.20). White line lesions detected in parity 1 showed moderate genetic correlation with RLRV (0.65 ± 0.19), FL (0.53 ± 0.18), and LOC (0.44 ± 0.21), and those detected in parities ≥ 2 were correlated to BQ (-0.27 ± 0.10) and LOC (0.37 ± 0.16). The trimming status had moderate negative correlations with LOC and FL, suggesting that the pre-selection process for which cows are presented to the hoof trimmer is not random, but rather is associated with mobility and the conformation of the cow.

Key Words: hoof lesions, conformation traits, trimming status

0381 Genetic parameters for number of embryos produced by superovulated donors as heifers or cows using an in vivo or in vitro technique.

C. Jaton[*1,2], A. Koeck[1], M. Sargolzaei[1,2], C. A. Price[3], C. Baes[1], F. S. Schenkel[1], and F. Miglior[1,4], *[1]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [2]Semex Alliance, Guelph, ON, Canada, [3]Faculté de Médecine Vétérinaire, Université de Montreal, St.-Hyacinthe, QC, Canada, [4]Canadian Dairy Network, Guelph, ON, Canada.*

Genetic gain in a population can be improved by using multiple ovulation and embryo transfer (MOET) in elite females. Multiple embryos can be produced using two different techniques, either using superovulation and producing the embryos in vivo or using ovum pickup (OPU) and in vitro production (IVP) of the embryos. Moreover, embryos can be produced by donor cows or virgin heifers as young as 7 mo of age. The objectives of this study were to assess the genetic parameters for the number of embryos produced by Holstein donors superovulated either in vivo or in vitro and for the number of embryos produced by donors either as a cow or a heifer at embryo recovery. Data was provided by Holstein Canada and contained the number of viable embryos from every successful flushing performed across Canada. After editing, 137,446 records of superovulation performed on 54,463 donors between 1992 and 2014 provided information about the type of technique used, and 130,252 records from 51,323 donors provided information about the status of the donor (heifer or cow) at embryo recovery. Bivariate repeatability animal model analyses were performed. Heritability estimates for the donor were between 0.135 (0.007) and 0.155 (0.038), whereas estimates for the service sire were close to zero (from 0.004 ± 0.002 to 0.019 ± 0.010), indicating that the number of embryos produced is influenced by the genetic potential of the donor and not by the service sire. Moreover, moderate repeatability estimates indicated that the number of embryos produced should be somewhat consistent within a donor. Genetic correlations found for the number of embryos produced using either type of technique was strong (0.834 ± 0.094) for the donor, but not significant for the service sire (-0.202 ± 0.234). For the number of embryos produced by either a heifer or a cow, the genetic correlations were 0.702 (0.058) for the donor and 0.699 (0.206) for the service sire. Overall, our results suggest that the number of embryos produced by a superovulated donor should be similar regardless of the technique (in vivo or in vitro) used or the status (heifer or cow) of a donor at embryo recovery. On the other hand, using the same service sire will not increase similarity between the two techniques, but could influence the number of embryos produced by a donor as a heifer or as a cow in a similar way.

Key Words: superovulation, Holstein, genetic parameter

0382 Estimation of genetic progress and profitability of dairy herds using varying proportions of in-vitro produced sexed embryos. K. Kaniyamattam[1], J. Block[2], P. J. Hansen[1], and A. De Vries[*1], [1]*Department of Animal Sciences, University of Florida, Gainesville,* [2]*OvaTech LLC, Gainesville, FL.*

The objective of the study was to estimate the genetic and economic performance of a dairy herd in which varying proportions of animals were impregnated with in-vitro produced sexed embryos (IVP-ET) obtained from the genetically best heifers. A daily dynamic stochastic model that includes the 12 genetic traits in the lifetime Net Merit index (NM$) was used. Phenotypic performance depended on genetic values. A herd of 1000 milking dairy cows, heifers and embryos were simulated over time. Genetic progress came from selecting superior donors and external sires. Eleven scenarios were evaluated, from 0% IVP-ET conceptions to 100% IVP-ET conceptions, with increments of 10% points. Each scenario was run 20 times. Animals with the greatest Estimated Breeding Value (EBV) for NM$ were selected as donors. Recipients were selected from heifers first, and from cows with the greatest EBV for fertility traits second. Sexed semen was used on the genetically better heifers for 2 inseminations. All other non-recipients were inseminated with conventional semen. To maintain a 33% annual cow cull rate, surplus heifer calves were sold based on the lowest EBV of NM$ and received a premium price based on their EBV of NM$. Results were measured by the true breeding values (TBV) of NM$ of all cows and profit per cow per year in yr 15 after the start of the IVP-ET program, and cumulative profit in the 15 yr after the start of the program. The mean ± SE of TBV of NM$ of all cows was $608 ± 7 greater for 100% IVP-ET compared with 0% IVP-ET in yr 15. The maximum increase in profit per cow per year (and optimum IVP-ET program) in yr 15 when embryo costs were $120 and $160 was $125 (100% IVP-ET) and $75 (42% IVP-ET), respectively, compared with a 0% IVP-ET program. Because return on investment in an IVP-ET program is not immediate, the 15-yr cumulative discounted profits per cow in comparison with the 0% IVP-ET program at embryo costs of $80, $120, and $160 were obtained at 72% IVP-ET, 21% IVP-ET, and 0% IVP-ET, respectively. The optimal proportions of IVP-ET depended greatly on the costs of embryos and the sale price of surplus calves. In conclusion, the use of IVP-ET at current prices was profitable but the optimal amount of IVP-ET was sensitive to realistic variations in prices of embryos and surplus heifer calves.

Key Words: in-vitro production, embryo, profit

0383 Single-step genomic prediction accuracies for lactation and reproduction traits in Yorkshire sows. D. M. Thekkoot[*1], R. A. Kemp[2], N. J. Boddicker[2], and G. Plastow[3], [1]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada,* [2]*Genesus Inc., Lethbridge, AB, Canada,* [3]*Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Most economically important traits associated with lactation and reproduction in pigs are either less heritable, sex-limited, expressed later in life, or difficult to measure on a routine basis. Genomic predictions using single-step BLUP (SSBLUP) methodologies, which utilizes information on phenotypes, pedigree and markers from genotyped and non-genotyped animals simultaneously, is an alternative to phenotype and pedigree based (BLUP) methods. The objective of this study was to estimate and compare prediction accuracies for lactation and reproduction traits using SSBLUP and BLUP methods. Data from 2481 litters from 1431 Yorkshire sows farrowed between August 2011 and August 2015 were used in this study. Of these 1161 sows were genotyped using Illumina's Porcine SNP60 Bead Chip. The sows were weighed and scanned for back fat and loin depth before farrowing and at weaning. Piglets were weighed at birth, weaning and death. Feed consumption of each sow during lactation was measured using the Gestal feed recording system. Reproductive traits studied were total number born, number born dead, number alive at 24 h and number weaned. Lactation traits analyzed were average daily feed intake of sow during lactation, sow body weight, back fat and loin depth at farrowing, body weight, back fat and loin depth loss during lactation, and litter weight gain from birth to weaning. The training data included sows born before April 1, 2013, and validation data included sows (n = 242) born on or after April first 2013. BLUP breeding values for animals in the validation data were computed using all information from the test data plus pedigree information for animals in the validation data. Both SSBLUP and BLUP evaluations were computed using MiX99 software. Accuracies for animals in the validation data were estimated as the correlation between their estimated breeding values and phenotypes, corrected for fixed effects, divided by the square root of heritability of the trait. For all traits studied, prediction accuracies using SSBLUP were higher (0.23 to 0.84) than those from BLUP (0.18 to 0.72). On average the SSBLUP accuracies were 39% and 33% higher, respectively for reproductive and lactation traits. The results indicate that the SSBLUP methodology produces more accurate estimated breeding values for lactation and reproduction traits in pigs.

Key Words: single-step genomic prediction, pig, reproduction, lactation

0384 WS Influence of first calving date on stayability in *Bos indicus* crossbred cows. B. N. Engle*, C. A. Gill, J. O. Sanders, D. G. Riley, J. E. Sawyer, and A. D. Herring, *Department of Animal Science, Texas A&M University, College Station.*

Longevity is one of the most important, complex, and difficult to improve traits sought by cow-calf producers. Consequently, a measurement or tool that could be utilized early in a cow's life to predict her future reproductive performance would be advantageous to producers and researchers alike. In this study, we sought to determine the effect of first calving season period on stayability in Nellore-crossbred females through 5 yr, 6 yr, and 7 yr of age. Stayability through each age was scored as a binary trait, with 1 indicating the cow remained in the herd and 0 indicating she was culled, given either a perfect calving or weaning record. Each female was assigned a value of 1, 2, 3, or 4 corresponding to the respective 21-d period of her first calving season (for first, second, or third 21-d period, or > 63 d, respectively). Cow stayability models were evaluated through mixed model procedures (PROC MIXED in SAS). Of the cows with perfect calving records, more ($P < 0.05$) females that calved in the first 21-d period remained in the herd than those that calved in the second 21-d period through 5 yr (66.9% vs. 53.6%), 6 yr (60.0% vs. 45.9%), and 7 yr of age (56.7% vs. 39.3%). They also differed ($P < 0.005$) from females whose first calf was born 63 d or later into the calving season through ages 5 (66.9% vs. 36.0%), 6 (60.0% vs. 29.5%), and 7 (56.7% vs. 27.2%). Of the cows with a perfect weaning record, more ($P < 0.05$) of the females that calved in the first 21-d period of the calving season remained in the herd through 5 yr (56.1% vs. 31.0%) and 6 yr of age (48.3% vs. 26.0%) than heifers whose calf was born at the end of the calving season. These results document that regardless of the culling criteria, *Bos indicus* crossbred heifers that calve early in their first calving season are more likely to maintain a perfect calving or weaning record later in life than females that calve late in the first calving season. Consequently, there is potential that the heifer's first calving season period may be used as valuation or culling criteria when selecting for stayability and longevity, or when merchandizing beef replacements.

Key Words: beef cows, calving season, stayability

0385 Use of a threshold animal model to estimate calving ease and stillbirth (co)variance components for U.S. Holsteins. J. B. Cole*[1], D. J. Null[1], and S. Tsuruta[2], [1]*Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD,* [2]*University of Georgia, Athens.*

(Co)variance components for calving ease and stillbirth in U.S. Holsteins were estimated using a single-trait threshold animal model and two different sets of data edits. Six sets of approximately 250,000 records each were created by randomly selecting herd codes without replacement from the data used for the December 2015 national evaluations, and from a second extract using more stringent edits than the official run. The stricter edits required that records have a valid dam ID in addition to a known sire, cows have corresponding lactation records, and animals have a breed composition of at least 93.75% of the breed of evaluation. Calving ease was recorded on a five-point scale ranging from no assistance needed (most common) to extreme difficulty (least common). Stillbirth was coded as a binomial trait indicating whether or not the calf was alive 48 h postpartum. Gibbs sampling was used to estimate (co)variance components from each sample; 100,000 samples were drawn, the first 10,000 rounds were discarded as burn-in, and every fifth sample was retained. The model included fixed parity (1 through 5) and sex-of-calf effects, and random herd-year-season, animal (direct), maternal, maternal permanent environment, and residual error effects. (Co)variance components and heritabilities were averaged over the six replicates of each scenario for each trait and are shown (with standard errors). Direct animal effects in the animal model are comparable to sire calving ease and sire stillbirth in the sire-maternal grandsire (S-MGS) model, and heritabilities were similar for the S-MGS and animal models. Maternal heritabilties were slightly lower in the animal model. Heritability estimates were very similar between scenarios within traits, although maternal heritabilities were slightly higher using the new edits. These differences may be due in part to larger estimates of direct-maternal covariances than reported in previous studies, as well as stricter requirements for known parent IDs in the new edits. The implementation of an animal model for calving traits will provide direct estimates of genetic merit for all animals, not only males, and the adoption of stricter

Table 0385.

	Calving Ease		Stillbirth	
Component of variance	Official	New edits	Official	New edits
Herd-year-season	0.6312 (0.07)	0.7294 (0.14)	0.1064 (0.007)	0.0873 (0.005)
Direct genetic	0.2679 (0.02)	0.3233 (0.07)	0.0546 (0.002)	0.0370 (0.004)
Maternal genetic	0.0997 (0.02)	0.1118 (0.02)	0.0467 (0.002)	0.0572 (0.006)
Direct-maternal covariance	0.0387 (0.02)	0.0489 (0.04)	0.0083 (0.002)	0.0164 (0.002)
Maternal permanent environment	0.1604 (0.02)	0.2364 (0.06)	0.0731 (0.003)	0.0373 (0.007)
Residual	1.8558 (0.21)	2.0667 (0.32)	1.0000 (0.000)	1.0000 (0.000)
Direct heritability	0.09 (0.01)	0.09 (0.02)	0.03 (0.002)	0.03 (0.003)
Maternal heritability	0.03 (0.01)	0.04 (0.01)	0.04 (0.001)	0.05 (0.005)

edits will improve data quality without having large effects on the (co)variances used in the evaluation. It also is anticipated that such a change will increase correlations of U.S. evaluations with other Interbull participants for calving traits.

Key Words: animal model, calving traits, (co)variance components

0386 Genetic parameters for production traits and heifer pregnancy in Red Angus cattle.

R. J. Boldt*[1], S. E. Speidel[2], M. G. Thomas[2], L. Keenan[3], and R. M. Enns[2],[1]*Department of Animal Sciences, Colorado State University, Fort Collins,* [2]*Department of Animal Sciences, Colorado State University, Fort Collins,* [3]*Red Angus Association of America, Denton, TX*

Heifer pregnancy (HPG) is a prediction of the probability that a female will conceive during her first breeding season, typically at a year of age. An inherent issue in the genetic prediction of HPG is that phenotypes can only be collected on females, which limits the amount of information available. To overcome this, inclusion of correlated traits that can be recorded on both sexes, or fertility traits recorded on males could be used to improve accuracy of HPG predictions. Therefore, the objective of this study was to estimate genetic parameters for HPG, 205-d weight (WW), 160-d post weaning gain (PWG), 365-d weight (YW), and scrotal circumference (SC). The project included records on 142,146 animals from the Red Angus Association of America. (Co)Variance parameters were estimated using multiple, two trait animal models and a REML procedure. Heritability and genetic correlations between HPG and production traits were then calculated. Contemporary group was included as a fixed effect for all analyses, additionally, sex and age of dam were included for BW, WW, PWG, and YW analyses, and the linear effect of age was fit for HPG. The random effect of animal was used to estimate additive genetic effects for all analyses, the random effect of dam was fit for the WW and YW analyses to estimate maternal effects, and a random, maternal permanent environment effect was included for WW. Heritability estimates were 0.58 ± 0.01, 0.27 ± 0.01, 0.22 ± 0.01, 0.29 ± 0.01, 0.45 ± 0.02, and 0.12 for BW, WW, PWG, YW, SC, and HPG (averaged across all analyses on the underlying scale), respectively. Genetic correlations between HPG and BW (−0.06 ± 0.05), SC (−0.08 ± 0.09), WW maternal (−0.02 ± 0.09), PWG (0.06 ± 0.07), YW maternal (0.00 ± 0.11), had confidence intervals that included or were near zero, suggesting minimal genetic relationship between the traits. Correlations were highest between HPG and WW direct (0.29 ± 0.08) and YW direct (0.21 ± 0.07). These results suggest that Red Angus females with high genetic potential for weight at 205 d and 365 d have an increased probability of becoming pregnant during their first breeding season. Additionally, the traits WW or YW could be used to help improve accuracy of HPG genetic predictions.

Key Words: beef cattle, genetic correlation, growth, heifer pregnancy

0387 Daily rumination time in Italian Holstein cows: Heritability and correlation with milk production.

R. Moretti*[1], R. Bozzi[1], C. Maltecca[2], F. Tiezzi[2], S. Chessa[3], D. Bar[4], and S. Biffani[3], [1]*University of Florence, Italy,* [2]*North Carolina State University, Raleigh,* [3]*Institute of Agricultural Biology & Biotechnology-CNR, Lodi, Italy,* [4]*SCR Europe, Gariga di Podenzano, Italy.*

The aim of the study was to investigate the genetic variation of daily rumination time (min) and its correlation with test-day milk production (kg). Data for the analysis consisted of 91,589 records for rumination time and milk yield from 398 cows (age: 43.21 ± 16.11 mo), collected from September 2014 to October 2015 in two Italian Holstein herds (TAD and MIL). There were 493 calvings, and data distribution across parities was 46.4%, 26.7% and 26.7% for first, second and later parities, respectively. DIM classes were defined as one class for every 30 d, resulting in 11 classes, and there were a total of 378 herd-test-day contemporary groups. The average rumination time was 513.51 ± 115.84 min, and the average milk yield was 33.59 ± 9.18 kg.

Pedigree information was available for 11,634 animals. A Repeatability Animal Model was fitted using the AIREMLF90 software. Herd, yr/mo of calving, and DIM classes within parity were treated as fixed effects, while herd-test-day, permanent environmental, and the additive genetic cow effects were treated as random. Rumination time was longer in pluriparous than in primiparous cows and showed a decreasing trend across DIM. On average, at the beginning of the lactation, pluriparous cows ruminated 75 min longer than primiparous. As expected, pluriparous cows had a higher production levels across DIM than primiparous, with a peak around DIM class 2 and 3 (i.e., 60–90 d). The herd with the highest daily rumination time had the lowest milk production yield: the fixed effects solutions were 569.5 min and 25.8 kg (Herd TAD; rumination time and milk yield, respectively) and 446.4 min and 31.9 kg (Herd MIL; rumination time and milk yield, respectively). The heritabilities for test-day milk yield and daily rumination time were 0.13 (SE = 0.06) and 0.32 (SE = 0.09), respectively. Although the negative phenotypic correlation observed, genetic correlation between the two traits was 0.38 (SE = 0.47); this high standard error is possibly the consequence of the dataset dimension. So far, rumination time has been used as a key monitor of dairy cow health at farm level. Investigating its genetics aspect and the relationship with other important yields and health traits may turn this management tool in a new informative selection criterion for

the dairy cattle breeding strategies.

Key Words: rumination time, milk production, genetic variation

0388 Relationship between linear type and fertility traits in Nguni cows. T. J. Zindove*[1], K. A. Nephawe[2], S. P. Ndou[3], and M. Chimonyo[1], *[1]University of KwaZulu-Natal, Pietermaritzburg, South Africa, [2]Tshwane University of Technology, Pretoria, South Africa, [3]University of Manitoba, Winnipeg, Canada.*

The objective of the study was to assess the dimensionality of seven linear traits (body condition score, body stature, body length, heart girth, navel height, body depth and flank circumference) in Nguni cows using factor analysis and indicate the relationship between the extracted latent variables and calving interval and age at first calving. The traits were measured between December 2012 and November 2013 on 1559 Nguni cows kept under thornveld, succulent karoo, grassland and bushveld vegetation types. Low partial correlations (−0.04 to 0.51), high Kaiser statistic for sampling adequacy (MSA) scores and significance of the Bartlett sphericity test ($p < 0.01$) showed that there were significant phenotypic correlations between the linear traits and the data were suitable for factor analysis. Two factors had eigenvalues greater than 1. Factor 1 included body condition score, body depth, flank circumference and heart girth and represented body capacity of cows. Factor 2 included body length, body stature and navel height and represented frame size of cows. Calving interval and age at first calving decreased linearly with increase of factor 1. There was a quadratic increase in age at first calving as factor 2 increased ($P < 0.05$). It was concluded that the linear type traits under study can be grouped into two distinct factors, one linked to body capacity and the other to the frame size of the cows. Small-framed cows with large body capacities have shorter CI and AFC.

Key Words: Nguni cows, body depth, calving interval, flank circumference, heart girth

0389 Estimation of genetic parameters for birth to weaning traits in meat goats. K. M. Andries*, F. Bebe, A. McKay, A. Bodrick, and A. Hartell, *Kentucky State University, Frankfort.*

Meat goat production in American grew repeatability in the early 2000s and has started to slow in growth over the past several years. Different reasons have been given for this decline, including limited improvement in animal performance and production. There has been a limited amount of research into the genetic parameters for goat growth and repeatability of dam production. A project was conducted at Kentucky State University to evaluate heritability and genetic correlations of birth and weaning weights in meat goat kids and to evaluate the heritability and repeatability of number of kids born and weaned by meat goat does in a multi-breed herd of meat goat. Records of birth to weaning performance and dam reproduction were collected between 2005 and 2015 in the meat goat research herd at Kentucky State University. The data set included 886 kidding records. The data included birth type, number reared, birth and weaning weights and daily gain between birth and weaning. The data was analyzed using ASReml with maternal effects in an animal model. The results of this study found that direct heritability of birth weight was 0.27% ± 0.081 and maternal heritability of 0.14 ± 0.035. For weaning weight heritability estimates were 0.33 ± 0.078 and 0.25 ± 0.042 for direct and maternal, respectively. Genetic correlation between these two traits was 0.39 ± 0.102 and the maternal correlation was 0.56 ± 0.074. Reproduction is one of the most economically important traits in livestock production. Number of kids born and weaned is critical for success of the meat goat industry. We used a repeated measures model in ASReml on the dam performance data set that contained 886 kidding records. We found that the heritability for number of kids born was 0.07 ± 0.068 with a repeatability of 0.14 ± 0.044 and for number of kids weaned was 0.18 ± 0.092 and 0.25 ± 0.046 for heritability and repeatability, respectively. Based on this research birth and weaning weights in meat goats are highly heritable and maternal effects on weaning weight are high. While heritability of number of kids born was low, the repeatability was significantly and number of kids weaned had a moderate heritability. Repeatability of both traits was lower than expected.

Key Words: meat goat, heritability, repeatability

0390 Economic selection index coefficients for terminal traits in Beefmaster cattle. K. P. Ochsner*[1], R. M. Lewis[1], M. D. MacNeil[2], and M. L. Spangler[3], *[1]University of Nebraska, Lincoln, [2]Delta G, Miles City, MT, [3]University of Nebraska, Lincoln.*

In the design of an economic selection index, the relative importance of traits in the breeding goal is reflected by their economic weighting in the index. The objective of this study was to develop an economic selection index for Beefmaster cattle for a terminal production system where bulls will be mated to mature cows with all resulting progeny harvested. Selection criteria were chosen from expected progeny differences (EPD) currently reported by Beefmaster Breeders United (BBU), and included yearling weight (YW), ultrasound rib-eye area (UREA), ultrasound rib fat (UFAT), and ultrasound intramuscular fat percentage (UIMF). Goal traits, which directly influence profitability in a terminal system, included hot carcass weight (HCW), marbling score (MS), rib-eye area (REA), 12th–rib fat (FAT), and feed intake (FI). Phenotypic and genetic parameter values among the selection criteria and goal traits were obtained from literature. National averages of feed prices, veterinary costs, and carcass premiums/discounts from 2010 to 2014 were used to establish income and expenses associated with a terminal system. Economic values

were determined from a simulation of 100,000 animals using SAS 9.4. Values were obtained by approximating the partial derivatives of the profit function by perturbing traits one at a time, by one unit, while holding the other traits constant at their respective means. In the simulation, the means (SD) for HCW, MS, REA, FAT and FI were based on literature values, and were 320 (38.8) kg, 5.4 (0.9) marbling score units, 76.5 (9.3) cm^2, 1.2 (0.32) cm, and 8.59 (1.09) kg, respectively. Relative economic values for HCW, MS, REA, FAT and FI were found to be 91.29, 17.01, 8.38, −7.07, and −29.66, respectively. By using phenotypic (co)variances among the selection criteria in the derivation, index coefficients may be applied to phenotypic measures. Index coefficients for phenotypic measures of YW, UREA, UFAT and UIMF were 0.74, 0.08, −31.04, and 13.32, respectively. By using genetic (co)variances among the selection criteria in the derivation, index coefficients may be applied directly to EPD. Index coefficients for EPD of YW, UREA, UFAT and UIMF were 1.72, 0.81, −36.60, and 12.37, respectively. The application of this index would aide Beefmaster breeders in their sire selection decisions, facilitating genetic improvement for a terminal breeding objective.

Key Words: beef cattle, economic weight, selection index

0391 Genomic regions associated with residual feed intake of divergently selected lines of Yorkshire pigs when fed a low-energy, high-fiber diet.

E. D. Mauch*[1], N. V. Serão[2], J. M. Young[3], J. F. Patience[1], N. K. Gabler[1], and J. C. M. Dekkers[1], *[1]Department of Animal Science, Iowa State University, Ames, [2]North Carolina State University, Raleigh, [3]North Dakota State University, Fargo.*

Feed intake and efficiency remain key targets for improvement in the pork industry, as feed is the number one source of production costs. To better understand feed efficiency, divergent selection for residual feed intake (RFI) was performed in purebred Yorkshire pigs for 10 generations at Iowa State University. Phenotypes for RFI (n = 2623) and component traits were recorded across generations and lines (High RFI and Low RFI). A corn and soybean-meal based diet that was higher in energy and lower in fiber content (HELF) was fed during selection. To explore the effect of diet on RFI, a lower-energy, higher-fiber (LEHF) diet was fed to a subset of pigs from generations 8, 9, and 10 (n = 314). The LEHF diet had 18% less net energy and 175% more neutral detergent fiber, yet lysine to metabolizable energy ratios were similar between diets. Pigs were genotyped using the Illumina Porcine SNP60 BeadChip. (Serão et al., 2016) reported genomic regions on *Sus scrofa*chromosome (SSC) 2 and 6 associated with RFI of pigs fed the HELF diet (n = 1692). The objective of this study was to identify genomic regions associated with RFI when pigs were fed a LEHF diet. Using bivariate models for RFI between diets, heritability of RFI was estimated to be 0.24 ± 0.05 for the HELF diet and 0.35 ± 0.17 for the LEHF diet, while the genetic correlation of RFI between diets was 0.82 ± 0.28. Pigs (n = 310) fed the LEHF diet with phenotypes and genotypes for 46,467 SNP, after quality control, were used for a genome wide associate study. GenSel4 was used to fit BayesB and C models with $\pi = 0.9933$. Results from BayesC found no significant genomic associations for RFI. BayesB identified associations for RFI on SSC 6 and 14 that each explained ~0.75% of the genetic variance and on SSC 1, 5, and 16 that each explained ~0.50% of the genetic variance. None of these regions overlapped with those reported by Serão et al. (2016). In conclusion, RFI is a polygenic trait with many QTL across the genome with small effects and those effects may depend on the diet fed. This work was supported by AFRI-NIFA Grant no. 2011–68004–30336.

Key Words: genomic regions, RFI, swine

0392 Genetic architecture of feed efficiency in mid-lactation Holstein dairy cows.

L. C. Hardie*[1], M. J. VandeHaar[2], R. J. Tempelman[2], K. A. Weigel[3], L. E. Armentano[4], G. R. Wiggans[5], R. F. Veerkamp[6], Y. de Haas[7], M. P. Coffey[8], E. E. Connor[9], M. D. Hanigan[10], C. R. Staples[11], Z. Wang[12], and D. M. Spurlock[1],*[1]Iowa State University, Ames, [2]Michigan State University, East Lansing, [3]University of Wisconsin, Madison, [4]University of Wisconsin, Madison, [5]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [6]Animal Breeding and Genomics Centre, Wageningen University, Netherlands, [7]Animal Breeding and Genomics Centre, Wageningen UR Livestock Research, Netherlands, [8]SRUC, Edinburgh, UK, [9]USDA-ARS, Animal Genomics and Improvement Laboratory, Beltsville, MD, [10]Virginia Tech, Blacksburg, [11]Department of Animal Sciences, University of Florida, Gainesville, [12]University of Alberta, Edmonton, Canada.*

The objective of this study was to explore the genetic architecture and biological basis of feed efficiency in lactating Holstein cows. In total, 4918 cows with actual or imputed genotypes for 60,671 SNP had individual feed intake, milk yield, milk composition, and body weight records. Cows were from research herds located in the United States, Canada, the Netherlands, and Scotland. Feed efficiency defined as residual feed intake (RFI) was calculated as the residual of the regression of DMI on milk energy (MilkE), metabolic body weight (MBW), and body weight change along with systematic effects of parity class by days in milk fitted as a fifth order Legendre polynomial (fixed), diet within experiment within location (random) and test week (random). Adjusted phenotypes for DMI, MilkE, and MBW were calculated as the sum of the animal and residual components from the regression of each trait on the same systematic effects used for RFI. Animal

relationships were represented with a genomic relationship matrix. Genome-wide association studies were performed for RFI, DMI, MilkE, and MBW using the Bayes B method in GenSel version 4.4 with 1% of SNP assumed to have a non-zero effect. One megabase windows with the greatest percent of the total genetic variation explained by the markers (TGVM) were identified, and within windows explaining more than 0.5% of the TGVM, the SNP with the highest posterior probability of a non-zero effect was tested for significant additive and dominance effects. Marker-based heritabilities were estimated for RFI (0.10), DMI (0.25), MilkE (0.20), and MBW (0.44). Tentative results for RFI identified regions explaining the greatest percent of the TGVM on chromosomes X, 9, and 14, and all tested SNP had significant additive effects ($p < 0.05$). Four of the 10 regions with the greatest effect on DMI also were included in the 10 regions with greatest effects on RFI, but not in the top 10 regions for MilkE or MBW, suggesting a genetic basis for intake that is unrelated to energy consumption required for milk production or maintenance. Candidate genes found within windows explaining the greatest percent of the TGVM for RFI include solute carrier family 25 member 14 and leptin. In conclusion, feed efficiency is a polygenic trait exhibiting genetic variation distinct from that underlying maintenance requirements and milk energy output.

Key Words: residual feed intake, genome-wide association study, feed efficiency

---

0393 Analysis of genetic residual feed intake in Danish Holstein cows by covariance functions using random regression models. C. Pfeiffer*, B. Li, P. Lovendahl, and J. Lassen, *Department of Molecular Biology and Genetics, AU Foulum/ Aarhus University, Tjele, Denmark.*

Feed efficiency is of major concern due to economic reasons and environmental impacts but also because of limited feed resources. So far, feed efficiency cannot be defined unambiguously. One trait to select for can be residual feed intake (RFI), which is primarily determined by dry-matter intake (DMI), production traits and body weight. The aim of this study was to derive variance-covariance components of RFI over the first 44 lactation wk in primiparous Danish Holstein cows by a covariance function from a tri-variate random regression analysis to describe genetic and permanent environmental effects of average DMI, average metabolic body weight (mBW) and average kg milk (Mkg) over the whole lactation. Commonly, RFI is derived from phenotypic regression and subsequently genetically analyzed. In total, 22,375 records of 648 primiparous Holstein cows from the Danish Cattle Research Centre were used. Phenotypic information was collected between 2003 and 2015 over the entire standard-lactations. The random regressions were fitted using DMU 6.5.2. The pedigree was traced back as far as possible resulting in 16,339 animals. After estimating variance-covariance components of DMI, mBW and Mkg, the covariance function was applied to directly derive RFI due to the assumption that RFI is defined as a depended genetic variance of DMI, body weight and milk yield. The approach gave reliable results for RFI. Heritabilities for RFI ranged from 0.05 to 0.15. The highest heritability for RFI was observed in the first wk of lactation, the lowest in lactation wk 22. Heritabilities for the traits DMI, mBW and Mkg ranged from 0.30 to 0.46, 0.53 to 0.61 and 0.25 to 0.55, respectively. The genetic variance of RFI was on average 9.5% (ranging from 4.3% in lactation wk 23 to 28.7% in lactation wk 1) of the genetic variance of DMI. Heritabilities of RFI, DMI, mBW and Mkg were in accordance with previous studies. The genetic variance of RFI in DMI has to be considered as low to moderate. Results imply that a genetic improvement of DMI, independent of production, is limited, except for the first 4 wk of lactation where the genetic variance of RFI was > 20% of the genetic variance of DMI.

Key Words: dairy cow, random regression model and residual feed intake

---

0394 Greenhouse gas emission related traits differ in RFI divergent lactating dairy cows. D. Hailemariam*[1], G. Manafiazar[1], J. Basarab[1,2], F. Miglior[3,4], G. Plastow[1], Z. Wang[1], *[1]Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]Lacombe Research Centre, Alberta Agriculture and Forestry, Lacombe, AB, Canada, [3]Canadian Dairy Network, Guelph, ON, Canada, [4]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada.*

In dairy cattle, the magnitude of dry matter intake (DMI), methane (CH_4) and carbon dioxide (CO_2) reduction in feed efficient (-RFI) lactating cows is not well documented. The objective of this study was to quantify the comparative advantage of -RFI lactating dairy cows managed in an intensive tie-stall system with regard to DMI, CH_4 and CO_2 emission. RFI was predicted for 43 lactating dairy cows with components of metabolic body weight (MBW), empty body weight change (EBWC), and milk production energy requirements (MPER) over 255 d in milk (DIM) using a random regression technique, and correspondingly, DMI, CH_4, CO_2 and other traits were measured. CH_4 and CO_2 emissions were measured from lactating dairy cows using a GreenFeed system (C-Lock Inc., Rapid City, SD). The measurement was performed in three batches (15 cows in each) twice a day (0900–1200; 1800–2030 h) for 14 consecutive test days. Before each test period cows were allowed to visit the unit twice a day (4–7 d) for adaptation purpose. The RFI prediction revealed 19 cows with–RFI (efficient) and 24 cows with +RFI (inefficient). The mean dry matter intake (DMI), CH_4 production (g/day), CH_4

yield (g/kg of DMI), CH_4 g/kg of milk, milk yield (kg/d) and CO_2 g/d were calculated for both-RFI (N = 19) and +RFI (N = 24) groups. Data was analyzed using t test for each trait and the result indicated that -RFI cows have significantly (P < 0.05) decreased DMI (20 ± 3 vs. 23 ± 3), CH_4 g/d (334 ± 71 vs. 392 ± 70), and CO_2 g/d (12,070 ± 1348 vs. 12,895 ± 1704) and CH_4 g/kg of milk (9 ± 2 vs. 10 ± 2) compared with their +RFI counterparts. As expected, body weight, milk yield and CH_4 (g/kg DMI), were not statistically significant (P > 0.05), between -RFI and +RFI groups. Taken together, feed efficient lactating dairy cows compared with the inefficient cows consumed less feed, emitted less daily CH_4 (g/d), CH_4 (g/kg of milk) and CO_2 (g/d) by 13.0, 14.8, 10, and 6.4% respectively, without differing in milk production.

Key Words: RFI, methane, carbon dioxide

0395 Genetic relationship between methane emissions and conformation traits in Danish Holstein cattle. L. Zetouni[*1], M. Kargo[1,2], J. Lassen[1], *[1]Aarhus University, Tjele, Denmark, [2]SEGES, Aarhus N, Denmark.*

Conformation traits have been widely explored in dairy cattle evaluation, being a part of the total merit index for Holstein cows in different countries. They have been used as a way to access the cow's condition in general, based on its body features. Lots of studies have analyzed the relationship between conformation traits and other traits of interest in dairy cattle, such as fertility, longevity and feed efficiency, but little is known about how methane emissions correlate with conformation traits. Therefore, our goal was to evaluate the genetic correlations between methane and six conformation traits in Holstein cows: height (H), body depth (BD), chest width (CW), dairy character (DC) and body condition score (BCS). Data was collected on 1114 Holstein cows from 11 commercial herds in Denmark. Methane emission was measured during milking in milking robots, and then quantified using information on milk production, weight and days carried calf to predict carbon dioxide production and multiplied by the ratio between methane and carbon dioxide. Bivariate linear models were used in the analysis to estimate the correlations between methane and each one of the traits analyzed. Heritabilities estimates were moderate, ranking around 0.3 for methane and between 0.11 (for CW) and 0.5 (for H) for the other traits. The estimated genetic correlations were mainly positive, implying that the bigger the cow, the more methane it produces. Our results could be partially explained by the fact that, in general, broader, deeper cows eat more, and it is a known fact methane production is associated with higher feed intake in ruminants. Due to high standard errors of the estimates further analyses are being conducted to more deeply evaluate and understand how conformation traits relate to methane emissions.

Key Words: methane, conformation traits, genetic correlations

0396 Genetic variation of predicted milk fatty acids groups in Canadian Holsteins. S. G. Narayana[*1], F. S. Schenkel[1], A. Fleming[1], A. Koeck[1], F. Malchiodi[1], J. Jamrozik[1,2], M. Sargolzaei[1,3], M. Corredig[4,5], B. Mallard[1,6], A. Ali[7], and F. Miglior[1,2], *[1]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [2]Canadian Dairy Network, Guelph, ON, Canada, [3]Semex Alliance, Guelph, ON, Canada, [4]University of Guelph, ON, Canada, [5]Gay Lea Foods, Guelph, ON, Canada, [6]Department of Pathobiology, OVC, University of Guelph, ON, Canada, [7]Department of Mathematics and Statistics, University of Guelph, ON, Canada.*

The objective of this study was to investigate genetic variability of mid infrared predicted fatty acids groups in Canadian Holstein cows. Milk samples were collected by CanWest DHI (Guelph, ON, Canada) and Valacta (Ste.-Anne-de-Bellevue, QC, Canada) during routine milk recordings. Milk samples were analyzed using MilkoScan FT6000 spectrometers (Foss, Hillerød, Denmark). Milk mid infra-red spectra generated from January 2013 to July 2015 were standardized and then predicted for five groups of fatty acids: short-chain (C_4–C_{10}), medium-chain (C_{12}–C_{16}), long-chain (C_{17}–C_{22}), saturated (no double bond), and unsaturated (one or more double bonds) fatty acids. The predicted fatty acid values were log transformed to improve normality. The data set included 49,127 test-day records from 10,029 first lactation Holstein cows in

Table 0395.

Table 1. Heritabilities and correlations between methane and conformation traits

		Methane			
	h^2	r_g	SE	r_e	SE
BCS	0.4	-0.009	0.2	-0.14	0.08
BD	0.14	0.45	0.24	-0.12	0.07
CW	0.11	0.3	0.3	-0.13	0.06
H	0.5	-0.12	0.2	0.0963	0.0931
DC	0.12	0.12	0.2	0.05	0.07
Methane	0.3	-	-	-	-

BCS = body condition score; BD = body depth; CW = chest width; H = height; DC = dairy character
r_g = genetic correlations; r_e = residual correlations

810 herds. The total number of animals in the pedigree was 76,074. The random regression animal test-day model included: days in milk, herd test day, and season-age of calving (polynomial regression) as fixed effects, and herd-year of calving, animal and permanent environment effects as random polynomial regressions, and random residual effect. The significance of fixed effects and the best degree of the fixed Legendre polynomial regressions for season-age effect (third degree) were determined using AI-REML. Bayesian methods with Gibbs sampling were then used for fitting models with different degree of random regressions, assuming the best degree for fixed regressions, and the same increasing degree for all random effects (from intercept only to 4thdegree). Fourth degree random regressions yielded the best fitting based on the Deviance Information Criterion (DIC). No polynomials with degree higher than 4 were fit due to low number of cows with more than 5 fatty acid measurements and the cubic shape of the phenotypic distribution of the fatty acid groups. The estimate of average daily heritability over the lactation for medium-chain fatty acid (0.37) was higher than for short-chain (0.30) and long-chain (0.24). The average daily heritability for saturated fatty acid (0.38) was larger than for unsaturated fatty acid group (0.23). These results provide evidence for the existence of genetic variation in fatty acids groups, and thus indicate possibility of altering milk fatty acid composition through genetic selection.

Key Words: milk fatty acids, mid-infrared, random regression model

---

0397 Genetic correlations between predicted milk fatty acids and milk production traits in Canadian Holsteins.

A. Fleming*[1], F. S. Schenkel[1], A. Koeck[1], F. Malchiodi[1], A. Ali[2], B. Mallard[3], M. Corredig[4], and F. Miglior[1,5], *[1]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [2]Department of Mathematics and Statistics, University of Guelph, ON, Canada, [3]Department of Pathobiology, OVC, University of Guelph, Guelph, ON, Canada, [4]University of Guelph, ON, Canada, [5]Canadian Dairy Network, Guelph, ON, Canada.*

The fatty acid profile of milk is of importance due to its implications on human health and nutrition, and technological attributes. Any consideration of selection for fatty acids requires knowledge of their genetic relationship with other milk production traits. The objective of this study was to investigate the genetic correlations between mid-infrared predicted milk fatty acids and recorded production traits and somatic cell score (SCS) in Canadian Holsteins. Test-day records for milk yield, fat and protein percentage, fat:protein ratio, and SCS, along with predicted quantities of short (4 to 10 carbon length), medium (12 to 16 carbon length), and long-chain (17 to 22 carbon length) fatty acid groups were analyzed. First lactation Holstein cows between the ages of 19 and 43 mo with at least 3 test-day fatty acid records were considered in the analysis. A total of 109,249 records from 29,542 Holstein cows and 2198 herds acquired between January 2013 and April 2015 were used. Genetic analysis was performed using bivariate sire random regression models fitted using the Average Information-Restricted Maximum Likelihood (AI-REML) procedure in the DMU package with Legendre polynomials used to describe the regression curves. Daily genetic correlations were averaged across the lactation. Strong genetic correlations of 0.90, 0.96, and 0.88 were found between fat percentage and short, medium, and long-chain fatty acids, respectively. Ranges of genetic correlations for fatty acid groups and milk yield (−0.48 to −0.50), protein percentage (0.69 to 0.80), and fat protein ratio (0.51 to 0.63) were similar to those found between the production traits and milk fat percentage. Weak, negative genetic correlations were observed between SCS and short and medium-chain fatty acids (−0.14 for both), while a weak, positive correlation was found between SCS and long-chain fatty acids (0.17). Milk fatty acids had moderate to strong genetic correlations with production traits, but weak genetic correlation with SCS. However, disentangling the high correlation of fatty acids with fat percentage may be challenging for selection purposes.

Key Words: fatty acid, milk production, genetic correlation

0398 Genetic associations between milk β-hydroxybutyrate and fatty acids in early first lactation of Canadian Holsteins.

A. Koeck*[1], J. Jamrozik[2,3], A. Fleming[1], F. S. Schenkel[1], R. K. Moore[4], D. M. Lefebvre[4], D. F. Kelton[5], and F. Miglior[1,3], *[1]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, [2]Center for Genetic Improvement of Livestock, University of Guelph, Guelph, ON, Canada, [3]Canadian Dairy Network, Guelph, ON, Canada, [4]Valacta, Ste.-Anne-de-Bellevue, QC, Canada, [5]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

Hyperketonemia (or ketosis) is one of the most frequent diseases in dairy cattle. As clinical ketosis is not widely recorded, the level of milk β-hydroxybutyrate is used as its indicator. Milk fatty acid profile is considered to be related to the energy balance of cows in early lactation. The objective of this study was, therefore, to investigate the genetic associations between milk β-hydroxybutyrate and milk fatty acids in early first lactation of Canadian Holstein cows. Test-day data were available on milk β-hydroxybutyrate and five fatty acid groups: short-chain (C_4–C_{10}), medium-chain (C_{12}–C_{16}), long-chain (C_{17}–C_{22}),

saturated (no double bond) and unsaturated (one or more double bonds). Only the first cow's test-day record between 5 and 40 DIM was considered for all traits, because most of the metabolic changes occur over this time period. The data set consisted of 23,345 cow records from 1541 sires and 2510 herds. Data were analyzed with a 6-variate linear sire model using the Average Information-Restricted Maximum Likelihood (AI-REML) procedure in the DMU package. Heritability of 0.13 was found for milk β-hydroxybutyrate. Heritability estimates for fatty acids ranged from 0.10 to 0.29. Genetic correlations between milk β-hydroxybutyrate and short chain, medium chain and saturated fatty acids were low and not significantly different from zero. Genetic correlations between milk β-hydroxybutyrate and long chain and unsaturated fatty acids were 0.51 and 0.48, respectively. These results confirm the known relationship between milk β-hydroxybutyrate and energy balance status in early lactation, explained by the release of long chain fatty acids from the mobilization of body fat reserves.

Key Words: milk β-hydroxybutyrate, fatty acid, genetic correlation

---

0399 Relevance of mid-infrared spectroscopy predictions of milk fine composition and technological properties for selective breeding.

V. Bonfatti*[1], D. Vicario[2], L. Degano[2], and P. Carnier[1], *[1]Department Comparative Biomedicine and Food Science, University of Padova, Legnaro, Italy, [2]National Simmental Cattle Breeders Association, ANAPRI, Udine, Italy.*

To evaluate the potential use of novel milk infrared predictions as indicator traits in selective breeding, genetic variation in 92 traits, describing the fine composition and technological properties of milk, and their predictions was assessed in the Italian Simmental (IS) population. The genetic relationship between measured traits (MT) and infrared predictions (IP) was investigated. Fatty acid and protein composition, lactoferrin and mineral contents were available for 1040, 3337, 558, and 689 individual milk samples, respectively. Measures of pH and milk coagulation properties were available for 3438, and 3266 samples, respectively. Curd yield and curd composition were obtained by laboratory micro-cheese making techniques for 1177 samples. Infrared calibration models were developed for all traits and IP were obtained for 143,198 spectra of 17,619 IS cows. (Co)variance components for MT and IP were estimated in a set of bivariate analyses, each including one MT and its IP. There was a positive relationship between the R^2 in cross-validation (R^2_{CV}) of calibration models and the decrease in both the phenotypic variance ($r = 0.78$; $P < 0.01$) and the additive genetic variance ($r = 0.61$; $P < 0.01$) of IP compared with the estimates for MT. For the 92 traits, the average decrease in total variance of IP compared with the variance of MT was approximately 35%. The decrease in genetic variance was on average 64%. As a consequence, 88 traits exhibited lower h^2 estimates for IP than for MT. The R^2_{CV} exhibited a positive relationship ($r = 0.57$; $P < 0.01$) with the estimated genetic correlation (r_a) between MT and IP. For calibration models having $R^2_{CV} > 0.75$, r_a between IP and MT was greater than 0.9. The variability in the estimated r_a values increased when R^2_{CV} decreased and, for calibration models having moderate predictive ability, estimates of r_a ranged from 0.2 to 1.

Calibration equations showing high predictive accuracy would lead to a faster genetic progress compared with calibration models having moderate or low prediction accuracy. Nevertheless, the estimated r_a between IP and MT was generally very high, even when calibration models had moderate R^2_{CV}. Hence, even calibrations showing low predictive accuracy may be successfully used in selective breeding, particularly when multiple predictions per animal are available from the routine application of calibration models.

Key Words: infrared spectroscopy, animal breeding, fine milk composition

0400 Markers associated with metabolome, and microbiome measures in a grain and sugar challenge in dairy heifers.

H. M. Golder*[1], J. Thomson[2], S. Denman[3], C. McSweeney[3], and I. J. Lean[1], *[1]Scibus, Camden, Australia, [2]Montana State University, Bozeman, [3]CSIRO Animal, Food and Health Services, Queensland Bioscience Precinct, St. Lucia, Australia.*

The aim of this preliminary study was to identify associations between the bovine genome, metabolome, and microbiome in cattle subjected to a grain and sugar challenge. The objective was to identify markers for ruminal acidosis. Genome wide association was performed on Holstein heifers ($n = 34$ samples with quality DNA out of 40) that were allocated to 5 feed additive groups. Heifers were fed twice daily a 62% forage:38% concentrate total mixed ration at 1.25% of bodyweight (BW) dry matter (DM)/d for a 20-d adaptation period with their additive(s). Fructose (0.1% of BW/d) was added to the ration for the last 10 d of adaptation. On d-21 heifers were challenged with a ration consisting of 1% of BW DM wheat and 0.2% of BW fructose plus their additive(s). Stomach tube rumen samples were collected weekly and at 5 time points over 3.6 h after consumption of the challenge ration on d-21 and analyzed for pH, and ammonia, D- and L-lactate, and volatile fatty acids (VFA) concentrations and relative abundance of total bacteria and archaea using an Illumina MiSeq platform. All rumen fermentation measures were normalized and combined to produce an eigenvector to indicate the risk of ruminal acidosis. Bovine DNA was sequenced using the Geneseek® Genomic Profiler Bovine 150K Illumina SNPchip. Genome wide association was completed using an additive model and linear regression with PCA population stratification and a Bonferroni correction for multiple comparisons. There were few genome associations found with rumen pH,

acetate, propionate, total VFA, or ammonia concentration or the relative abundance of the Firmicutes and Bacteroidetes phyla ($P < 0.5$). A number of associations occurred for D-lactate, L-lactate, and total lactate concentration and the acidosis eigenvectors at all time points before d 21 ($P < 0.05$). Ten associations were found at one time-point only for butyrate and valerate concentrations ($P < 0.05$). A number of associations were found with the Actinobacteria, Chloroflexi, Euryarchaeota, Fibrobacteres, Proteobacteria, and Tenericutes phyla at one or more time points ($P < 0.05$). Gene-wide associations with the metabolome and microbiome were present despite the small population size and suggest the presence of markers for ruminal acidosis. Qualitative trait loci and candidate gene analysis is being conducted.

Key Words: genome wide association, lactic acid, ruminal acidosis

BREEDING AND GENETICS SYMPOSIUM: RESILIENCE OF LIVESTOCK TO CHANGING ENVIRONMENTS

0401 Production, biological, and genetic responses to heat stress in ruminants and pigs.

L. H. Baumgard*[1], J. T. Seibert[1], S. K. Kvidera[1], A. F. Keating[1], J. W. Ross[1], and R. P. Rhoads[2], *[1]Iowa State University, Ames, [2]Virginia Tech, Blacksburg.*

Heat stress (HS) compromised efficient animal production and reduced livestock output during the summer was traditionally thought to result from decreased nutrient intake. Our data from ruminants and monogastrics challenge this dogma and indicate that heat-stressed animals utilize homeorhetic strategies to modify metabolic and fuel selection priorities independently of feed intake. Systemic shifts in bioenergetics are characterized by increased basal and stimulated circulating insulin. Hepatocytes and myocytes also show clear differences in glucose production and metabolic flexibility, respectively, during HS. Intriguingly, HS animals do not mobilize adipose tissue despite being in both a negative energy balance and catabolic state. The origin of the aforementioned metabolic changes may lay at the gastrointestinal tract. For a variety of reasons, HS compromises intestinal integrity. Increased permeability to luminal contents results in local and systemic inflammatory responses. Consequently, heat-stressed animals are simultaneously confronted with life-threatening hyperthermia and endotoxemia. Determining how these systems are homeostatically and homeorhetically coordinated to prioritize acclimation and survival vs. agriculturally productive purposes would presumably reveal mechanisms amenable to manipulation. Interestingly, thermoregulatory and production responses to HS are only marginally related. In other words, increases in body temperature indices poorly predict the decrease in both milk yield and growth. Further, HS-induced decreased feed intake is also an inaccurate predictor of milk yield or growth during HS. This suggests that traits associated with production and thermoregulation during HS may be governed by separate genomic loci and potentially interdependent biological mechanisms. Thus, selecting animals with a "tolerant" phenotype based solely or separately on thermoregulatory capacity or production may not ultimately increase HS resilience. Therefore, the variation of multiple phenotypes and genotypes needs to be accounted for to generate a more comprehensive heat tolerant animal. In summary, HS is one of the primary hurdles to efficient animal production. Defining the physiological mechanisms through which HS and other environmental factors influence complex, multifactorial traits, is critical for developing approaches to ameliorate current production issues and is a prerequisite for generating future strategies (genetic, managerial, nutritional, and pharmaceutical) to maximize livestock efficiency.

Key Words: heat stress, genetics, insulin, tolerance

0402 Breeding for resilience to heat stress effects: A comparison across dairy ruminant species.

M. J. Carabaño*[1], M. Ramón[2], C. Díaz[1], A. Molina[3], J. M. Serradilla[3], M. D. Pérez-Guzmán[4], *[1]INIA, Madrid, Spain, [2]CERSYRA-IRIAF-CLM, Valdepeñas, Spain, [3]Universidad de Córdoba, Spain, [4]Centro Regional de Seleccion y Reproduccion Animal (CERSYRA-IRIAF). Junta de Comunidades de Castilla La Mancha, Valdepeñas, Spain.*

Dairy animals are more susceptible to heat stress (HS), because milk production results in a large metabolic heat strain. As a consequence, selection for increased milk production will tend to decrease animals' tolerance to increasing heat loads. A comprehensive approach to characterize HS effects on dairy production and to develop breeding tools to select for heat tolerance (HT) was followed by making use of available milk recording information, climatological data and genomic information on three dairy ruminant populations, Holstein cattle and local breeds Manchega sheep and Florida goats raised in the warm southern regions of Spain. Heat stress thresholds were around 55/63 (15/18) and 63/65 (19/20) for average daily values of THI (°C temperature) for fat/protein yields in Holstein and Manchega, respectively. For goats, HS thresholds could not be clearly identified. Sufficient genetic variability was observed in productive response to heat to consider this trait for selection in the three populations. Genetic antagonism between milk production and HT (ability to maintain milk production under high heat loads) was found for the three populations but stronger for cattle and goats. Several selection criteria including eigen-components of the response variability (looking for tolerance criteria independent of production level) were compared and slopes of the genetic response curves in the HS region were recommended. Estimated genetic correlations between production

under cold and comfort or heat conditions was different from unity in all species (down to 0.3 in cattle), indicating the different genetic mechanisms involved in heat and cold tolerance. Genome-wide association studies using slopes of polynomial curves of response as pseudo-phenotypes have been performed. Beside genomic regions related to fat metabolism (e.g., ACSL3), regions highlighting the effect of HS on the regulatory activity of transcription factors (TBL1XR1, DCHAU1), a number of genes involved in basic processes related to proteins transport and intracellular signal transduction (CNIH3 and CNIH4 ubiquitines and chaperones such as NVL from the chaperone-like AAA-ATPase family) showed signinficant signals. Although the use of milk recording and weather data has been proven useful to identify HT animals, the use of finer phenotypes together with genomic information are deemed important to succeed in selecting HT animals while maintaining productivity.

Key Words: heat tolerance, selection, dairy ruminants

0403 Climate change and selective breeding in aquaculture. P. Sae-Lim*, *Nofima, Ås, Norway.*

Aquaculture is an important sector that strengthens food security. Based on FAO, aquaculture production has to increase up to 42.9% to meet the global population demand in 2020. According to the reports by IPCC and FAO, climate change may result in global warming, sea-level rise, changes of ocean productivity, water shortage, and more frequent extreme climate events. Climate change may affect aquaculture directly and indirectly, depending on climatic zones, aquaculture activities, and farmed species. Climate change may introduce opportunities—rise of temperature may increase growth and open up new farming opportunities due to aquatic species migration—as well as several challenges to aquaculture. First, genotype-by-environment interactions (GxE) may increase because aquatic animals may expose to more fluctuating rearing environments. Rainbow trout (*Oncorhynchus mykiss*), the most popular farmed salmonid worldwide, has a very narrow range of optimal temperature to grow. The magnitudes of GxE, i.e., average genetic correlation (r_g), from 1964–2013 were reviewed across 38 species. The review revealed strong re-ranking for growth of rainbow trout in different temperatures (r_g = 0.36), indicating lower-than-expected production in suboptimal rearing temperature when selecting for growth based only on optimal rearing temperature. Second, it can be hypothesized that climate change may increase environmental variance in sensitive genotypes. Third, climate change may facilitate an outbreak of (new) pathogens or parasites, increasing mortality and hence reducing production. Fourth, 20% reduction of ocean productivity worldwide has been predicted, implying a decline of fishmeal and fish oil supplies and hence the replacement of the raw materials may become more important in the future. Finally, reduction in biodiversity may threaten genetic variation and the ecosystems of wild stocks. Furthermore, this may imply a lack of founder populations for breeding in the future. To ensure the food security, the impacts of climate change have to be addressed through resource management, reduction of environmental impacts, and selective breeding strategies. Breeding goals may change toward "resilience," i.e., stability of performance under fluctuating rearing environments or toward new trait mean. The breeding goals may include disease resistance or tolerance for emerging pathogens and parasites. Anyhow, more research is needed to better understand the opportunities of selective breeding for resilient animals in aquaculture under climate change. To avoid any loss of biodiversity in wild stocks, an international gene bank of the wild stocks may store genetic resources of founder populations for future breeding programs.

Key Words: climate change, genotype-by-environment interaction, selective breeding

0404 Introgression of genes conveying resistance to heat stress into cattle populations using the "Slick" genetic variant as a model. S. R. Davis*, R. J. Spelman, and M. J. Littlejohn, *Livestock Improvement Corp., Hamilton, New Zealand.*

There are ~270 million dairy cows globally and over 75% of these are found in hot climates and most of these have not undergone intensive, genetic selection. The ability to integrate genetically-improved cows into tropical cattle populations will underpin improvement of production performance.

The main impediment to the introduction of genetically-improved, high producing dairy cattle, typically from temperate countries, into tropical climates is the relatively poor heat tolerance and low tick resistance of the cattle breeds common in temperate climes. The concept of using gene introgression to improve heat tolerance and tick resistance was given momentum more than 15 yr ago following the identification of "slick," a major, dominant, gene for heat tolerance (and likely, tick resistance), segregating in the Senepol beef breed.

Our discovery, in 2013, of the "slick" causal mutation, a truncation of the prolactin receptor, provided the impetus to embark on crossbreeding of NZ dairy cattle with Senepol to enhance dairy performance in the tropics. A further advantage of the Senepol is that it is a *Bos taurus* breed, avoiding the potential disadvantages of *Bos indicus* crossbreds, which includes poor milk let down and late age at first calving.

The "slick" mutation is an enabling genetic variation which provides the necessary physiological traits (notably sweating ability) to improve animal welfare and performance in hot climates. The characteristics of NZ dairy breeds provide fertility, grazing ability and lactation performance on high roughage diets.

The primary objective of the breeding program is to produce homozygous "slick" bulls that have 75% NZ dairy genetics. The (5 yr) breeding program requires crossbreeding to produce 50% dairy F1 daughters; using these animals as egg

donors through JIVET to produce 75% dairy F2 offspring and then inter-crossing the lines to generate homozygous sires. Gene editing of the "slick" mutation directly into dairy sires is not a practical option in NZ at the current time.

Further improvements in tropical dairy cow development are possible if more genetic variations associated with heat tolerance are found, although introgression of additional variations (for example, coat color) will be challenging in a breeding program such as that outlined here.

Key Words: Senepol, thermoregulation, dairy

0405 Genetic solutions to infertility caused by heat stress. P. J. Hansen*[1], S. Dikmen[2], J. B. Cole[3], M. S. Ortega[1], and G. E. Dahl[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]Uludag University, Faculty of Veterinary Medicine, Department of Animal Science, Bursa, Turkey, [3]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD.*

Reproductive function in mammals is very susceptible to disruption by heat stress. In lactating dairy cows, for example, pregnancy rates per insemination can be as low as 10–15% in the summer vs. 25–40% in cool weather. Reduced fertility is caused by a combination of (1) the negative consequences of the physiological adjustments engaged to minimize hyperthermia during heat stress and (2) direct deleterious effects of elevated body temperature on the gamete and embryo (i.e., heat shock). There is genetic variation body temperature regulation during heat stress as well as in cellular resistance to elevated temperature. Thus, opportunities exist for improving reproduction during heat stress by modifying livestock genetically to improve body temperature regulation and cellular resistance to heat shock. Genetic improvement can be achieved by identifying genetically superior animals within a breed (heritability for rectal temperature during heat stress is 0.17) as well as by transferring genes from thermotolerant breeds to thermosensitive ones. A successful example of gene transfer is for a mutation in *PRLR* causing the slick hair phenotype. Holstein cattle inheriting this mutation have increased ability to regulate body temperature during heat stress and are less likely to experience a decrease in milk yield during summer than other Holsteins. Among the genes conferring cellular resistance to heat shock is a mutation in the promoter of *HSPA1L* identified in cattle. Selection for the beneficial allele of this gene, as well as other genes controlling cellular resistance to heat shock, might reduce the damage to the oocyte and embryo caused by elevated body temperature.

Key Words: heat stress, infertility, reproduction, body temperature

---

0406 Resilience and lessons from studies in genetics of heat stress. I. Misztal*, *University of Georgia, Athens.*

Production environments are expected to change, mostly to hotter climates but also possibly more extreme and drier. This raises a question whether the current generation of farm animals can cope with the changes or should they be specifically selected for changing conditions. In general, genetic selection produces animals with smaller environmental footprint but also with smaller environmental flexibility. Some answers are coming from heat stress research across species, with heat tolerance partly understood as a greater environmental flexibility. Specific studies in various species show complexities of defining and selecting for heat tolerance. In Holsteins, the genetic component of heat stress on production approximately doubles in second and quadruples in third parity. Best production under heat stress is by cows with elevated body temperature, probably at a risk of increased mortality. In hot but less intensive environments, the effect of heat stress on production is minimal although the negative effect on fertility remains. Mortality peaks under heat stress and increases with parity. In Angus, the effect of heat stress is stronger only in selected regions, probably due to adaptation of calving seasons to local conditions and crossbreeding. Genetically, while the direct effect shows variability due to heat stress, the maternal does not, probably due to dams shielding calves from environmental challenges. In pigs, the effect of heat stress is strong in commercial but almost none in nucleus farms. This is partly due to lower pig density and better heat abatement in nucleus farms. Under intensive management, heat stress is less evident in drier environments because of more efficient cooling. A genetic component of heat stress exists but it is partly masked by improving management and selection based on data from elite farms. Genetic selection may provide superior identification of heat-tolerant animals but a few cycles may be needed for clear results. Also simple traits exist that are strongly related to heat stress, e.g., slick hair in dairy and shedding intensity in Angus. Defining resilience/robustness may be difficult especially when masked by improving environment. Under climate change, the current selection may be adequate if it (1) is accompanied by constantly improving management, (2) uses commercial data and (3) includes traits important under climate change such as mortality.

Key Words: G x E interaction, animal stress, robustness

0407 Genomic selection for methane emission.

Y. de Haas*[1], J. E. Pryce[2], E. Wall[3], S. McParland[4], C. I. V. Manzanilla Pech[1], G. Difford[5], and J. Lassen[5], *[1]Animal Breeding and Genomics Centre, Wageningen UR Livestock Research, Netherlands, [2]Agribio, Department of Economic Development, Jobs, Transport and Resources and La Trobe University, Melbourne, Australia, [3]SRUC, Edinburgh, UK, [4]Teagasc, Moorepark, Fermoy, Co. Cork, Ireland, [5]Center of Quantitative Genetics and Genomics, Department of Molecular Biology and Genetics, Aarhus University, Foulum, Denmark.*

Climate change is a growing area of international concern, and it is well established that the release of greenhouse gases (GHG) is a contributing factor. Of the various GHG produced by ruminants, enteric methane (CH_4) is the most important contributor. One mitigation strategy is to reduce methane emission through genetic selection. Our first attempt used beef cattle and a GWAS to identify genes associated with several CH_4 traits in Angus beef cattle. The Angus population consisted of 1020 animals with phenotypes on methane production (MeP), dry matter intake (DMI), and weight (WT). Additionally, two new methane traits: residual genetic methane (RGM) and residual phenotypic methane (RPM) were calculated by adjusting CH_4 for DMI and WT. Animals were genotyped using the 800k Illumina Bovine HD Array. Estimated heritabilities were 0.30, 0.19 and 0.15 for MeP, RGM and RPM respectively, and estimated genetic correlations of MeP with DMI and WT were 0.83 and 0.80, respectively. Strong associations with MeP were found on chromosomes 4, 12, 14, 19, and 30. We have recently tried another approach in dairy cattle, where we aimed to enlarge the reference population for genomic selection by combining data on methane emissions in dairy cattle using data from 5 countries (Australia, Denmark, Ireland, the Netherlands and UK). The total dataset consists of 3060 dairy cows, of which most were genotyped, but with various kinds of SNP chips. We ended up with a uniform set of SNPs for each cow. Even though three different types of measurement equipment (laser, sniffer and SF_6) and protocols (measuring for 3 d, 1 wk, multiple weeks) were used, these data will be analyzed jointly to establish genetic and genomic parameters for enteric methane. The average methane production was 448 g/d in Australia (354 cows); 554 g/d in Denmark (1769 cows); 381 g/d in IRL (260 cows); 549 g/d in NL (457 cows); and 325 g/d in UK (216 cows). This clearly shows that the populations and diets are different in addition to the equipment and protocol. Therefore, a multi-trait approach will be used in the analysis. Following the experiences of a similar project (gDMI), it is expected that each country will benefit for contributing to an international reference set with increased accuracies of the estimates.

Key Words: esnteric methane, genomic selection, international collaboration

0408 How is genomics changing cattle breeding?

D. Boichard*[1], V. Ducrocq[1], P. Croiseau[1], and S. Fritz[1,2], *[1]GABI, INRA, AgroParisTech, Universite Paris Saclay, Jouy-en-Josas, France, [2]Allice, Paris, France.*

Genomic selection offers considerable flexibility to increase genetic trends in dairy cattle breeding, through a decrease in generation interval, an increase in selection intensity, and an increase in reliability for females and for low heritability traits. It is also an opportunity for more sustainable breeding, in terms of breeding goal and genetic variability. With a shorter generation interval, there is a big risk of increasing inbreeding if semen dissemination policy of elite bulls is not changed. However, using a large number of young bulls both as service bulls and bull sires is a simple solution for both maximizing genetic trend while reducing inbreeding trend. Female genotyping is a key challenge for within herd selection and, simultaneously, for replacing current reference populations based on progeny tested bulls, assembling new ones in breeds of more limited size, and for selection of newly recorded traits. At a reasonable price and coupled with use of sexed semen, female genotyping is profitable for the farmers and is becoming a routine practice in an increasing number of herds. New applications are generated, such as renovated mating plans, efficient management of genetic defects, prediction of cows' future career and optimization of culling policy. With more diverse bulls on the market and with female genotyping, genomic selection also opens new avenues for more customized breeding across herds or production systems. A big challenge is to reduce the dependency of genomic predictions on relationship between candidates and the reference population. A strong effort is presently dedicated to integrating genome sequence information into predictions, to improve their accuracy and persistency. To increase the accuracy, within and especially across breeds, causal variants or very close proxies should be identified and included in the predictions, while discarding or limiting the weight of many other variants generating noise. In the longer term, further customization of selection will be possible by accounting for GxE interactions. Important developments are also necessary to decrease loss of favorable alleles through genetic drift.

Key Words: dairy cattle, genomic selection

0409 Genomic prediction using imputed sequence data in dairy and dual purpose breeds. M. Erbe[*1,2], M. Frischknecht[3,4], H. Pausch[5], R. Emmerling[1], T. H. Meuwissen[6], B. Gredler[3], B. Bapst[3], I. Consortium[7], K. U. Götz[1], and H. Simianer[2], *[1]Bavarian State Research Centre for Agriculture, Institute for Animal Breeding, Grub, Germany, [2]Georg-August-University, Department of Animal Sciences, Animal Breeding and Genetics Group, Göttingen, Germany, [3]Qualitas AG, Zug, Switzerland, [4]Bern University of Applied Sciences, School of Agricultural, Forest and Food Sciences HAFL, Zollikofen, Switzerland, [5]Technische Universität Müchen, Chair of Animal Breeding, Freising, Germany, [6]Norwegian University of Life Sciences, Department of Animal and Aquacultural Sciences, Ås, Norway, [7]Interbull Centre, Uppsala, Sweden.*

Technical progress has made it possible to re-sequence individuals within a reasonable time frame and at acceptable costs. However, as sequencing all individuals of a breeding population is still too expensive, only key individuals of a population contributing most to the genetic variation usually are chosen to be sequenced. All other individuals genotyped with common single nucleotide polymorphism (SNP) arrays are then imputed up to all known SNPs and possibly biallelic short insertions or deletions (indels) at sequence level. Different simulation studies have shown that using sequence data for genomic prediction can have a positive effect on the accuracy and the stability of marker effect estimates especially when using variable selection methods. We thus tested these hypotheses with two different data sets: one with over 6000 Fleckvieh bulls genotyped with 50k or 777k and one with over 2000 Brown Swiss dairy cattle genotyped with 30k, 50k or 777k, both imputed to sequence level with a reference set of 150 and 123 sequenced individuals, respectively. With the Fleckvieh data set, no or only very slightly higher prediction accuracies were found with imputed sequence data than with SNP array data for six different traits studied. This was true for different genomic BLUP models as well as for GBCPP, a fast EM-based variable selection method similar to Bayes Cπ. Attempts to reduce noise by modeling only specific subsets of SNPs (e.g., very accurately imputed SNPs, SNPs from genic regions) generally improved prediction compared with modeling all imputed SNPs. Sequence-based predictions did not appear to be more stable as prediction ability decreased similarly for both 50k and sequence data when sires and/or grandsires of candidates were removed from the calibration set. For Brown Swiss, a slight increase in prediction accuracy was found for non-return rate after 56 d in heifers when modeling all imputed SNPs with GBCPP compared with modeling only SNPs from the 50k array. Using prior biological information by modeling only the 50k most significant SNPs obtained from a genome-wide association study did not improve prediction accuracy, but outperformed prediction based on the 50k array. Possible explanations for the limited success of genomic prediction with sequence data are inaccuracies in imputed genotypes, especially for variants with small minor allele frequencies, lack of proper models to account for the underlying genetic architecture, and incompleteness of genome maps and structural annotation.

Key Words: genomic prediction, sequence data

0410 Multi-breed genomic evaluations for 1 million beef cattle in Ireland. A. Cromie[*1], R. Evans[2], F. Kearney[2], D. Berry[3], M. C. McClure[1], and J. McCarthy[4], *[1]Irish Cattle Breeding Federation, Bandon, Ireland, [2]Irish Cattle Breeding Federation, Bandon, Co. Cork, Ireland, [3]Teagasc, Moorepark Research Centre, Fermoy, Cork, Ireland, [4]Irish Cattle Breeding Federation, Cork, Ireland.*

Key stakeholders in Ireland (Irish Cattle Breeding Federation, Teagasc and the Department of Agriculture and Marine) are currently developing multi-breed genomic evaluations for some 1 million beef cattle. The project is co-funded through the EU's Rural Development Program, with the overall objective of increasing rates of genetic gain for key traits related to profitability and environmental sustainability within the Irish suckler beef herd. A total of $338 million has been allocated to the project over the 6-yr period (2015–2020), of which some 15% will be allocated toward the cost of genotyping and related genomic evaluations.

Phase 1 of the project is underway, with 300k beef animals genotyped in 2015. This is in addition to a further 100k animal's which were genotyped in 2013 and 2014, as part of an initial Irish government and industry funded initiative to help establish the required infra-structure (phenotypes and genotypes) for large scale multi-breed genomic evaluations. All animals have been genotyped on the International Dairy and Beef chip (IDB), with the latest version (the IDBv3) being a customised 54k chip developed in conjunction with Teagasc and Illumina Inc. It is anticipated that a further 300k animals/year will be genotyped in 2016 and 2017, resulting in a total of 1 million beef animals required for routine genomic evaluations by end 2017. Phase 2 of the project, will result in a further 1 million animals being genotyped in 2018–2020, bringing the total requirement for routine genomic evaluations to in excess of 2 million animals.

Analysis to-date has been based on a subsample of some 100k sires and cows with reliable evaluations for key profit traits. Single-step genomic evaluations using Mix99 software have been applied to the dataset, with an almost doubling of reliability from the current 20% to almost 40% for individual traits and the relevant economic indexes. Initial feedback from industry has been very positive, with an expectation that the evaluations will become official from August 2016, after which we anticipate running routine evaluations, based on the

increasing genotype and phenotype data every 2–3 mo.

FUNCTIONAL ANNOTATION OF ANIMAL GENOMES (FAANG) ASAS-ISAG JOINT SYMPOSIUM

0411 Important lessons from complex genomes.

T. R. Gingeras*, *Cold Spring Harbor Laboratory, Functional Genomics, NY.*

The approximately three billion base pairs of the human DNA represent a storage devise encoding information for hundreds of thousands of processes that can go on within and outside of a human cell. This information is revealed in the RNAs that are composed of 12 billion nucleotides considering the strandedness and the allelic content each of the diploid copies of the genome. Results stemming from the efforts to catalog and analyze the RNA products made by cells in the human (ENCODE), fly-worm (modENCODE) and mouse ENCODE projects have shed light on both the functional content and how this information is organized by various genomes. In human cells, a total of ~161,000 transcripts present within ~50,000 genic regions represent our previously best manually-curated annotation (based on v 7 Gencode) of the transcriptome. The results from the ENCODE project point to considerable supplementation of these data. Analyses of these transcriptome data sets have resulted in important and under appreciated lessons such as: (1) pervasive genome-wide transcription prompts a need to redefine the definition of a gene, (2) expression ranges follow transcript types and subcellular localization, (3) expression of isoforms of a gene by a cell do not follow a minimalistic strategy, and (4) genomic characteristics of potential *trans*-acting enhancer regions are distinguishable from other types of *cis*-acting regulatory regions. These and other lessons drawn from the landscape of both coding and non-coding RNAs present in eukaryotic cells have been used to assist in understanding and organizing what is often seen as dauntingly complex genomes.

Key Words: annotation, ENCODE, transcriptome

0412 Causal inference of molecular networks integrating multi-omics data.

F. Peñagaricano*, *University of Florida, Gainesville.*

Recent developments of massively parallel technologies allow assaying different biological molecules at very high throughput rates, including sequencing and genotyping of DNA, quantifying whole-genome gene expression, including measuring mRNA and microRNA abundance, identifying genome-wide epigenetic modifications, such as DNA methylation, and measuring different proteins and cellular metabolites. These advancements provide unprecedented opportunities to uncover the genetic architecture underlying phenotypic variation. In this context, the main challenge is to decipher the flow of biological information that lies between the genotypes and the phenotypes under study; in other words, the new challenge is to integrate multiple sources of molecular information, i.e., multiple layers of omics data, to reveal the causal biological networks that underlie complex traits. It is important to note that knowledge regarding causal relationships among genes and phenotypes can be used to predict the behavior of complex systems, as well as to optimize management practices and selection strategies. Here, we describe a multistep procedure for inferring causal gene-phenotype networks underlying complex phenotypes integrating multi-omics data. We initially assess marginal associations between genotypes and either intermediate phenotypes (such as gene expression) and endpoint phenotypes (such as carcass fat deposition and muscularity), and then, in those genomic regions where multiple significant hits co-localize, we attempt to reconstruct molecular networks using causal structural learning algorithms. These algorithms attempt to infer networks assuming that the pattern of conditional independencies observed in the joint probability distribution of these set of correlated variables are compatible with the unknown causal model. As a proof of principle of the significance of this integrative approach, we show the construction of causal molecular networks underlying economically relevant meat quality traits in pigs using multi-omics data obtained from an F2 Duroc x Pietrain resource population. Interestingly, our findings shed light on the mechanisms underlying some known antagonist relationships between important phenotypes, for instance, carcass fat deposition and meat lean content. More generally, the proposed methodology allows further learning regarding phenotypic and molecular causal structures underlying complex traits in farm species.

0413 Genotypes to phenotypes: Lessons from functional variation in the human genome and transcriptome.

B. E. Stranger*, *Section of Genetic Medicine, Department of Medicine, Institute of Genomics and Systems Biology, Center for Data Intensive Sciences, University of Chicago, IL.*

Complex trait association mapping in humans has successfully identified genetic loci influencing trait variation for hundreds of different phenotypes, including disease. The vast majority of associated loci localize to non-coding regions of the genome, suggesting possible effects on gene regulatory mechanisms. Without a clear understanding of the regulatory code of the human genome, deep characterization of the molecular function(s) of genetic variants in the human genome has become increasingly important for defining that code and for understanding genetic associations to complex traits. Studies of the human

transcriptome, its complexity, and its relation to genetic variation in a variety of contexts have proven highly informative for understanding genome function and for suggesting testable hypotheses involving candidate genes for complex traits and the functional mechanisms though which they may act. These approaches are increasingly leading to successful functional characterization of trait-associated variants, in some cases, suggesting possible targets for trait manipulation. Finally, these characterizations are being used to build models predicting variant function, further extending possible applications.

Key Words: genome function, non-coding variants, regulatory mechanisms

0414 Recurrent chimeric transcripts in human and mouse.

S. Djebali[*1,2,3], B. Rodríguez Martín[2,3], E. Palumbo[2,3], D. D. Pervouchine[2,3], A. Breschi[2,3], C. Davis[4], A. Dobin[4], G. Alonso[5], A. Rastrojo[5], B. Aguado[5], T. R. Gingeras[4], and R. Guigó[2,3], *[1]GenPhySE, INRA, Castanet-Tolosan, France, [2]Universitat Pompeu Fabra (UPF), Barcelona, Spain, [3]Bioinformatics and Genomics Program, Centre for Genomic Regulation (CRG), Barcelona, Spain, [4]Cold Spring Harbor Laboratory, Functional Genomics, NY, [5]Centro de Biología Molecular Severo Ochoa (CSIC- UAM), Madrid, Spain.*

The formation of chimeric transcripts (chimeras) has been widely reported. Some of them reflect underlying chromosomal rearrangements, or are the results of the propensity of reverse transcriptase to engage in template switching, however, a proportion of cases genuinely appear to correspond to *trans*-splicing of RNAs, as has previously been described.

Here we use ENCODE and mouse ENCODE deeply sequenced and bio-replicated RNaseq data from 18 human and 30 mouse samples, and the ChimPipe program, to identify chimeras occurring in multiple biological samples (recurrent), and between the same pairs of genes in human and mouse, since they are more likely to be transcriptionally induced and functional.

Recurrent common chimeras tend to connect gene pairs located on the same chromosome and relatively near to each other (< 100kb), therefore pointing to polymerase read-through, however interchromosomal chimeras are also observed, pointing to *trans*-splicing. Importantly, these recurrent chimeras tend to maintain an open reading frame, and could therefore generate chimeric proteins. We also observe that not only the gene-to-gene connection is conserved, but strikingly so are specific junction sites. The genes connected in common chimeras tend to be involved in morphogenesis and body plan formation, and consistently tend to be detected in cell lines of embryonic origin.

Validation of human chimeras by RT-PCR yielded a success rate of 50%, and subsequent cloning and sequencing revealed novel transcript structures, of which some preserve the domains from the two parent genes. Applying this method to multiple animal species and breeds will help us understanding chimera evolution as well as reveal some links between genotype and phenotype.

Key Words: chimeras, transcripts, *trans*-splicing

0415 Improving genomic selection across breeds and across generations with functional annotation.

B. Hayes[*1], A. J. Chamberlain[2], H. Daetwyler[3], C. J. Vander Jagt[2], and M. E. Goddard[4], *[1]Department of Economic Development, Melbourne, Australia, [2]Dairy Futures Cooperative Research Centre, Bundoora, Australia, [3]Department of Economic Development, Jobs, Transport and Resources, Bundoora, Australia, [4]Department of Primary Industries, Melbourne, Australia.*

Identification of causal mutations which affect complex traits in livestock (including production, health and fertility) could accelerate genetic gains for these traits by improving the accuracy of genomic estimated breeding values, particularly across breeds and with greater persistency of accuracy across time. Identification of these causal mutations could also reveal facets of the biology underlying such traits. A significant proportion of the genomic variation in cattle, for *Bos taurus* breeds at least, has been identified. The 1000 bull genomes project now includes whole genome sequences from 1682 cattle of 55 breeds, from which 67.3 million variants (64.8 million SNP, 2.5 million indel) have been identified. The challenge is now to determine which subset of these variants affect complex traits. This challenge is magnified by the fact that the size of effects of the causal mutations are likely to be small, given the large number of mutations typically affecting complex traits. We propose that an approach that includes (1) a multi-breed reference population (necessary to break down the extensive linkage disequilibrium that exists within many livestock breeds), (2) intermediate phenotypes, such as gene expression and protein abundance, where mutation effect is much larger than on the complex trait phenotype, (3) genome annotation information, to identify which classes of variants are more likely to affect complex traits, and (4) a genomic prediction algorithm that uses all this information simultaneously, will lead to identification of causal mutations on a genome-wide scale. Several examples identifying potential causal mutations affecting milk composition from dairy cattle are given. The results highlight the need for better annotation of the bovine genome—many of the most significant mutations are in poorly annotated genomic regions, likely regions regulating gene expression. The functional annotation of animal genomes (FAANG) consortium will greatly improve this situation.

Key Words: genomic selection, functional annotation

0416 Integrating dynamic omics responses for universal personalized medicine. G. I. Mias*, *Michigan State University, East Lansing.*

The advent of readily available omics technologies, and the recent Precision Medicine Initiative announced by the White House and National Institutes of Health are guiding our efforts to make advances in the implementation of personalized medicine. High quality genomes are now complemented with other dynamic omics data (e.g., transcriptomes, proteomes, metabolomes), that may be used to profile temporal patterns of thousands of molecular components in individuals. We are pursuing the profiling of multiple such omics in parallel $n = 1$ studies that extend the pilot integrative Personal Omics Profiling (iPOP) approach to diseases affecting the immune system. In particular, we will describe our investigations that follow longitudinally healthy and asthmatic individuals, and the integration of multiple omics obtained from peripheral blood cells, that we believe may provide novel medical insights. Concurrently, we are developing the necessary statistical and computational methodology for integrating the different omics platforms toward a medical interpretation, including our MathIOmica framework. Our approach enables us to query RNA sequencing, mass spectrometry (proteomics/metabolomics) and any longitudinal omics data, starting from lab samples to raw data, and including downstream quantitation methods for each analysis. We will present a clinically relevant classification scheme of longitudinal patterns, integration that accounts for missing data and uneven time sampling, and ultimately a biological interpretation and dynamic visualization of an integrated profile. Additionally, we are developing the necessary experiments and data sets for future iPOP investigations, with dense profiling of cell-drug treatment responses utilizing Rituximab and other interventions. Our combined transcriptome-proteome profiles enable us to reconstruct dynamic pathways of Rituximab's action on B-cells on a global scale. In summary, our clinical, laboratory and computational investigations are providing the next steps in the development of omics data generation and integration, toward a universal personalized medicine implementation.

0417 A review of sequencing and assembly methods that enhance computational use. W. C. Warren*, *McDonnell Genome Institute, Washington University School of Medicine, St Louis, MO.*

In essence high quality genome references are proven to be a necessity to enable research on so many levels of biological investigation including disease etiology, small molecule drug screening and interactions, canonical disease pathway manifestation, and so many others. To date very few genomes can be classified as near finished, defined as only missing small regions that are recalcitrant to known molecular biology methods. Ultimately our goal is to produce contiguous chromosomes for genomes de novo at the lowest cost. So far most published de novo genome assemblies are derived from deep coverage Illumina only sequencing, most often utilizing two popular but independent assembly algorithms, yet all are documented to be inadequate for numerous types of genetic investigation. During this surge of short reads genome assembly new long read sequencing technology arrived, albeit at considerable cost, ~6-fold higher than pure Illumina de novo assembly approaches. However, long reads, now averaging ~14 kb in length, have transformed our ability to capture most chromosomes that compel us to fund these approaches to obtain higher quality. Our lab and others now routinely assemble human genomes with N50 contig lengths of 10 Mb and up to 53 Mb size contigs, contigs defined as uninterrupted consensus sequence. In our studies we have seen how an incomplete genome sequence was hindering studies designed to detect signatures of selection in the poultry industry, such as missing microchromosome sequence assignments and partial or completely missing gene models in the chicken. In the chicken, despite the use of older long read sequencing technology (average read length of 8 kb), we observed an increase of ~180 Mb in assembled size, added 1920 new gene models and reduced gaps by sevenfold among ordered chromosomes. Given the intense interest in better genome reference models, I will review the generally compartmentalized phases for producing high quality genome references and provide examples of analysis outcome.

Key Words: assembly, genome reference, long reads

COMPANION ANIMAL

0418 *Ehrlichia canis* in canines from Culiacan, Sinaloa, Mexico. I. Enríquez Verdugo*, B. E. Lopez Gallegos, C. Barraza Tizoc, N. Castro del Campo, D. Solis Carrasco, S. M. Gaxiola Camacho, J. Gaxiola Montoya, and M. C. Rubio Robles, *FMVZ-Universidad Autonoma de Sinaloa, Culiacan, Mexico.*

Ehrlichia canis is a Gram-negative obligate intracellular bacteria and is recognized as the causative agent of Canine Monocytic Ehrlichiosis (CME). CME is transmitted by the bite of previously infected ticks, and the main vector includes *Rhipichepalus sanguineus*. In the last decade, this tick has been considered a potential zoonotic pathogen, particularly in the area of veterinary medicine. Clinical diagnosis is based on history, clinical signs, hematological studies, cytology, serology and isolation methods. The aim of this study was detection of *Ehrlichia canis* in dogs from Culiacan, Sinaloa, Mexico by ELISA technique. The study was done in the laboratory of parasitology from the FMVZ-UAS. Blood from 81 dogs, with or without clinical signs or presence of ticks, was collected in sterile EDTA tubes from each dog using the cephalic vein. The bacteria was detected by blood smear and each sample was stained with Wright's solution and observed under light microscopy (100x) using a double blind approach. The serological study was performed using ELISA techniques (IDEXX® 4Dx). Detection of *E. canis* was performed using light microscopy, resulting in 11 positive samples and a frequency of 13.5%. Serological tests resulted in 14 samples reacting to the presence of specific antibodies against the bacteria, and a frequency of 17.2%. In conclusion, the presence of *Erhlichia canis* in dogs from Culiacan, Sinaloa, Mexico, indicates a risk to public health due to the close contact with pet dogs and the vector *Rhipichepalus sanguineus*, causing dogs to be a factor for the dissemination of this zoonotic pathogen.

Key Words: *Ehrlichia canis,* canine, blood, ELISA

419 Effect of dietary composition over food preferences of dogs. J. Figueroa, S. A. Guzmán-Pino, S. Morales*, and C. Muñoz, *Universidad de Chile, Santiago.*

The feeding behavior of dogs has been studied during several years by food preference tests that allow formulating new and specifics diets satisfying animals' needs and increasing animals' pleasure. Nevertheless, besides the sensorial characteristics of diets (smell, taste, viscosity, etc.), nutrient composition (energy, protein, dry matter, etc.) may influence dogs' food preferences. The aim of this study was to analyze the relationship between the nutritional compositions of dog's diets and their associated preferences. A database of preference test from 10 yr (2003–2013) was obtained from the Research Center of Pet Feeding Behavior (Facultad de Ciencias Veterinarias y Pecuarias, Universidad de Chile). Preference tests performed during those years consisted on the placement of two simultaneous feeders in the front of dogs' cannels during 10 consecutive minutes. Food was weighted at the beginning and end of each test to calculate animals' food intake. In each preference test, the nutritional composition of both diets was analyzed, and the difference between the nutrient components of the most preferred diet (A) and the other diet (B) was used for the statistical analysis. To evaluate how nutritional components or group of components may explain food preferences, data was analyzed by doing a principal component (PC) analysis using the princomp procedure of the statistical software SAS. A linear regression was performed between each principal component obtained and dogs' preferences. Later, a Spearman correlation was performed with the nutritional components that represented the greatest variability within the main component that showed a significant linear regression. The first tree principal components presented eigenvalues close to 1 that explained the 74% of the data variability (37.4, 25.1 and 12.5%, respectively). After the linear regression between each principal component and dogs' food preferences (diet A) it was observed that only the third component (dry matter, nitrogen-free extract and metabolizable energy) presented a relation ($P = 0.040$). Dry matter and nitrogen-free extract showed negative correlations with preferences ($r = -0.239$; $P = 0.008$ and $r = -0.188$; $P = 0.039$), respectively. These results show that some nutritional components may affect the food preferences of domestic dogs. Diets humidity, followed by carbohydrate fractions, seems to have the highest repercussion on dogs' behavior during a food choice test.

Key Words: domestic dog, food preferences, nutrient composition

0420 Hind limb kinematics of the Weimaraner at the trot. L. Carlisle[1], M. C. Nicodemus*[1], and K. Slater[2], *[1]Mississippi State University, Starkville, [2]Banfield Pet Hospital, Magnolia, TX.*

Large dog breeds are plagued with hip dysplasia, and yet, some larger breeds such as the Weimaraner have been reported to have a lower percentage rate of hip dysplasia within the general population. Temporal variables of the trotting Weimaraner have been reported as being unique from other large breeds. Understanding the uniqueness of the gait mechanics of the Weimaraner may assist in early clinical diagnosis of hip dysplasia and help in the understanding of why this particular breed has a lower rate of dysplasia. Therefore, study objectives were to measure the trotting hind limb kinematics of the Weimaraner. Six American Kennel Club registered Weimaraner dogs were filmed at 60 Hz being led on even, natural footing at the trot (velocity: 1.9–2.3 m/s). Reflective markers

attached to palpation points on the proximal and distal aspects of the lateral side of the hind limb were tracked and analyzed using APAS (Ariel Dynamics Inc., Trabuco Canyon, CA). Ten strides per dog were used to determine means + SD of measured kinematic variables. Selection of strides was based on soundness, gait correctness, consistency, and noticeable foot placement and lift-off. During the trot the dogs stayed fairly level across the hindquarters demonstrating minimal horizontal displacement of the pelvis (2.8+0.7 cm) throughout the stride cycle. This may be due to the relatively minimal horizontal displacement of the trotting hind paw (9.7+2.1 cm) suggesting despite the presence of suspension during the stride the hind limbs stay fairly low to the ground at the trot similar to that seen in the German shepherd. When comparing the joint data collected for the Weimaraner to other large dog breeds (Labrador, Rottweiler), joint angular displacements were comparable in the hip joint (29.8+1.0°), but slightly less range of motion than the other breeds in the tarsal (36.1+3.7°) and stifle (46.8+5.6°) joints. This could be related to breed differences or could be attributed to weight differences as the other breeds were heavier made breeds in which obese dogs were found to increase range of motion with increased weight to assist in absorbing the extra concussion. Furthermore, the slightly less angular displacements of the tarsus and stifle would also explain the minimal pelvic horizontal displacement in which this reduced lifting and dropping of the hindquarters will assist in minimizing concussive forces. These kinematic variables demonstrate uniqueness within the breed and suggest further kinematic research of other large dog breeds.

Key Words: Weimaraner, kinematics, trot

0421 The effect of source and drying process on amino acid composition and protein quality of dried poultry used in high-quality pet diets and select human foods.

L. M. Molnar*[1], C. G. Aldrich[1], S. Beyer[1], C. K. Jones[1], and R. L. Dake[2], *[1]Kansas State University, Manhattan, [2]American Dehydrated Foods, Springfield, MO.*

Information regarding composition, functionality, acceptability, and nutrient utilization of new protein sources used in pet foods can be relatively scarce. The objective of this experiment was to evaluate nutrient composition and protein efficiency ratio (PER) of various poultry proteins used in processed pet and some human foods. The experimental protein sources were analyzed for proximate and amino acid composition. Experimental protein sources from spray dried egg (SDEG), chicken by-product meal (CPBM), chicken meal (CKML), 6 fluid-bed-dried chicken samples (FBC 1–6), fluid bed dried turkey (FBDT), 4 spray-dried chicken samples (SDC 1–4), and a spray-dried high fat chicken (SDHF) were added to a N-Free basal ration in exchange for an equal portion of the corn starch and dextrose to provide 10% CP. Day old male broiler chicks (Cobb X Cobb) were acclimated to battery pens for 7 d with ad libitum access to starter diet (23% CP) and water. Chicks were fasted overnight then allotted to pen by weight. Pen (5 chicks ea) was the experimental unit with four pens per treatment randomly assigned to battery (block). Chicks were fed treatment diets for 10 d then weighed and feed intake recorded. The PER was computed as chick gain per unit protein intake and analyzed for differences using the GLIMMIX procedure of SAS (v9.4). The CP ranged from 50.1% for SDEG, to 67.4% and 67.7% for the CBPM and CKML, to an average of 71.7% for the FBC1–6, 73.3% for FBDT, average 74.6% for the SDC1–4 and 45.6% for the SDC5. The CBPM, CKML, and FBC6 had the highest hydroxyproline levels, the EAA:NEAA were high (> 0.95) for all samples except CBPM, CKML, and FBC6 (0.70, 0.70 and 0.80, respectively) and availability of lysine exceeded 95% for all samples. The PER for SDEG was 4.84. When PER was expressed as % of egg PER (EGGPER) the CBPM and CKML were lower ($P < 0.05$; 71% and 62%) than egg PER. FBC1–5 and FBDT did not differ from EGGPER, but the FBC6 was lower ($P < 0.05$; 88.2% of EGGPER) The SDC1–5 had a lower ($P < 0.05$) EGGPER (average of 85.6%) than fluid bed dried chicken. These data suggest that gently drying poultry via fluid-bed retained protein quality similar to SDEG and may differ slightly relative to spray-drying. However, whether this was because of process or ingredient composition differences was not fully elucidated by this study.

Key Words: pet food, protein ingredients, chick PER

0422 The amino acid composition and protein quality of various poultry and vegetable proteins commonly used in the production of dog and cat diets.

R. A. Donadelli*[1], C. G. Aldrich[1], C. K. Jones[1], R. S. Beyer[1], and R. L. Dake[2], *[1]Kansas State University, Manhattan, [2]American Dehydrated Foods, Springfield, MO.*

Novel protein ingredients support the growth of the pet food market and new product development. However, some new protein sources (e.g., spray-dried chicken, rice protein concentrate, pea protein concentrate, and potato protein concentrate) have limited or no data available regarding their protein quality. The objective of this study was to evaluate several new protein ingredients used in the pet food industry for nutrient composition and protein quality using a chick protein efficiency ratio (PER) assay. Following proximate and amino acid analysis, 7-d old male Cobb x Cobb broilers were fed experimental diets for 10 d. Birds were allotted to pen ($n = 6$) by weight and randomly assigned to battery ($n = 4$). To the N-free basal ration test proteins were included to contribute 10% CP. The experimental protein sources included spray-dried egg (SDEG), spray-dried egg white (SDEW), spray-dried egg enriched with yolk (SDEY), chicken byproduct meal (CBPM), chicken meal (CKML), low temperature air-dried chicken meal (TACM), low temperature and pressure-fluid-bed-dried chicken (TPCK), spray-dried chicken (SDCK), whey protein

concentrate (WPCT), corn gluten meal (CGML), corn protein concentrate (CPCT), potato protein isolate (PPIS), rice protein concentrate (RPCT), pea protein isolate (PEPI), soy protein isolate (SPIS), and soybean meal (SBML). Data were analyzed using the GLIMMIX procedure of SAS (v9.4). Proximate analysis of all test ingredients were compatible with values reported previously except for the higher fat content of SDEG. Chicks fed SDEG, SDEY, and TPCK had the highest PER ($P < 0.05$; 5.18, 5.37, and 5.33, respectively) and the CBPM and CKML were the lowest among the poultry proteins for EAA:NEAA (0.79 and 0.74), PER (3.59 and 2.91), and Lys availability (84.1% and 78.0%). Among the vegetable proteins PPIS and SBML had the highest ($P < 0.05$) PER values (3.60 and 3.48) and Lys availability (95.4% and 93.4%). Whey protein concentrate and CPCT had the lowest PER values (−0.90 and −0.80), despite the high CP (76.10% and 78.83%) and Lys availability (95.2% and 88.9%). In general the chick PER method was effective at comparing the quality of protein sources and was consistent with the EAA:NEAA and Lys availability.

Key Words: protein ingredients, pet food, protein efficiency ratio, PER

0423 The effect of Miscanthus grass as a fiber source in cat diets on nutrient utilization and stool consistency. R. A. Donadelli*, C. G. Aldrich, and I. C. Alvarenga, *Kansas State University, Manhattan.*

High levels of insoluble fiber are commonly used in cat foods to increase energy dilution (weight loss) and to promote digesta flow (reducing hairballs). There are two commonly used fibers: cellulose (CE) and a beet pulp (BP). Miscanthus grass (MG) is a C4 forage grown for its cellulose content. Nutritional information for MG is scarce; therefore, the objectives of this study were to determine the effect of 10% fiber in cat diets on nutrients digestibility and stool consistency. Experimental diets were based on 90% of ration (low ash chicken byproduct meal, brewers rice, corn, wheat, corn protein concentrate, minerals and vitamins, both as recommended allowances NRC, 2006) plus 10% of each fiber source. The feeding trial was approved by Institutional Animal Care and use Committee at Kansas State University Research Compliance Office. Cats, 12 American shorthairs, were group-housed but fed individually in cages during 9-d adaptation and kept individually caged during the 5-d collection period. Animals were fed twice daily in a replicated Latin square design, with water available throughout the experimental period. Diets and feces were analyzed for proximate analysis and acid insoluble ash (AIA); additionally, apparent total tract digestibility (ATD) and urine pH were computed. Data was analyzed using statistical software (SAS v9.4) using the GLM procedure. Cats maintained body weight throughout the duration of the study (average 4.6 kg). Food intake, defecation frequency, fecal scores, and urine pH were not different ($P < 0.05$) (average 374.8g*d^{-1}, 1.2*d^{-1}, 3.1, 6.94, respectively). The DM and OM digestibility of BP were greater ($P < 0.05$) than for cats fed MG or CE for both TFC (DM; 81.14, 76.22, 75.45%, OM; 85.85, 80.47, 79.37%, respectively) and AIA (DM; 71.18, 69.54, 61.98%, OM; 77.5, 74.46, 67.49%, respectively) methods. The CP digestibility was not different among treatments for TFC (average 85.34%) and for AIA greater ($P < 0.05$) for MG than CE with BP intermediate (81.18, 74.59, 78.21%, respectively). The EE digestibility by TFC were similar for MG and CE and each greater ($P < 0.05$) than BP (89.15 and 89.64 vs. 84.96%, respectively) and by AIA there was no difference among the treatments (average 82.15%). While differences in ATD observed the values for MG were within the range of those for CE and BP for both methods of assessment. Miscanthus grass appears to be an effective alternative to BP and CE in high fiber cat diets.

Key Words: fiber, cat, Miscanthus grass, cellulose, beet pulp, digestibility

0424 The effect of feed form on diet digestibility and cecal fermentation in rabbits. I. C. Alvarenga*[1], C. G. Aldrich[1], and M. Kohles[2], *[1]Kansas State University, Manhattan, [2]Oxbow Animal Health, Murdock, NE.*

Companion rabbits are commonly fed dry forages supplemented with formulated mixes based on finely chopped hay (alfalfa or timothy), grain and grain co-products, vitamins, and minerals. These may be offered as a muesli, a pellet, or extruded into kibbles; but, whether one form is beneficial relative to the other for companion rabbits has not been reported previously. Therefore, the objectives of this experiment were to determine the effects of diet form (muesli, pelleted, or extruded) on rabbit intake, weight, digestibility, and cecal fermentation. Fifteen New Zealand rabbits were randomly assigned to one of 3 treatment groups of 5 animals each and fed pelleted, extruded, or muesli diets in a completely randomized design experiment. Rabbits were placed in individual cages with ad libitum water and food for 45 d. Digestibility was calculated based on results from intake measurements and collection of feces by total collection (TFC) and by two methods for determining acid insoluble ash (AIA) as an internal marker (AIA1; Vogtman et al. (1975), and AIA2; Keulen and Young, 1977). Cecal fermentation was assessed at the conclusion of the experiment by measuring cecal pH, ammonia, and VFA following exsanguination and organ harvest. Feed intake was higher ($P < 0.05$) for pelleted and extruded diets (133.1g/d and 135.0g/d vs. 98.8g/d), but weight change was not different among treatments (average −1.2 g/d). By TFC the DMD of muesli and extruded were greater ($P < 0.05$) than pelleted (69.1, and 65.2 vs. 50.6%). DMD by AIA1 was not significantly different between treatments ($P > 0.05$; 58.1, 55.3, 64.4% for muesli, pelleted and extruded, respectively) and for AIA2 DMD was greater ($P < 0.05$) for pelleted followed by muesli and extruded (71.8 vs.

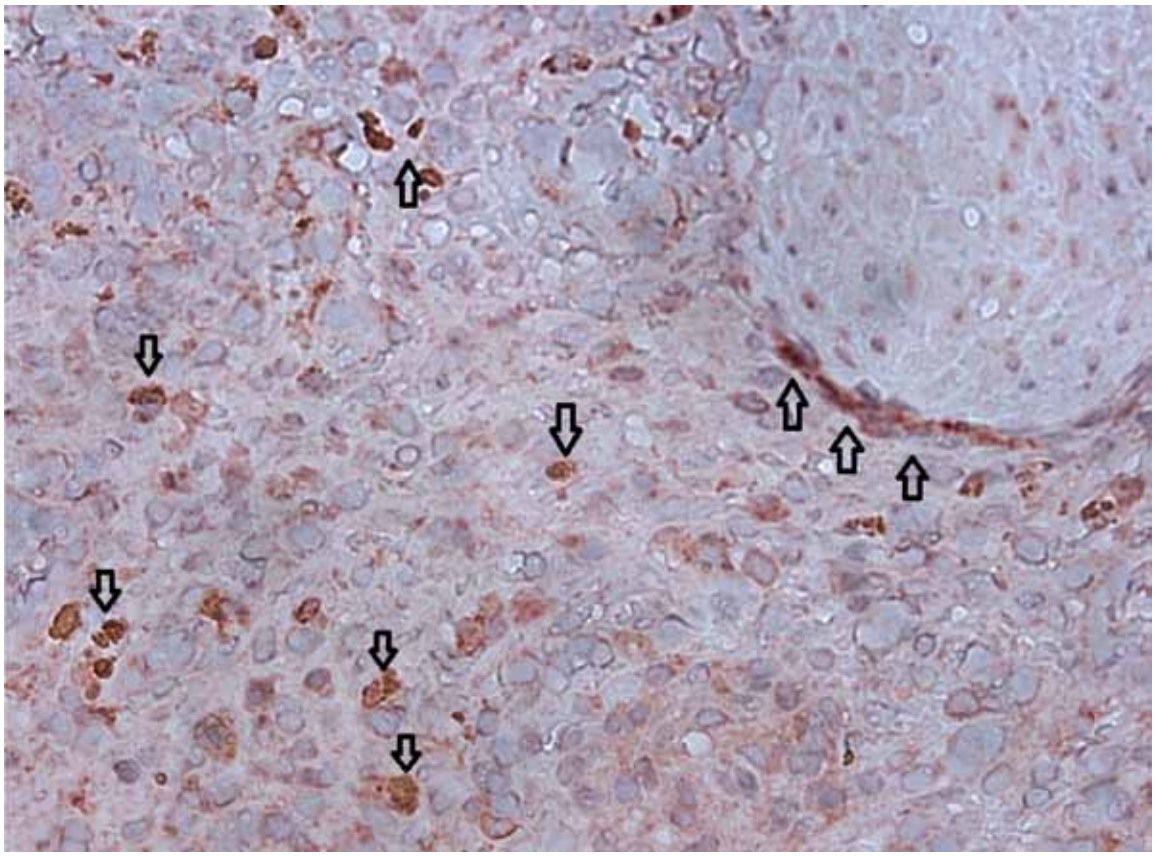
68.5 vs. 62.0%, respectively). Between the two AIA methods the AIA2 had much lower variation among each mean than AIA1 (SEM = 0.44 vs. SEM = 5.37). Rabbits fed pelleted and extruded diets had lower pH ($P < 0.05$) compared with muesli (6.38 and 6.42 vs. 7.02, respectively), the cecal butyrate concentration was higher ($P < 0.05$) in rabbits fed extruded and pelleted diets than muesli (12.4% and 11.38%, vs. 8.4%, respectively), and proprionate was higher ($P < 0.05$) in rabbits fed muesli than pelleted or extruded diets (10.2% vs. 7.7% and 6.6%, respectively). This would indicate higher fiber fermentation for extruded and pelleted diets. These results suggest that diet composition rather than processing had a greater impact on digestion and fermentation.

Key Words: rabbit, AIA, digestibility, extruded, pelleted

0425 Canine hemangiosarcoma expresses luteinizing hormone (LH) receptors. K. Zwida* and M. A. Kutzler, *Oregon State University, Corvallis.*

Throughout most of the developed world, surgical sterilization via gonadectomy has become a common tool for combating the overpopulation of unwanted dogs as well as to eliminate the risk of reproductive diseases in pet dogs. However, canine gonadectomy increases the risk of several non-reproductive long-term disorders, possibly due to a loss in negative feedback to the anterior pituitary, which results in supraphysiologic circulating concentrations of LH. In addition to its reproductive hormone action, LH is a powerful mitogen in extragonadal tissues with LH receptors. Studies have confirmed the presence of LH receptors in vascular endothelial and smooth muscle cells in humans. Hemangiosarcoma is a rapidly growing, highly invasive cancer arising from the lining of blood vessels (mostly commonly the spleen in dogs). Gonadectomized (spayed) female dogs have two times the risk for developing hemangiosarcoma compared with unaltered females. We hypothesized that LH receptors would be present in vascular cells of canine hemangiosarcoma. The aim of study was to investigate if LH receptors were expressed in primary and metastatic lesions of canine splenic hemangiosarcoma using immunohistochemistry. Formalin-fixed surgical biopsies submitted to the Oregon State University Veterinary Diagnostic Laboratory were paraffin-embedded and sectioned (6 μm) onto charged slides. Testicular tissue from a separate dog obtained following castration was used as a positive control. All slides were deparaffinized, rehydrated, subjected to heat-induced epitope retrieval (#S1700, Dako). Endogenous peroxidase activity was inactivated with 3% H_2O_2 and nonspecific binding was blocked with 1% horse serum. Goat polyclonal anti-human LHR antibody (SC-26341, Santa Cruz Biotechnology) was applied at a 1:50 dilution. Negative controls from each tissue were treated in the same way except in absence of primary antibody. Slides were then reacted with biotinylated horse

Fig 0425.



anti-goat IgG (Vector Laboratories, Burlingame, CA) and incubated with preformed avidin-biotin-peroxidase complex (#PK6105, ABC kit, Vector Laboratories) followed by Nova Red Peroxidase substrate (#SK4800, Vector Laboratories). Slides were counter-stained with hematoxylin, dehydrated, and mounted. Images were digitally captured at 400X magnification. LH receptor expression (cytoplasmic and granular) was found in splenic stromal cells of a primary tumor from one dog (identified by arrows on figure) but not in a primary splenic tumor or a mesenteric metastatic tumor from two other dogs. There was no positive staining in the negative sections. This is the first report shows that LH receptors are present in canine hemangiosarcoma and provides evidence for how gonadectomy may increase the incidence of cancer in dogs.

Key Words: dog, gonadectomy, immunohistochemistry

0426 Rabbit maternal pheromone delivered in ointment decreases heart rate in domestic dogs during a simulated thunderstorm. G. M. Pirner* and J. J. McGlone, *Texas Tech University, Lubbock.*

Thunderstorm-related anxiety is common in domestic dogs and is characterized by anxious behaviors such as pacing, vocalizing, or environment or self-destruction. Interomones are olfactory chemical cues released by one species that can elicit behavioral and physiological responses in a second species. Previous studies suggest that interomones can alter dog behavior. This study was designed to examine the effects of a rabbit maternal-neonatal pheromone (2-methylbut-2-enal; 2MB2) delivered via topical ointment on heart rate and behavior of domestic dogs. Twelve dogs of varying age, breed, and sex experienced two treatment ointments applied to the snout: a control ointment with no interomone (CON); or an ointment containing 1 µg/mL of 2MB2. Treatments were assigned using a completely random crossover design with two testing rooms and two treatments. Baseline heart rate (HR) and behavior (standing, lying, pacing, and vocalizing) were recorded throughout each trial. Trials consisted of a 15 min "before" period, at the end of which the designated treatment was administered and a simulated thunderstorm played for 15 min ("during"). This was immediately followed by a third 15-min recovery period ("after"). Data were analyzed using the General Linear Models Procedure of SAS (SAS Inst., Inc., Cary, NC) and Least Squares Means were compared. HR increased 9.5% at the onset of the simulated thunderstorm ($P < 0.05$); however, HR of dogs receiving 2MB2 returned to baseline approximately 5 min into the simulated thunderstorm compared with dogs receiving CON, whose HR remained elevated for most of the 15 min period. Throughout the "during" period, HR of dogs receiving 2MB2 was 13% lower than that of dogs receiving CON ointment (124 ± 4.02 vs. 143 ± 3.95 bpm, respectively; $P < 0.05$). Time dogs engaged in each behavior did not differ between treatments. The interaction between individual and treatment was significant ($P < 0.01$) for HR, indicating that 2MB2 influenced individuals differently. The rabbit maternal pheromone 2MB2 delivered in an ointment to the snout may act as an interomone in dogs, and provides a natural, fast-acting therapy for some dogs experiencing thunderstorm-related anxiety.

Key Words: dog, pheromone, thunderstorm

0427 Evaluation of nutrient digestibility and fecal scores in domestic dogs (*Canis lupis familiaris*) fed raw meat diets varying in protein source. C. A. Iennarella*, C. J. Iske, C. L. Morris, *Iowa State University, Ames.*

Few commercially available raw meat diets (RMD) formulated for exotic carnivores managed in zoological institutions, (typically beef or horse-based), are available. Recently, a 100% pork-based RMD was commercially developed and may provide an alternative dietary option for managing carnivores in the zoological community. The objective of this study was to evaluate the nutrient composition, fecal scores, and apparent total tract macronutrient and energy digestibilities of the pork diet compared with 3 existing RMDs commonly fed to zoologically managed carnivores using the domestic dog as a model. Four intact male dogs (*Canis lupis familiaris*) were utilized in a repeated 4x4 Latin square design consisting of 14-d periods including 10 d for diet transition followed by 4 d of fecal collection. Four raw meat dietary treatments varying in protein source were evaluated and included horse (H), pork (P), and two different beef diets (B1, B2). Diets and feces were analyzed for dry matter (DM), organic matter (OM), crude protein (CP), crude fat (fat) and energy according to AOAC methodology. Feces were scored using the following scale: 1 = very hard, dry feces to 7 = watery diarrhea (Nestle Purina). Dogs were individually fed to maintain body weight and body condition based on energy intake before initiation of the study. Data were analyzed using the mixed models procedure of SAS. Treatment nutrient concentrations ranged for DM (32.2–36.2%), OM (91.1–94.9%), CP (50.3–61.7%), fat (25.1–38.3%), and gross energy (5.8–6.4 Kcal/g). Fecal scores were lower ($P < 0.05$) when dogs were fed H (1.2) and B2 (1.9) diets compared with P (2.7) and B1 (3.1). Digestibility of nutrients and energy ranged from 83.3–92.4%, 88.4–95.3%, 93.8–97.7%, 94.9–98.2%, and 91.3–95.5% for DM, OM, CP, fat, and energy, respectively. Dogs fed B2 had greater ($P < 0.05$) DM (92.4%), OM (95.3%), CP (97.7%), and GE (95.5%) digestibilities but lower ($P < 0.05$) fat digestibility (94.9%) than all other diets evaluated. The results of this study suggest these RMDs were comparable in nutrient composition and apparent total tract digestibility, indicating dogs effectively digest RMDs containing various protein sources. Fecal scores were all 3.1 or less; therefore, RMDs did not result in reductions of digestibility or in diarrhea and all

diets utilized in this study may be effective options for managing exotic carnivores.

Key Words: raw meat diets, dogs, exotic canids

0428 Miscanthus grass utilization as a dietary fiber source for dogs. R. Antunes Donadelli*, C. G. Aldrich, and I. C. Alvarenga, *Kansas State University, Manhattan.*

Pet foods formulated to aid weight loss by energy reduction may include high levels of fiber (8 to 10%). This fiber may be added as beet pulp (BP), cellulose (CE), or other crop residues. *Miscanthus giganteus* (MG) is a purpose grown C4 grass that produces large quantities of fiber. However, there is no published data supporting the use of MG in dogs. The hypothesis of this study was that MG would be utilized as a fiber source similar to CE and BP in dog diets. Each experimental diet contained 10% test fiber and 90% basal ration (chicken byproduct meal, brewers rice, corn, wheat, corn protein concentrate, minerals, and vitamins) to meet the recommended allowance according to NRC (2006). The experimental protocol was approved by Institutional Animal Care and use Committee at Kansas State University. Twelve Beagle dogs (average weight 10.6 kg) were housed individually in metabolism cages in environmentally controlled rooms and fed experimental diets for 14 d (9-d adaptation and 5-d collection) in a replicated Latin square design. Diets and all feces (TFC) were analyzed for proximate analysis and acid insoluble ash (AIA) and apparent total tract digestibility (ATD) was computed. Data were analyzed with statistical software using the GLM procedure (SAS v9.4). Food was readily accepted by all dog and each maintained weight throughout the study. There were no differences in defecation frequency, but fecal scores (1 = soft, 5 = hard and firm) were lower (softer; $P < 0.05$) for BP (3.15) than MG (3.63) or CE (3.68). Dry fecal excretion was estimated at 46.9 and 63.1 g*d^{-1} for TFC and AIA, respectively. The DM and OM digestibility were greater ($P < 0.05$) for dogs fed BP than MG but less than those fed CE for TFC (DM; 81.32, 78.0, and 77.21%, OM; 86.06, 82.12, and 80.81%, respectively) and AIA (DM; 76.55, 72.20, 68.92%, OM; 81.58, 76.68, 73.56%, respectively). The CP digestibility was greater ($P < 0.05$) for MG than BP and CE for both TFC and AIA methods. The EE digestibility was greater ($P < 0.05$) for the MG and CE than BP for both TFC and AIA. The AIA method predicted nutrient digestibility with similar magnitude and rank to TFC. Further, differences among treatments for ATD occurred among treatments the results indicate that MG is a viable dietary fiber alternative to CE and BP in dog foods.

Key Words: fiber, dog, Miscanthus grass, cellulose, beet pulp, digestibility

429 The effect of milled sorghum fractions on diet utilization by dogs. I. C. Alvarenga*, C. G. Aldrich, and R. A. Donadelli, *Kansas State University, Manhattan*

Sorghum is an abundant starch source that has many potential health benefits. Some pet food companies have adopted whole sorghum in their formulations, however sorghum flour and (or) its seed coat which is rich in polyphenolics might provide added benefit to companion animal diets. The objective of this experiment was to evaluate diets utilizing sorghum flour (SFD), and sorghum mill feed (SMF) relative to whole sorghum (WSD), and conventional grains (rice, corn and wheat; CON) in a typical dog diet. Adult (1–3 yr) Beagle dogs ($n = 12$; 10.6 kg ± 1.4) were randomly assigned to individual pens with ad libitum access to water. Dogs were fed twice daily and adapted to diet (9 d) then feces and urine were collected for 5 d over 4 periods in a replicated Latin square design. Fecal excretion was estimated using Cr_2O_3as an external marker and apparent total tract digestibility was computed. Number of defecations and feces were scored on a subjective 5-point scale (1= runny, 5 = hard and dry). Results were analyzed with statistical software using GLM procedure of SAS (v 9.4). Dry matter digestibility (DMD) was greater ($P < .05$) for SFD than CON and WSD, which were greater ($P < 0.05$) than SMF (86.0, 83.0, 81.1, and 65.9%, respectively). The organic matter (OMD), energy (DED), and protein (PRD) digestibility followed a similar relationship among treatments (OMD 90.7, 88.1, 86.4, and 70.06%; DED 90.3, 87.2, 85.4, and 70.2%; PRD 81.8, 77.5, 77.2 and 67.2%, respectively). In contrast, fecal scores were highest ($P < 0.05$; 3.91) for SMF, intermediate for the WSD and SFD (3.74 and 3.77) and lowest ($P < 0.05$) for CON (3.58). As well the number of defecations per day was higher ($P < .05$) for SMF than all the other treatments (3.03 vs. average 2.21). While SMF may contain some beneficial phenolic compounds it decreased nutrient digestibility and yielded firmer stools relative to the other treatments. Mostly due to the higher fiber content of this milled sorghum component. In contrast, removing the fibrous cortical layer resulted in higher digestibility for SFD and may provide beneficial functional properties to modern pet food kibble.

Key Words: sorghum, pet food, digestibility, flour, mill feed

COMPANION ANIMAL SYMPOSIUM: BEHAVIOR AND THE HUMAN-ANIMAL BOND

0430 Cognitive assessment protocols for use with companion animals. B. Milgram*, *CanCog Technologies, Toronto, ON, Canada.*

This presentation will provide an overview of the three main technologies that have been used to train and assess cognitive ability in companion animals, will discuss the utility of each and their relationship between all three. The first technology utilizes an approach, known as Operant conditioning, and is a method of training animals that follows a sequence of distinct steps—each of which uses reward to motivate the animals to learn and a process referred to as shaping in which reward is provided for incremental responses. This approach can be used to shape a broad spectrum of behaviors, such as responding to specific commands or stimuli. In dogs, these behavioral testing protocols have long been used to train groups of animals to carry out specific behavioral functions, and include military working dogs and seeing eye dogs as examples. The procedures followed have been well established and there is a large population of animal trainers who are highly skilled in the art.

The second type of protocol, which is one that we have used extensively, is one in which animals are presented with a specific problem and over repeated testing learn to solve the problem, initially by a process of trial and error learning. We have used this procedurel to try to understand the cognitive structure of the canine (and feline) brain, how cognition develops, how it changes with age and how it compares with that of the human. The specific problems are referred to as neuropsychological tests, because their performance can be linked specific neural structures. These protocols are useful for safety and efficacy screening drugs and other interventions. They can also be used in developing interventions for use in humans, with the dog serving as a translatable animal model.

The final technology involves the development of standardized questionnaire to assess cognitive function and is a procedure used only for assessment. The rationale for developing this questionnaire came from the realization that cognitive function can decline dramatically with age in dogs. This cognitive decline has been labeled cognitive dysfunction syndrome (CDS). The actual functions, however, are not limited to behaviors linked to cognition, but also behaviorsthat could be linked to other aging processes. To date, there is little evidence that CDS as defined by questionnaires is a correlate of other measures of canine cognition.

Key Words: operant-condition, neuropsychologal testing, cognitive dysfunction syndrome

0431 Objective evaluation of affective states in dogs. R. T. S. McGowan*, *Nestlé Purina Research, St. Louis, MO.*

It has long been the impression of most pet owners that dogs have rich emotional lives and that their experiences affect them profoundly in ways similar to how humans are affected. However, there is a lack of methodology to objectively assess affective states in animals, especially positive states. It is widely accepted that there is more to good well-being than the absence of negative states and it is increasingly being accepted that the wellbeing of an animal is greatly influenced by its affective state. Animals continually experience "reward cycles" as they pass through appetitive, consummatory and post-consummatory phases during their daily activities (e.g., eating, playing, problem-solving). High arousal positive emotions (e.g., excitement, anticipation) are associated with appetitive phases, sensory pleasure (e.g., comforting touch, hedonic taste) occur during consumption and low arousal positive emotions (e.g., satisfaction, relaxation) accompany post-consumption phases. This talk will highlight methodology that can be used to evaluate these positive states in dogs, providing examples from studies in both research and shelter settings. Dogs are an ideal non-human model for studying positive affective states because they have traditionally lived in close contact with people (so we are good at reading them and they are even better at reading us), are capable of forming close attachments to people (providing opportunity to study the human animal bond from the animal's perspective) and are kept throughout the world as both companions and working animals (a better understanding of their affective states will help to promote optimal wellbeing). Using behavioral tests (e.g., human interaction, cognitive bias, problem solving) coupled with non-invasive physiological measures (e.g., cardiac activity, salivary cortisol, thermal fluctuations) we can glean new insights into how to measure affective states in dogs. By using a holistic approach that incorporates both behavioral and physiological measures, we can produce scientifically sound evidence to identify which emotions animals experience and how animals express these affective states through their behavior. With this holistic approach we can develop a more objective understanding of animal wellbeing.

Key Words: dogs, affective state, non-invasive physiological indicators

0432 The human-animal bond: Science-based approaches to improving companion animal welfare and adoption outcomes. C. C. Croney*, *Purdue University, W. Lafayette, IN.*

There is substantial literature documenting the myriad mutually beneficial effects of the human-animal bond. While such relationships typically enhance the health and well-being of both people and their animal companions, the bond can

weaken or fail to be established if the animals do not meet the expectations of the people with whom they interact. The behavioral component of animal welfare is particularly important in this regard, and requires significant attention, as owners of companion animals are often intolerant of behavior problems. These include behaviors characterized as nuisances, such as excessive vocalizations, those that result in aggression toward people or other companion animals, or behaviors that result in injury to the animal or damage to property. Problem behaviors are among the most commonly stated reasons for cat and dog relinquishment, abandonment and euthanasia. Thus, understanding key factors that impact behavioral well-being in these species is important whether the animals are maintained in or intended to be rehomed from breeding programs, shelters, rescues or elsewhere. Consequently, a comprehensive assessment plan for meeting the needs of animal companions that includes their mental and behavioral well-being is necessary to protect the human–animal bond. It is therefore imperative to develop and validate key metrics of companion animal welfare that are practical for field as well as laboratory purposes. Considerations and challenges in developing such metrics will be reviewed, using the development of care and welfare standards for breeding dogs for illustrative purposes.

Key Words: behavior, companion animal, well-being

0433 2015 Corbin Award Winner: Behavior and training of companion and zoo animals.

C. L. Morris*, *Iowa State University, Ames.*

Activity or behavior varies tremendously across taxa and activity itself separate plants from animals. Regardless if we consider a dog competing on an agility course or a hyena standing for voluntary jugular blood collection, we must understand the science of behavior, the natural history and the instinct of the animal in order for successful training to occur. Repeated behaviors result from either positive or negative reinforcement, whereas behaviors diminish with application of positive or negative punishment. Once we identify reinforcements or punishments relevant to the behavior and specific animal, training and behavior modification become more black and white. This science and theory of animal training are well rooted in the work of Skinner and Pavlov. However, difficulties in animal training occur when trainers or animal managers fail to understand what motivates or reinforces a specific animal or the relevant species-specific natural histories. Animal trainers typically use food to motivate or train animals; however, the animal must want that food item for it to be of value. Subjects of same species may not find similar value in reinforcement items. In addition, failure to understand instinctive behavior patterns typically related to obtaining food or social structures may lead to limitations in training or behavior modification. The term "Instinctive Drift" occurs when animals have been trained to a new learned behavior that ultimately drifts back toward an instinctive behavior. Often this behavioral drift can be mislabeled by animal trainers as disobedience or misbehavior but is frequently related to instinctive behaviors associated with feeding or obtaining food or other inate insticts such as herding. Similarly, some aggression issues in dogs may be prevented or mitigated at a young age if owners had increased awareness of the dynamic social structure of dogs. Stereotypic behaviors are typically thought of as negative repetitive behaviors that originate from artificial environments that do not allow animals to satisfy their normal behavior repertoire, and these behaviors can be difficult to modify. While the science and theory of animal training and behavior are critical to excelling as an animal trainer and manager, it is equally critical to understand natural history, instinctive behaviors and motivation. Therefore, great animal trainers not only understand the science and theory of behavior, they also consider the uniqueness of individual animals they manage.

Key Words: training, behavior, companion animals, zoo animals

COMPANION ANIMAL SYMPOSIUM: FUNDAMENTALS OF PROTEIN NUTRITION

0434 Global protein supply: Present and future considerations and availability.

D. L. Schaefer*, *Cargill, Wichita, KS.*

A key differentiator in the development and marketing of pet food is the source of protein. Producers and marketers are reaching further and using more creativity in product development. This presentation will focus on global trends in the availability of protein for the use in pet diets.

Key Words: protein, companion animal, global source

0435 Alternative protein supplies for petfood.

G. Bosch*, *Wageningen University, Netherlands.*

The combination of a growing human population, increasing standards of living and urbanization in developing countries fuels global demand of protein sources for consumption by humans and animals. Increasing food production is, however, highly challenging as required resources such as land, water and fossil energy are limiting and the environmental impact of crop and livestock production already needs to be minimized. Various efforts are focused on changing the demand as well as on the production of proteins. Global food supplies can be increased by improving production efficiencies. Production of underperforming crop and livestock production systems can be improved through management and new technologies. In addition to increased production of conventional foods, alternative and sustainable foods are being developed. It is therefore clear that also the landscape of available ingredients for the pet food industry will change further the coming years. The additional

alternative proteins can originate from biomass sources previously left as waste. Leaf proteins present in by-products from crops like sugar beet or from grass are already available in large volumes. Technologies are being developed that can extract these leaf proteins yielding colorless protein isolates for (pet)food applications. Various sources of organic waste can be converted by insects (e.g., black soldier fly larvae), which can be used as a high quality and sustainable protein source. Additionally, alternative proteins can also originate from "novel" ways of production. Production systems of aquatic protein sources (microalgae, duckweed, seaweed) are rapidly advancing and do not compete for good agricultural land. These protein sources have a high water content, however, and require separation technologies that are still costly and energy consuming, therefore, requiring further development. Acceptability of vegetable proteins can be facilitated by transforming them into fibrous structural patterns of meat. In the long run, laboratory cultured meat using muscle stem cells may even replace meat from conventional livestock. These examples illustrate that there are multiple alternative protein supplies for future petfoods, although still considerable time is required to further develop the products and reach production volumes for large-scale applications. Furthermore, ingredients still require evaluations beyond chemical characterization including in vivo testing of nutritional and (dys)functional properties as well as safety attributes. Finally, acceptance of alternative ingredients by pet owners may be difficult in some areas of the world. However, awareness of owners regarding global food security continues to grow, which will facilitate the application of these ingredients in petfoods.

Key Words: food security, novel proteins, sustainability

0436 Amino acid requirements and protein digestibility and assessment in dogs with considerations for cats. A. K. Shoveller*, *University of Guelph, ON, Canada.*

Dietary protein remains a key focus for pet food manufacturers; however, few properly designed amino acid (AA) requirement studies have been conducted in adult dogs. Data examining the effects of dietary protein in dogs exist, but few studies provide an understanding of the dietary AA provided or the digestibility and metabolic availability of those AA when different ingredients are utilized. Furthermore, there is a dearth of data on the effects of different food processing parameters on AA bioavailability in dogs. Effects of processing are important as new regulatory requirements for food safety have been implemented. Previous estimates of AA requirements used chemically defined diets and long adaptation periods and may have resulted in AA requirements that are lower than what is required to support protein synthesis. Carbon oxidation approaches have been developed to measure AA requirements of dogs using more appropriate adaptation periods and common ingredients. In addition, secondary measures of AA adequacy, such as taurine status and immune function, also should be investigated to further optimize dietary approaches for dogs. Greater knowledge of AA requirements will lead to better overall protein quality in commercial dog food and provide a better basis for formulation of diets for canine clinical cases.

Key Words: amino acid, requirements, protein, dogs, digestibility, metabolic availability

---

0437 Idiosyncrasies of amino acid metabolism in dogs and cats. D. L. Harmon*, *University of Kentucky, Lexington.*

Both the dog and cat have been domesticated for thousands of years yet they retain some unique metabolic nuances. While both are classified as members of the order carnivora they each have nutritional and metabolic requirements that differ from the majority of domestic species. The dog is considered a nutritional omnivore adapting to a wide range of foods and nutrient sources, whereas the cat is a strict carnivore showing little nutritional or metabolic adaptation with changes in diet. The cat has little ability to adapt amino acid degrading enzymes to dietary protein restriction and conservation of protein and shows little change in urea cycle activity with changes in diet. This contrasting adaptability leads to differences in the nutrient profiles required by each. In addition to requiring greater quantities of dietary protein, the cat requires a dietary source of taurine because of its obligate use of taurine for bile acid conjugation and a limited ability to synthesize taurine from sulfur amino acids. Although taurine is not strictly required in the diet of dogs, it has been suggested that taurine may be required in the diets of certain large breed dogs. Like cats, dogs also use taurine for bile acid conjugation, but they have a greater taurine synthetic ability and can adapt for use of glycine for bile acid conjugation. Both the dog and cat require a dietary source of arginine with the cat being extremely sensitive to its absence. This occurs as a result of the limited ability of cats to endogenously synthesize ornithine and citruilline to maintain urea cycle activity because of low intestinal enzyme activities compared with omnivores. The cat also has a limited ability to use tryptophan to synthesize niacin. Again this occurs from evolutionary adaptations in enzyme levels. Additional nuances include higher requirements for sulfur amino acids in the cat because of needs for hair and felinine synthesis. Overall, the cat appears somewhat unique but metabolically and nutritionally it appears similar to other strict carnivores.

Key Words: feline, companion animal

COMPARATIVE GUT PHYSIOLOGY

0438 β-hydroxybutyrate and glucose concentrations in the blood of dairy calves. F. X. Suarez-Mena*, W. Hu, T. S. Dennis, T. M. Hill, J. D. Quigley, R. L. Schlotterbeck, *Provimi, Brookville, OH.*

This research was conducted to determine how blood β-hydroxybutyrate (BHBA) and glucose are impacted by age, time of day, voluntary starter intake, stress, weaning, and intake restriction in 1- to 9-wk-old calves and to see if either is an acceptable proxy for starter intake. Male Holstein calves were fed a 27% CP, 17% fat milk replacer at 660 g DM daily to weaning on d 42, along with free-choice starter (20% CP, 41% starch) and water. Jugular blood was sampled at 0800, 1200, and 1600 h and within 5 min of sampling BHBA and glucose concentrations were estimated using test strips (Nova Max® Plus meter, Nova Biomedical). Age effects were estimated by sampling blood weekly (d 6, 13, 20, 27, 34, 41, and 48). To determine vaccination stress, a *Pasteurella* vaccine was administered after blood sampling at 0800 h on d 36. Effect of voluntary starter intake was tested by selecting calves for low and high intakes (d 35 to 39) and sampling on d 40, 41, 43, and 44. Starter intake restriction was tested by restricting intake in 6 of 12 calves and sampling on d 60 and 61. Data were analyzed using several mixed model procedures (repeated measures, regression, etc.) in SAS. Time of day did not impact blood BHBA or glucose to wk 6, but did in wk 7 ($P < 0.05$). Blood glucose was greater ($P < 0.05$) in the first 5 wk compared with wk 6 and 7. Blood BHBA increased ($P < 0.02$; $R^2 = 0.28$) and glucose decreased ($P < 0.02$; $R^2 = 0.23$) with increasing starter intake. Blood BHBA declined ($P < 0.05$) due to vaccination but glucose was unaffected. Starter intake restriction reduced BHBA for 3 d ($P < 0.05$) and glucose for 2 d ($P < 0.05$) after intake restriction. Around weaning (d 40 to 44), BHBA and glucose increased ($P < 0.05$) with increasing starter intake. Blood BHBA was positively and glucose negatively related with starter intake; however, relationships were weak, variable, and impacted by time of day, stress, and intake restriction. Over 30% of calves tested ≤ 0.2 mmol/L BHBA when consuming > 1250 g/d of starter, and test strip increments were 0.1 mmol/L which represented > 25% of the mean blood BHBA concentration. In this study, neither blood BHBA nor glucose were an acceptable proxy for estimating starter intake.

Key Words: blood β-hydroxybutyrate, dairy calves, intake

0439 Comparison of intestinal goblet cell staining methods in turkey poults. S. O. Osho*, T. Wang, N. L. Horn, and O. Adeola, *Department of Animal Sciences, Purdue University, West Lafayette, IN.*

This study compared the intestinal goblet cell density of turkey poults at two different ages using Alcian blue-Periodic acid shiff (AB-PAS) and Mucicarmine stains. Neutral mucins are stained with PAS while acidic mucins are stained with AB. Mucicarmine is specific to the mucins of epithelial origin and it is currently used for human samples, Mucicarmine may have advantages for use in animals as a result of the methodological simplicity of staining as compared with AB-PAS. Jejunum samples were taken from 80 turkey poults at 21 and 28 d, and were assigned to two treatments which consisted of AB-PAS and Mucicarmine stains in a completely randomized design. A mid-section of jejunum from each bird was taken and placed in 10% buffered formalin for 48 h, dehydrated with ethanol, cleared with Sub-X and placed in a paraffin, prepared on two slides, and then tissues were briefly cleared and hydrated. Each slide was stained with either AB-PAS reagents or Mucicarmine reagents. Goblet cell counts were taken from four villi per slide and the villi height was measured and averaged. There was no difference in the goblet cell density between the staining methods AB-PAS and Mucicarmine at 21 or 28 d post-hatching. These results show that both staining methods are viable for assessment of goblet cell density in turkey poults.

Key Words: goblet cells, jejunum, stain

0440 The development of a cecum-cannulated gnotobiotic piglet model to study the human gut microbiota. N. D. Aluthge*[1], W. Tom[2], T. E. Burkey[2], D. E. Hostetler[2], K. D. Heath[2], C. Kreikemeier[2], and S. C. Fernando[2], [1]*University of Nebraska, Lincoln,* [2]*University of Nebraska, Lincoln.*

Research conducted over the past decade using high-throughput DNA sequencing technologies have provided valuable insights into the importance of the human gut microbiota in host health and disease. Most of these studies, however, have been associative and causality of the gut microbiota in human health-associated conditions has been difficult to demonstrate due to the lack of a suitable animal model which can faithfully recapitulate the interactions between the human host and the gut microbiota. The domestic pig (*Sus scrofa*) has been used as a clinically relevant model to study various aspects of human disease and shares a high degree of anatomical, physiological, and immunological similarities with humans, thus being a potentially valuable model for human gut microbiota studies. This study was conducted with the objective of establishing human gut microbial communities in gnotobiotic piglets and to investigate the potential of using cecum cannulation as a means of obtaining microbial community samples for time series and microbial gene expression studies. Six germ-free

piglets derived using cesarean section were transferred into isolator bubbles and at 7 d of age, 3 piglets were inoculated with fecal bacteria from high body mass index (BMI > 30) human donors and the remaining 3 animals were inoculated with fecal bacteria from low BMI (BMI < 25) donors. After weaning, the piglets with the high BMI microbiota were provided a high-fat (HF) diet while the piglets with the low BMI microbiota were fed a low-fat (LF) diet. At wk 7, the high BMI microbiota piglets were cecum-cannulated and the low BMI microbiota piglets were similarly cecum-cannulated at wk 8. A cecal sample was collected from each animal immediately before surgery for use as a control for comparing cecal bacterial communities. Cecal samples were collected via the cannulae from all animals at weekly intervals until wk 10 (when the animals were euthanized). The cecal samples were sequenced using the Illumina MiSeq™ DNA sequencing platform to characterize the bacterial community composition. Comparison of the cecal bacterial communities of the cannulated piglets before surgery and at later time points revealed similar composition (PERMANOVA, $p = 0.105$), indicating no negative impact of cannulation on cecal bacterial community structure. BMI-Diet type had a significant impact on structuring cecal bacterial communities (PERMANOVA, $p < 0.001$). These results point to the potential use of cecum-cannulated humanized piglets as a model system to study the human gut microbiota.

Key Words: human microbiota, high-throughput DNA sequencing, piglet model

COMPARATIVE GUT PHYSIOLOGY SYMPOSIUM

0441 Diet, gut microbiome, brain and behavior.

J. Bienenstock*, *McMaster Brain-Body Institute, Hamilton, ON, Canada.*

The gut microbiome consists not only of bacteria but also viruses (virome) and fungi (mycobiome). There is considerable evidence that gut bacteria influence the structure and function of both the enteric and central nervous systems and that changes in the microbiome can affect mood and cognitive functions. Dietary change alters the gut bacterial content and also the virome and these are in turn associated with changes in behavior and cognition. The pathways whereby these changes occur are multiple and interacting, and we are only just beginning to understand how these occur, but their importance to animal health is undoubted. This presentation will explore how microbes effect these changes and the pathways that may be involved in so doing from lumen to brain.

Key Words: microbiome, gut-brain axis, virome

0442 Butyrate increases tight junction protein expression and enhances tight junction integrity in porcine IPEC-J2 cells stimulated with LPS.

H. Yan*[1] and K. M. Ajuwon[2], *[1]Purdue University, West Lafayette, IN, [2]Department of Animal Sciences, Purdue University, West Lafayette, IN.*

The intestinal mucosal barrier is maintained by tight junctions, which are intercellular adhesion complexes and prevent the passage of pathogens and toxins through the paracellular space. Dysfunction of tight junctions induced by endotoxin and mycotoxin is highly associated with a variety of gastrointestinal disorders in pigs. Butyrate has been shown to possess immunological and metabolic modulatory effects in various cells and tissues. Therefore, we investigated protective effect of butyrate on cell integrity and tight junction protein expressions during LPS stimulation in porcine IPEC-J2 cells. We found that butyrate (1mM) and LPS (10μg/ml) significantly induced TNFα, IL-1β, IL-6, IL-8 and MCP1 expression ($P < 0.05$) as well as IL-8 secretion. However, although LPS upregulated TLR4 expression, butyrate downregulated it ($P < 0.01$) indicating butyrate could inactivate LPS stimulation of TLR4 pathway. Barrier integrity was investigated with trans-epithelial electrical resistance (TEER) and fluorescein isothiocyanate-dextran (FITC-dextran) uptake based tests. Treatment with LPS for 24 h significantly decreased TEER ($P = 0.01$) and increased cell permeability ($P = 0.02$). On the contrary, butyrate (1 mM) significantly increased TEER ($P < 0.01$) and decreased cell permeability ($P < 0.01$), indicating that butyrate could increase cell integrity and enhance epithelial barrier against LPS-induced damage. Butyrate also induced *Claudin-1* ($P = 0.09$), *Claudin-3* ($P < 0.01$) and *Claudin-4* ($P < 0.01$) mRNA expression, and Claudin-3 protein expression ($P < 0.05$) in a dose-dependent manner, perhaps accounting for the increase in epithelial barrier integrity induced by butyrate. Butyrate also increased ($P < 0.01$) activation of Akt by phosphorylation, whereas LPS exerted the opposite effect. Taken together, butyrate increased basal immune response and enhanced the integrity of the intestinal mucosal barrier against LPS-induced damage through an upregulation of cytokine expression and an increase in the synthesis of tight junction proteins.

Key Words: Akt, butyrate, epithelial barrier integrity, IPEC-J2 cells, tight junction protein

0443 Understanding host-microbiota interplay using nutrimetabonomics.

S. P. Claus*[1], C. I. Le Roy[1], M. J. Woodward[1], and R. M. La Ragione[2], *[1]University of Reading, Reading, UK, [2]University of Surrey, Guildford, UK.*

Gut microbiota are now recognized as fundamental partners of the host's health. Normally, the host-microbiota symbiosis results in a healthy metabolic phenotype. But as the

environment changes, our metabolism adapts to maintain homeostasis within an optimal metabolic space, and so do our microbiota. So how does this interplay result in an optimal metabolic state? And how can this be measured? Nutrimetabonomics is a useful tool to assess the metabolic state of the host in response to environmental perturbations. Here, we will illustrate how it was used to gain new understanding of the metabolic disruptions triggered by *Brachyspira pilosicoli*-induced spirochaetosis, a common condition in poultry farms. We will discuss how a better knowledge of the host metabolic response to the pathogen, and to the antibiotic treatment, can help design new therapeutic alternatives to antibiotics.

Key Words: gut microbiota, nutrimetabonomics, host-pathogen interaction

0444 Effects of dietary fibers on obesity related physiological parameters in C57BL/6 mice.
C. Liu, A. K. Singh, M. Stewart, J. H. Uyehara-Lock, and R. Jha*, *University of Hawaii at Manoa, Honolulu.*

Obesity, a metabolic disease resulting from an imbalance between caloric intake and expenditure, is a global concern. Studies suggest that the intake of dietary fiber improves metabolic health; however, the amount of dietary fiber and the fiber type that contribute to this improvement is unclear. This completely randomized study investigated the effect of 1.25, 2.5, and 5.0% (w/w) glucomannan or oat β-glucan in the diet versus a control diet on metabolism. Obesity related variables such as liver steatosis, and short chain fatty acid (SCFA) production was evaluated in diet-induced obese male C57BL/6 mice. Six-wk-old mice (n = 84) were fed one of 7 diets for 12 wk. On d 84, whole blood was collected and serum metabolites were analyzed. Small liver lobe portions were used to examine steatosis severity and cecum samples were analyzed for SCFA concentration. The glucomannan diets had an interaction between fiber and their inclusion levels for relative liver weight ($P < 0.05$) and percent steatosis ($P < 0.001$). The oat b-glucan diet resulted in lower serum triglyceride concentrations ($P < 0.05$), whereas including glucomannan in the diet resulted in higher acetate and propionate levels ($P < 0.05$) in comparison to the other dietary treatments. In the liver, the inclusion of 2.5 and 5% of fiber caused a decrease in microvesicular fat in comparison to the inclusion of 1.25% of fiber. This study highlights that the inclusion of glucomannan and oat β-glucan fiber in the diet at specific inclusion levels is capable of having significant effects on relative liver weight, percent steatosis, and serum triglycerides in obese mice. Glucomannan decreased the severity of mediovesicular fat, while both fibers decreased severity of macrovesicular fat. Thus, supplementing a diet with an adequate amount of specific dietary fiber may be a strategic method to reduce obesity in animals, and this may eventually be translated toward treating human obesity to reduce obesity related health issues.

Key Words: fiber, obesity, mice

0445 The gut microbiome as a regulator of physiology, brain and behavior: Implications for the treatment of stress-related disorders.
G. Clarke*[1], T. F. O'Callaghan[1,2], P. Ross[1], and C. Stanton[1], *[1]University College Cork, Cork, Ireland, [2]Teagasc Food Research Centre, Cork, Ireland.*

It has become increasingly clear that multiple aspects of host physiology are heavily influenced by the gut microbiome. Included in this remit is not just host metabolism and body composition but also a marked influence on the stress response via the hypothalamic-pituitary-adrenal axis. This is clear from studies in microbiota-deficient germ-free animals who display exaggerated responses to acute stressors that can be normalized by monocolonization with certain bacterial species including *Bifidobacterium infantis*. Also coming into focus is microbial regulation of the metabolism of tryptophan, an essential amino acid and precursor to serotonin, a key neurotransmitter within both the enteric and central nervous systems. The gut microbiota may thus be a tractable target for treating or preventing stress-related microbiome-gut-brain axis disorders and metabolic diseases. Moreover, the implications of these findings need to be considered in the context of new control points for endocrine-immune-metabolic targeting in farm and domestic animal physiology and behavior.

Key Words: gut microbiome, stress, tryptophan

---

446 The microbiota-gut-brain axis: A key regulator of neural function across the life span.
J. F. Cryan*, *University College Cork, Cork, Ireland.*

The microbiota-gut-brain axis is emerging as a research area of increasing interest for those investigating the biological and physiological basis of neurodevelopmental, age-related and neurodegenerative disorders. The routes of communication between the gut and brain include the vagus nerve, the immune system, tryptophan metabolism, via the enteric nervous system or by way of microbial metabolites such as short chain fatty acids. Studies in animal models have shown that the development of an appropriate stress response is dependent on the microbiota. Developmentally, a variety of factors can impact the microbiota in early life, including mode of birth delivery, antibiotic exposure, mode of nutritional provision, infection, stress as well as host genetics. At the other extreme of life, individuals who age with considerable ill health tend to show narrowing in microbial diversity and a proinflammatory phenotype. Stress can significantly impact the microbiota-gut-brain axis at all stages across the life span. Recently, the gut microbiota has been implicated in a variety of conditions including autism, schizophrenia and Parkinson's disease. Moreover, fundamental brain processes from adult

hippocampal neurogenesis to prefrontal cortex myelination to microglia activation have been recently shown to be regulated by the microbiome. Further studies will focus on understanding the mechanisms underlying such brain effects.

Key Words: myelin, neurodevelopment, psychobiotic, stress

0447 Microbial modulation of the neonatal immune system: Lessons from infants and piglets.

S. M. Donovan*[1], M. Wang[2], L. A. Davidson[3], I. Ivanov[4], and R. S. Chapkin[4], *[1]University of Illinois, Urbana, [2]Unversity of Illinois, Urbana, [3]Texas A&M Unversity, College Station, [4]Texas A&M University, College Station.*

Studies from germ-free and gnotobiotic animals clearly demonstrate that basic developmental features of the mammalian immune system depend on interactions with the microbiome. The objective of this presentation is to review how early life nutrition and the microbiome influence immune development and function in the neonate. Comparative aspects between different forms of nutrition (mother-fed versus artificially reared) on systemic and mucosal immunity and findings across species (human versus piglet) will be highlighted. Briefly, our laboratory has shown that the T cell and natural killer cell repertoire and cytokine secretion profiles differ by mode of nutrition in both species. In addition, although the composition of the microbiota differs between human infants, being bifidobacteria-predominant, and piglets, where lactobacilli predominate, the microbiome composition of both species responds to mode of nutrition and the addition of prebiotics to formula. Data from our group on the impact of transfaunation of breast-fed infant microbiome into piglets on piglet gut gene expression will be presented. Lastly, findings from our laboratory showing cross-talk between the bacterial metagenome and the intestinal epithelial transcriptome of human infants using shed epithelial cells will be described. Supported by NIH grant no. R01 HD061929 and Hatch ILLU-698–311.

Key Words: microbiota, human, swine, immunity, nutrition

0448 The growing importance of defining gut "health" in animal nutrition and health.

P. Celi*[1], A. J. Cowieson[2], F. Fru-Nji[2], A. M. Kluenter[2], and V. Verlhac[3], *[1]Faculty of Veterinary and Agricultural Sciences, University of Melbourne, Parkville, Australia, [2]DSM Nutritional Products, Kaiseraugst, Switzerland, [3]DSM Nutritional Products, Village-Neuf, France.*

Optimal gastrointestinal health (effective immune status, normal and stable microbiota, absence of inflammatory state) and functionality (digestion and absorption of feed) are essential for sustainable animal production (growth, milk yield, meat and egg quality). However, while gut health is an increasingly important topic in animal nutrition, a clear scientific definition is still lacking although it has been used repeatedly in animal health. A clear definition of gut health and how it can be measured is required to monitor animal health and to evaluate the effects of any nutritional intervention on animal performance. While in human medicine gut health is often associated with the "absence of clinical diseases," this definition cannot be applied to farm animals as it is well known that animal performance can be impaired without any clinical signs of disease. Perhaps a more comprehensive definition of gut health would be "a steady state where the microbiome and the intestinal tract exist in symbiotic equilibrium and where the welfare and performance of the animal is not constrained by intestinal dysfunction." This definition combines the principal components of gut health, namely diet, effective structure and function of the gastrointestinal (GIT) barrier and normal and stable microbiota, with effective digestion and absorption of feed and effective immune status. All these components play a critical role in GIT physiology, animal health, welfare and performance. Clarity of understanding of gut health will require the characterization of the interactions between all of these components. The development of biomarkers of gut health is imperative to gain clarity of understanding of the patho-physiological events that influence the intestinal barrier, its functionality and the ecology of the GIT microbiota. While there is considerable knowledge in biomarkers that are indicative of the GIT ability to digest, absorb, transport and secrete major macro and micronutrients, a large gap in the literature exists in relation to biomarkers of GIT permeability, GIT barrier function, or biomarkers that are indicative of the functional presence of beneficial microbiota or their metabolites. Therefore, future research should focus on the establishment of a reference panel of biomarkers of gut health to be used in farm animals and address the issue of standardization of techniques and methodologies to study gut health.

Key Words: biomarkers, gut health, microbiome

0449 The microbiome and animal health.

G. B. Penner*[1], T. A. McAllister[2], S. Li[3], J. C. Plaizier[3], E. Khafipour[3], and L. L. Guan[4], *[1]University of Saskatchewan, Saskatoon, Canada, [2]Lethbridge Research and Development Centre, AAFC, AB, Canada, [3]Department of Animal Science, University of Manitoba, Winnipeg, Canada, [4]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

For monogastrics, the linkage between the microbiome and animal health has been established, and it is known that colonization of the gastrointestinal tract (GIT) stimulates development of the immune system. In ruminants, the microbiome has largely been evaluated to assess the potential contribution

toward feed digestion and adaptive responses as a consequence of dietary change. For example, previous research has shown a positive relationship between the Firmicutes:Bacteroidetes ratio and milk fat yield, and that the abundance of Clostridiales (family VIII) is negatively associated with feed conversion. A positive association for the systemic acute phase response caused by a severe form of subacute ruminal acidosis and the prevalence of *Escherichia coli* in the rumen has also been reported. Separating cause and effect continue to be a challenge with this area of research. The ruminal microbiome is responsive to diet and changes are particularly evident when comparing high-forage and high-grain feeding scenarios. That said, there is evidence to suggest that the microbial community is relatively resistant to change and can revert back to a composition similar to the original community structure after being disturbed. The microbiome robustness presents a challenge when modifications to the community structure may be desired. Moreover, differences between the digesta associated versus mucosa and epithelia associated communities are present and these communities change throughout the GIT. While understanding the rumen microbiome is important, more distal regions of the GIT have not been thoroughly examined. The change in microbial community structure along the GIT may not be that surprising given changes in retention time and substrate availability. In addition, microbial-host crosstalk mechanisms may differ among regions helping to explain why the microbial community structure differs. Understanding the regulation of the microbial-host communication may provide the necessary information to develop practical strategies to modulate the microbial community structure. Accordingly, evaluating strategies to manipulate microbial colonization and succession in pre-ruminants appears to be a logical intervention strategy. In addition to the core microbiome, diversity of the microbiome appears to be a critical aspect and calves that develop scours have been reported to have lower diversity when evaluating the fecal microbiome. Thus, a systematic approach to improve our understanding of the relationship between microbiome, or at least key species, is needed to advance this area. Such research will require an in depth understanding of both the microbiome and host gastrointestinal physiology.

Key Words: gastrointestinal tract, microbiome, cattle

0450 In vitro fermentation characteristics of agricultural products and coproducts and its effect on the large intestinal microbiota of swine.

U. P. Tiwari*[1], S. Mattus[1], K. Neupane[2], and R. Jha[1], *[1]University of Hawaii at Manoa, Honolulu, [2]University of Hawaii, Leeward Community College, Pearl City.*

Dietary fibers and resistant starches are fermented in the gastrointestinal tract (GIT) and alter the microbial community. Specific microbes in the GIT are found to promote host health, the microbial population is also dependent on the type of fermentation substrates available in the GIT. Alternative feedstuffs are explored and evaluated to contribute in reducing feed costs of swine. These feedstuffs are typically rich in fiber and/or resistant starches which may provide prebiotic effects for the pigs. Six alternative feedstuffs were evaluated for their fermentation characteristics and effect on the microbiota of the large intestine of swine using an in vitro model. Three fibrous (macadamia nut cake, MNC; barley brewers grain, BBG; wheat millrun, WMR) and three starchy (Okinawan sweet potato, OSP; yam, and taro) feedstuffs along with inulin and blank as a positive and negative control, respectively were used in this study. After two-step enzymatic digestion assay, residues were fermented using fresh pig feces as microbial inoculum and gas production were recorded periodically. The residue after 72 h of microbial fermentation was used for genomic DNA isolation. The V3 region of the 16S rDNA of the genome was amplified using bacterial primers and the product used to generate banding profiles via temperature gradient gel electrophoresis (TGGE). The unique profile created by each sample was analyzed, and compared with determine similarities between samples. The fibrous feedstuffs (MNC, BBG and WMR) were most closely related to each other, and to inulin, indicating they may cause a health-promoting shift in the microbial community as inulin. The starchy feedstuffs (OSP, yam and taro) also showed similarities to each other, but were less related to inulin, with the exception of OSP, which had a similar profile to inulin. The MNC was least similar to the starchy feedstuffs. Total gas production of OSP (298), inulin (291) and taro (276) were significantly higher ($P < 0.01$) than MNC (87) and BBG (75 mL/g sample). In conclusion, some of the alternative feedstuffs tested may exert comparable prebiotic effects to inulin, thus may be included in swine diets to favorably impact the GIT microbiota.

Key Words: coproducts, fermentation, gut microbiota

0451 Analysis of the gut microbiome in beef cattle and its association with feed intake, growth, and efficiency.

P. R. Myer*[1], J. E. Wells[2], T. P. L. Smith[2], L. A. Kuehn[2], and H. C. Freetly[2], *[1]University of Tennessee Institute of Agriculture, Knoxville, [2]USDA-ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Next-generation sequencing has taken a central role in studies of microbial ecology, especially with regard to culture-independent methods based on molecular phylogenies of the small-subunit ribosomal RNA gene (16S rRNA gene). The ability to relate trends at the species or genus level to host/environmental parameters using 16S profiling has proven powerful. Within the rumen and lower gastrointestinal tract (GIT), the diverse microbial ecosystems present are essential for the host to digest plant material and regulate nutrient uptake and utilization. Their examination utilizing next-generation technologies has been instrumental to aid in the understanding of

the microbial-associated interactions throughout the gut with intake, growth, and feed efficiency. Using a feed efficiency design in which steers were selected from two contemporary groups and were ranked based on their standardized distance from the bivariate mean (ADG and ADFI), four steers with the greatest deviation within each Cartesian quadrant were sampled (n = 16/group; 2 groups) to examine the association of the microbiome throughout the gut with ADG, average daily DMI (ADFI), and feed efficiency. In addition, phylogenetic analyses of the ruminal bacterial community were compared based on varying sequencing technologies, 16S variable region selection, and short read 16S amplicons, near full-length 16S amplicons, and metagenomic sequence. In all studies, although no differences in bacterial diversity and richness metrics were revealed among the quadrants, finer changes in the relative abundance of microbial populations and operational taxonomic units did reveal differences between feed efficiency groups ($P < 0.05$), suggesting throughout the GIT, the microbial communities differ at the 16S level in cattle that vary in ADG, ADFI, and feed efficiency. However, additional phylogenetic analyses on the rumen bacterial community demonstrated that utilizing near full-length 16S reads may be useful in conducting a more thorough study, or for developing a niche-specific database to utilize in analyzing data from shorter read technologies when budgetary constraints preclude use of near-full length 16S sequencing. Partially funded by National Institute of Food and Agriculture Grant no. 2011–68004–30214, National Program for Genetic Improvement of Feed Efficiency in Beef Cattle.

Key Words: feed efficiency, microbiome, 16S rRNA

CONTEMPORARY AND EMERGING ISSUES SYMPOSIUM: COMMUNICATING ANIMAL SCIENCES EFFECTIVELY

0452 Public perceptions of animal-sourced genetically modified food products. W. K. Hallman*, C. L. Cuite, and X. K. Morin, *Rutgers University, New Brunswick, NJ.*

The success of agricultural biotechnology depends as much on consumer acceptance of Genetically Modified (GM) products as it does on the ability to create them. To explore public perceptions of GM food products, we surveyed a nationally representative sample of 1148 American adults during October 23–27, 2013. The data was collected by GFK Knowledge Networks from an internet panel recruited using proportional random sampling. The data was weighted to project to the U.S. population, and has a margin of error of ± 3%. The results show that despite the ongoing controversy over GM foods, 50% of Americans report having heard or read little or nothing about them, 55% report that they know very little or nothing at all about them, and two-thirds (66%) say they have never discussed the issue of GM foods with anyone. Estimates are that 75% of processed foods in the U.S. contain ingredients derived from GM crops. However, only 43% of Americans say that they believe that there are foods containing GM ingredients in supermarkets right now, while 4% say there are no such foods in U.S. supermarkets, and 51% say they don't know. Many of those who believe that there are GM foods in the supermarket are confused about which products are available. For example, while 75% correctly believe that there are products in U.S. supermarkets containing GM corn, and 59% correctly believe that there are products containing GM soy, nearly as many (56%) believe that GM tomatoes, GM Wheat (55%), and GM Chicken (50%) products are available and 35% believe that GM salmon are currently for sale. Moreover, even though GM food products have been on the market in the U.S. for more than two decades, only 26% of Americans believe that they have ever eaten a food containing GM ingredients. Yet, while most Americans say they have heard and read little about GM foods, know little about them, have never had a conversation about them, don't believe they are currently in the supermarket, and don't believe they have ever eaten them, most are willing to express an opinion about the acceptability of GM food products. When asked directly, only 10% of consumers say they approve of GM animal-sourced food products, 44% say they disapprove of them, and 43% neither approve nor disapprove of them, or are unsure. However, there is much greater public acceptance expressed when specific product benefits are described.

Key Words: public perceptions, genetically modified, animal-sourced foods

0453 What is the science of science communication for? And why should animal scientists care? D. Kahan*, *Yale Law College, New Haven, CT.*

The source of nearly every science-communication misadventure can be traced to a single mistake: the confusion of the processes that make science valid for the ones that vouch for the validity of it. The scientific knowledge that individuals rely on in the course of their everyday lives is far too voluminous, far too specialized for any—including a scientist—to comprehend or verify for herself. So how do people manage to pull it off? What are social cues they rely to distinguish the currency of scientific knowledge from the myriad counterfeit alternatives to it? What processes generate those cues? What are the cognitive faculties that determine how proficiently individuals are able to recognize and interpret them? These questions not only admit of scientific inquiry; they demand it. Unless we understand how ordinary members of the public ordinarily do manage to converge on the best available evidence, we will never fully understand why they occasionally do not, and what can be done to combat these noxious sources of ignorance. I will discuss these basic themes and relate them to the stake that the animal science community has in the

advancement of the new science of science communication.

Key Words: science communication

0454 Cracking the code: Making complex information understandable. A. Perry*, *The Center for Food Integrity, Gladstone, MO.*

Consumer beliefs do not always align with the scientific consensus. Consumers may not accept an idea even though science says it is true. Consumers do not fully understand the science that individuals in animal agriculture find so simple. Our challenge is to find better ways to bridge the communication gap by using shared values to earn consumer trust. In partnership with Iowa State University, CFI was the first to build a research-based consumer trust model. Our peer-reviewed and published model for building consumer trust in today's food system shows that shared values are more important than skills and technical expertise in building consumer trust. The social decision-making process is complex. Building trust is step one. Explaining the complex scientific concepts around animal agriculture is step two. The ability to break down existing communication barriers is critical to fostering informed decision making that leads to consumer confidence.

Key Words: consumers, complex, communication, food

0455 Communicating animal science effectively. D. R. Williams*, *National Cattlemen's Beef Association, Centennial, CO.*

Having spent the past 25 yr of my career helping companies and organizations communicate during crises ranging from Alar in apples to Pink Slime in ground beef, I have learned a number of lessons about what works and does not work in communicating science effectively. The first lesson is to not lead with science! People react to issues that could impact their family's health and well-being with emotion. Responding with facts and figures is unlikely to calm their fears. So the first step in communicating effectively is to acknowledge their concerns, whether you believe they are rational or not. By acknowledging that their concerns are legitimate you open the door to sharing factual information. I have a formula for responding effectively I call the "Two Cs." We care, and we're capable. We care about the same things they do: the safety of our food, the care of animals, the future of our planet and the health and well-being of our families. Once you have established that common ground, you can focus on addressing differing viewpoints on the "facts" of the matter. In this panel discussion I will share real-life examples of how this technique has been used to communicate animal science effectively.

CSAS GRADUATE STUDENT ORAL COMPETITION I

0456 Ensiling barley varieties selected for varied levels of in vitro NDF degradability. N. G. Preston*[1,2], J. Nair[1], P. Yu[1], D. A. Christensen[1], J. J. McKinnon[3], and T. A. McAllister[4], *[1]University of Saskatchewan, Saskatoon, Canada, [2]Lethbridge Research and Development Centre, Agriculture and Agri-food Canada, AB, Canada, [3]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada, [4]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, AB, Canada.*

This study characterized the ensiling traits and digestibility of three barley varieties ranked for in vitro NDF degradability (NDFD). CDC Cowboy (H-NDF), CDC Copeland (I-NDF), and Xena (L-NDF) were ranked as high, intermediate, and low NDFD based on commercial silage samples ($n = 80$) collected over 2 yr. Barley varieties were planted the same day in one location and ensiled at the mid-dough stage in replicated mini or bunker silos. Silos were opened after 60 d of ensiling for chemical and microbial analysis. Silage from mini silos was exposed to air with temperature continuously measured and samples collected at 3, 7, 14, and 21 d. Silage was collected periodically from bunker silos during feed out. In vitro NDFD after 30 h of incubation in rumen fluid was estimated for silage collected after 60 d. Data were analyzed using the Proc Mixed procedure of SAS as a complete randomized design with fixed effect of variety and ensiling method, and random effect of silo within variety, and day as a repeated measure for aerobic stability. In vitro NDFD did not differ among varieties. Terminal pH was lowest ($P < 0.01$) for H-NDF in mini silos. The pH of H-NDF was higher ($P < 0.01$), and I- and L-NDF lower ($P < 0.01$) in bunker than mini silos. Lactate and acetate levels were higher ($P < 0.05$) in H-NDF mini silos, with acetate levels of all varieties being lower ($P < 0.01$) after ensiling in mini silos as compared with bunker silos. Day 60 I-NDF in mini silos had higher ($P < 0.01$) ADF and NDF levels, with method of ensiling affecting fiber levels ($P < 0.01$) with increased ADF and NDF in H-NDF and L-NDF in bunker as compared with the mini silos. The H-NDF silage was less aerobically stable than other silages as reflected by increasing ($P < 0.01$) temperature and pH ($P < 0.05$) and decreased levels of lactic acid ($P < 0.05$) and water-soluble carbohydrates ($P < 0.01$) over the exposure period. Using in vitro NDFD of field silage to select barley silage varieties for improved fiber digestibility proved difficult due to the effects of time of harvest and the fermentation process on this trait.

Key Words: barley silage, NDF degradability, aerobic stability0

457 Characterization of the variation in the daily excretion of fecal constituents and digestibility predictions in beef cattle fed feedlot diets using near infrared spectroscopy. L. J. Jancewicz*[1,2], G. B. Penner[3], M. L. Swift[4], J. J. McKinnon[1], C. L. Waldner[5], and T. A. McAllister[2], *[1]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada, [2]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, AB, Canada, [3]University of Saskatchewan, Saskatoon, Canada, [4]Hi-Pro Feeds, Okotoks, AB, Canada, [5]Department of Large Animal Clinical Sciences, Western College of Veterinary Medicine, University of Saskatchewan, Saskatoon, Canada.*

The 24-h variation in fecal nutrient excretion and accuracy of digestibility predictions using spot samples collected from feedlot cattle were evaluated using near infrared spectroscopy (NIRS). Six heifers were individually housed and randomly assigned to one of two feeding frequencies; once per day (0900), or twice per day (two equal feedings at 0900 and 1700), first over a backgrounding period, followed by a finishing period. Heifers were fed the backgrounding diet for 21 d, transitioned to the finishing diet over 20 d, which was fed for 21 d. During the last 4 d of both periods, total fecal collections were conducted at 4-h and 4-d-24-h intervals and NIRS calibrations were used to predict fecal organic matter (OM), starch, nitrogen (N), neutral detergent fiber (NDF), acid detergent fiber (ADF) and acid detergent lignin (ADL). Estimated total tract digestibility (eTTD) using NIRS predicted fecal nutrients and ADL and apparent total tract digestibility (aTTD) of DM, OM, starch, NDF, and ADF determined using previously derived NIRS calibrations were calculated at each 4-h interval as well as over 4 d. Fecal DM (%), NDF, and ADF varied among 4-h interval samples in the backgrounding period, and fecal DM, starch, NDF, ADF, and ADL varied in the finishing period. Fecal starch was able to predict aTTD during both feeding periods (backgrounding: R2 = 0.96, $P < 0.01$; finishing: R2 = 0.98, $P < 0.01$). Most 4-h interval samples could be used to predict eTTD of nutrients and aside from starch in the finishing period, there were no differences for eTTD using fecal samples collected at any of the 4-h intervals versus those collected over 4 d. The NIRS calibrations for predicting aTTD coefficients using the 4-h interval samples or the 4 d-24-h composite were least accurate for NDF and ADF. Spot fecal samples collected at any time point from multiple cattle have potential to predict digestibility. However, timing of sampling after feeding must be standardized to predict starch digestibility during the finishing period, with samples between 0–4 h and 8–16 h generating estimates of both starch concentration and digestibility that were closest to that derived from 4-d-24-h composite samples.

Key Words: fecal nutrients, fecal starch, 24-h variation, feedlot cattle, near infrared spectroscopy

0458 Effect of energy substrate and days on feed on plasma insulin response in finishing beef heifers. F. Joy*, K. M. Wood, and G. B. Penner, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada.*

The objective of this study was to determine the effect of dietary energy source and days on feed (DOF) on plasma insulin concentration and insulin responsiveness when subjected to an arterial glucose challenge. Eight heifers were randomly allocated to 1 of 2 finishing diets consisting of a barley-based control (CON; $n = 4$; 75.2% barley grain, 6% barley silage, 9.8% canola meal and 9% vitamin and mineral supplement on a DM basis) or a diet where a high-lipid byproduct-pellet replaced 60% of the barley grain and canola meal relative to CON (HLP; $n = 4$). Diets were formulated to be iso-caloric and iso-nitrogenous, but the CON had greater starch (46.6 vs. 39.5%) and lower ether extract (3.8 vs. 5.7%) than HLP. The 160-d study period was divided into four 40-d periods (P1, P2, P3, and P4). On the final day of each period, 7.57 mmol/kg $BW^{0.75}$ of dextrose was infused and the insulin response was analyzed in plasma collected at 0, 5, 10, 15, 20, 25, 30, 45, 60, 90, and 120 min post-infusion. Data were analyzed using a mixed model (fixed effects of treatment, period, and the treatment × period interaction). Period was included as a repeated measure. The 12-h fasting plasma insulin concentration did not differ ($P = 0.40$) between the treatments averaging 1.51 μg/L. However, insulin concentration increased from P1 (1.17 μg/L; $P < 0.01$) to P3 (1.81 μg/L) and P4 (1.60 μg/L) with the latter not differing. Area under the curve for insulin following the glucose challenge tended ($P = 0.08$) to increase with DOF, but did not differ by diet. The peak insulin concentration following the glucose challenge increased from 8.42 during P1 to 11.3 μg/L during P3 ($P = 0.048$) and the time to attain the peak tended to increase ($P = 0.09$) with DOF, but was not affected by treatment ($P > 0.1$). A tendency ($P = 0.07$) for a treatment × period interaction was observed for peak insulin concentration with HLP attaining a greater peak than CON in all periods except P2. The results of this study indicate that insulin concentration and the insulin insensitivity to a glucose challenge in growing beef heifers increase with advancing DOF and this increase is independent of energy substrate fed. Increasing insulin resistance may be one factor leading to reduced energetic efficiency associated with advancing DOF in finishing cattle.

Key Words: beef, insulin, finishing

0459 Effect of digestible fiber content of barley silage on lactation performance and chewing activity of lactating dairy cows in comparison with corn silage. B. Refat[*1,2], D. A. Christensen[3], J. J. McKinnon[4], J. Nair[1], A. D. Beattie[5], T. A. McAllister[6], W. Yang[7], and P. Yu[1], *[1]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada, [2]Animal Production Department, Faculty of Agriculture, Zagazig University, Egypt, [3]University of Saskatchewan, Saskatoon, Canada, [4]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada, [5]Department of Plant Sciences, College of Agriculture and Bioresources, University of Saskatchewan, Saskatoon, Canada, [6]Lethbridge Research and Development Centre, AAFC, AB, Canada, [7]Lethbridge Research and Development Centre, AAFC, AB, Canada.*

There is a limited knowledge on evaluating barley silage with different digestible fiber content on dairy cow performance. The objective of this study was to evaluate the effects of barely silage varieties selected for varying rates of in vitro NDF digestibility on DM intake (DMI), milk production, and total chewing activity of high-yield dairy cows in comparison with corn silage. Four early lactating multiparous Holstein cows (average body weight = 703 ± 78 kg; days in milking = 101 ± 25; parities = 2.75 ± 0.83) were used in a 4 × 4 Latin square design. The cows were fed diets that contained 49% barley-based concentrate and 51% forage (DM basis). The forage consisted of 10% alfalfa hay and 41% silage. The four whole plant silages were: corn silage (P7213R), CDC Cowboy barley silage, CDC Copeland barley silage, and Xena barley silage. The diets were formulated to meet the nutrient requirements by lactating dairy cows producing 40 kg of milk using NDS software. The in vitro 30 h NDF digestibility (NDFD) of CDC Cowboy, CDC Copeland and Xena varieties were 37, 31, and 29%, respectively. The experiment consisted of 18 d of adaptation and 5 d of data collection. Statistical analyses were performed using PROC MIXED procedure of SAS 9.4 with significance declared at $P < 0.05$. The results indicate that barley silage variety did not influence DMI, milk production and chewing activity ($P > 0.1$). The CDC Cowboy with higher NDFD did not result in an improvement in milk yield (averaged 35.3 ± 1.71 kg/d, $P > 0.1$), feed efficiency (averaged 1.37 ± 0.07 DMI/milk yield, $P > 0.1$), and total chewing activity (averaged 892 ± 23 min/d, $P > 0.1$) compared with other barley silage varieties. Cows fed the corn silage had similar DMI (averaged 26.3 ± 1.4 kg/d, $P > 0.1$) but produced more milk than those fed barley silage (40.1 vs. 35.3 ± 1.71 kg/d, $P < 0.05$). As a result, the cows fed corn silage had improved feed efficiency compared with those fed barley silage (1.57 vs. 1.37 ± 0.07 DMI/milk yield, $P < 0.05$). The results of this study indicate that feeding barley silage with higher digestible fiber content does not necessarily result in greater milk production performance. However, feeding corn silage has potential to produce more milk and better feed efficiency compared with barley silage.

Key Words: fiber digestibility, chewing activity, milk yield

0460 Daytime pasture vs. free-stall barn access: What do dairy cows with year-long outdoor experience prefer? E. R. Shepley[*1], E. Vasseur[2], and R. Bergeron[3], *[1]McGill University, Ste.-Anne-de-Bellevue, QC, Canada, [2]McGill University, Ste.-Anne-de-Bellevue, QC, Canada, [3]University of Guelph, ON, Canada.*

Provision of regular exercise to dairy cows is a topic that has received an increasing amount of interest in recent years. Pasturing cows not only addresses the current issue of restricted movement found in many production units, but also has positive effects on health and welfare. The objective of the current study was to investigate cow preference for day-pasture access or a free-stall barn under Eastern Canadian summer climatic conditions. Two important components were introduced in the current study: the use of a herd with year-round outdoor experience and the provision of the same feed options (fresh forage and silage) inside and on pasture. Thirty-two lactating organic Holstein cows were submitted to a 6-d preference cycle comprised of three 2-d phases. Cows were restricted to a free-stall barn (forced-indoor), restricted to pasture (forced-outdoor), or provided the choice between staying in a free-stall barn or going to pasture (free-choice) for a 7-h period in between morning and evening milking. Live observations of activities (feeding from the feeder, grazing, lying down, and other) were conducted every 2 min by scan sampling during the forced-outdoor and choice phases. A group level *t* test was used to test whether preference of cows to be outdoors differed from 0% (choice to stay in free-stall), 50% (indifference), and 100% (choice to go to pasture). An independent 2-sample *t* test was used to compare time spent in conducting the observed activities inside to those outside. Cows spent more time at pasture when provided the choice (range h 1 to h 6 across wk: 68.4 to 87.4%), displaying partial preference for the outdoors in h 1, and h 3 to h 6 (difference from 0%; $P < 0.01$) and complete preference for outdoor in h 2 (difference from 0 and 50%; $P < 0.01$), when the percentage of cows choosing to be outside was the highest. Cows conducted the same levels of activities on pasture as in the free-stall barn ($P > 0.05$), with cows grazing more than eating silage from the feeder on pasture (33.1 vs. 10.2%, respectively) and eating fresh forage over silage when indoors (33.6 vs. 4.2%, respectively). This study showed that when provided with year-long outdoor access, dairy cows

chose day-time pasture access over free-stall barn, and freshly-cut forage or pasture over silage.

Key Words: dairy cow, preference test, outdoor access

0461 Can regular exercise and more comfortable stalls improve cleanliness and lameness in tie-stall dairy cows? S. Palacio*[1,2], S. Adam[3], R. Bergeron[4], D. Pellerin[5], A. M. de Passillé[6], J. Rushen[6], D. B. Haley[7], T. J. DeVries[8], and E. Vasseur[1], *[1]McGill University, Ste.-Anne-de-Bellevue, QC, Canada, [2]McGill University, Ste.-Anne-de-Bellevue, QC, Canada, [3]Valacta, Ste.-Anne-de-Bellevue, QC, Canada, [4]University of Guelph, ON, Canada, [5]Universite Laval, Quebec, Canada, [6]Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada, [7]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Canada, [8]Department of Animal Biosciences, University of Guelph, ON, Canada.*

Tie-stall dairies are still one of the major housing systems around the world and with growing industry requirements to meet animal welfare standards, providing options to help producers meet these animal welfare standards is a priority. The objective of the study was to evaluate how minor stall modifications and/or regular exercise (access to pasture and winter exercise) affected the welfare of Holstein cows housed in tie-stalls. Twenty lactating cows/farm on 12 tie-stall farms were visited and assessed 4 times over 1 yr. Visit 1 was conducted toward the end of the pasture season, visit 2, 9–30 d after modifications were applied, visit 3, toward the end of the winter, and visit 4, 1 yr after visit 1. Stall modifications were applied to half of the study cows on each farm with most modifications being a re-adjustment of the tie-rail. Assessments of animal welfare consisted of animal and housing-based measures, as well as a management questionnaire. Farms were separated on whether they provided exercise (Exc) or not, as well as cows that were kept on modified (Mods) stalls or in unmodified stalls; differences in cow cleanliness, BCS and lameness were analyzed with a mixed model. Farm was nested in Exc and was included as a random effect and Exc, Mods and their interaction were treated as fixed effects. On visit 2 (in winter) 20% more cows had dirty udders when kept in modified stalls with exercise compared with unmodified stalls with exercise (30 vs. 10% respectively, $P < 0.05$). On visit 3, there were 20% fewer lame cows in the herds with exercise (18%) compared with herds with no exercise (38%) ($P < 0.05$). On visit 4, there were 9% more cows with dirty udders in modified stalls (16%) compared with unmodified stalls (7%) ($P < 0.05$). Results show that exercise can have a beneficial effect on lameness, especially during the winter months, and that modifications intended to improve stall comfort might cause some increase in cow dirtiness. However, this increase in dirtiness must be weighed against the potential benefits of a providing dairy cows with more adequate and comfortable stalls.

Key Words: regular exercise, tie-stall improvement, dairy cow

0462 *Saccharomyces cerevisiae* boulardii improves acute phase response and phagocytosis during weaning in dairy calves. B. Fomenky*[1,2], J. Chiquette[1], P. Y. Chouinard[3], and É. M. Ibeagha-Awemu[1], *[1]Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada, [2]Département des Sciences Animales, Université Laval, Québec, Canada, [3]Département des Sciences Animales, Université Laval, Québec, Canada.*

The use of direct fed microbials (DFM) as alternatives to antibiotic growth promoters in farm animal production continues to stimulate research and commercial interest. During the early period of life, inadequate immune development and weaning stress contributes to increase susceptibility to infectious diseases in calves. Currently, it is less clear how DFM elicit acute phase immune response in calves. This study aimed to investigate the effect of *Saccharomyces cerevisiae* and *Lactobacillus acidophilus* on acute phase response and phagocytosis during the early period of calf growth.

Forty eight Holstein calves (2–7 d old) were grouped according to body weight and circulating IgG and randomly assigned to four treatments as follows; Control (CTRL)-fed milk replacer with starter diet introduced gradually in the third week of the experiment; CTRL supplemented with *Saccharomyces cerevisiae boulardii CNCM I-1079* ($7.5x10^9$ cfu/L milk replacer + $3x10^9$ cfu/kg feed) (SCB); CTRL supplemented with *Lactobacillus acidophilus BT1386* ($2.5x10^8$ cfu/L milk replacer + $1x10^9$cfu/kg feed) (LA); and CTRL supplemented with tetracycline (528 mg/L milk) and neomycin (357 mg/L milk) before weaning and chlortetracyclin (55 mg/kg) after weaning (ATB). After weaning calves received hay in addition to starter diet and their respective treatments. Serum samples on experiment d 29 and 43 (pre-weaning), 46, 49, 51, and 54 (weaning) and 58 and 65 (post-weaning) were used for measurements of C-reactive protein and haptoglobin. Likewise, polymorphonuclear neutrophils (PMN) were isolated from plasma on d 15 and 43 (pre-weaning), 47 and 54 (weaning), 59, 66, and 87 (post-weaning), stimulated with lipopolysaccharide and phagocytosis beads pH rhodo Green *E. coli* bio particles. Phagocytosis was then measured using flow cytometry. The effects of treatments were analyzed using a complete randomized block design with repeated measures and PROC MIXED of SAS with Tukey adjustments for multiple comparisons.

Serum concentrations of C-reactive protein and haptoglobin in SCB-treated calves increased during weaning (d 54; $P < 0.05$) when compared with CTRL, LA and ATB-treated calves. Concentrations of C-reactive protein tended to increase on d

65 (post weaning; $P < 0.10$) with SCB compared with CTRL or ATB. The PMN from calves on SCB increased ($P < 0.05$) phagocytosis during weaning (d 47) as compared with CTRL.

Data show that SCB has immunomodulatory effects in calves and a possible role in enhancing innate immune and inflammatory responses of calves during the critical stress period of weaning. Direct fed SCB might play a role in innate immunity as an early defense system against infections in calves.

Key Words: calf, *Saccharomyces cerevisiae*, C-reactive proteins, haptoglobin, innate immunity

0463 Effect of lipid supplementation and type of lipid on fatty acid composition of the ruminal epithelium and short-chain fatty acid transport.

A. C. Verdugo* and G. B. Penner, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada.*

The objective of this study was to evaluate the effect of lipid supplementation and the type of lipid on the fatty acid (FA) composition of the ruminal epithelium and short-chain fatty acid (SCFA) transport. Twenty-one Holstein steers (194 ± 10.7 kg) were blocked by BW and randomly assigned to 1 of 3 treatments differing in FA supply and composition. The control treatment (CON) contained 2.9% ether extract whereas the FA treatments contained 6.2% ether extract with the lipid coming from saturated (SAT; tallow and palmitic acid) or unsaturated sources (UNSAT; flax and Megalac). All calves were fed at 3% BW on a DM basis. After a 30-d feeding period, steers were killed and samples of the ruminal tissue were collected for FA analysis and to evaluate SCFA uptake and flux in Ussing chambers. Data were analyzed as a randomized complete block design using a mixed model with orthogonal contrasts to evaluate the effect of FA supplementation and the type of the FA supplement. There was a tendency for increased FA concentration in ruminal tissue for supplemented calves ($P = 0.10$), and SAT calves tended to have less FA than UNSAT (15.1 vs. 20.1 g/100 g; $P = 0.06$). Ruminal tissue from SAT had a tendency for greater monounsaturated FA (37.5 vs. 32.0; $P = 0.08$) and had less polyunsaturated FA (17.0 vs. 23.0; $P = 0.03$) than UNSAT. The changes in major FA classifications were largely due to an increase for C16:0 (25.2 vs. 24.2%; $P = 0.02$), decrease in C16:1 (1.65 vs. 10.32%; $P = 0.02$), and a decrease in EPA (0.19 vs. 0.38; $P < 0.01$) for SAT relative to UNSAT. Acetate uptake was not affected by FA supplementation ($P \geq 0.25$), but providing supplemental FA increased propionate [0.61 vs. 0.37 nmol/(cm2 × min); $P = 0.05$] and butyrate uptake [0.82 vs. 0.45 nmol/(cm2 × min); $P = 0.03$)] by the ruminal epithelium. Moreover, feeding SAT increased butyrate uptake relative to UNSAT [1.06 vs. 0.59 nmol/(cm2 × min); $P = 0.01$)]. There was a tendency for an increase in propionate flux across the ruminal epithelium with FA supplementation [0.65 vs. 0.56 μ mol/(cm2 ×h)], but there were no differences between SAT and UNSAT. The results from this study indicate that providing supplemental FA may alter ruminal epithelial FA composition and enhance SCFA transport relative to non-supplemented calves.

Key Words: short-chain fatty acid, absorption, palmitic

0464 Degradation kinetics and bypassed nutrients of value added pellet products based on combination of new co-products from bio-fuel/bio-oil processing, low grade of peas, and lignosulfonate chemical compound at different levels for ruminants.

V. Guevara*, D. A. Christensen, J. J. McKinnon, and P. Yu, *Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada.*

New co-product, carinata meal, from bio-fuel processing is ready to be used as animal feed nowadays. Conventional co-product, canola meal, has high levels of methionine and cysteine, but limiting in lysine. Low grade of peas contains high starch content and also has high levels of lysine and tryptophan. There is little information available on nutrient profile, as well as degradation kinetics, especially when it blends with other feedstuff as a pellet. The aim of this project was to test and develop eight high value added pellet products (BPP) based on combination of co-products from bio-fuel/bio-oil processing, low grade of peas and lignosulfonate at different levels for ruminants. Statistical analyses were performed using PROC NLIN and PROC MIXED procedures of SAS 9.4 with significance declared at $P < 0.05$. The results showed that BPP1 (low level of carinata meal, high level of peas and no lignosulfonate), BPP2 (low level of carinata meal, high level of peas and lignosulfonate), BPP5 (low level of canola meal, high level of peas and no lignosulfonate), BPP6 (low level of canola meal, high level of peas and lignosulfonate) and BPP8 (high level of canola meal, low level of peas and lignosulfonate) had the higher rate of degradation (Kd) ($P < 0.05$). There were no significant differences between all blend pellet products (BPP) on soluble fraction in situ (S), insoluble but potentially degradable fraction in situ (D) and undegradable fraction in situ (U) ($P > 0.10$). BPP3 (high level of carinata meal, low level of peas and no lignosulfonate), BPP4 (high level of carinata meal, low level of peas and lignosulfonate) and BPP7 (high level of canola meal, low level of peas and no lignosulfonate) and BPP8 had the higher rumen undregradable dry matter (BDM) ($P < 0.05$); while BPP1, BPP2, BPP5 and BPP6 had the higher effective degradability of dry matter (EDDM) ($P < 0.05$). In conclusion pellet products with high level of co-products had the higher rumen undegradable dry matter. Further study on intestinal digestion of nutrients is needed.

Key Words: canola, carinata, lignosulfonate

0465 The different effects of ferrous glycine chelate and ferrous sulfate to intestinal porcine epithelial cells. Z. Zhuo*, *College of Animal Science, Zhejiang University, Hangzhou, China.*

This study was conducted to investigate the effects of ferrous glycine chelate and ferrous sulfate on cell proliferation and gene expression of iron related transporters in intestinal porcine epithelial cells (IPEC-J2). When IPEC-J2 cells covered 80~90% of the Petri dish, they were treated with different concentration of $FeSO_4$ and Fe-Gly (0, 50, 100, 200 μ mol/L as the low concentration; 16,000, 32,000, 64,000, 128,000 as the high concentration) for 12 h and 2 4h to determine the cell survival rate. Besides, IPEC-J2 cells were also treated with $FeSO_4$ and Fe-Gly (50 μ mol/L as iron) for 2 h, and then quantitative Real-time PCR was applied to detect the mRNA expression of DMT1, FPN1, Dcytb and PepT1. The results showed that both $FeSO_4$ and Fe-Gly nearly have no toxicity to cells in low concentration; however, high concentration of iron solution could significantly affect cell survival. The influence on cell viability caused by $FeSO_4$ was more obvious in high concentration compared with Fe-Gly. The qRT-PCR results revealed that Fe-Gly had significant lower expression of DMT1, FPN1 and Dcytb than FeSO4 ($P < 0.05$), while there was no difference on the expression of PepT1. For the physiological function of Dcytb, DMT1 and FPN1 are related with iron ions transportation, it reminded us that $FeSO_4$ may own more free iron ion than Fe-Gly in the same concentration. Fe-Gly had a better stabilization than FeSO4, which means it can prevent iron toxicity to cell when in a high concentration.

Key Words: ferrous glycine chelate, ferrous sulfate, IPEC-J2, cell proliferation, gene expression

0466 The effect of SNPs in the promoter on expression of CYP2E1 gene and boar taint. H. E. Archer*[1], M. Jafarikia[2], B. Lillie[3], F. Schenkel[2], and E. J. Squires[1], *[1]Department of Animal Bioscience, University of Guelph, ON, Canada, [2]Center for Genetic Improvement of Livestock, University of Guelph, ON, Canada, [3]Department of Pathobiology, Ontario Veterinary College, Canada.*

Boar taint, an unfavorable odor detected in the meat of intact male pigs, is caused by the accumulation of two compounds: androstenone and skatole. Despite mounting welfare concerns, surgical castration of all male piglets is still the most common control method in production systems. The need for new methods to control boar taint is therefore a necessity. Genetic selection represents one such alternative. Among the genes known to be involved in boar taint metabolism, CYP2E1 has repeatedly proven influential. The aim of this study was to identify SNPs within the CYP2E1 promoter affecting gene expression and boar taint. Genotypes were obtained from a previously developed list of 7 single nucleotide polymorphisms (SNPs) on 66 boars from three major swine breeds: Duroc, Landrace and Yorkshire. RNA was isolated from liver tissue and quantitative PCR was performed to measure CYP2E1 gene expression. Association analysis was run correlating genotype and CYP2E1 expression (ΔCT) using PROC GLM (SAS Version 9.4). Weight was included as a fixed effect. The effect of breed, androstenone and skatole concentrations on CYP2E1 expression were also tested. All SNPs had a MAF > 0.05. Results indicated that 1 SNP within the CYP2E1 promoter was significantly associated with CYP2E1 expression at $\alpha < 0.05$. An additional 3 SNPs demonstrated association at $\alpha < 0.10$. While weight was significantly associated with gene expression, breed was found to have no effect. Significant within breed variation in CYP2E1 expression was observed, indicating significant differences in gene expression among individuals. Androstenone and skatole were significantly associated, with means of 1.33 ug/g and 0.58 ug/g, respectively. Though SNPs were significantly associated with gene expression, no associations were observed between gene expression and androstenone or skatole in fat. Due to this lack of association between expression and boar taint, results indicate that CYP2E1 mRNA expression alone is not a key indicator for boar taint.

Key Words: boar taint, CYP2E1, SNP

0467 Nutritional evaluation of barley varieties grown for silage. J. Nair*[1], D. A. Christensen[2], P. Yu[1], A. D. Beattie[3], T. A. McAllister[4], D. Damiran[1], N. Preston[1,5], L. Fuhr[6], and J. J. McKinnon[7], *[1]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada, [2]University of Saskatchewan, Saskatoon, Canada, [3]Department of Plant Sciences, College of Agriculture and Bioresources, University of Saskatchewan, Saskatoon, Canada, [4]Lethbridge Research and Development Centre, AAFC, AB, Canada, [5]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, AB, Canada, [6]Dairy Smart Nutrition, Saskatoon, SK, Canada, [7]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada.*

This study evaluated the nutritional and neutral detergent fiber (NDF) digestibility characteristics of common barley varieties grown for silage by beef and dairy operations in western Canada. Of 135 silage samples collected over two crop years (2012 and 2013), 80 samples harvested at the mid-dough stage, representing seven varieties (Conlon, CDC Copeland, CDC Cowboy, Falcon, Legacy, AC Metcalfe and Xena) were selected for analysis. Chemical composition, NDF digestibility (NDFD) and indigestible NDF (INDF) content were analyzed as randomized complete block design with year as random blocking factor using mixed model procedure of SAS (9.4). Average pH

and dry matter (DM) were 4.05 ± 0.17 and 36.8 ± 4.1, respectively. AC Metcalfe had higher ($P < 0.05$) CP content relative to CDC Copeland and Xena with intermediate values for the other varieties. Acid detergent fiber (ADF) content was higher ($P < 0.05$) for CDC Cowboy and AC Metcalfe relative to Conlon. Similarly, CDC Cowboy had a higher ($P < 0.05$) NDF content relative to Conlon, Falcon and Legacy. AC Metcalfe had a higher ($P < 0.05$) lignin content than CDC Copeland. Starch content of Legacy and Conlon was higher ($P < 0.05$) than that of CDC Cowboy with intermediate values for the other varieties. Neutral detergent fiber digestibility (%NDF) after 6 ($NDFD_{6h}$) and 30 h ($NDFD_{30h}$) of incubation in an ANKOM Daisy^{II} system indicated that Legacy and Falcon had a higher ($P < 0.05$) $NDFD_{6h}$ relative to the other varieties; while CDC Cowboy had the highest ($P < 0.05$) $NDFD_{30h}$ followed by CDC Copeland, AC Metcalfe, Falcon and Conlon with Xena and Legacy being the lowest. Rumen in situ incubation for 288 h to determine the INDF (% NDF) content of barley varieties indicated that CDC Cowboy had a higher ($P < 0.05$) potentially digestible NDF (pdNDF) content relative to AC Metcalfe with other varieties being intermediate. Silage fermentation parameters including VFA, lactate and ammonia concentrations did not differ among varieties. These results indicate that barley varieties grown for silage in western Canada vary with respect to chemical composition, NDFD and pdNDF content and suggest that nutritional as well as agronomic characteristics are important for producers to consider when selecting barley varieties for silage. Selection pressure by plant breeders for increased NDFD may help lead to new or improved forage barley varieties for ruminant production systems.

Key Words: barley silage, variety, NDFD

0468 The repeatability of gonadotropin releasing hormone-induced release of luteinizing hormone and its association with fertility in dairy cattle.

M. Gobikrushanth*[1], P. A. Dutra[1], C. A. Felton[2], T. C. Bruinjé[1], M. G. Colazo[2], S. Butler[3], and D. J. Ambrose[1,2], *[1]Department of Agricultural Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]Livestock Research Branch, Alberta Agriculture and Forestry, Edmonton, AB, Canada, [3]Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Co. Cork, Ireland.*

Objectives were to: (1) determine repeatability and variability of plasma LH concentrations in response to exogenous GnRH administration and (2) examine associations among categories of LH release, plasma estradiol, ovulatory response and first service conception rate in dairy cattle. Lactating Holstein cows (35 primiparous, 65 multiparous) received one injection of $PGF_2\alpha$ (cloprostenol, 500 µg, d 0) followed by GnRH (gonadorelin, 100 µg, d 3; Presynch) and were subjected to an Ovsynch protocol starting on d 10, with timed-AI (TAI) occurring at ~75 d postpartum. Blood samples were collected immediately before (0 h) and 2 h after the GnRH of Presynch and the second GnRH of Ovsynch to determine plasma LH concentrations. Cows were ranked based on LH concentrations after the second GnRH of Ovsynch, from highest to lowest, and those in the top ($n = 33$) and bottom ($n = 33$) thirds were classified into HIGH- and LOW-LH categories. Differences in plasma LH and estradiol concentrations among parity and LH categories were analyzed using MIXED procedure of SAS. Repeatability was analyzed using the CORR procedure and binomial data using the GLIMMIX procedure of SAS. Mean (± SEM) LH concentrations (ng/mL) before GnRH were 0.4 ± 0.04 and 0.6 ± 0.03, while, the mean LH 2 h after GnRH were 8.3 ± 0.7 (range 1.0 to 27.4, CV 80.7%) and 10.0 ± 0.7 (range 0.7 to 28.4, CV 67.3%), during Presynch and Ovsynch assessments, respectively. The correlation between GnRH-induced LH concentrations during Presynch and Ovsynch assessments was $r = 0.19$ ($P = 0.06$). The proportion of cows that remained in HIGH- and LOW-LH categories during both Presynch and Ovsynch assessments was 35.3 and 33.3%, respectively. The mean plasma LH concentration (ng/mL) after GnRH was significantly greater ($P < 0.01$) for HIGH-LH (17.6 ± 0.6) than LOW-LH (2.8 ± 0.6) category. Similarly, cows in the HIGH-LH category had greater plasma estradiol than those in LOW-LH category (2.7 ± 0.3 vs. 1.1 ± 0.3 pg/mL; $P < 0.01$). In addition, cows in the HIGH-LH category had greater ovulatory response (97.0 vs. 78.8%; $P = 0.03$) and increased first service conception rate (44.1 vs. 24.2%; $P = 0.04$) than cows in the LOW-LH category. The mean plasma LH concentration in multiparous cows was significantly greater at Presynch assessment (9.3 ± 0.8 vs. 6.3 ± 1.1; $P = 0.03$) and numerically greater at Ovsynch assessment (10.7 ± 0.8 vs. 8.7 ± 1.1; $P = 0.16$) than in primiparous cows. In summary, GnRH-induced LH concentrations were highly variable and weakly repeatable. However, cows with higher GnRH-induced plasma LH concentrations 2 h after second GnRH of Ovsynch had greater ovulatory response and conception rates.

Key Words: LH variability, repeatability, fertility

0469 Use of low-cost, non-nutritive adsorbents as intestinal binding agents to sequester the boar taint compound androstenone.

P. Park*, I. B. Mandell, C. F. M. de Lange, and J. Squires, *Department of Animal Biosciences, University of Guelph, ON, Canada.*

Boar taint is an unpleasant odor and taste detected from pork of some intact males when cooked, caused by high accumulation of the testicular steroid androstenone and the indole skatole. Currently available research exploring dietary approaches to control androstenone is scarce. The objective of this study was to evaluate for the efficacy of binding agents in vivo against androstenone and its impacts on performance in intact male pigs, following up on previous works in vitro.

The study aims to capitalize on a hormone-recycling phenomenon which takes place in the gastrointestinal tract of animals, called enterohepatic circulation. Four adsorbents have been assessed for their binding effectiveness against androstenone in our laboratory; these were previously used in studies which successfully mitigated negative effects associated with mycotoxin ingestion in production animals. All additives bound androstenone in high efficacies in vitro, which warranted evaluation of the effectiveness of these binders in swine diets to reduce its levels in plasma and fat. Ninety ($n = 90$) purebred Duroc boars (123 ± 6 d of age at start of experiment) were equally allocated ($n = 18$) and fed 1 of 4 diets added with 2% bentonite (BNT), 3.5% diatomaceous earth (DE), 15% spent filter aid (SFA), or 0.7% hydrated sodium-calcium aluminosilicate (HSCAS) for at least 28 d followed by 14 d of recovery. All groups were compared with a control entire male group ($n = 18$) fed a typical corn-soybean meal finisher diet. Plasma samples and backfat biopsies were collected at d 0, 14, 28, 42, and 56 of trial. Pigs were weighed weekly and calculated for growth performance parameters. Estrone-1-sulfate in plasma was analyzed as a positive control for enterohepatic circulation. Analysis of trends during the treatment period were performed using the PROC MIXED repeated measures procedure in SAS (SAS Institute, Cary, NC, USA). There were no differences in ADG, ADFI, or FCR across diets ($P > 0.05$) throughout the treatment period. In addition, there were no significant decreases in backfat or plasma androstenone and estrone-1-sulfate across pigs fed treatment diets by d 28 ($P > 0.05$). However, there was a wide variation in plasma and fat androstenone concentration, which may result from the process of transporting the pigs into a novel environment and mixing. Further research using of crossbred pigs that will not be mixed and/or transported into unfamiliar groups is needed to conclusively evaluate the efficacy of these treatments.

Key Words: boar taint

0470 The effect of sorting wheat or barley, based on the predicted CP of individual seeds, on physical characteristics and in vitro dry matter digestibility.

K. Sahtout*[1], D. Beaulieu[1], G. B. Penner[2], and T. A. McAllister[3], [1]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada,* [2]*University of Saskatchewan, Saskatoon, Canada,* [3]*Lethbridge Research and Development Centre, AAFC, AB, Canada.*

Nutrient values are based on sample averages, ignoring variability among seeds. The objective of this experiment was to determine if fractions obtained by separating kernels based on predicted CP (PCP) have different physical characteristics and DM digestibility (DMD). Second, we determined if grinding method and intensity influence digestibility of each fraction. The BoMill TriQ (TriQ), which uses near infrared transmittance spectroscopy (NIT), was used to separate individual kernels based on PCP. In the first study, the TriQ was used to sort 6 wheat sources into 10 fractions. Sixty kernels from each fraction were randomly chosen for measurement of length, width, height, area, geometric mean diameter, perimeter, sphericity, color, and mass. Data were analyzed using a mixed model with the fixed effect of fraction. Physical characteristics were similar among fractions ($P > 0.10$), except color, where lower PCP content had greater L* (54.12 vs. 50.95; $P < 0.05$). In the second study, 2 fractions [high CP (HCP) vs. low CP (LCP)] were produced from 5 sources of wheat and barley. The unsorted grain and each fraction were ground through a hammer mill (0.188 or 0.375 mm screens) or a roller mill to produce coarse and finely ground treatments. The roller mill was adjusted to produce samples with a similar processing index (wt/v) to the hammer mill. In vitro DMD and total gas production (TGP) were determined after a 12-h incubation. Data were analyzed independently by grain source including the effect of fraction, grinder, degree of processing, and interactions. The TGP (ml) and DMD (%) were similar among fractions ($P > 0.10$). The TGP and DMD of barley ground using a hammer mill was greater ($P < 0.10$) than when processed using a roller mill (59.4 ± 2.0 and 24.0 ± 2.0; 41.8 ± 1.0 and 24.0 ± 1.0, respectively) and a similar response was observed for wheat ($P < 0.10$; 63.8 ± 1.4 and 27.8 ± 1.5; 42.3 ± 0.8 and 26.3 ± 0.8, respectively). Increasing the degree of processing increased TGP ($P < 0.10$; 47.4 ± 2.0 and 35.9 ± 2.0; 48.9 ± 1.5 and 42.7 ± 1.4, respectively) and DMD ($P < 0.10$; 36.2 ± 1.0 and 29.6 ± 1.0; 36.4 ± 0.8 and 32.2 ± 0.8, respectively) of barley and wheat. Sorting individual seeds for PCP produces fractions with comparable physical characteristics, DMD, and in vitro TGP.

Key Words: grinding, near infrared transmittance spectroscopy, single seed sorter

0471 The effect of binding feed emzymes to spores of *Bacillius subtlis* and *Bacillius coagulans* on in vitro NDF digestibility in ruminal batch cultures.

C. L. Rosser*[1,2], L. Jin[3], K. A. Beauchemin[1], M. Oba[2], S. M. Cutting[4], and T. W. Alexander[1], [1]*Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, AB, Canada,* [2]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada,* [3]*Lethbridge Research and Development Centre, AAFC, AB, Canada,* [4]*School of Biological Sciences, Royal Holloway University of London, Egham, UK.*

Immobilization of enzymes on *Bacillus* spores has been shown to enhance enzyme stability. Binding feed enzymes to spores may therefore protect them in the rumen environment and improve enzyme efficacy. The objective of this study was to determine whether a xylanase feed enzyme bound to the surfaces of *Bacillus subtilis* or *Bacillus coagulans* spores would improve in vitro ruminal NDF digestibility compared with free

enzyme. Three separate in vitro ruminal batch cultures were performed on different days using the following treatments: *B. subtilis* spore-bound enzyme (BsubE; 1.0×10^9 *B. subtilis* spores + 0.1 mg xylanase enzyme protein); *B. coagulans* spore-bound enzyme (BcoaE; 1.0×10^9 *B. coagulans* spores + 0.1 mg xylanase enzyme protein); free enzyme (ENZY; 0.1 mg xylanase enzyme protein); and control (CON; water). The treatments were applied to alfalfa hay (2-mm particle size) 4 h before incubations. Rumen fluid was collected from two cannulated heifers and mixed with Menke's buffer (3:1) under anaerobic conditions to make inoculant. Serum vials containing pre-treated alfalfa hay (0.5 g) were filled with 60 mL of inoculant and then incubated on a shaker (39°C) for 0, 3, 6, 12, 24, and 48 h. Triplicate vials were removed at each time point to measure gas production, methane emission, and alfalfa digestibility. Gas production (ml/g dry matter (DM)) at 48 h was not different between BsubE, BcoaE, or ENZY ($P > 0.05$); however, it was reduced in CON vials compared with the other treatments ($P < 0.001$). Methane emissions at 24 and 48 h (ml/g DM) were least for CON (25.2 and 29.8 mL/g, respectively), intermediate for the spore treatments (25.8 and 30.5 g/ml for BsubE; 25.9 and 30.7 g/ml for BcoaE), and greatest for ENZY (35.4 and 39.0 mL/g, respectively; $P = 0.011$). In vitro DM digestibility was not different at 24 h ($P = 0.36$), but at 48 h there was a difference between CON (78.9%) and BsubE, BcoaE and ENZY (average 80%; $P = 0.018$). There was a tendency for greater NDF digestibility at 48 h in the enzyme treatments, compared with CON ($P = 0.075$). These data showed that the feed enzyme enhanced digestion of alfalfa. However, there was no difference when the enzyme was applied in free-form or bound to spores. Protection of feed enzymes through absorption to *Bacillus* spores may be more effective when the enzymes are unstable in a ruminal environment.

Key Words: feed enzyme, rumen digestibility, spores

0472 Characterization of bovine nasopharyngeal lactic acid bacteria and their in vitro antimicrobial activities against the respiratory pathogen *Mannheimia haemolytica*.

S. Amat[*1,2], E. Timsit[1], D. B. Holman[2], and T. W. Alexander[3], *[1]Department of Production Animal Health, Faculty of Veterinary Medicine, University of Calgary, AB, Canada, [2]Lethbridge Research and Development Centre, Agriculture Agri-Food Canada, AB, Canada, [3]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, AB, Canada.*

Most research on bacteria in the bovine nasopharynx has focused on pathogens implicated in respiratory disease. There is limited information on commensals, such as lactic acid bacteria (LAB), which are important to mucosal health and have been investigated as probiotics to inhibit pathogens. The purpose of this study was to characterize the bovine nasopharyngeal LAB and their in vitro antimicrobial activities against *Mannheimia haemolytica*. The diversity of nasopharyngeal LAB was investigated in two separate studies using DNA– or culture-based techniques. In the first study, nasopharyngeal samples were collected from calves ($n = 14$) on a farm before shipment to a feedlot (d 0), and then 2, 7, and 14 d after feedlot placement. Swabs were processed for DNA extraction and the 16S rRNA gene was PCR-amplified and sequenced using the MiSeq platform. In the second study, nasopharyngeal swabs were collected from calves ($n = 70$) sampled at feedlot entry and 60 d afterward. The swabs were processed for the isolation of LAB using selective media. A subset of LAB ($n = 66$) was identified by sequencing the full-length 16S rRNA gene and isolates were subsequently screened for inhibition of *M. haemolytica* using the agar slab method. From the first study, high–throughput sequencing showed that the total LAB (defined as the order *Lactobacillales)* constituted 4.2% of the nasopharyngeal bacterial microbiota and consisted of 23 genera. Within LAB, 6 different families were identified that included *Streptococcaceae* (49.2%), *Carnobacteriaceae* (23.9%), *Aerococcaceae* (16.0%), *Enterococcaceae* (5.6%), *Lactobacillaceae* (5.3%), and *Leuconostocaceae* (0.26%). The relative abundance of total LAB increased by 97% from d 0 to 2 and remained greater for the 14 d of feedlot placement, compared with d 0 ($P < 0.05$). Interestingly, however, the *Lactobacillaceae* family decreased ($P < 0.05$) from d 0 to 2, demonstrating that not all *Lactobacillales* members increased after feedlot arrival. Using culture–based methods, only 6 genera of LAB were isolated: *Streptococcus* (39.2%), *Lactobacillus* (37.1%), *Enterococcus* (10.3%), *Aerococcus* (9.3%), *Corynebacterium* (3.1%), and *Pediococcus* (1.0%). Among the screened LAB isolates, species within *Lactobacillus* exhibited the strongest inhibition against *M. haemolytica*, with zones of inhibition ranging between 16 and 23 mm. Our results show that the relative abundance of nasopharyngeal LAB can change after cattle are transported to a feedlot and that some LAB are able to inhibit the respiratory pathogen *M. haemolytica*. These LAB may have potential as nasal probiotics for the mitigation of bovine respiratory pathogens.

Key Words: lactic acid bacteria, probiotic, bovine nasopharynx

0473 Severity and prevalence of ruminal acidosis during the diet transition for commercial feedlot cattle. B. I. Wiese*[1], S. Hendrick[2], J. J. McKinnon[3], J. Campbell[1], and G. B. Penner[4], *[1]Department of Large Animal Clinical Sciences, University of Saskatchewan, Saskatoon, Canada, [2]Coaldale Veterinary Clinic, Coaldale, AB, Canada, [3]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada, [4]University of Saskatchewan, Saskatoon, Canada.*

The objective of this study was to determine the severity and prevalence of ruminal acidosis in commercial feedlot cattle during the transition to a finishing diet. Previously backgrounded steers (n = 907) and heifers (n = 998) were chosen as a source population and housed separately in 8 pens with an average of 227 ± 13 and 249 ± 6 hd/pen, respectively. Within the source population, 16 steers (mean BW ± SD = 435.1 ± 32.8 kg) and 16 heifers (mean BW ± SD = 382.7 ± 49.4 kg) were used to measure reticulo-ruminal pH using an orally administered pH measurement system; however, 3 systems were not recovered on slaughter. Cattle were fed 3 times daily and were transitioned from a diet containing (forage:concentrate; F:C) 62:38 to 20:80 (DM basis) over 40 d. Dry matter intake was assessed at the pen level. The effect of diet and day within diet were analyzed using the MIXED procedure in SAS, with diet and sex as fixed effects. Dry matter intake was greater for steers than heifers (10.2 vs. 9.3 kg/d; $P < 0.01$) and increased from diet 1 to diet 3, reaching a peak of 10.2 kg/d, before declining to 9.4 kg/d in diet 6. Mean reticulo-ruminal pH ($P < 0.01$) declined from pH 6.45 in diet 1 to pH 6.10 in diet 6. Heifers had greater mean pH than steers (6.38 vs. 6.33) when averaged over the diet transition ($P = 0.04$). Area (pH min)/d) and duration (min/d) that pH was < 5.6 increased with decreasing F:C ($P < 0.01$), as did the standard deviation from mean pH ($P < 0.01$). Over the entire transition period 24/29 study animals experienced at least one bout indicative of acidosis (pH < 5.6 for > 180 min) but the average daily prevalence was 5.4%. The prevalence of reticulo-ruminal acidosis increased with decreasing F:C (peak of 13.5%). When days within a diet were evaluated, lowest mean pH was observed 2-d post diet change ($P < 0.01$). Results indicate that daily prevalence for ruminal acidosis ranges between 1 and 13% with the risk increasing with decreasing F:C. The susceptibility to ruminal acidosis may differ between steers and heifers and the second day relative to a diet change appears to be the day with the greatest risk.

Key Words: diet transition, feedlot cattle, ruminal acidosis

0474 Comparison of digestion and particle-associated bacteria after in situ incubation of different barley varieties in the rumen of cattle. H. E. Yang*[1,2], C. A. Zotti[2], J. J. McKinnon[1], and T. A. McAllister[2], *[1]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada, [2]Lethbridge Research and Development Centre, AAFC, AB, Canada.*

The chemical composition of barley grain, including the structure of starch, can vary among barley varieties and result in different digestion efficiencies. It is not known if compositional differences in barley can affect the particle-associated bacteria (PAB) involved in digestion. Therefore, the objective of this study was to characterize the in situ rumen digestion and PAB of four barley grain varieties. Three ruminally-cannulated cattle were fed a diet of 60% barley silage, 37% barley grain and 3% supplement. Four different barley varieties (Fibar, Xena, McGwire and Hilose) and corn as a control were included in the experiment. Ground grains (3 g) were placed in nylon bags and incubated in the rumen of cattle for 0, 2, 4, 12, 24, and 48 h. At each time point, triplicate bags were removed from each animal and analyzed for dry matter (DM), starch and crude protein (CP) disappearance. A second set of bags (n = 3) containing 5 g of each grain were incubated for 2, 4, and 12 h and DNA was extracted to characterize PAB via 16S rRNA gene sequencing. McGwire had the highest effective degradability (ED) of DM ($P < 0.01$), followed by Xena, Fibar, Hilose, and corn, respectively. The ED of starch was highest ($P < 0.01$) for Xena, followed by McGwire, Fibar, Hilose, and corn, while CP disappearance was not affected by grain type. Overall, 15 phyla were identified after analysis of 16S rRNA genes. Barley variety did not affect the relative abundance of phyla however they did differ with incubation time. *Firmicutes* (19.2%), *Bacteroidetes* (18.27%) and *Proteobacteria* (8.89%) were the dominant phyla after 2 h of incubation. By 12 h, *Bacteroidetes* decreased to a relative abundance of 4.3%. In contrast, *Firmicutes* increased in abundance over time, accounting for 45.9 and 82.1% of PAB after 4 and 12 h of incubation, respectively. Principal Coordinate Analysis showed that bacterial populations clearly grouped according to incubation time. At the family level, *Lactobacillaceae* increased over time, with a relative abundance of 0.76, 6.49, and 76.3% at 2, 4, and 12 h, respectively, reflecting an increasing presence of lactic-acid producing bacteria. This study found that the diversity of PAB on barley grain was not affected by barley variety, despite there being differences in digestion kinetics. However, time affected PAB, illustrating that the bacterial biofilm involved in the digestion of grains clearly undergoes compositional shifts during ruminal digestion.

Key Words: barley, rumen, microbiota

0475 Carbohydrate spectroscopic features of bio-oil co-products in relation to rumen degradation kinetics in ruminants. X. Li[*1,2], W. Xu[1], J. Yang[1], Y. Zhang[1], and P. Yu[2], *[1]College of Animal Science and Technology, Northeast Agricultural University, Harbin, China, [2]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada.*

The objectives of this study were to investigate the carbohydrate structure makeup associated with dry matter (DM) rumen degradation kinetics of three commonly used bio-oil co-products in ruminants. Three bio-oil products (rapeseed meal, canola meal and soybean meal) from three different sources in both Canada and China were collected in 2014. The carbohydrate spectral features were investigated using attenuated total reflectance-Fourier transform infrared spectroscopy instrument. The rumen degradation kinetics was determined according to the in situ nylon bag method with 3 rumen cannulated lactating Holstein cows at Rayner Dairy Teaching and Research Facility, University of Saskatchewan, Canada. The PROC MIXED procedure of SAS 9.3 was used for spectral data and degradation kinetics data analyses. The PROC CORR procedure of SAS was used to investigate the relationship between carbohydrate structure makeup and metabolic characteristics. Significances were declared at $P < 0.05$.The results showed that the peak area intensities of structural carbohydrate related region and its multiple peaks height were all lower in rapeseed meal and canola meal compared with soybean meal ($P < 0.05$). The cellulosic compound related spectral region had lower peak area and peak height intensities in rapeseed meal and canola meal than soybean meal ($P < 0.05$). Additionally, structural carbohydrate to total carbohydrate ratio and cellulosic compound to total carbohydrate ratio were all lower in rapeseed meal and canola meal than soybean meal ($P < 0.05$). For in situ DM rumen degradation kinetics, rapeseed meal had significantly lower soluble fraction than soybean meal. Rapeseed meal and canola meal had significantly lower potentially degradable fraction and higher undegradable fraction in comparison with soybean meal ($P < 0.05$). Compared with soybean meal, rapeseed meal and canola meal had higher rumen bypass DM content, and lower rumen effectively degradable DM content. There is a close relationship between carbohydrate spectral parameters and nutrient metabolic characteristics. The peak area intensity of functional group such as structural carbohydrate, cellulosic compound related region and their ratio to total carbohydrate were all positively related with DM degradable fraction and negatively correlated with DM undegradable fraction ($P < 0.05$). In conclusion, canola meal genetically developed from rapeseed meal shares similar carbohydrate structure and nutrition availability with rapeseed meal. The unique carbohydrate molecular spectral bands in the mid-IR region are highly associated with the nutrient utilization of bio-oil co-products in ruminants.

Key Words: carbohydrate molecular structure, vibrational spectroscopic profiles, nutrient metabolic characteristics

0476 Low protein diets produce divergent effects on energy balance. R. C. Zapata[*1], A. Pezeshki[2], A. Singh[1], N. J. Yee[1], and P. K. Chelikani[1], *[1]University of Calgary, AB, Canada, [2]Oklahoma State University, Stillwater.*

Background: The protein leverage theory postulates that diets low in dietary protein increase total energy intake due to overconsumption of carbohydrates and fat in an attempt to meet protein requirements. However, little is known of the mechanisms by which protein deficiency elicits such behavioral and metabolic adaptations, promotes positive energy balance and increases the risks for obesity and associated metabolic disorders.

Objectives: Our objectives were to determine the effects of graded degrees of protein restriction on (1) energy balance, body composition, glucose tolerance, gut hormones, (2) sympathetic signaling and, (3) key regulatory markers of thermogenesis in liver, skeletal muscle and brown adipose in diet-induced obese (DIO) rats.

Methods: The DIO rats were randomized to receive one of 4 isocaloric high-fat diets with graded concentrations of protein (n = 8/group; 4.40 kcal/g): Control (15% protein, CON), 10% (10P), 5% (5P), 0% (0P) for 2 wk, followed by realimentation to CON for 2 wk. Food intake, energy expenditure, body composition, glucose tolerance, plasma hormone concentrations, and tissue gene and protein expressions were measured. Data were analyzed by linear mixed models or ANOVA.

Results: We found that during protein restriction, compared with CON, 0P decreased energy intake but increased energy expenditure which led to reduced body weight, fat and lean mass, 5P increased energy intake and energy expenditure which led to reduced body weight and lean mass, and 10P increased energy intake but did not affect body weight and composition. These diet-induced alterations in energy expenditure are in part mediated through enhanced β-adrenergic signaling coupled with upregulation of key thermogenic markers (UCP1, β-Adrenergic receptors, fibroblast growth factor-21, irisin) in the brown adipose, liver and skeletal muscle. The 0P decreased plasma peptide YY, leptin, insulin, C-peptide and tended to decrease amylin and glucose-dependent insulinotropic peptide. The 0P and 5P induced fatty liver, reduced energy digestibility, and decreased lean mass and body weight that persisted beyond the restriction period. In contrast, moderately low protein diets promoted gain in body weight and adiposity following the period of protein restriction.

Conclusion: In summary, our novel findings demonstrate that low protein diets produce divergent effects on energy balance by engaging sympathetic signaling. Importantly, moder-

ately low protein diets could exacerbate preexisting susceptibility to weight gain and obesity. Funding: NSERC, ALMA

Key Words: low protein, energy balance, obesity

CSAS GRADUATE STUDENT POSTER COMPETITION

0477 Effect of high dietary canola meal inclusion in lactating sows on nutrient digestibility and sow and piglet performance. D. E Velayudhan* and C. M. Nyachoti, *University of Manitoba, Winnipeg, Canada.*

The aim was to determine the effects of high canola meal inclusion levels in sow lactation diets on nutrient digestibility, reproductive performance, milk composition and piglet performance. Forty five sows (n = 15) with an average parity of 1.8 (SD = 0.83) were randomly assigned to 1 of 3 dietary treatments; corn soybean meal control diet with 0, 15, and 30% canola meal (Diet A, B and C, respectively). All diets were formulated to be similar in standardized ileal digestible amino acids and NE, and were formulated to meet or exceed NRC (2012) nutrient requirement recommendations for lactating sows with an average post-farrowing BW of 210 kg, an expected average BW loss of 5.8 kg, and an expected piglet ADG of 230 g. Sows were moved to farrowing rooms and given the experimental diets from d 111of gestation until weaning on d 21. All sows were weighed and backfat thickness measured on d 111 of gestation and also on d 0, 7, and 21 post-farrowing. Litters were weighed on d 0, 7, and 21. Weaning to estrous interval in sows was also recorded. Blood samples, 2 h post feeding and milk samples were collected from sows on d 0, 7, and 21 to analyze plasma urea nitrogen (PUN) and milk composition, respectively. Fecal samples were collected on d 10, 11, and 12 post-farrowing to determine energy and nutrient digestibility. All data were analyzed as a randomized complete block design using mixed procedures of SAS 9.3 (SAS Inst., Cary, NC). There were no effects of higher levels of dietary canola meal inclusion on lactation feed intake, sow BW and backfat change, and weaning to estrous interval ($P > 0.10$). Also, there were no dietary effect on piglet mortality and piglet ADG ($P > 0.10$). There were no differences in the sow milk composition among dietary treatments ($P > 0.10$). However, sows fed 15 and 30% canola meal had lower ($P < 0.05$) PUN values compared with those fed control diet, on d 0, 7, and 21 post-farrowing. Also, apparent total tract digestibility of DM, GE, CP and P declined ($P < 0.05$) with increasing levels of canola meal inclusion. It was concluded that inclusion of up to 30% canola meal in lactation diet can support satisfactory sow and litter performance.

Key Words: canola meal, performance, sow

0478 Transcriptome analysis of the intestinal tissues of cattle suggests an association among host immune responses, lipid metabolism and the super-shedding of *E. coli* O157. O. Wang*[1], T. A. McAllister[2], G. Plastow[3], B. Selinger[4], K. Stanford[5], and L. L. Guan[6], *[1]University of Alberta, Edmonton, Canada, [2]Lethbridge Research and Development Centre, AAFC, AB, Canada, [3]Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [4]University of Lethbridge, AB, Canada, [5]Alberta Agriculture and Forestry, Lethbridge, Canada, [6]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Super-shedder cattle, which are defined as cattle shedding > 4 log of CFU of *Escherichia coli* O157 (O157) per g of feces, are responsible for the majority of O157 excretion into the farm environment. Colonization of the rectal anal junction by O157 is integral to super shedding. The objective of current study was to further understand the molecular mechanisms of colonization during super-shedding through investigating the transcriptome of the whole intestinal tract of cattle. We hypothesized that the difference in gene expression profiles between the anterior and distal part of intestine underlies the tropism of O157 toward the distal colon, and that transcriptomes of intestinal tissues differ between super-shedders and steers fecal-negative for O157 (non-shedders). RNA-sequencing (Illumina HiSeq 2000, 100 bp paired-end) was performed for intestinal tissues, including duodenum, proximal jejunum, distal jejunum, cecum, spiral colon and descending colon collected from 5 super-shedders and 5 non-shedders. Sequencing data were processed using a Tophat2, HTseq and edgeR pipeline, and gene function analysis was performed using Ingenuity Pathway Analysis. The number of genes detected in tissues ranged from 16,846 ± 639 (cecum) to 18,137 ± 696 (distal jejunum), and the functional analysis indicated that cell-mediated and humoral immune functions were enriched for the transcriptomes of small intestinal tissues, reflecting their greater immune activity. The number of differentially expressed genes between super-shedders and non-shedders ranged from 1 (duodenum) to 248 (distal jejunum) (false discovery rate < 0.05). Up-regulated genes in super-shedders, including F3, GPR123 and CCR9 in distal jejunum, and GP2 and CD36 in descending colon, indicated possible increased activation of cell-mediated immune responses in these two intestinal regions of super-shedders. Up-regulated APOA1, GPAM, PLIN1 and APOB in descending colon of super-shedders suggested altered lipid metabolism. This is the first report of transcriptome analysis for intestinal tissues of cattle, and our current findings indicate that the tropism of O157 toward the distal part of the colon may be due to less active immune protection in the large intestine. Furthermore, both host

immunity and lipid metabolism may play a role in the interaction between the cattle host and O157. The identified genes may be potential genetic indicators for O157 super-shedding in cattle.

0479 Determination of standardized total tract digestibility of phosphorus in flaxseed meal fed to finishing pigs without or with phytase supplementation. J. W. Kim* and C. M. Nyachoti, *University of Manitoba, Winnipeg, Canada.*

This experiment was conducted to determine the phosphorus (P) digestibility of flaxseed meal (FM) fed to finishing pigs and effect of phytase supplementation on P digestibility for finishing pigs. A total of 18 growing barrows [(Yorkshire × Landrace) × Duroc] with an average body weight (BW) of 78.7 ± 2.4 kg (mean ± SD) were randomly allotted to 3 treatments to give 6 replicates per treatment. Pigs were housed for 10 d in adjustable metabolism crates (1.80 × 0.6 m) with 5 d of adaptation periods and 5 d of total collection periods in a temperature-controlled room (22 ± 2°C). A semi-purified diet based on corn starch-sucrose containing 320 g/kg of FM as the sole source of P was fed without or with phytase supplementation at the level of 500 FTU/kg. A P-free diet mainly based on corn starch, sucrose, and gelatin was also prepared to estimate the endogenous P losses (EPL). Pork gelatin was added to the diets for maintaining similar crude protein in all experimental diets. Vitamins and all minerals except P were included in the diets according to requirements for finishing pigs (NRC, 2012). Pigs were fed at 40 g/kg BW at the beginning of experiment. The daily feed allowance was offered in two equal portions at 0800 and 1600 h. Pigs had free access to water. Results indicated that total feed and P intake were not different between diets without or with phytase supplementation. However, phytase supplementation increased ($P < 0.01$) apparent total tract digestibility (ATTD) and standardized total tract digestibility (STTD) of P in FM diet. The ATTD of P and STTD of P were increased from 31.4% to 45.8% and from 37.3% to 51.8%, respectively. Phytase supplementation also decreased ($P < 0.05$) P concentration (1.95 vs. 1.62%) in feces. Total P output was tended to decrease ($P = 0.08$) in pigs fed diets containing FM with phytase. The basal EPL was calculated at 151 ± 20 mg/kg of DMI in pigs fed the P-free diet. In conclusion, dietary phytase supplementation may increase P digestibility in FM fed to finishing pigs.

Key Words: flaxseed meal, phosphorus, phytase

Table 0479.

Table 1. Digestibility of phosphorus (P) in experimental diets fed to finishing pigs[1]

	Flaxseed meal[2]			
	-	+	SEM	P-value
Feed intake, g/d				
Total feed intake	2877	3108	93.4	0.111
P intake	6.85	7.34	0.222	0.157
Fecal output				
Total feces, g/d	244	247	15.9	0.902
P in feces, %	1.95[a]	1.62[b]	0.081	0.017
P output, g/d	4.72	3.97	0.276	0.081
Digestibility, %				
ATTD[3] of P	31.4[b]	45.8[a]	2.90	0.006
STTD[3,4] of P	37.3[b]	51.8[a]	2.90	0.005

[1] Each value represents the mean of 6 replicates per each treatment.
[2] -, without phytase; +, with phytase (the activity of microbial phytase added to the diets was 500 FTU/kg).
[3] ATTD = Apparent total tract digestibility; STTD = Standardized total tract digestibility.
[4] Values for the STTD were calculated by correcting the ATTD values for the basal endogenous loss of P. The basal endogenous loss of P was estimated in pigs fed the P-free diet at 151 ± 20 mg/kg of DMI.

0480 The effects of partial replacement of barley starch with lactose on production and ruminal fermentation characteristics in dairy cows. E. De Seram*[1], G. B. Penner[1], and T. Mutsvangwa[2], [1]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada,* [2]*University of Saskatchewan, Saskatoon, Canada.*

Previous studies have reported improved DMI and milk production when dietary starch was replaced with sugars in corn-based diets, but there is limited work with barley-based diets. Because corn and barley starch differ in their rates and extents of ruminal degradation, it is important to determine if replacement of barley starch with sugars is beneficial as has been reported for corn. The objective of this study was to determine the effects of partial replacement of barley starch with lactose (as dried whey permeate; DWP) on DMI, milk yield and composition, and ruminal fermentation characteristics. Eight lactating Holstein cows (97 ± 10 d-in-milk; 733 ± 63 kg BW)

were used in a replicated 4 × 4 Latin square design experiment with four dietary treatments. Experimental periods consisted of 18 d of adaptation and 10 d of measurements. Four cows in one Latin square were ruminally cannulated. Cows were fed a barley-based diet (3.6% total sugar [TS]; control), or diets that contained 6.6, 9.6 or 12.6% TS on a DM basis. Dietary TS content was increased by the replacement of barley grain with DWP, which contained 83% lactose. Diets were isonitrogenous (17.2% CP) and starch contents of the control, 6.6, 9.6, and 12.6% TS diets were 24.3, 22.2, 21.2 and 19.1%, respectively. The inclusion of DWP did not affect DMI (mean = 26.6 kg/d) and milk yield (34.3, 35.0, 35.6, and 34.6 kg/d for the control, 6.6, 9.6, and 12.6% TS diets, respectively); however, milk lactose content tended to increase quadratically ($P = 0.07$) as TS content increased. There was a linear decrease ($P = 0.03$) in ruminal NH_3–N concentrations as TS content increased. Ruminal pH tended to decrease linearly as TS content increased ($P = 0.06$; 6.32, 6.31, 6.34, and 6.22 for the control, 6.6, 9.6, and 12.6% TS diets, respectively). Total ruminal VFA concentrations were not affected ($P > 0.05$) by diet; however, there was a linear increase ($P = 0.04$) in butyrate concentration as TS content increased. Plasma urea-nitrogen concentrations were not affected by diet, but milk urea-nitrogen concentrations tended to change in a cubic manner as TS content increased ($P = 0.08$; 14.1 15.1, 14.0, and 13.7 mg/dL for control, 6.6, 9.6, and 12.6% TS diets, respectively). These results suggest that partial replacement of barley starch with lactose improves ruminal N efficiency by decreasing ruminal NH_3–N concentration, but production performance was unaffected

Key Words: barley starch, lactose, production, ruminal fermentation

0481 Potential to improve fiber digestion in the rumen of cattle through inoculation with bison rumen contents.

C. Griffith[*1,2], G. O. Ribeiro Jr.[2], V. Bremer[3], M. Oba[4], T. A. McAllister[5], and K. A. Beauchemin[2], *[1]University of Alberta, Edmonton, Canada, [2]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, AB, Canada, [3]Elanco Animal Health, Greenfield, IN, [4]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [5]Lethbridge Research and Development Centre, AAFC, AB, Canada.*

We hypothesized that inoculating the rumen of cattle with bison rumen contents would improve the ruminal degradability of forage by enhancing the cellulolytic capacity of the rumen microbiome. Sixteen ruminally cannulated beef heifers were fed a diet of 70% barley straw (78.0 ± 3.89 neutral detergent fiber [NDF]) and 30% supplement (36.6 ± 0.76 CP, 37.6 ± 1.41 NDF) on a dry matter (DM) basis. Cattle were inoculated with bison rumen contents twice, 2 wk apart. Intact bison rumens were obtained from an abattoir and transported in insulated containers in a heated truck. Rumens were opened and contents mixed in a heated tub under CO_2. Rumen contents were removed from the cattle, weighed and approximately 72% of the contents (DM basis) were replaced by mixed bison rumen contents in each transfer. The in situ technique was used to measure ruminal degradation of canola straw, barley straw, timothy hay, and alfalfa hay before inoculation and 11 d after the second inoculation. Duplicate bags (10 × 20 cm; 6 g DM/bag) were incubated in the rumen of each heifer for 0, 4, 8, 12, 24, 48, 96, 120 h. The percentage NDF disappearance (NDFD) from the bags was analyzed as: $NDFD = A + B(1\text{-}e^{-k\text{-}d(time\text{-}lag)})$, where A = soluble fraction, b = slowly digestible fraction, K_d = rate of digestion of fraction b, and lag = time before digestion began; and effective ruminal degradability (ERD) = A+B(kd/(kd+kp)) where kp = rate of passage (measured for each animal). Transfer of rumen contents decreased ($P < 0.05$) the potentially digestible fraction (A+B) in barley straw, but increased it in alfalfa hay ($P < 0.05$) (Table 1). No effect of inoculation on ERD were observed, suggesting fiber utilization by cattle was not substantially improved by introducing

Table 0481.

		Pre-inoculation		Post-inoculation		
Feed	Variable	Mean	STD	Mean	STD	*P* value
Canola straw	ERD	21.9	2.59	22.0	1.56	0.92
	A+B	37.4	1.31	36.3	2.20	0.12
Barley straw	ERD	38.5	3.87	37.5	2.55	0.21
	A+B	60.1	1.14	58.5	1.29	0.002
Timothy hay	ERD	45.0	3.87	44.4	3.46	0.50
	A+B	69.2	1.60	68.6	1.45	0.14
Alfalfa hay	ERD	40.8	2.76	40.1	2.64	0.49
	A+B	52.2	0.87	54.1	1.29	<0.001

A+B = % total digestible NDF fraction, ERD = % effective ruminal degradability of NDF; STD = standard deviation

microbes from bison rumen contents.

Key Words: bison, effective ruminal degradability, microbiome

0482 CNCPS fractions of value added pellet products based on combination of new co-products from bio-fuel/bio-oil processing, low grade of peas and lignosulfonate chemical compound at different levels for ruminants. V. Guevara*, D. A. Christensen, J. J. McKinnon, and P. Yu, *Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada.*

Carinata meal, new co-product from bio-fuel processing, is ready to be used as animal feed nowadays. Canola meal has high levels of methionine and cysteine, but limiting in lysine. Pulse products contain high starch, also have high levels of lysine and tryptophan. There is little information available on chemical profile, as well as its nutritive value especially when it blends with other feedstuff as a pellet. The aim of this project was to test and develop eight high-value added pellet products (BPP) based on combination of co-products from bio-fuel/bio-oil processing, low grade of peas and lignosulfonate at different levels for ruminants. Statistical analyses were performed using PROC MIXED procedure of SAS 9.3 with significance declared at $P < 0.05$. The results from CNCPS 6.5 system indicated all canola based pellet products BPP5 (low level of canola meal, high level of peas and no lignosulfonate), BPP6 (low level of canola meal, high level of peas and lignosulfonate), BPP7 (high level of canola meal, low level of peas and no lignosulfonate) and BPP8 (high level of canola meal, low level of peas and lignosulfonate) showed higher levels of indigestible protein (PC, $P < 0.05$) and higher soluble true protein (PA2, $P < 0.05$). All carinata based pellet products showed the higher fiber bound protein (PB2, $P < 0.05$). BPP3 (high level of carinata meal, low level of peas and no lignosulfonate), BPP4 (high level of carinata meal, low level of peas and lignosulfonate), BPP7 and BPP8 had the higher levels of water-soluble carbohydrates (CA4, $P < 0.05$); BPP1 (low level of carinata meal, high level of peas and no lignosulfonate), BPP2 (low level of carinata meal, high level of peas and lignosulfonate), BPP5 (low level of canola meal, high level of peas and no lignosulfonate) and BPP6 showed the higher levels of starch (CB1, $P < 0.05$), while BPP1, BPP3 and BPP4 had higher digestible fiber (CB3, $P < 0.05$). In conclusion, carinata meal can be used as a potential feed ingredient for ruminants.

Key Words: canola, carinata, lignosulfonate

0483 Comparison of barley silage with varying digestible fiber content to corn silage on rumen fermentation characteristics and microbial protein synthesis using RUSITEC technique. B. Refat*[1,2], D. A. Christensen[3], J. J. McKinnon[4], J. Nair[1], A. D. Beattie[5], T. A. McAllister[6], W. Yang[7], and P. Yu[1], *[1]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada, [2]Animal Production Department, Faculty of Agriculture, Zagazig University, Egypt, [3]University of Saskatchewan, Saskatoon, Canada, [4]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada, [5]Department of Plant Sciences, College of Agriculture and Bioresources, University of Saskatchewan, Saskatoon, Canada, [6]Lethbridge Research and Development Centre, AAFC, AB, Canada, [7]Lethbridge Research and Development Centre, AAFC, AB, Canada.*

The effect of barley silage with enhanced in vitro fiber digestibility on rumen fermentation characteristics and microbial protein synthesis has not been well investigated in barley grown in western Canada. The objective of this study was to evaluate the effects of barely silage with varying in vitro NDF digestibility (IVNDFD) in comparison to corn silage on rumen fermentation characteristics and microbial protein synthesis using rumen simulation technique (RUSITEC). The experiment was a completely randomized design with four treatments. The experimental diet contained 49% barley-based concentrate and 51% forage (DM basis). The forage consisted of 10% alfalfa hay and 41% silage. The four whole plant silages were: T1 = P7213R corn silage, T2 = CDC Cowboy barley silage, T3 = CDC Copeland barley silage, and T4 = Xena barley silage. The experiment consisted of 10 d of adaptation and 6 d of data collection. Statistical analyses were performed using the PROC MIXED procedure of SAS 9.4 with significance declared at $P < 0.05$. The 30 h IVNDFD of corn silage, CDC Cowboy, CDC Copeland and Xena varieties were 27, 37, 31, and 29%, respectively. Barley silage T2, with the highest IVNDFD, had no effect on rumen fermentation characteristics ($P > 0.10$) when compared with T3 and T4 barley silage. However, corn silage vs. the average of T2, T3 and T4 barley silage ($P < 0.05$) had lower ruminal pH (6.65 vs. 6.73), greater molar proportion of propionate (28 vs. 23%) and lower C2/C3 acid ratio (1.8 vs. 2.2). Nutrients disappearance of total mixed ration (DM and CP) were not affected by the treatments. On the other hand, corn silage in T1 had the highest DMD compared with the average DMD of barley silages in T2, T3 and T4 (69.1 vs. 64.8%, $P < 0.05$). There was no significant effect of higher digestible fiber content in T2 on bacterial protein production compared with T3 and T4 (averaged 49.5 mg/d) while T1 diet had a higher bacterial protein

production than the average of T2, T3 and T4 (53.5 vs. 49.5 mg/d, $P < 0.05$). These results imply that higher in vitro NDF digestibility of barley silage might not necessarily correspond with greater impact on rumen fermentation and microbial protein synthesis. However, feeding the corn silage had a higher microbial protein produced in the rumen and may enhance the dairy cattle performance compared with the barley silages.

Key Words: bacterial N production, rumen fermentation, RUSITEC

0484 Phosphorus utilization on dairy farms in Manitoba. V. P. Senaratne*, E. J. McGeough, K. H. Ominski, and J. C. Plaizier, *Department of Animal Science, University of Manitoba, Winnipeg, Canada.*

A survey was performed on 19 dairy farms in Manitoba representing a range of sizes, feeding, housing and management systems to identify factors that affect the utilization of dietary phosphorus (P) by lactating dairy cows. Each farm was visited once to collect milk, blood, feed and feces samples as well as production data from 10 early/peak, 10 mid-lactation, and 10 late lactation cows. Phosphorus content of feed (FEED P), feces (FECAL P), milk (MILK P), blood (BLOOD P) and calcium content of feed (Ca) were determined. Pearson correlation analysis among the various measures was conducted using SAS 9.4 software. The average P contents (DM basis) of FEED P, FECAL P, MILK P, and BLOOD P was 0.41% (0.34 and 0.53%), 0.76% (0.30 and 1.35%), 0.09% (0.05 and 0.12%) and 2.04 mmol/L (1.34 to 3.04 mmol/L), respectively. The output of P in milk (P OUT) which is obtained by multiplying MILK P with daily milk yield (MY), was positively correlated with the MILK P, FEED P, MY, Parity, Ca and negatively correlated with days in milk (DIM). But no correlation was observed with the BLOOD P and FECAL P. FEED P was positively correlated with the MILK P, FECAL P, MY, and negatively correlated with Ca and DIM. BLOOD P was positively correlated with Ca and DIM, but not correlated with any other measures (Table 1). Results show that the P content of diets, and feces vary considerably among cows and among farms, suggesting that the P contents in diets and feces can be reduced. Furthermore, more than 50% of the animals received diets which contain excess P levels than the NRC (2001) recommendations. The P content of blood was not indicative of P output in milk, nor the P contents of the diet or feces. The output of P in milk was highly correlated with the yield and P content of milk, but a 1% increase in the dietary P content lead to a 0.21% increase in P OUT. Better understanding of the dynamics between these dietary and cow factors can help to develop efficient P management strategies to improve P utilization and avoid excess P use.

Key Words: phosphorus, dairy, cow

0485 Effect of variety and level of inclusion of barley grown for silage on performance and carcass characteristics of growing and finishing beef steers. J. Nair*[1], D. A. Christensen[2], P. Yu[1], T. A. McAllister[3], D. Damiran[1], and J. J. McKinnon[4], *[1]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada, [2]University of Saskatchewan, Saskatoon, Canada, [3]Lethbridge Research and Development Centre, AAFC, AB, Canada, [4]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada.*

This study was designed as a 3 × 2 factorial to evaluate three barley silage varieties when included at two (high and low) inclusion rates on performance and carcass characteristics of beef steers. Barely varieties CDC Cowboy (CB), CDC Copeland (CL) and Xena were chosen based on results of a preliminary study for high (CB, 37.0%), medium (CL, 31.1%) and low (Xena, 28.8%) NDF digestibility (NDFD; % NDF). For the present trial, the three varieties were seeded and managed identically including harvesting at the mid-dough

stage for ensiling. Crossbred steers (n = 288; 320 ± 23 kg) were allotted to one of 24 pens (12 steers/pen) with each pen assigned to one of 6 treatments for a 68-d backgrounding (BK) and 148-d finishing program. Diets with the low inclusion level during BK consisted of 40.1% BS, 9.4% brome grass hay (hay), 40.1% barley grain (BG), 5.6% canola meal (CM) and 4.8% mineral-vitamin supplement (supplement; %DM), while high inclusion diets consisted of 53.5% BS, 9.4% hay, 26.7% BG, 5.6% CM and 4.8% supplement. During finishing, low inclusion diets consisted of 5.0% BS, 87.0% BG, 3.5% CM and 4.5% supplements while high inclusion diets consisted of 15.0% BS, 77.0% BG, 3.5% CM and 4.5% supplement (%DM). Actual NDFD averaged 37.6 ± 3.5, 34.7 ± 3.8 and 36.9 ± 3.0% for CB, CL and Xena, respectively. Data were analyzed as completely randomized design with pen as the experimental unit and treatment as the fixed effect using the mixed model procedure of SAS (9.4). During BK, cattle fed CB exhibited lower ($P < 0.01$) ADG and end of period BW (EBWT) than cattle fed CL or Xena. Low BS inclusion resulted in greater ($P < 0.01$) ADG and EBWT relative to high inclusion diets. The DMI during BK was less ($P < 0.01$) for steers fed CB relative to those fed CL, with Xena being intermediate. Low BS inclusion resulted in greater ($P < 0.01$) DMI than high inclusion. Feed efficiency was greater ($P = 0.02$) for steers fed low, relative to high inclusion diets. During finishing, ADG and DMI were greater ($P < 0.01$) for steers fed high BS inclusion diets. However, over the entire trial, performance and carcass characteristics were not impacted by treatment except for carcass weight where steers fed CL had heavier ($P = 0.04$) carcasses relative to those fed CB or Xena. These results indicate that barley variety and inclusion level will impact performance of growing cattle. Barley variety has a minimal impact on finishing performance.

Key Words: barley silage, cattle, performance

0486 Development of a genetic marker panel for ketosis in dairy cattle. V. Kroezen[*1], F. Miglior[1,2], F. S. Schenkel[1], and J. Squires[1], *[1]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, ON, Canada, [2]Canadian Dairy Network, Guelph, ON, Canada.*

During the transition period high-yielding dairy cattle are susceptible to ketosis, a metabolic disease which has negative impacts on the health, fertility and milk production of the cow. Genetic selection of animals resistant to developing ketosis is a potential solution to the economic losses faced by producers, as well as the reduced herd health and welfare associated with this disease. Genetic evaluations for ketosis, a health trait with low heritability, would benefit from the additional information provided by genetic markers. The objective of this study is to identify novel single nucleotide polymorphisms (SNP) within candidate genes for ketosis to be incorporated into a custom marker panel. Investigating candidate genes provides the opportunity to discover SNP with a functional role that are not currently included on commercially-available marker panels. A list of 123 candidate genes, selected based on biological relevance, were selected for in silico investigation; this includes genes which encode key enzymes and regulatory factors involved in metabolic pathways, genes that have been shown to be differentially expressed in ketotic animals, and genes that have been proposed by genome-wide association studies (GWAS). A preliminary GWAS from our group identified 462 SNP from high-density genotypes that are associated with de-regressed estimated breeding values for ketosis. These SNP were mapped to genes involved in pathways that were expected to be involved in ketosis (i.e., PPAR signaling pathway, CoA biosynthesis), as well as unexpected (i.e., T and B cell receptor signaling, apoptosis). Within the candidate genes, putative SNP were identified by aligning sequence data from online cDNA libraries with the gene reference sequence. The variant calling program, Sequencher 4.9, was used to identify SNP and their corresponding amino acid substitutions. SNP were prioritized for inclusion in the panel based on their Sorting Intolerant From Tolerant prediction score, to select polymorphisms which would most likely alter the function of the encoded protein. A set of 1081 SNP were incorporated onto a custom low-density panel. To our knowledge, this is the first custom panel composed of markers found in candidate genes that are specific to ketosis. The second phase of this project will use this panel to genotype several thousand cows from herds originating from Quebec, Canada; these data to be collected spring 2016.

Key Words: ketosis, SNP, candidate gene

0487 Taxonomic assessment of the rumen microbiome of bulls under backgrounding and finishing diets. E. O'Hara[*1,2], M. Zhou[1], S. M. Waters[2], M. E. Walpole[3], P. Gorka[4], M. Woodbury[5], G. B. Penner[6], and L. L. Guan[1], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]Teagasc Grange Animal and Bioscience Department, Dunsany, Co. Meath, Ireland, [3]Department of Animal and Poultry Science, University of Saskatchewa, Saskatoon, Canada, [4]University of Agriculture in Krakow, Poland, [5]Department of Large Animal Clinical Sciences, University of Saskatchewan, Saskatoon, Canada, [6]University of Saskatchewan, Saskatoon, Canada.*

To examine the effect of backgrounding and finishing diets on the rumen microbial community in beef cattle, 16 healthy beef bulls were blocked by BW and randomly assigned to 1 of 2 dietary regimes: a backgrounding diet (BCK: 45% grain) or a high-grain finishing diet (FIN: 80% grain). Initiation of both diets was staggered such that both groups received their final diets for 30 d. At the end of the treatment period, bulls were

slaughtered and samples of mixed ruminal digesta were collected for microbial analysis. A 454 pyrosequencing was performed on DNA amplicons, targeting the bacterial/archaeal partial 16S rRNA genes and protozoal partial 18S rRNA gene. Taxonomy was assigned using QIIME, with only those OTUs represented at > 0.05% in more than 4 bulls/treatment considered for downstream analysis. As a whole, the bacterial community of BCK was more diverse than FIN ($P < 0.01$). The bacterial phyla *Firmicutes, Bacteroidetes,* and *Proteobacteria* dominated regardless of treatment, with *Spirochaetes* (0.83% vs. 0.29% total bacteria) and *Fibrobacteres* (2.36% v 0.09%) higher in BCK ($P < 0.05$). *Choloroflexi* (0.44%; $P < 0.05$) was only found in in the BCK group. Twenty-four genera were affected by treatment, with *Ruminococcus* (6.92% vs. 2.13%) and *Fibrobacter* (2.36% vs. 0.09%) greater in abundance in BCK ($P < 0.05$) than FIN. *Succinivibrio* was among the genera that increased in FIN (2.12% vs. 0.025%; $P < 0.05$) relative to BCK, and *Megasphera* appeared exclusively in FIN (1.45%). Archaeal composition was not affected, with the *Methanobrevibacter gottschalkii* clade predominating in both groups. However, the methanogen community for BCK was more diverse ($P < 0.01$) than for FIN. The protozoal genus *Epidinium* predominated under both treatments (74–77% abundance), and the genus *Eudiplodinium* appeared exclusively in FIN bulls (6.42%, $P < 0.05$). Our results revealed that the responses to treatment differed across the three microbial groups, suggesting that future studies are needed to define their respective roles in rumen function during diet change.

Key Words: rumen microbiome, backgrounding diet, finishing diet

0488 The transition cow: May the odds be ever in her favor. Y. Schuermann*[1], A. St-Yves[1], N. Dicks[1], R. C. Bohrer[1], R. Mondadori[2], G. Welsford[1], V. Boyer[1], M. Taibi[1], V. Higginson[1], S. Hartley[1], E. Madogwe[1], V. Bordignon[1], B. Baurhoo[1], and R. Duggavathi[1], *[1]McGill University, Ste.-Anne De Bellevue, QC, Canada, [2]Federal University of Pelotas, Capão do Leão, Brazil.*

Longevity is a key component of sustainable dairy farming. High-yielding dairy cows often suffer from ovarian dysfunction and infertility leading to reduced reproductive and productive longevity. Infertility has been attributed to the metabolic stress during the transition period. However, potential metabolic alterations that may dysregulate ovarian functions have not been completely cataloged. Our objective was to characterize metabolic parameters of dairy cows during the transition period. In the first experiment, we examined the metabolic profiles in circulation to pinpoint time-points of major changes. We collected weekly blood samples from Holstein cows ($N = 15$) from 3 wk before until 12 wk after calving. As expected, glucose levels reduced during pre-calving weeks to reach a nadir at 3 wk post-calving ($P < 0.05$) and the first increase in glucose concentration occurred at 10 wk post-calving ($P < 0.05$). Also, β-hydroxybutyric acid levels increased from calving until wk 3 of lactation ($P < 0.05$) and subsequently returned to baseline. Levels of triglycerides decreased during pre-calving weeks, while significant increase occurred at 5 wk post-calving ($P < 0.05$). Total cholesterol concentrations increased from the third to seventh week post-calving ($P < 0.05$). Total bile acid levels increased from 3 wk to 2 wk before calving and stayed elevated throughout the transition period ($P < 0.05$). Oxidative stress indicator, glutathione, decreased to reach a nadir by 7 wk in lactation ($P < 0.05$), while the ferric reducing ability of plasma remained constant ($P > 0.05$). Thus, post-calving wk 3 to 7 are associated with major changes in metabolic indicators in circulation. In the second experiment, we evaluated changes in liver mRNA levels and circulating metabolic indicators during the periods of major metabolic changes above. We collected blood and liver biopsy samples from Holstein dairy cows at 3 wk pre-partum, during the calving week and 7 wk post-partum ($N = 13$). Quantitative PCR analyses ($N = 4$) did not reveal any changes in the hepatic mRNA abundance of genes indicative of liver functions including acyl-CoA:cholesterol acyltransferase 1 (*ACAT1)*, Paraoxonase-1 (*PON1*) and sterol regulatory element-binding factor-1 (*SREBF1*) during wk 6–7 post-calving compared with peri-calving period. Taken together, transition period in dairy cows features increasing cholesterol, triglycerides, total bile acids and decreasing glucose and glutathione compared with pre-calving period. However, these changes appear to be independent of alterations in mRNA levels in the liver. Further studies, including liver function assays, are required to thoroughly investigate the relationship between liver health and alterations in circulating metabolic indicators during transition period in dairy cows.

Key Words: cow, liver, infertility

0489 Effect of dietary wheat bran inclusion on nutrient digestibility in weaned pigs. B. Koo*, M. M. Hossain, and C. M. Nyachoti, *University of Manitoba, Winnipeg, Canada.*

Wheat bran (WB) as a source of insoluble fiber has been shown to confer gut health benefits in weaned piglets. However, there is limited data on the influence of WB inclusion in weaner pig diets on digestibility. Thus, the aim of this study was to assess the effect of a 4% dietary inclusion of coarsely milled (1088 µ of particle size) WB on nutrient digestibility in weaned pigs. Six barrows (7.3 ± 0.1kg BW) fitted with a T-cannula at the distal ileum were fed one of two test diets consisting of: (1) a barley-wheat-corn-soybean meal-based diet (Control) and (2) a WB diet with 4% coarsely milled WB. Diets were assigned according to a 2x2 Latin square design repeated three times. At the end of the second period, all pigs were fed a 5% casein-corn starch-based diet to estimate basal endogenous amino acid (AA) losses. Each period lasted 9 d consisting of

5 d for adaptation followed by 2 d for fecal collection and 2 d for ileal digesta collection (12 h/d). All pigs were fed diets mixed with 0.3% titanium dioxide as an indigestible marker to calculate apparent total tract digestibility (ATTD), apparent ileal digestibility (AID) and standardized ileal digestibility (SID) of nutrients. Treatment means were compared using the Student *t* test procedure of SAS (SAS Inst. Inc., Cary, NC). Piglets fed the WB diet had lower ATTD of organic matter and AID of dry matter (DM) compared with those fed the control diet (89.4 vs. 88.3% and 60.8 vs. 66.4%; $P < 0.05$). However, piglets fed the WB diet had higher ATTD of fat compared with those fed the control diet (70.4 vs. 62.6%; $P < 0.05$). There were no differences in the AID and SID of nitrogen (N) and AA between the two diets ($P > 0.10$). Average AID values (%) were 66.3, 80.5, 41.5, 79.9, 80.4, 80.9, 87.2, 81.3, 71.6, and 76.0 for N, Arg, His, Ile, Leu, Met, Phe, Thr, and valine, respectively. Respective average SID values (%) were 79.7, 88.9, 66.4, 86.3, 84.5, 85.2, 90.3, 84.8, 80.2, and 82.7. In conclusion, results indicated that dietary inclusion of WB increased ATTD of fat and reduced ATTD of OM and AID of DM in weaned piglets. Further research is warranted to evaluate effects of WB, especially on growth and health performance, gut microbiota and fecal and/or ileal digesta volatile fatty acids production.

Key Words: digestibility, piglets, wheat bran

0490 Effect of steam flaking and seed type on carbohydrate molecular structure features associated with nutrient availability of legume seed in ruminants.

X. Li[*1,2], V. Racz[1], B. Laarveld[1], Y. Zhang[2], and P. Yu[1], *[1]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Canada, [2]College of Animal Science and Technology, Northeast Agricultural University, Harbin, China.*

The objectives of this study were to evaluate the effect of steam flaking processing and different seed type on carbohydrate spectroscopic features in relation to degradation kinetics. Six different sources of peas from Duck Lake and COOP were processed at Canadian Feed Research Center (CFRC, University of Saskatchewan, North Battleford, Canada). The carbohydrate molecular structure makeup was detected using attenuated total reflectance-Fourier transform infrared spectroscopy instrument at molecular spectroscopy lab, Department of Animal and Poultry Science, University of Saskatchewan. Three rumen-cannulated lactating Holstein cows were used to determine the in situ rumen degradation kinetics of DM and starch at Rayner Dairy Teaching and Research Facility (RDTRF). Statistical analyses were performed using the PROC MIXED procedure of SAS 9.3. The Tukey method was used for multi-treatment comparison. Difference was declared at $P < 0.05$. The results of univariate molecular spectral analyses showed that the whole pea seed had a significantly higher ratio of structural carbohydrate to total carbohydrate area than split pea seed (0.313 vs. 0.307; $P < 0.05$). The spectral ratio of cellulosic compound to structure carbohydrate area was significantly affected by steam flaking treatment, which was higher in flaking pea seed than the control (0.153 vs. 0.135; $P < 0.05$). Additionally, steam flaking treated pea seed also had a significant higher spectral ratio of cellulosic compound to total carbohydrate area than control untreated pea seed as a control (0.047 vs. 0.042; $P < 0.05$). In conclusion, steam flaking affected the inner molecular makeup of pea seed, which may be highly associated with the nutrient utilization.

Key Words: flaking, pea seed type, molecular structure

0491 Dynamics of progesterone concentrations and insemination outcomes in dairy cows.

T. C. Bruinjé[*1], M. Gobikrushanth[1], R. C. Guimarães[1], and D. J. Ambrose[1,2], *[1]Department of Agricultural Food and Nutritional Science, University of Alberta, Edmonton, Canada, [2]Livestock Research Branch, Alberta Agriculture and Forestry, Edmonton, Canada.*

The objective was to evaluate the association between milk progesterone (P4) concentrations and its dynamics with insemination outcomes. In-line milk P4 records (Herd Navigator, DeLaval Inc.) relating to 605 inseminations (AI) were assessed from two dairy farms. Only cows that had confirmed luteolysis (P4 declined to < 5ng/mL) and ovulation (P4 increased to > 5 ng/mL) were included. The day of luteolysis was considered d 2 and AI occurred on d0. Progesterone at d 2, 5, 10, 14, and maximum P4 (Peak) within d 21 were considered, in addition to the rate of increase in P4 (e.g., d 2 to d 5). Insemination outcomes were defined as open (P4 > 5 ng/mL for < 20 d; $n = 357$), pregnant (P4 > 5 ng/mL for > 45d; $n = 170$) or pregnancy loss (P4 > 5 ng/mL for > 20 to $\leq$ 45 d, $n = 78$). Progesterone concentrations were modeled against outcomes of AI and parity, while herd and AI (first or second) were considered random variables, and data analyzed using MIXED procedure of SAS. Milk P4 at d 2 tended to be lower ($P = 0.10$) in pregnant (3.33) than in open (3.44) or cows that suffered pregnancy loss (3.44). Pregnant cows had greater P4 ($P < 0.01$) than open cows at d 10, 14 and at Peak (9.6, 18.3 and 23.4 vs. 8.3, 16.7 and 20.3, respectively). Rate of P4 increase (ng/mL/d) was also greater ($P < 0.01$) in pregnant than in open cows from d 2 to 14, d 2 to Peak, d 5 to 10, d 5 to 14 and d 5 to Peak (0.9, 1.0, 1.1, 1.6 and 1.5 vs. 0.8, 0.9, 0.9, 1.4 and 1.3, respectively). However, the aforesaid dynamics of P4 did not differ among cows that remained pregnant or suffered pregnancy loss. Primiparous cows had higher P4 ($P < 0.03$) than multiparous cows at d 2, 5, 10, 14 and at Peak (3.5, 4.8, 10.8, 19.7 and 23.6 vs. 3.3, 3.0, 7.7, 16.0 and 21.2 ng/mL, respectively). Furthermore, primiparous cows had a greater rate of P4 increase ($P \leq 0.05$) than

multiparous from d 2 to 5, d 2 to 14, d 2 to Peak, d 5 to 10, d 5 to 14, d 5 to Peak and d 10 to 14 (0.2, 1.0, 1.0, 1.2, 1.6, 1.4 and 2.2 vs. −0.1, 0.8, 0.9, 0.9, 1.4, 1.3 and 2.0, respectively). Cows that conceived, regardless of whether or not they suffered pregnancy loss, had greater P4 concentrations (except on d 2) and a greater rate of P4 increase than open cows. Also, primiparous cows consistently had greater P4 concentrations and rate of increase than multiparous cows.

Key Words: in-line milk progesterone, estrous cycle, fertility

CSAS SYMPOSIUM: REDUCING THE USE OF ANTIBIOTICS IN LIVESTOCK PRODUCTION

0492 Alternatives to antibiotics in swine and poultry.

D. Schokker*[1,2] and M. A. Smits[1,2,3], [1]*Wageningen UR Livestock Research, Netherlands,* [2]*Animal Breeding and Genomics Centre, Wageningen, Netherlands,* [3]*Wageningen UR, Central Veterinary Institute, Lelystad, Netherlands.*

To reduce the risk for the spread of antibiotic resistant bacteria from livestock to humans, the European Union banned the use of antibiotics as growth promoters in animal feeds for pigs and poultry since January 2006. As a result, the use of veterinary prescribed antibiotics increased in a sort of compensation phenomenon. In intensive husbandry systems, veterinary prescribed antibiotics are mainly used around birth and in newborn animals.

To study the effects of antibiotic usage during early life stages, we performed several experiments in piglets and poultry. We analyzed both the short-time and long-term effects at the level of intestinal microbiota and intestinal mucosal functions. To this end, we applied metagenomics, transcriptomic and immunologic analytical approaches on intestinal tissues and luminal contents, taken at different intestinal locations and at different time-points after treatment. These studies clearly demonstrated both short-term and long-term effect on the expression of immune related genes. We hypothesized that that these long-lasting effects are due to differences in the programming of the gut immune system as induced by the temporary early life perturbation of the gut microbiota.

To search for alternatives for antibiotic growth promoters, a large variety of farming approaches are proposed, including organic acids, probiotics and prebiotics, enzyme, clays and minerals, trace elements, and botanicals. In this presentation, we will show the effect of the administration of fructooligosaccharides (FOS) to suckling piglets on intestinal microbiota and gene expression. Twelve days of intervention with FOS resulted in a bifidogenic effect in the colon of treated piglets. Furthermore, after 23 d of intervention with FOS, decreased expression in immune related gene sets was observed in treated piglets.

In this context, it is also important to identify major intrinsic and extrinsic factors that (co)determine the early life gut microbial colonization of livestock species. From literature it is already known that several extrinsic factors are important, including the sow/mother-hen and the environment. Here we show data that indicate that also the genetic make-up of host is an important factor in the early life microbial colonization of the gut and consequently for immune system development.

In conclusion, during early life, the interplay between the host (genetics), environment (nutrition and/or management), in association with the microbiota modulate bacterial colonization, drives gut development and immune maturation. The use of antibiotics during early life stages perturbs this interplay significantly with serious consequences for the functionality of the host immune system.

0493 Management of dairy cows to improve resistance to infectious diseases.

P. Lacasse*[1], N. Vanacker[2,3], S. Lanctôt[2,4], and S. Ollier[2], [1]*Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada,* [2]*Sherbrooke R&D Centre, Sherbrooke, QC, Canada,* [3]*Université de Sherbrooke, Sherbrooke, QC, Canada,* [4]*McGill University, Montréal, QC, Canada.*

The incidence of infectious diseases varies greatly during the lactation cycle. Most new cases of clinical mastitis appear at the beginning of lactation (transition period), and the incidence increases with the level of milk production. In addition to mastitis, the majority of other infectious diseases becomes clinically apparent during the first 2 wk of lactation. During this time, cows are in negative energy balance and they must mobilize body reserves to balance the deficit between food energy intake and energy required for milk production. Cows undergoing energy deficit have a weakened immune system, which increases their susceptibility to infections. Therefore, we evaluated the effects on blood metabolite concentrations and immune functions of limiting milk production in early lactation to reduce the negative energy balance. In a first experiment, multiparous Holstein cows were milked either once a day or twice a day for the first postpartum week. In a second experiment, the amount of milk harvested was limited by milking cows incompletely (about one-third of expected milk production was collected) twice a day until d 5 after calving. In a third experiment, first-wk milk production was limited by administering a prolactin secretion inhibitor, quinagolide, during the first days of lactation. Globally, the results of these studies indicate that reducing the amount of milk harvested postpartum while maintaining milking stimuli reduces metabolic stress and immunosuppression without compromising productivity of high-yielding dairy cows. The second period that has the highest incidence of new intramammary infections

(IMI) is the period immediately following drying-off, during early mammary gland involution. The importance of the dry period is often underestimated as many of these new infections are only detected after the next calving. A cow's risk of acquiring a new IMI during the dry period increases with milk production at drying-off but decreases as mammary gland involution progresses. In this context, we tested whether prolactin inhibition could be used to reduce milk production at drying-off and to accelerate the rate of mammary involution after cessation of milking. In late-lactation cows, quinagolide decreased milk production within the first day of treatment and induced more rapid changes in concentrations of several markers of mammary gland involution after drying-off. In addition, quinagolide improved the resistance to IMI suggesting that prolactin inhibition could be a new strategy for facilitating drying-off. Innovative management can be used to reduce dairy cow's susceptibility to infection and antibiotic utilization.

Key Words: mastitis, transition period, blood metabolites

0494 Selection for disease resistance in swine.

G. Plastow*, *Livestock Gentec, Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Infectious disease is a major problem for swine production around the world despite successes in terms of biosecurity and vaccination. Perhaps the best known examples of disease resistance pertain to infection with *E. coli* F4 (K88) or F18, which cause scours in young pigs and can result in significant morbidity and mortality. In other cases, there is variation in susceptibility but all pigs become sick. Porcine respiratory and reproduction syndrome (PRRS) is an example of a disease where all pigs are infected by PRRSV but the impact on the host varies. For example, the amount of virus produced and the growth of the infected pigs varies significantly between individuals. Genome wide association studies identified a relatively large effect on chromosome 4 (SSC4) and Boddicker et al. (2012 *J. Anim Sci* 90:1733) reported that this region explained 15.7% of the genetic variance for viral load and 11.2% for gain. Subsequently a putative functional variant in *GBP5* was identified as the likely causative mutation (Koltes et al., 2015 *BMC Genomics* 16:412). Two regions of the genome were identified as explaining a similar amount of variation in PCV2 susceptibility (Engle et al., 2014 *Proc. 10th WCGALP).* Although these findings offer potential tools to reduce the impact of these two major viruses through genomic assisted selection, it would be very difficult to combine such tools for all of the important diseases. One option may be to select for animals that respond better to infection, maintaining growth and/or rapidly recovering. This is described as resilience or robustness. A new study is underway to investigate resilience using a "natural challenge" model consisting of a number of different agents including PRRSV as well as Swine Influenza Virus, *Haemophilus parasuis* and *Streptococcus suis*. A number of approaches are being used to try to identify biomarkers that will predict resilience in high health status pigs to reduce the impact of infection and contribute to reducing the use of antimicrobials in production. For example, Kommadath et al. (2015 *BMC Genomics* 15: 452) used RNaseq to identify gene expression patterns before infection with *Salmonella* that predict different outcomes in terms of carriage of the pathogen. A second option in the future may be to use gene editing to manipulate the early stages of infection and develop novel resistance as was recently demonstrated so remarkably for PRRSV by Prather and colleagues (Whitworth et al., 2016 *Nature Biotechnology* 34:20).

Key Words: health, pigs, resilience

0495 Genomic approaches to characterizing and reducing antimicrobial resistance in beef cattle production systems.

M. A. Javed[1], C. Klima[1], A. A. Cameron[1], T. W. Alexander[1], R. Zaheer[1], K. Munns[1], and T. A. McAllister*[2], *[1]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, AB, Canada, [2]Lethbridge Research and Development Centre, AAFC, AB, Canada.*

The current rate of resistance development against antimicrobials (AMR) available for use in human medicine is a global health threat. The discovery and design of new antibiotics is nearly at a standstill and as a result, the approximately 700,000 global deaths attributed to AMR infections yearly is expected to rise. Intensive livestock operations, including beef production systems require the use of antimicrobials to ensure animal health and to optimize growth efficiency. As a result the microbes present in the feedlot environment can be exposed to multiple classes of antimicrobials and have the potential to harbor, acquire or develop resistance. To understand the magnitude and risk of AMR in this setting, it is important to assess the prevalence and diversity of AMR determinants in the microbial population. AMR bacteria are traditionally identified by isolation and growth in the presence of selective antibiotics. However, more recent advances in genomics have enhanced the precision of AMR characterization. Whole-genome, metagenomic, and RNA sequencing provide new avenues for the rapid detection of AMR determinants in microbial communities, including unculturable organisms. Metagenomic approaches can be used to identify both previously characterized and novel AMR mechanisms in recalcitrant bacteria which may serve as an environmental reservoir of resistance genes. Metagenomic approaches can also be used to place AMR genes within the context of mobile genetic elements, providing information with regard to the likelihood of their dissemination among microbial communities. Genomics may also play a key role in mitigating and developing alternatives to antimicrobials such as probiotics. RNA-seq-based

transcriptomics and Tn-seq may also provide new ways to examine the cellular mechanisms that may promote AMR or prevent it. Finally, CRISPR-Cas gene-editing shows promise as a tool to directly reduce AMR by killing AMR-resistant organisms without harming beneficial microbes. All these technological developments provide new opportunities to better identify, quantify, and mitigate resistance to antimicrobials as well as develop alternatives.

Key Words: antimicrobial resistance, bacteria, beef, cattle, CRISPR-Cas, genomics, metagenomics

0496 Nurturing healthy gut microbiome: route to increased disease resistance in ruminants.

L. L. Guan*[1] and N. Malmuthuge[2], [1]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada,* [2]*1Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Perturbations in gut microbiota colonization during early life have been shown to present long lasting influences to the host immune responses, health and metabolism as well as subsequent microbial succession. These perturbations can be caused by nutritional imbalances, differing feeding methods, nutritional regimes and antibiotic treatments during the early life. Management of ruminants can vary significantly due to different feeding practices and it relies heavily on antibiotics prevention/treatments for diarrhea and pneumonia in pre-ruminants. However, our understanding on the influence of such management practices on gut microbiome as well as ruminant health and metabolism is very limited. Our recent study has revealed that feeding of heat-treated colostrum soon after birth enhances the colonization of beneficial bacterium, bifidobacteria, which is well-studied using mouse models and has been shown to have greater impact on mucosal immune system development as well as weight gain in children. Besides, the colonization of bifidobacteria in calf gut has been suggested as a preventive mechanism of pathogenic *E. coli* that causes neonatal calf diarrhea. The use of next generation sequencing approaches to study calf gut microbiome and linking the early microbial composition with that of calf phenotypes have reported that higher abundance of *Fecalibacterium* is associated with decreased diarrhea incidences and increased body weight, suggesting linkages between gut microbiome, calf health and growth. Moreover, diet-driven changes in rumen microbiome are related to the development of subacute ruminal acidosis, a prevalent metabolic disorder in adult cattle. Thus, understanding on gut microbiome and their link to gut/rumen development and metabolism will provide means to improve health in ruminants via microbial manipulation. Such manipulation methods toward nurturing a healthy gut microbiome not only improve the disease resistance in ruminants, but may also decrease the heavy antibiotic usage that is in practice in the industry.

Key Words: disease resistance, gut microbiome

0497 Pre- and probiotics for increased disease resistance in the nonruminant animal.

C. M. Nyachoti*, *University of Manitoba, Winnipeg, Canada.*

In addition to formulating diets for poultry and swine to optimize performance outcomes, an equally important goal is to apply nutritional interventions to support a healthy and functional gastrointestinal tract. The latter has gained considerable interest as the utilization of in-feed antibiotics and some ingredients (such as those derived from animals) has come under increased scrutiny and may no longer be an option. To this end, feed additives such as pre- and probiotics have been suggested as feed additives with potential to mitigate enteric diseases in poultry and swine raised under antibiotic-free feeding programs. Prebiotics are ingredients that are selectively fermented and lead to specific changes in the composition and (or) activity of gut microbiota (e.g., bifidobacteria and lactobacilli) that confer beneficial effects to the host. Various carbohydrate components, including fructooligosaccharides and transoligosaccharides and other fiber types (e.g., inulin, sugar beet pulp, and coarsely ground wheat bran) have been reported to cause prebiotic effects in poultry and swine. Moreover, it has been reported that dietary supplementation with carbohydrases may generate carbohydrate components in the gut that could enhance gut health and function partly by acting as prebiotics. Probiotics are live microorganisms which when administered in adequate amounts confer a health benefit on the host. The beneficial effects of these additives are mediated through one or more of the following mechanisms in the gut: stimulation of a healthy microbiota, prevention of enteric colonization by pathogens, improving digestive capacity and lowering the pH, improving mucosal immunity, or enhancing gut tissue maturation and integrity. Bacillus, yeast and lactic acid-producing bacteria such as *Lactobacillus*, *Bifidobacterium*, and *Enterococcus* are the most common groups of organisms used as probiotics. This presentation will highlight recent studies on the utilization of pre- and probiotic utilization in the nutritional management of gut health and function in the nonruminant animal. Also, the mechanisms underlying the effects of these additives will be discussed along with the possible reasons for the inconsistencies often seen among studies with regards to the efficacy of these additives.

Key Words: prebiotics, probiotics, poultry, swine

0498 Investigating the antimicrobial activity of pasteurized and raw camel milk against foodborne pathogens: Listeria monocytogenes and *E. coli* O157:H7. M. Ayyash*, *UAE University, Al-Ain, United Arab Emirates.*

The objectives of this study were to investigate the antimicrobial activity of pasteurized camel milk against foodborne pathogens (*L. monocytogenes* and *E. coli* O157:H7) at different incubation temperatures, and to examine the influence of pasteurization on antimicrobial activity of camel milk at different incubation temperatures. Pasteurized or raw camel milks were inoculated with a cocktail of *L. monoctogenes* or a cocktail of *E. coli* O157:H7, separately. Inoculated camel milk was incubated at 10°C, 25°C, and 37°C and sampled at 0, 2, 4, 8, and 24 h of incubation time. This procedure was exactly applied using pasteurized bovine milk as a control for this experiment. All experiments were repeated at least three times. Chemical compositions of all milks were determined. pHs during incubation, total bacterial count in raw camel milk, and thermoduric bacteria in pasteurized milks were monitored. During incubation time, *L. monocytogenes* growth increased dramatically after 2 h when incubated at 25°C and 37°C but no significant growth observed at 10°C. *E. coli* O157:H7 showed similar behavior. Interestingly, growth of *L. monocytogenes* and *E. coli* O157:H7 in pasteurized camel milk were significantly lower than in pasteurized bovine milk. In general, the growth of *L. monocytogenes* in camel milk was suppressed by 15–18% and 8–10% after 8 and 24 h of incubation, respectively. However, growth suppression of *E. coli* O157:H7 ranged from 5–21% and 6–14% after 8 and 24 h of incubation time, respectively. Growth suppression of *E. coli* O157:H7 was influenced significantly by temperature but not suppression of *L. monocytogenes* growth. In conclusion, our results showed that camel milk possesses antimicrobial activity against foodborne pathogens (*Listeria monocytogenes* and *E. coli* O157:H7). Moreover, pasteurization process has insignificant effect on antimicrobial activity of camel milk. Further investigations are need to identify and characterize antimicrobial agents in camel milk.

Key Words: camel milk, *Listeria monocytogenes*, *E. coli* O157:H7, antimicrobial activties

0499 Application of fluorescent probes to determine localized salt concentrations within cheese matrices and their influence on metabolic activity of entrapped bacterial cells. C. D. Hickey[1], V. Fallico[1], Z. Burdikova[1], M. G. Wilkinson[2], and J. J. Sheehan[*1], *[1]Teagasc Food Research Centre Moorepark, Co. Cork, Ireland, [2]University of Limerick, Ireland.*

The influence of salt on microbial growth and activity in cheese has received much prior attention. However, the way in which salt within cheese matrices affects bacterial physiology to control cell growth is not fully elucidated. Application of advanced microscopy techniques to determine salt concentration at a localized level is of interest to understand interactions between cheese matrix physico-chemistry and microbial activity before, during and post-brining of cheese. The objective of this study was to determine the presence of and effects of localized salt gradients associated with brine salting on microflora physiology and metabolic activity of the individual starters, *S. thermophilus* and *L. helveticus* used in cheese manufacture. Cheeses were manufactured in 3 replicate trials, brined for 66 h and sampled at the high-salt outside and low-salt inside layers before, during and post-brining. Localized salt concentrations were determined using CoroNa Green Sodium Indicator by Confocal Laser Scanning Microscopy. The average salt content in the outside layer post brining was ~3.8%. The response of cytoplasmic membrane integrity of bacterial cells and levels of free reactive oxygen species to salt concentrations were assessed using fluorescent probes combined with Flow Cytometry. There were greater levels of membrane damage and oxidative stress observed in *L. helveticus* compared with *S. thermophilus* at all times. Confocal imaging clearly identified localized variations in salt concentrations and illustrated the penetration distance of the brine solution into the matrix during and post-brining. Overall, this study showed a differing impact of varying salt levels on cheese starter physiology and metabolic activity in vivo, dependant on starter type and confirmed that the methodologies used have the potential to identify ripening hotspots at a localized level. It opens up further opportunities to apply fluorescent probes to gain a deeper understanding of the influence of cheese matrix physicochemistry on the metabolic activity of entrapped bacteria and thus to control cheese manufacture processes to achieve greater consistency in ripened cheese quality.

Key Words: cheese, salt gradients, metabolic activity

0500 Inducing HT-29 colon cells apoptosis by the extracellular polymeric substances isolate from *L. casei* strains. W. Di[*1], L. Zhang[1], X. Han[2], [1]*Harbin Institute of Technology, China,* [2]*Harbin Institute of Technology, China.*

Nine *Lactobacillus* strains (*L. casei* X11, *L. casei* X12, *L. casei* K11, *L. casei* J5, *L. rhamnosus* J10, *L. casei* M5, *L. casei* M23, *L. rhamnosus* IN4125, and *L. casei* SB27) were obtained from the Chinese traditional fermented foods of minority nationalities or infant feces based on the previous research in our laboratory (4 strains from Sinkiang, 3 strains from Gansu, 1 strain from Tibet, 1 strain from infant feces). Fermentation broths from skim milk produced by the nine *Lactobacillus* strains were screened for anti-proliferation activity on HT-29 cells by MTT assay. The results showed that four strains exerted higher anti-proliferation activity on HT-29 effects than positive control ((*Lactobacillus rhamnosus GG, LGG*). Crude and acidic exopolysaccharides isolated from the 4 strains (*L. casei* K11, *L. casei* M5-L, *L. casei* SB27, *L. casei* X12) at different concentrations (10, 20, 100, 200, and 500 μg/mL) were systematically assessed for the anti-proliferation activity on human colon cancer HT-29 cells. Further the apoptosis induced by exopolysaccharides (EPSs) were analyzed by flow cytometry (FCM) on HT-29 cells. The colon cancer cells treated with *L. casei* SB27 acidic exopolysaccharides achieved the highest rate of apoptosis, 24.3% cells were found apoptosis and 1.4% cells in necrosis. The results of cell cycle analysis on HT-29 cells cycle treated with exopolysaccharides showed that *L. casei* SB27 acidic exopolysaccharides could slow the conversion rate of HT-29 cells from G phase to S phase, prolong the cell cycle and reduce the proliferation of colorectal cancer cells. The results of HT-29 cells Caspase-3 activity treated with *L. casei* acidic SB27 fraction showed that Caspase-3 was activated and achieve the significantly highest of all the samples at 2.79- fold compared with control group at 1.2- fold. The result of Hoechst 33258 staining shown that HT-29 colon cells treated with *L. casei* SB27 acidic exopolysaccharides appeared bright condensed dots compared with untreated with exopolysaccharides samples.

Key Words: *L.casei* strains, exopolysaccharides, HT-29 colon cancer cells apoptosis

0501 Comparative genomics of *Lactobacillus brevis* uncovers its common capability for efficiently synthesizing neuroactive γ-aminobutyric acid. Q. Wu[*1], H. M. Tun[2], Y. S. Law[1], E. Khafipour[2], and N. P. Shah[1], [1]*School of Biological Sciences, University of Hong Kong, Pokfulam, Hong Kong,* [2]*Department of Animal Science, University of Manitoba, Winnipeg, Canada.*

γ-Aminobutyric acid (GABA) is the chief inhibitory neurotransmitter in mammalian central nervous system and has shown anti-hypertensive and anti-depressant activities to the host after oral administration. However, its content in natural animal and plant products is too low to deliver benefits to human. Thus, GABA synthesized by food-grade bacteria such as *Lactobacillus* and *Bifidobacterium* is an important source and its producers could be used for manufacturing GABA-rich fermented dairy foods. Many GABA-producing *Lactobacillus* and *Bifidobacterium* strains have been isolated and characterized in the last decade and have shown strain-specific capability in the synthesis of GABA. Among these GABA producers, *Lactobacillus brevis* seems to be the most common cell factory for synthesizing GABA. In this study, comparative genomic approach was used to identify which LAB species have the common ability to produce high amount of GABA and to identify the essential genetic elements for GABA production. It was found that gene encoding glutamic acid decarboxylase (GAD) and an intact *gad* operon were present in all the sequenced strains of *L. brevis* at the species level, but not all the strains of other *Lactobacillus* and *Bifidobacterium* species possess an intact *gad* operon including a regulator *gadR*, a *gadA*- or *gadB*-encoding GAD, and an antiporter *gadC*. This suggests the common capability of *L. brevis* to synthesize GABA. Moreover, enzyme assay for two GADs from *L. brevis* indicated that both enzymes are functional with high activities. Carbohydrate utilization by model strain *Lb. brevis* NPS-QW-145 generated different lactic acid production, which showed strong positive correlation with its GABA yields suggesting that intracellular lactic acid production triggers its GABA biosynthesis, which was also evidenced by the intracellular pH level of the cells. Moreover, among all of acid resistance (AR) pathways in *Lb. brevis*, GAD pathway contributed to late acid resistance whereas tyrosine decarboxylation (TDC) and arginine deimination (ADI) pathways were activated during lag and log phases, which were confirmed by transcriptional profiles and concentrations of the end metabolites of each AR. The present study highlights the common capability of *Lb. brevis* for highly efficient biosynthesis of GABA.

Key Words: comparative genomics, γ-aminobutyric acid, *Lactobacillus brevis*

0502 Effect of incubation temperature on yield and molar mass of EPS during fermentation of milk by *Streptococcus thermophilus* DGCC 7785 and the impact on the rheological properties of acid milk gels. S. N. Khanal[*1] and J. A. Lucey[2], [1]*University of Wisconsin, Department of Food Science, Madison,* [2]*Wisconsin Center for Dairy Research, Madison.*

Some strains of *Streptococcus thermophilus* produce exopolysaccharides (EPS) during milk fermentation. It is unclear if there is any change in the yield, or properties, of EPS when milk is fermented at different temperatures. We investigated the yields of both ropy and capsular forms of EPS, and the

physical properties of ropy EPS that were isolated during the fermentation of milk by *S. thermophilus* strain DGCC 7785. Reconstituted skim milk was fermented at 33, 39, and 45°C until pH reached 5.2, 4.9, 4.7 and 4.5. Fermented milk was then heated to 80°C for 10 min and whey (containing bacterial cells) was obtained by decantation. Whey was ultrafiltered with sufficient diafiltration using 100 kDa membrane at 45°C to remove soluble sugars and proteins. The UF retentate was centrifuged and the supernatant and pellet were analyzed for ropy and capsular EPS, respectively. Ultrafiltration of whey from a non-EPS producing strain was also performed as a control for estimating the amount of capsular EPS. Molar mass of ropy EPS samples were analyzed using size exclusion chromatography multi-angle laser light scattering (SEC-MALLS). Rheological properties of fermented milk gels were analyzed using small-strain dynamic oscillatory measurements. The yield of ropy EPS was 102, 108, and 55 mg/L when milk was fermented at 33, 39, and 45°C respectively, whereas the yields of capsular and total EPS were 102, 132, and 102 mg/L, and 204, 241, and 157 mg/L for these fermentation temperatures (33, 39, and 45°C). Significantly higher ($P < 0.05$) yields of capsular and total EPS were produced at 39°C. Total EPS content significantly ($P < 0.05$) increased from 150 mg/L to 257 mg/L when the pH of milk decreased from 5.2 to 4.5. Molar mass of ropy EPS ranged from 2.0×10^6 to 2.8×10^6 g/mol, exhibiting no significant ($P > 0.05$) effect of temperature or pH values during fermentation. Gelation pH (~ 5.3) of milk did not change with incubation temperature, whereas storage modulus values of the final gel (at pH 4.5) significantly ($P < 0.05$) increased (58, 135, and 410 Pa at 45, 39, and 33°C, respectively) with a decrease in fermentation temperature.

Key Words: exopolysaccharides, fermented milk, *Streptococcus thermophilus*

0503 Probiotic-fermented maillard reaction products: New functional food for cardiovascular health.
S. Kim*, *Korea University, Seoul, Korea (The Republic of)*.

Cardiovascular diseases (CVDs) are the leading contributors to adult mortality worldwide and will continue to dominate mortality trend in the future. Unhealthy dietary practices of consuming foods which are high in calories and/or cholesterol are commonly associated with elevated oxidative stress and accompanied by an increased risk of CVDs. Recently, dietary approach using probiotic intervention is increasingly recognized as a natural health improving supplement, attributed to their long history of safe use with beneficial effects on gastrointestinal health. Probiotic *Lactobacillus* strains are frequently incorporated in yogurts and fermented milk products, but other dairy products are also widely available and potentially developed as functional dairy probiotic foods. Maillard Reaction Products (MRPs) are compounds that can be produced through non-enzymatic reaction between lactose and milk protein (whey protein concentrates or sodium caseinate), which possess antioxidant activity and may exert protective effect in CVDs. Despite these suggestions, no attempt has been made to incorporate probiotics into MRPs and to evaluate their potential applicability on cardiovascular health. Thus, the potential cardiovascular health benefits of MRPs fermented by *Lactobacillus* strains were determined in the present study. In vitro studies demonstrated that hydrolysates of MRPs fermented by *L. gasseri* or *L. fermentum* strain exhibited significantly higher proteolytic, antithrombotic, and radical scavenging activities compared with unfermented MRPs. Hydrolysates of these fermented MRPs also significantly inhibited the 3-hydroxy-3-methylglutaryl-CoA reductase activity, which is the rate-liming enzyme in the cholesterol biosynthetic pathway. In animal studies, feeding of *Lactobacillus* fermented MRPs to acute pulmonary thromboembolism-induced mice were shown to attenuate serum cholesterol levels and thrombotic activity, improve liver enzymes activity, as well as overcome severe body paralysis or death. Additionally, *Lactobacillus* fermented MRPs were also capable of regulating mRNA expression level of cholesterol metabolism related genes and modulating gut microbiome in rats fed with high-cholesterol diet. My talk highlights on the recent findings and biological mechanisms by which probiotic fermented MRPs exert their beneficial effects on cardiovascular health.

Key Words: probiotics, functional food, cardiovascular health

0504 An ancient, species-specific tagatose-6-phosphate pathway in *Lactobacillus casei* group for galactose reduction in cultured dairy foods.
N. P. Shah* and Q. Wu, *School of Biological Sciences, University of Hong Kong, Pokfulam.*

Residual lactose and accumulated galactose in cultured dairy foods lead to several medical and industrial concerns such as lactose intolerance, galactosemia, and browning of pizza during baking. Our previous comparative KEGG study on galactose metabolism pathways in sequenced LAB strains has uncovered the presence of tagatose-6-phosphate (T6P) pathway in all of the completely sequenced *Lactobacillus casei* group strains including *Lb. casei*, *Lb. paracasei* and *Lb. rhamnosus*. In this study, we have demonstrated that T6P pathway, but not Leloir pathway, in *Lb. casei* group is more efficient for lactose and galactose catabolism than Leloir pathway in selected strains of *Lb. acidophilus* group, *Streptococcus thermophilus* and *Lb. bulgaricus* cultured in galactose- or lactose-based MRS media. However, the activity of β-galactosidase, which is a key enzyme in Leloir pathway in *Lb. casei* group strains, was not detected. In the milk, *Lb. casei* group strains catabolize less lactose than *Str. thermophilus*, *Lb. bulgaricus* and *Lb. acidophilus* group, but very limited galactose was accumulated in milk. Moreover, co-cultivation

of *Lb. casei* group with *Str. thermophilus* or *Lb. bulgaricus* generated less galactose or lactose in the cultured milk. In addition, comparison of *lac-gal* gene cluster in sequenced *Lb. casei* group strains has shown the presence of an unknown PTS (PTS^{Unk}) in this region. The EIIC of PTS^{Unk} has conserved protein domain found in EIIC of PTS^{Gat} (galactose-specific PTS) and its gene expression was also highly up-regulated (> 200 fold changes) in the presence of galactose suggesting its possible role for galactose phosphorylation. In addition, it was found that *lac-gal* clusters in the genomes of *Lb. casei* group strains are not associated with any HGT events suggesting that this cluster may be an ancient pathway. This study demonstrates the use of *Lb. casei* group strains as functional dairy starter for lactose or galactose depletion in milk. Further characterization of PTS^{Unk} in *Lb. casei* group using genetic manipulation has been performed.

Key Words: galactose catabolism, *Lactobacillus casei* group, tagatose-6-phosphate pathway

0505 Characterization of the fatty acid composition of retail bovine milk and vegetable milk in Chile.

E. Vargas-Bello-Pérez*, P. Toro-Mujica, D. Enriquez-Hidalgo, M. A. Fellenberg, *Pontificia Universidad Católica de Chile, Santiago.*

In Chile, there is a lack of information regarding the lipid quality of bovine and vegetable milks and this can cause consumer confusion. The objective of this study was to characterize and compare the fatty acid (FA) composition between bovine (whole, semi-skimmed and skimmed) and vegetable milks that are offered in Chile. To maximize representativeness, the availability of bovine and vegetable milks in the three biggest stores located in five of the main cities of Chile was assessed in February 2015, before sampling. Santiago's stores presented the greatest offer of those beverages and therefore the analysis of the beverages found in Santiago's stores were evaluated. During a 4-wk period in March and April (summer) 2015, retail bovine milk (n = 62) and vegetable milk (n = 27) samples were collected. A multivariate analysis was performed to determine which FA were responsible for the differentiation between milk by origin and type of milk. The multivariable analysis included a correlation matrix, a factorial analysis (by principal components (PC) method) and a cluster analysis. Three PC were selected from factorial analysis, those explained 0.72 [PC 1 (0.54); PC 2 (0.11); and PC 3 (0.07)] of the overall variance in the data. PC 1 was related to the saturated FA and some monounsaturated FA such as C18:1 trans-11. High scores for this PC were associated with whole milk samples. PC 2 was represented by n-3 FA and the higher scores were found in semi-skimmed milk samples. PC 3 was related with C18:2 trans-9, trans-12 and C20:4 n-6 and skimmed milk samples; and vegetable milk showed the higher scores. C18:1 trans-11 and C18:2 cis-9, trans-11 were only found in retail bovine milk. Data were analyzed by using ANOVA and when significant differences were detected, means were separated using Tukey test. Compared with semi-skimmed, skimmed and vegetable milks, whole milk was higher (P < 0.05) in contents of saturated FA (10.3, 1.48 and 2.23 vs. 21.9 g/L) and monounsaturated FA (3.6, 0.48 and 5.4 vs. 7.3 g/L). Compared with bovine retail milk, vegetable milk had the highest (P < 0.05) contents of polyunsaturated FA (0.78 vs. 5.9 g/L) and this was related to its high content of C18:2 cis-9, cis-12. Data from this study can serve as a reference for estimating dietary intake for future studies. This study showed evidence that vegetable milk have a more "polyunsaturated FA profile" than retail bovine milk.

Key Words: milk fat composition, milk quality, oleic acid, linoleic acid, bovine

0506 Effect of milk protein intake and casein: Whey ratio in breakfast meals on postprandial glucose, satiety ratings and subsequent meal intake.

B. Kung*[1], S. Paré[1], A. J. Tucker[1], G. H. Anderson[2], A. J. Wright[1], and H. D. Goff[1], *[1]University of Guelph, ON, Canada, [2]University of Toronto, ON, Canada.*

Novel satiating dairy-based breakfast products have potential to reduce the risk of developing and improve management of type 2 diabetes and obesity. Whey and casein proteins may induce different physiological effects on blood glucose, induction of satiation and satiety. Whey proteins have been associated with acute satiation, compared with the prolonged feelings of satiety from casein. The purpose of this work is to investigate the impact of breakfast meal milk casein:whey ratio and protein concentration on postprandial blood glucose, appetite ratings, and subsequent food intake. In a randomized, controlled, double-blinded study, healthy young adults (n = 32, 16 m/f, 23.4 ± 3.1 y, BMI 22.2 ± 2.5 kg/m^2) consumed milk (250ml) with normal (80:20) or modified (40:60) casein:whey protein ratio at normal (3.1%) or high (9.3%) protein concentration, or water (control), along with 2 servings of breakfast cereal. Following an overnight fast and up to 120 min following the breakfast meal, participants had their plasma glucose concentrations determined from finger-prick samples, completed a series of scale ratings to assess satiety and consumed a weighed ad libitumpizza lunch. Repeated measures ANOVA followed by Tukey-Kramer's post hoc testing was performed. Incremental area under the curve (AUC) glucose values showed significant attenuations in postprandial plasma glucose concentration for all milk treatments, relative to control (P < 0.05). Also, the high protein treatments (9.3%) had significantly attenuated glucose concentrations compared with those with lower protein (3.1%). However, there was no effect of casein:whey protein ratio on blood glucose. Treatments were not associated with differences in total area under the curve for individual scale ratings of Hunger, Desire to Eat, Fullness, and Prospective Consumption. Nor were differences observed in mean appetite score (P = 0.86) or subsequent

lunch intake ($P = 0.06$). Therefore, since consumption of high protein milk treatments with breakfast cereal was associated with the lowest plasma postprandial glucose concentration, new high-protein dairy breakfast products should be considered for product development.

Key Words: appetite, dairy protein, glycemia

0507 Influence of sodium reduction on the rheological characteristics of cottage cheese cream dressing.

H. L. Damiano*, *University of Idaho, Moscow.*

Once a popular dairy product, creamed cottage cheese consumption has decreased over the past several decades. There are a number of reasons for this, including free whey formation during storage, which consumers find unappetizing. Free whey formation is often a result of cream dressing separation. Cream dressing is added to provide flavor and texture to the curd, and its appearance, texture, and stability during storage is an important factor in consumer acceptance of creamed cottage cheese. Despite this, there is little published data on cottage cheese cream dressing; the bulk of the literature focuses on cottage cheese curd and its physicochemical properties. The objective of this study was to evaluate the effect of sodium reduction on the rheology of cottage cheese dressing over time. Dressing samples were prepared with 2.2%, 1.48%, and 0.73% w/w NaCl, with the 2.2% NaCl formulation acting as a control. Samples were acidified to pH 4.5, 5, and 5.5. Rheological tests (shear rate, strain, and frequency sweeps) were conducted in triplicate at 8°C and 25°C. Tests were conducted within 48 h after acidification and again after 14 d of storage at 4°C. Dressing viscosity increased over time regardless of salt amount and type; dressings had greater viscosity at 8°C compared with 25°C. As NaCl was reduced from 2.2% to 0.73%, viscosity generally decreased. Interactions among the hydrocolloids, proteins, and salt led to the formation of a three dimensional network, causing all formulations to display weak gel behavior under oscillatory shear. This structure increased during storage because the hydrocolloids had more time to interact with the milk proteins. Dressing pH had the most significant effect on structure, with a greater degree of solid-like behavior occurring closer to the isoelectric point of casein (pH = 4.6). Dressing made with lower salt concentrations generally saw a greater increase in G' over the 14-d storage period. Although changing NaCl concentration led to rheological differences, they were generally not significant. Thus, these results indicate that manipulating NaCl concentration in cottage cheese dressing can be made to mimic full salt formulations in terms of rheological properties by simultaneously adjusting pH

Key Words: cottage cheese, rheology, salt reduction

0508 A rapid and nondestructive fluorescence-based analyzer for monitoring the changes in deproteinized whey powder during storage.

K. Sajith Babu* and J. K. Amamcharla, *Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan.*

Deproteinized Whey (DPW) is a co-product obtained during ultrafiltration of whey. Subsequently, it undergoes unit operations like evaporation, crystallization, and spray drying resulting in a non-hygroscopic, free-flowing powder containing more than 80% lactose. Generally, DPW powder contains 2–7% protein, 3–4% moisture, and 8–11% ash. DPW is widely used as a replacer for sweet whey powder or lactose in bakery and confectionary applications, drink mixes, snack foods, and in certain ice-cream formulations. DPW powders may undergo chemical and physical changes such as caking, Maillard browning, and oxidation during storage. Amaltheys analyzer (Spectralys Innovation, Romainville, France) is a compact and portable fluorometer designed with 2 excitation light-emitting diodes at 280 and 340 nm. It is a rugged optical design with a low noise and enhanced UV sensitivity linear charge-coupled device. The objective of the present study was to use Amaltheys analyzer for monitoring Maillard changes during storage of DPW powder. For this purpose, 30 DPW samples were collected from a commercial manufacturer from different lots of production and storage periods. The FAST index (fluorescence of advanced Maillard products and soluble tryptophan) and the whey protein nitrogen index (WPNI) for DPW powders were measured by fluorescence-based Amaltheys analyzer. Additionally, colorimetric L*, a*, and b* values and water activity (a_W) were also determined. The changes in terms of color and a_W of DPW powder effected by storage time exhibited definite correlations. The L* values of DPW powders ranged from 85.86–92.02 and a_W values ranged from 0.307–0.418. It was observed that lightness (L*) was negatively correlated ($R = -0.71$; $P < 0.01$) with a_W of DPW powders. On the other hand, redness (a*) value was positively correlated ($R = 0.82$; $P < 0.01$) with a_W of DPW powders. From the Amaltheys analyzer, the highest FAST index was observed as 362.24 for the powder with a_W of 0.394. On the other hand, the lowest FAST index observed was 87.16 at a_W of 0.381. It was also observed that FAST index was positively correlated ($R = 0.46$; $P < 0.05$) with redness (a*) value of DPW powders. A negative correlation ($R = -0.89$; $P < 0.01$) between FAST index and WPNI was observed. The FAST index and WPNI obtained using Amaltheys analyzer method is a simple, rapid, and low-cost method for the detection of Maillard changes in stored DPW powders.

Key Words: deproteinized whey powder, Maillard changes, FAST index

0509 Evaluation of mineral compositions in commercial Mongolian dried yogurts (Aaruul) marketed at retail stores in Mongolia. Y. W. Park[1], B. I. Davis[*1], J. H. Ko[2], K. P. Bastola[3], A. Siddique[1], and J. O. Jones[1], *[1]Fort Valley State University, GA, [2]Mongloia Huree University of ICT, Ulaanbaatar, Mongolia, [3]Fort Valley State University, GA.*

Dried yogurt products (DYPs: Aaruul) have traditionally been produced and consumed in Mongolia in various product shapes and packages. However, information on nutrients and mineral compositions of Mongolian DYPs are almost nonexistent. The objective of this study was to determine mineral compositions of commercial Mongolian DYPs. Five varieties (MD, KA, AC, AA, HU) of Mongolian DYPs were purchased at local retail outlets at Ulaanbaatar, Mongolia. Concentrations of 20 major and trace minerals were quantified by an Inductively Coupled Plasma Optical Emissions Spectrometer (Thermo Jarrel Ash Enviro 36, Worchester, MA) using argon as carrier gas and the USEPA Method 6010 at different wavelengths for each different minerals. The respective wavelengths used for the analysis of 20 elements were: Al, 396.2; B, 249.7; Ba, 233.5; Ca, 317.9; Cd, 228.8; Co, 228.6; Cr, 267.7; Cu, 327.4; Fe, 238.2; K, 766.5; Mg, 285.2; Mn, 257.6; Mo, 202.0; Na, 589.6; Ni, 231.6; P, 213.6; Pb, 220.4; Si, 251.6; Sr, 421.6; Zn, 206.2 nm. The ranges of dry matter (DM) and ash contents of DYPs were 67.7 to 96.6 and 1.3 to 4.1%, respectively, indicating the Mongolian Aaruul products contained very high DM and ash contents. The respective mean mineral concentrations (ppm, wet basis) of the highest (AC) and lowest (MD) brands were: Ca 5183, 1236; P 8934, 2419; K 6989, 1350; Na 1523, 233; Mg 440, 123; Fe 17.3, 5.20; Mn 0.787, 0.704; Cu 8.40, 7.53; Zn 34.1, 15.6. These data indicate that the AC brand contained significantly ($P < 0.01$) higher all macro and trace minerals than those of other four brands, which were apparently due to the higher levels of DM and ash in the AC compared with the other brands. The AC product contained much higher levels of P and K than those of the other brands, where the P and K contents were even greater than that of Ca in the products. Heavy metal (Pb, Cd and Ni) contents of all experimental Aarrul products appeared to be in normal ranges. It was concluded that most of the 20 mineral concentrations in Mongolian DYPs were very high, which were greater than those in powdered cow milk products reported previously.

0510 Potential protective effect of camel milk and yogurt with chromium on alloxan induced hyperglycemia in rats. M. M. Motawee[*1] and A. M. Badawi[2], *[1]National Organization for Drug Control and Research, Giza, Egypt, [2]ph.D, Giza, Egypt.*

Insulin and oral hypoglycemic agents are the main ways to treat diabetes mellitus and are effective in controlling hyperglycemia, but these kinds of drugs also have prominent side effects. Camel milk, Yogurt-Camel milk and Chromium have attracted a lot of attention for their potential effects in human health. The aim of this study was to investigate the prophylactic effects of Camel milk (CM), Yogurt-Camel milk (YCM) and Chromium Picolinate (CrPi) on diabetic animals. Oxidative stress and dyslipidemia are associated with diabetes mellitus. The samples of camel milk were collected fresh from Elareesh, Egypt, and were prepared for this study, Forty-eight adult male albino rats were classified into six groups: Group I control negative (-ve), animals of group 2 were rendered to diabetes by alloxan (145 mg/kg body weight, I.P.). Meanwhile, groups 3–6 were fed daily with CM products [(CM)\, (CM-CrPi), (YCM) and (YCM-CrPi)] for 6 wk then induced diabetes by alloxan. The study was assigned for 6 wk. The results revealed that the CM and YCM showed a significant decreases in serum glucose, glycosylated hemoglobin (HbA1C) and lipids level ($p < 0.05$) and improved lipid per-oxidation, serum insulin level, lipid profile and total antioxidant capacity (TAC) in diabetic rats. Both CM and YCM supplementation with CrPi potentially ameliorated effect in glucose, and oxidative stress and also increased serum insulin level in diabetic rats. The histopathological examination confirmed our results. In conclusion, the administration of CM and YCM with CrPi supplementation can lower the side effects of hyperglycemia, hyperlipidemia, improve antioxidant activity and healthy status of diabetes.

Key Words: alloxan, camel milk, chromium, yogurt

0511 Characteristics, composition and sensory properties of butter from cows on pasture versus indoor feeding systems. T. F. O'Callaghan[*1,2], H. Faulkner[2], S. McAuliffe[3], M. G. O'Sullivan[1], D. Hennessy[3], P. Dillon[3], K. N. Kilcawley[2], C. Stanton[1,2], and R. P. Ross[1], *[1]University College Cork, Ireland, [2]Teagasc Food Research Centre, Cork, Ireland, [3]Teagasc Animal and Grassland Research and Innovation Centre, Cork, Ireland.*

This study evaluated the effects of three widely practiced feeding systems of cows on the characteristics, quality and consumer perception of sweet cream butter. Fifty-four multiparous and primiparous Holstein Friesian cows were divided into three groups ($n = 18$) for an entire lactation. Group 1 was housed indoors and fed a total mixed ration diet (TMR), Group 2 was maintained outdoors on perennial ryegrass only pasture

(GRASS), while Group 3 was also maintained outdoors on a perennial ryegrass/white clover pasture (CLOVER).

Mid-lactation butter was manufactured in triplicate with milk from each group in June 2015, and was analyzed over a 6-mo storage period at 4°C for textural and thermal properties, fatty acid composition, volatile analysis and sensory properties.

The nutritional value of butters was improved by pasture feeding; having lower atherogenecity index scores than that of TMR butters. With this, pasture derived milks produced butter with significantly higher concentrations of CLA ($_{c9t11}$) ($P <$ 0.01) and β-carotene ($P < 0.05$). Alterations in the fatty acid composition of butter resulted in significant differences in textural and thermal properties, and spreadability index scores. Volatile analysis of butter by GC/MS identified 25 compounds present in each of the butters, five of which differed significantly ($P < 0.05$) based on feeding regimen including acetone, 2-butanone, 1-pentenol, toluene and β-pinene. Toluene was significantly ($P < 0.00$) correlated with pasture derived butter. Sensory analysis revealed significantly higher scores ($P <$ 0.01) for GRASS derived butter in several attributes including "liking" of appearance, flavor and color. Partial least square regression plots of fatty acid profiles showed clear separation of butter from grazed pasture-based diets from that of a TMR system, offering further insight into the ability of fatty acid profiling to verify pasture derived dairy products.

Key Words: cows diets, butter, conjugated linoleic acid

0512 Identification of protein fractions in ripened American style natural cheese manufactured utilizing recombinant bovine and camel chymosin by capillary electrophoresis.

A. C. Biswas* and L. Metzger, *South Dakota State University, Brookings.*

During ripening, natural cheese undergoes a series of complex proteolytic reactions that are critical for flavor development. The initial phase of proteolysis is caused by the milk clotting enzyme generally known as chymosin. Recently, recombinant camel chymosin (CHY-MAX® M) has been developed, and is commercially available as a milk coagulant for natural cheese manufacture. The objectives of this study were to identify and characterize the various protein fractions by CE in American style natural cheese manufactured utilizing CHY-MAX® Extra (recombinant bovine chymosin) and CHY-MAX® M (recombinant camel chymosin). The electropherograms obtained from CE analysis showed that there was a significantly ($P <$ 0.05) higher degree of hydrolysis of α_{S1}-CN and β-CN which resulted in the formation of smaller α_{S1}-CN f(1–23), α_{S1}-I-CN [α_{S1}-CN f(24/25–199)], and various γ-caseins fractions in the natural cheese manufactured utilizing bovine chymosin as compared with the natural cheese manufactured utilizing camel chymosin. It was also observed that a significantly ($P <$ 0.05) higher percentage of soluble nitrogen at pH 4.6 develop in the natural cheese manufactured utilizing bovine chymosin. These findings suggested that CE is a suitable technique to determine protein fractions in cheese, and CHY-MAX® M could be an appropriate alternative for CHY-MAX® Extra in American style natural cheesemaking to limit proteolysis.

Key Words: proteolysis, recombinant chymosin, capillary electrophoresis

0513 Effect of γ radiation on physicochemical properties, protein-protein interaction, and microstructure of whey proteins.

M. Guo*[1,2], X. Wang[3], F. Lee[2], J. Lv[4], and D. Zhang[2], *[1]College of Food Science and Engineering, Jilin University, Changchun, China, [2]University of Vermont, Burlington, [3]Northeast Agriculture University, Harbin, China, [4]Agriculture Academy of China, Beijing.*

Whey proteins are generally small globular proteins that could be modified by physical, chemical or other means to improve their functional properties. The effect of γ radiation on the physicochemical properties, protein-protein interaction and microstructure of whey proteins were investigated. Whey protein isolate (WPI) solutions (10–36% protein) were treated with different dosages (10–35 KGy) of γ radiation. The viscosity of 27% protein solution treated at 25 KGy was significantly increased from 2.19 (control) to 4.78 mPa.s (p < 0.01). Overall, the increase in viscosity of WPI solutions was most affected by the higher dosage of γ radiation (> 25 KGy) and viscosity also increased during the 6-mo storage after treatment. Effects of γ radiation level and storage time on the viscosity of whey protein solutions were significant (p < 0.05). Turbidity of WPI solutions increased from 0.14 to 0.16 for untreated and treated samples (35 KGy), respectively. Soluble nitrogen content decreased significantly from 100 to 54.7% in WPI solution after treated by radiation at 35 KGy. Sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) showed that protein cross-linking might occur in the whey protein solutions treated by γ radiation. Transmission Electron Microscopy (TEM) micrographs indicated that protein-protein interactions were induced by γ radiation in the treated WPI solutions, which displayed more uniform whey protein cluster structures compared with control samples. Results indicated that high intensity γ radiation could result in structure damages of whey proteins.

Key Words: whey protein, γ radiation, interaction, microstructure

0514 Effects of sodium polyphosphate on distribution of particle size of polymerized whey protein. M. Guo[*1,2], D. Liu[1], and C. Wang[1], *[1]College of Food Science and Engineering, Jilin University, Changchun, China, [2]University of Vermont, Burlington.*

Protein-based fat replacers have been used in dairy foods for many years. The objective of this study was to develop a novel fat replacer using whey protein concentrate (WPC). WPC was heated with sodium tripolyphosphate (STPP) to prepare polymerized whey protein particles as fat replacer for nonfat dairy product formulation. The effects of STPP concentration (0–1%, wt/wt), protein content (8–10%, wt/vol), pH (7.5–8.5), heating temperature (70–85°C), and time (5–25 min) on the particle size distribution were investigated. Results showed that heating WPC solution (8.0%, wt/vol) with 0.4% STPP at pH 7.5 at 85°C for 5 min resulted in 40% of particles in the range of 1–3 μm, which were as large as fat globules in dairy products. There were no large particles (> 10 μm) yielded when 0.4% STPP was added, but higher STPP levels (> 0.5%) produced larger particles (> 10 μm) at a unimodal distribution. The percentage of particle size between 1 and 3 μm decreased with increasing WPC concentration. A wide distribution or even multi-peaks with more large particles (> 10 μm) were observed when the mix was heated at higher pH values (8–8.5). When heating the mix at 70–85°C for 5 min, 20%-40% of the particles were in the range of 1–3 μm and prolonged heating time also generated large particles (> 10 μm). Results indicated that heating whey protein concentrate with STPP could produce particles/aggregates that might be suitable as fat replacer for non or low fat dairy products.

Key Words: fat replacer, sodium tripolyphosphate, whey protein concentrate

0515 Effects of ultrasound treatment on physicochemical properties of whey protein soluble aggregates. X. Shen[1], T. Fang[1], T. Zhang[1], and M. Guo[*1,2], *[1]Department of Food Science, College of Food Science and Engineering, JiLin University, ChangChun, China, [2]Department of Nutrition and Food Science, College of Agriculture and Life Science, University of Vermont, Burlington.*

Functional properties of whey protein could be improved by heat-induced aggregation. The aim of this study was to determine the effect of high-intensity ultrasound on thermal aggregation of whey proteins. Whey protein solutions were sonicated for 20 min using an ultrasonic probe (frequency: 20 kHz; amplitude: 20%) pre- and post-thermal aggregation (85°C for 30 min). Changes in particle size, zeta-potential, surface hydrophobicity, free sulphydryl group content (-SH), protein-protein interactions, turbidity, thermal denaturation properties and viscosity were studied. Soluble aggregates prepared with ultrasound treated post-thermal aggregation resulted in significantly smaller particle size and broader size distribution compared with those prepared by untreated or ultrasound treated pre-thermal aggregation ($P < 0.05$). It was suggested that the surface hydrophobicity of the soluble aggregates was slightly but significantly increased by ultrasound treated post thermal aggregation ($P < 0.05$). There was a significant reduction in turbidity of whey protein solutions by ultrasound treated post thermal aggregation ($P < 0.05$). The viscosity of WPI dispersions significantly decreased by ultrasound treated post-thermal aggregation ($P < 0.05$). Ultrasound treatment increased denaturation temperature (Td) and decreased DH of soluble aggregates slightly, suggesting that limited improvement of heat stability. There were no significant changes in zeta-potential, free sulphydryl group by ultrasound treatment either pre- or post-thermal aggregation ($P > 0.05$). Results indicated that ultrasound treatment on post thermal aggregation had considerable impact on particle size, surface hydrophobicity, turbidity, and viscosity of whey protein soluble aggregates.

Key Words: whey protein, thermal aggregation, physicochemical property

0516 Crystallization of calcium phosphate in stabilized-paste white mold cheese rinds. G. F. Tansman[*1], P. S. Kindstedt[1], and J. M. Hughes[2], *[1]Department of Nutrition and Food Sciences, University of Vermont, Burlington, [2]Department of Geology, University of Vermont, Burlington.*

Increased pH at the surface of traditional white mold cheese results in calcium phosphate (CaP) crystallization and accumulation of CaP in the rind. At the same time, this phenomenon results in depletion of CaP in the rest of the cheese wheel. An experiment was conducted to identify crystals that form in the rind of stabilized-paste white mold cheese and to correlate the crystallization phenomenon to pH gradients between the center and rind and to the diffusion of dissolved minerals from the center of the cheese to the rind. In this randomized block design, three batches of a Vermont stabilized-paste white mold cheese (batches representing blocks) were sampled throughout the aging process from 1 d post-manufacture to 4 d after packaging. Two wheels were removed from each batch on d 1, 4, 7, 10, 14, and 18, with d 0 representing the day of manufacture and packaging occurring on d 14. Three-millimeter-thick samples were cut from rind and center locations of each cheese and tested for moisture by forced draft oven drying, and the dried samples were tested for calcium and phosphorus by ashing and analyzing with ICP–AES. Rind and center pH measurements were collected from each wheel. Powder X-ray diffraction (PXRD) patterns were generated from cheese collected from the center and rind of each wheel to identify crystal phases. Petrographic microscopy (PM) images were also collected from rind and center samples to observe the size of

crystals. PXRD revealed that brushite ($CaHPO_4 \cdot 2H_2O$) deposited in the rind by d 10 with increasingly stronger PXRD signals for brushite apparent on d 14 and 18. PM revealed that the crystals grew to a maximum of 20 μm in diameter by d 18. The appearance of brushite corresponded to significant increases in rind pH, accumulation of CaP in the rind, and depletion of CaP in the center. Rind pH rose from approximately 5.1 on d 1 to approximately 5.3 by d 10 and to approximately 5.6 by d 18, while the center pH did not rise above 5.1. This was a considerably smaller pH increase than occurs in traditional white mold cheese. Nonetheless, the mechanism of crystallization and diffusion of dissolved CaP in stabilized-paste white mold cheese appears similar to that previously observed in traditional white mold cheese.

Key Words: cheese, crystals, brushite

0517 Effect of buffalo αs1-casein polymorphism on the semi-hard Monterey Jack-type cheese quality.

L. Li[1], Q. Zeng[1], D. Ren[*2], L. Huang[1], and Y. Tang[1], *[1]Buffalo Research Institute, Chinese Academy of Agricultural Science, Nanning, [2]Institute of Dairy Science, College of Animal Sciences, Zhejiang University, Hangzhou, China.*

The influence of α_{s1}-casein polymorphisms on milk processing properties, and cheese quality of cow milk have been well researched, while the effect of buffalo milk protein polymorphisms on cheese quality is still unclear. The objective of this study was to investigate the effect of buffalo α_{s1}-casein polymorphisms on the quality of semi-hard Monterey Jack-type cheese. Water buffalo milk with different α_{s1}-casein genotype (BB and AB) and the same κ-casein (BB) and β-casein (BB) type was collected from local dairy farm, mixed sample from milk tank was used as control. The protein/fat ratio of buffalo milk was standardized to 0.75(g/g), then fresh Monterey Jack-type cheese was made according to the standard procedure, vacuum-packaged and stored at 4°C, samples were tested at 7 d. The composition (fat, protein, ash, Ca and P), texture and color difference (CD) of cheese samples with manufactured from milk with different α_{s1}-casein (BB, AB and control) type were analyzed. Results showed that cheese made from milk with BB type α_{s1}-casein (BB type cheese) contained significantly lower fat, but higher protein, ash, Ca and P content in DM than AB type ($P < 0.05$). The Ca/protein content of BB type cheese was 3.78g/100g, which was also higher than AB type (3.51g/100g) and control (3.60 g/100g). For the texture, hardness and springiness of BB type cheese were 41.21 N and 6.31 mm, significant higher than AB type (29.45 N, 5.56 mm) and control (38.21 N, 5.25 mm), except that, the gumminess, adhesiveness and chewiness of BB type cheese were also higher than AB type ($P < 0.05$). For the CD, b value of BB type cheese was lower than AB type ($P < 0.05$), which means the cheese color of BB type was more white. In conclusion, the quality of semi-hard Monterey Jack-type buffalo milk cheese was related with α_{s1}-casein polymorphism, BB type cheese has the best texture and color for traditional Monterey Jack-type cheese.

Key Words: α_{s1}-casein polymorphism; buffalo milk; cheese quality

0518 Membrane fractionation of delactosed permeate to enhance salty taste.

L. D. Alexander[*1], M. A. Stout[2], M. Drake[2], S. L. Beckman[1], and L. Metzger[3], *[1]Midwest Dairy Foods Research Center, South Dakota State University, Brookings, [2]North Carolina State University, Raleigh, [3]South Dakota State University, Brookings.*

Delactosed permeate (DLP), commonly referred to as mother liquor, is a byproduct of lactose manufacture and is typically relegated to animal feed use. Previous work has established that compounds other than sodium, such as organic acids and potassium (K), contribute to the salty taste of DLP but that residual lactose suppresses salty taste. The objective of this study was to determine the viability of fractionating DLP into two components, one that would be re-cycled into the lactose manufacturing processing and one that would be used as a salt substitute. Two lots of commercial DLP were obtained from four different lactose manufacturers (totaling eight samples). The composition of these samples ranged from 27.9 to 39.7% total solids. Each DLP sample was diluted to approximately 5% TS using soft tap water and then subjected to nanofiltration (500 Da MWCO, NFW-3B-3838, Synder Filtration) in a batch process. Nanofiltration was performed until the flux rate dropped below 10 Lmh. Subsequently, the NF permeate fraction was concentrated to approximately 8% TS using reverse osmosis (RO) (RO2–3838-BS04, Parker-Hannifin). The initial DLP, NF retentate, and RO retentate were analyzed for total solids (vacuum oven) and ash (muffle furnace). Selected minerals (Ca, Na, Mg, P, S and K) were determined by plasma emission spectroscopy, lactose and organic acids by HPLC, and volatile compounds by GC–MS. A trained panel documented sensory properties of the liquid DLP and fractions at equivalent solids (8% (w/w)). The DLP displayed a variety of aromatic flavors including cardboard, beefy, and potato as well as distinct salty taste, consistent with previous studies. Nanofiltration of DLP followed by RO resulted in a fluid that was higher in salty taste ($p < 0.05$) than the DLP or NF retentate with consistent low, but distinct, bitter taste. Concurrent with increased salty taste, the RO retentate had higher K and Na, higher concentrations of citric, lactic and orotic acids and decreased lactose than the NF retentate ($p < 0.05$). Aromatic flavors present in DLP were detected in both NF and RO retentates suggesting the need to address removal of these flavors. Membrane fractionation of DLP can be applied to enhance its application as a salt substitute.

Key Words: delactosed permeate, nanofiltration, reduced sodium

0519 Characterization of queso fresco made with Na/K salt blends and stored for 12 wk.
D. L. Van Hekken*, M. H. Tunick, J. A. Renye, and P. M. Tomasula, *USDA-ARS, ERRC, Dairy and Functional Foods Research Unit, Wyndmoor, PA.*

Health-conscious consumers are looking for ways to reduce dietary sodium yet want their cheeses to have the flavor, texture, and shelf-life of full-salt cheese. The objectives of this study were to determine the effects of different Na-K salt blends and storage on the compositional, sensorial, microbial, functional, and rheological properties of Queso Fresco (QF), a fresh cheese with a distinct salty taste. QF was made in triplicate on different days with curds from each vat being divided and salted using 1.0% NaCl and 0.5, 1.0, 1.3, or 1.5% added KCl; a 2.0% NaCl QF control and a 0.75%:0.75% Na:K QF were also made. The QF were then stored at 4C for up to 12 wk.

Although the variation in salt treatments were in a fairly narrow range, 1.5 to 2.5% total salt, differences ($P < 0.05$) in some of the QF characteristics were noted. Moisture and ash levels were influenced by salt content while storage impacted moisture and salt levels, water activity, and pH. Only QFs with 1.0% NaCl and 1.3 or 1.5% KCl had sensory saltiness scores similar to the 2.0% NaCl QF control. Loss of free serum from the cheese matrix significantly increased up to 7.5% over the 12 wk of the study with the samples at the higher levels of salt retaining more of the serum in the cheese matrix. Aerobic microbial counts decreased slightly after 2 wk for QF containing > 1.5% salt, and all samples increased 1 to 2.7 logs by wk 10. The variation in the salt content did not alter the non-melt characteristic of the QF samples, while the 2% NaCl QF control had the lowest change in color when baked (130°C for 30 min) and the QF containing 1.0 to 1.5% KCl had the lowest color change when broiled (232°C for 5 min). No significant differences were noted in texture hardness, springiness, or chewiness or in the viscoelastic properties among the treatments or over time.

The minor differences in quality traits that resulted in aging QF made with 1% NaCl and 0.5 to 1.5% added KCl showed that KCl substitution was a viable route for reducing sodium in QF. The best overall Na-K blend for QFs were made using 1% NaCl and 1.3 or 1.5% KCl. Findings from this study will help in developing a reduced sodium QF that meets the demand of health-conscious consumers.

Key Words: cheese, queso fresco, reduced sodium

0520 Effect of micro-encapsulated iron salts on Cheddar cheese divalent cation balance and composition.
A. Arce* and Z. Ustunol, *Michigan State University, East Lansing.*

Milk is a considered an important source of macro- and micronutrients but naturally low in iron content. Cheese and other dairy products had been fortified with iron with low success due to negative changes in composition and organoleptic attributes. There is limited information about using micro-encapsulation of iron compounds in dairy products. Minerals have the ability to displace one another in any system; consequently, it is expected that encapsulation will avoid divalent cation displacement within the cheese matrix. The objective of this study was to analyze divalent cation balance in fortified Cheddar cheese with micro-encapsulated ferrous sulfate. Furthermore, proximate analysis was done to provide more information about any compositional changes after fortification.

Cheddar cheese was manufactured using standard Cheddar cheese procedures a total of three times. Cheddar cheese was either fortified with large micro-encapsulated ferrous sulfate (LMFS; 0.9536 g micro-encapsulated ferrous sulfate/Kg cheese, 700–1000 μm diameter) or small micro-encapsulated ferrous sulfate (SMFS; 1.7801 g microencapsulated ferrous sulfate/Kg cheese, 220–422 μm diameter). Iron treatment was incorporated to Cheddar cheese processing in the salting step but omitted for the control. After 90-d aging, calcium, iron, magnesium and zinc content were analyzed using Atomic Absorption Spectroscopy and percent recoveries were calculated. Moisture, ash, fat, and protein analysis were done using AOAC methods. All collected data was analyzed using one-way ANOVA and Tukey's HSD Test ($p = 0.05$).

Iron content for all treatments were significantly different ($P < 0.05$); approximately 0.03 mg Fe/g cheese for the control, 0.134 mg Fe/g cheese for LMFS, and 0.174 mg Fe/g cheese for SMFS. Results showed 81.3% iron recovery for LMFS and 90% iron recovery for SMFS. Proximate analysis, and magnesium, zinc and calcium content were not significantly different when comparing fortified cheeses with the control. Overall, micro-encapsulated ferrous sulfate caused no major changes in terms of Cheddar cheese composition and successfully increased iron content. Micro-encapsulated ferrous sulfate with smaller diameter showed slightly better results for iron retention in Cheddar cheese. The proposed fortified Cheddar cheese can help increase total iron intake for children, pregnant women, vegetarians and those whose diets are likely to be deficient in iron by providing at least 5 mg Fe (30% RDA) per serving.

Key Words: cheese, minerals, fortification

0521 Chemical characteristics and enhanced hepatoprotective activities of Maillard-reaction products derived from milk protein-sugar system.
N. S. Oh*, J. Y. Lee, J. Y. Joung, and Y. K. Shin, *R&D Center, Seoul Dairy Cooperative, Ansan, Korea (The Republic of)*

The objective of this study was to investigate the characteristics, antioxidative properties, and hepatoprotective effects of Maillard reaction products (MRP) from milk protein reacted with sugars. The MRP were obtained from milk protein, whey protein concentrates and sodium caseinate, using 2 types of

sugars, lactose and glucose, by heating the mixture at 55°C for 7 d in a sodium phosphate buffer (pH 7.4). Changes in the chemical modification of the milk protein were monitored by measuring the protein-bound carbonyls and PAGE protein profiles. The results showed that the amount of protein-bound carbonyls increased after Maillard reaction (MR). In addition, sodium dodecyl sulfate-PAGE analysis indicated a formation of high-molecular weight complexes through MR. The modification sites induced by MR of milk protein were monitored by matrix assisted laser desorption/ionization time-of-flight mass spectrometry analysis of tryptic-digested gel spots of MRP. As a result, modification and their localization in AA sequence of MRP was identified. Also, the MRP showed higher antioxidant activities than the intact milk protein, and they reduced intracellular reactive oxygen species production and inhibited the depletion of the reduced glutathione concentrations in the HepG2 cells. In particular, glucose-sodium caseinate MRP showed the highest biological activities among all MRP. Therefore, these results suggest that the MRP from milk protein reacting with sugars possess effective antioxidant activity and have a protective ability against oxidative damage.

Key Words: Maillard-reaction, milk protein, hepatoprotective effect

0522 Prediction of intact casein in cheese by using amaltheys: A front-face fluorescence analyzer.

Z. Liu[*1], K. Sajith Babu[1], A. Coutouly[2], F. Allouche[2], and J. K. Amamcharla[1], *[1]Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan, [2]Spectralys Innovation, Romainville, France.*

During cheese ripening, proteolysis is an important biochemical event which leads to texture and functionality changes over time. The intact casein content of cheese decreases during aging due to the enzymatic hydrolysis. However, because of the difference in storage history and compositional variability, it is difficult to rapidly estimate the amount of intact casein of different batches of cheese. In this study, the feasibility of using front-face fluorescence spectroscopy (FFFS) to predict the amount of intact casein in different cheese samples was evaluated by using fluorescence-based Amaltheys analyzer (Spectralys Innovation, Romainville, France). Twenty cheese samples from different manufacturers and with different storage time were used for this study. The intact casein was measured by fractionation of cheese proteins using Sharp's solution (pH = 4.6) and followed by nitrogen analysis using Kjeldahl method (6.38 conversion factor). Cheese was cut into the size which can fit the cuvette for fluorescence measurement using Amaltheys, and 5 fluorescence scans from 5 different locations on each cheese sample were analyzed. 3D fluorescence spectra were collected on each cheese sample at room temperature and processed using parallel factor analysis (PARAFAC) algorithms. PARAFAC scores were then used to build a calibration model against the reference intact casein values. Practical utility of the model was evaluated using the range error ratio (RER) and the ratio of prediction error to deviation (RPD). The RPD was found to be over 2 and RER was over 10, indicting a good practical utility of the model. Hence, FFFS can be used as an analysis technique to predict intact casein in cheese and the results indicate that Amaltheys analyzer can be a rapid and accurate device to analyze intact casein in cheese samples.

Key Words: front-face fluorescence spectroscopy, intact casein, cheese ripening

0523 Changes of the state of calcium and protein in low-fat and full-fat processed cheese during cheesemaking.

N. Shirashoji[*1,2], H. Aoyagi[2], T. Abe[1], and M. Ikeda[1], *[1]Food Research and Development Laboratory, Morinaga Milk Industry Co., Kanagawa, Japan, [2]Life Sciences and Bioengineering, Graduate School of Life and Environmental Sciences, University of Tsukuba, Ibaraki, Japan.*

"Creaming" is an increase in the viscosity of hot molten cheese during processed cheese cooking, and it is important for cheese manufacturers to control the viscosity during the production process. The objective of this study was to understand the interactions between protein, calcium, and fat in full-fat (FF)/low-fat (LF) processed cheese. Processed cheeses were made from 4-mo-old 9% fat Cheddar cheese and 2.3% tetrasodium pyrophosphate (TSPP). Anhydrous milk fat was added for FF cheese. A steam-jacketed kettle was used to heat 7 kg of the ingredients up to 80°C, and approximately 200 g of hot molten cheese was extracted during the holding process (80°C with shear) at certain points (0–40 min). It was poured into plastic bags, and rolled to a thickness of 4 mm, and cooled in chilled water. Both FF and LF cheeses had the same pH (5.6) and protein (24%) content. No moisture loss was observed during cooking. The viscosities of molten cheese were measured during holding time. The functional properties were assessed by hardness using a creepmeter, and degree of flow (DOF) values were measured using a modified UW-Melt profiler. The precipitate compositions of cheese dispersion after centrifugation were analyzed, and the serum phase of the cheese was extracted from the dispersion by ultrafiltration and the casein-bound calcium content was assessed. Creaming was observed in LF and FF cheeses. In LF cheese, the viscosity was drastically increased at 30 min holding time. Over-creaming was observed in FF cheese at 40 min holding time. As the holding time increased, the hardness of both cheeses increased, whereas the DOF of both cheeses decreased. LF cheese initially

showed much higher DOF values than the FF cheese; however, the value drastically decreased at ≥ 30 min holding time and indicated no significant difference ($P > 0.05$) with that of FF cheese, which showed a limited flow. Casein-bound calcium content initially decreased from 0 to 20 min and increased from 20 to 40 min for both cheeses. TSPP initially may have sequestered calcium, and casein–calcium pyrophosphate cross-links may have been formed during cooking. The protein content in the dry matter in the precipitate from FF cheese increased with the holding time. This may be due to the interaction between homogenized fat droplets and proteins. Currently, the types of protein interactions in the insoluble phase are being investigated and will be reported.

Key Words: processed cheese, calcium, creaming

0524 Effect of selenium fortification on mozzarella cheese quality. K. L. Peng[1], J. X. Liu[2], and D. X. Ren[*3], *[1]Institute of Dairy Science, College of Animal Science, Zhejiang University, Hangzhou, China, [2]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [3]Institute of Dairy Science, College of Animal Sciences, Zhejiang University, Hangzhou, China.*

Selenium (Se) is an important trace element that has significant impacts on human and animal health. The objective of this study is to investigate the effect of Se fortification on mozzarella cheese quality. The mozzarella cheese was made following the manufacturing procedures until hand-stretched and cooled in cold water. The made-up cheese was divided into five pieces of 1 kg each, and put into 2% salt water without (control) or with Se yeast (1.25, 2.5, 5, and 10 mg Se/L, respectively) overnight. The cheese was then cut, vacuum packaged and stored at 4°C for 3, 30, and 60 d until analysis. On d 3 after adding Se yeast at 1.25, 2.5, 5, and 10 mg Se/L, the Se content of the outside or center of cheese was at 27.6, 35.7, 42.3, and 45.1 μg/kg or 20.4, 22.7, 23.4, and 23.9 μg/kg, respectively, significantly higher than that in control (15.4 for outside and 15.7 for center). After storage for 60 d, the Se concentration of the outside reduced to 24.1, 31.6, 34.1 and 36.4 μg/kg, while that of cheese center increased to 22.3, 27.8, 30.1, and 31.9 μg/kg, respectively. No significant differences were found in the cheese composition and texture between the control and Se fortified cheeses. However, compared with the control, the functional properties (meltability, flowability and stretchability) were improved, while the pH and water activity were lower in the Se-fortified cheese (5 and 10 mg/L) after 60 d storage. For the total bacteria count, the 5 and 10 mg/L Se fortified cheese were significantly lower ($P < 0.05$), but the 1.25 and 2.5 mg/L Se fortified cheese were higher than the control. The results of this study indicated that the Se content in mozzarella cheese can be increased by dipped into Se fortified solution without affecting the cheese quality, and that Se could migrate from the outside into center of the cheese during the storage.

Key Words: mozzarella cheese, Se fortification, functional property

0525 Relationship between the yield of mozzarella cheese of buffalo's milk, milk quality and the recovery of constituents in whey. D. C. Sales[1], A. H. N. Rangel[1], J. G. B. Galvão Júnior[*2], L. H. F. Borba[1], A. R. Freitas[3], and E. O. Moura[1], *[1]Federal University of Rio Grande do Norte, Natal, Brazil, [2]University of New Hampshire, Durham, [3]Brazilian Agricultural Research Corp. (Embrapa), São Paulo, Brazil.*

The dairy industry measures the efficiency of its processes by the quality and yield of the final product, which are influenced by the quality of the milk. The aim of this study was to investigate the relationship between the yield of mozzarella cheese (MY) with the composition of buffalo milk and the recovery of constituents in whey (RW). The study involved tracking the processing of 30 lots of buffalo mozzarella in a dairy operation in northeast Brazil. For each batch a sample of raw milk and whey was collected to analyze the fat (F), total protein (TP), casein (C), lactose (L) and total solids (TS) via infrared spectroscopy. The somatic cell count (SCC/ml) of the milk was estimated by SOMATICEL®, and transformed by $\log_2$ (SCS). The MY is the relation between the cheese and milk mass (%); RW is the ratio between the constituent of whey versus that in milk (%). The MY relation to the level of the constituents in milk and RW was verified by the Pearson correlation (r) at a 5% level of significance, obtained by the SAS 2000 CORR procedure. Significant r between MY and other variables was not found ($p > 0.05$). There was a negative correlation between MY with F (−0.26), and a positive correlation with C (0.28), TP (0.27), L (0.11) and TS (0.01), demonstrating that the protein/fat ratio and casein content are factors directly related to efficiency in manufacturing mozzarella. The SCS has a weak and negative correlation with MY (−0.12), indicating that its increase in milk can result in lower manufacturing efficiency. The MY showed a negative correlation with RWTP (−0.19) and a positive correlation with RWF (0.17), RWL (0.17) and RWTS (0.29), indicating that TP (casein) should be used in the curd to promote MY and to reduce its losses in whey. The variables, C, TP, F, RWTS and RWTP have a greater influence on MY.

Key Words: dairy food, efficiency, losses in whey

0526 Transmission Electron Microscopy (TEM) identifies major microstructural changes in soft feta cheese. A. H. Vollmer*[1], D. J. McMahon[1], J. C. Grande[2], and N. N. Youssef[1], *[1]Western Dairy Center, Utah State University, Logan, [2]Analytical Sciences Laboratory, GE Global Research, Niskayuna, NY.*

Feta is a low-pH, rennet-set, brined cheese with a crumbly texture. If the cheese pH during manufacture is higher than ~4.8 at the point of brining, textural changes can be seen with the Feta cheese becoming softer as it ages. Our objective was to find the structural basis for this change in texture utilizing high-resolution transmission electron microscopy. Feta cheese was made using 136 kg standardized and pasteurized whole cow's milk (P/F = 0.72). The make procedure was modified by storing the packed curd overnight at 35°C (control; A), 20°C (B), and 3°C (C), respectively, before storage in brine at 3°C for up to 4 mo. This produced feta cheeses with the desired range of pH values (4.80, 4.88, and 5.17, respectively). Samples were taken during the make procedure (after renneting, before draining, and after the fourth turn), as well as during ripening (after 1, 7, and 90 d of brining), and immediately chemically fixed for transmission electron microscopy (TEM). A change of texture was macroscopically observed particularly during later stages of aging. To quantify these changes, texture profile analyses of samples taken at 120 d of brining were performed and demonstrated significant differences in hardness as indicated by a decrease in shear and compression force with higher cheese pH (B and C). TEM analysis revealed a major change in the formation of the protein network, which had formed a continuous matrix in the highest-pH feta cheese (C) after 90 d of brining, whereas it had remained largely open in the control feta cheese (A). Furthermore, high-magnification TEM analysis indicated a fundamental change in the protein matrix itself as it appeared to have dissolved into areas with less compact morphology. These changes were observed as early as 1 d after brining but were most pronounced after 90 d of brining. To quantitate texture differences in the protein matrix, morphometric image analysis was performed and corroborated the interpretation of the TEM data. Concluding, electron microscopy identified major microstructural changes that explain the softer texture of aged feta cheese as influenced by relatively small changes in cheese pH during production.

Key Words: microstructure, texture, morphometrics

0527 Performance shelf life extension of LMPS mozzarella using high-pressure treatment and low-temperature storage. L. A. Jiménez-Maroto*[1], S. Govindasamy-Lucey[2], J. J. Jaeggi[2], M. E. Johnson[2], and J. A. Lucey[1,2], *[1]University of Wisconsin, Madison, [2]Wisconsin Center for Dairy Research, Madison.*

Low moisture part skim (LMPS) mozzarella has a performance shelf life of approximately 3 mo (or less) at refrigeration temperatures. As an alternative to freezing to further extend the performance shelf life of reduced Na LMPS mozzarella, we tested the potential of high-pressure processing (HPP) and very low storage temperatures. Five replicate batches of reduced Na LMPS mozzarella were manufactured using Chymax M as coagulant. Mean composition of the reduced Na (1.0 ± 0.1% salt) LMPS mozzarella cheeses was 46.4 ± 0.4% moisture, 23.5 ± 0.3% fat, and 25.5 ± 0.2% protein. After ripening the cheese for 2 wk at 5°C, each batch was separated into two groups; one group was HPP treated (600 MPa for 3 min), the other was non-pressurized (control treatment). Each cheese group was further divided into three storage temperature treatments (+4, 0, and −20°C). The pH, rheological, textural, sensorial, and functional properties were determined after the HPP treatment, and after 3 and 5 mo of storage. Samples that were stored at −20°C were first thawed at 4°C for 7 d before analysis. Cheese functionality was monitored using texture profile analysis and dynamic low-amplitude oscillatory rheology. Changes in flavor, texture, shred properties, and pizza performance were evaluated using a 10-member panel trained in Quantitative Descriptive Analysis. HPP treatment caused an increase in pH from 5.2 to 5.3, but decreased cheese hardness, and decreased the melting point and shred straightness. HPP treatment did not affect cheese flavor or pizza functionality. At 3 mo, pH was unaffected by storage temperature, but was higher in HPP (5.3) than control (5.25) samples, cheese hardness was lower in HPP samples regardless of storage conditions, pizzas made with HPP samples and stored at 0 or −20°C presented reduced blister quantity and increased strand thickness, and cheese flavor and melting properties were unaffected by the treatments. At 5 mo, pH was lower in −20°C samples, HPP treatments, at all temperatures, showed higher maximum loss tangent; indicating higher flow of melted cheese, shred straightness was higher in HPP treated samples stored at 0°C and −20°C, and samples stored at 4°C presented difficulties when shredding. Cheeses will be monitored for 7, 9, and 12 mo. HPP and very low storage temperature could be used as an alternative to freezing to extend the performance shelf life of mozzarella cheese to more than 6 mo.

Key Words: high-pressure processing, freezing, mozzarella cheese functionality

0528 Hydrolysis of phosphates with a different chain length in water, milk and calcium caseinate.
W. H. Viotto*[1], and D. Maus[2], [1]*University of Campinas, Brazil,* [2] *University of Campinas, Brazil.*

Sodium phosphates, with different chain lengths, are widely used as emulsifiers in the manufacture of processed cheese for the stabilization of casein. The production of processed cheese involves heating and cooling steps, which can influence the phosphate chain length due to hydrolysis reactions that occur due to the heat treatment, pH and ionic environment. The objective of this work was to investigate the hydrolysis rate of phosphates with different chain sizes in water, milk and calcium caseinate during heat treatment. The salts used were sodium tripolyphosphate (TPS) (n = 3), sodium hexametaphosphate (HMPS) (n > 10) and a commercial salt SELF B4 (n = 30). Nuclear Magnetic Resonance ^{31}P was used to evaluate the phosphates hydrolysis products. Dual probe resonance was used, equipped with field gradient in the Z direction, coupled with spectrometer Bruker AVANCE III®. Analyses were performed using temperature ramp to mimic the steps of heating and cooling process of spreadable processed cheese manufacture. The heating was performed from 25°C to 90°C, followed by cooling to 5°C. The pH of salts in different matrices was determined. In water, the hydrolysis of the phosphates was started from 70°C. The higher the phosphate chain size, the lower the pH (SELF B4 = 3.61; HPMS = 6.60; TPS = 8.90) and higher the rate of hydrolysis (SELF B4 = 32.9%; HMPS = 13.6%; TPS = 9.0%). For milk, the onset of hydrolysis was at 50°C, with TPS showing a higher percentage of hydrolysis (23.3%, pH 8.00), followed by self B4 (20.5%, pH 6.20), and HMPS (12.1%, pH 6.80). In calcium caseinate, TPS hydrolysis was started from 40°C while hydrolysis of the HMSP and SELF B4 only occurred at 60°C. The hydrolysis of phosphates in caseinate (TPS = 6.7%; HMPS = 7.5%; SELF B4 = 7.2%) was less intense when compared with water and milk. The pH is close to neutral in calcium caseinate (TPS = 7,6; HPMS = 6.80; SELF B4 = 6.53) due to the high buffering capacity of the protein. The results indicate that hydrolysis of phosphates depended on the phosphate chain length; the matrix used and heat treatment but was mostly governed by pH. Therefore, the initial pH control in the manufacture of processed cheese is essential to control the rate of hydrolysis. Acknowledgment: São Paulo Research Foundation (FAPESP), grant no. 14/07291–3

Key Words: phosphates, hydrolysis, heat treatment

0529 Water mobility, texture and composition of requeijão cremoso manufactured with polyphosphates of different chain lengths.
W. H. Viotto* and V. R. Dias*, University of Campinas, Brazil.*

Requeijão cremoso is a Brazilian spreadable processed cheese made by heating a fresh curd (pH~5.5), in the presence of sodium polyphosphates with different chain lengths, under partial vacuum and stirring. The salts disrupt the casein micelle, by chelating the calcium, resulting in a more open and homogeneous protein matrix with superior water-binding and emulsifying properties. Differences in chain length of polyphosphates change the salt properties as their sequestering ability, buffering capacity, ability to hydrate and disperse caseins, and effectiveness in promoting emulsification. The study evaluated the effect of four commercial sodium phosphates with different chain sizes (n) on composition, water mobility and texture of requeijão cremoso. The following commercial emulsifying salts with different chain lengths (n) were applied: A (n = 2–10), B (n = 10–25), C (n = 25–30) e D (n > 50). The processed cheeses were formulated according to the legal requirements for requeijão cremoso: moisture content–maximum 65%; and fat content–minimum 55% on a dry weight basis. Emulsifying salt (1.8%), NaCl (1%) and water were added to the blend and the processed cheese was made in a Stephan-Geiger homogenizer-grinder. There was a difference in the kinetics and amount of immobilized water during the manufacture and storage of cheeses depending on the type of salt used. The use of the salt A, which presents a high proportion of tetrasodium pyrophosphate, resulted in cheeses with a greater content of calcium bound to casein, higher pH, and lower firmness when compared with cheeses produced with larger chain size phosphates (n > 10). These results can be explained by the presence of tetrasodium pyrophosphate (salt A), which favors interactions water-protein, resulting in a less firm texture cheese. Acknowledgment: São Paulo Research Foundation (FAPESP), grant no. 14/07291–3

Key Words: sodium phosphates, processed cheese, emulsifying salts

0530 Effect of carbon dioxide injection on protein interaction to reduce viscosity of high solids skim milk concentrates.
H. Dahiya*[1], L. Metzger[1], and H. A. Patel[2] *University of Campinas [1]South Dakota State University, Brookings, [2]Land O'Lakes Inc., Arden Hills, MN.*

Viscosity of skim milk concentrates (SMC) is an important property that constraints the extent of concentration obtained during evaporation and leads to problems like increased tube fouling, reduced heat transfer, and shorter run time. The objective of the present study was to investigate the effect of carbon

dioxide (CO_2) injection as an intermediate processing step to lower the pH of skim milk concentrate and decrease the viscosity of higher solids SMC. SMC with total solids (TS) 30% (w/w) pH 6.5 was warmed to 55°C and CO_2 was injected using a sparger fitted in-line, forming a closed loop with a positive displacement pump. CO_2 was injected at an injection pressure of 5.5×10^5 N/m^2 maintaining a flow rate of 1.4×10^{-3} m^3/sec until the pH was lowered to 6.05. Following this treatment SMC was concentrated to 55% (w/w) TS using a rotary evaporator under vacuum at 70°C. Apparent viscosity of the final concentrate was measured using an ATS Stresstech Rheometer at 55°C with shear rates from 50 s^{-1} to 1050 s^{-1} with 50 s^{-1} ramp. Concentrate was analyzed for particle size using Malvern Zetasizer Nano-ZS and for heat stability by measuring heat coagulation time using an oil bath maintained at 140°C. A sample from the same lot of SMC without the CO_2 injection treatment, concentrated and analyzed similarly, served as the control. The experiments were repeated at least twice and all results were analyzed for statistical significance (at $p < 0.05$) using SAS software. Significant difference ($p < 0.05$) in apparent viscosity was observed between CO_2 treated and control SMC samples. Concentrate obtained from CO_2 treated SMC sample had significantly ($p < 0.05$) lower viscosity compared with that obtained from untreated control sample. The dispersed particle size analysis revealed that concentrate from CO_2 treated SMC sample had lower particle size compared with the control. The changes in dispersed particle size and the resulting change in viscosity of skim milk concentrate can be explained by differences in casein and whey protein interaction between two samples as indicated by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE). In conclusion CO_2 injection can be used as a clean label treatment to control viscosity of highly concentrated SMC to eventually improve efficiency of drying process.

Key Words: skim milk concentrate, viscosity, CO_2 injection

0531 Hauling and receiving practices at dairy processing facilities. E. Kuhn*, J. Waite-Cusic, and L. Goddik, *Oregon State University, Corvallis.*

Milk hauling is an overlooked portion of the dairy industry and its impact on raw milk quality is not well characterized. Practices are mandated by the Pasteurized Milk Ordinance; however, gaps exist in the specifics of practices that could impact downstream milk and milk product quality. Description and classification of hauling and receiving practices and their relative impact could allow for the prioritization of improved practices that could improve quality throughout the dairy industry. The objective of this study was to identify current practices that could negatively impact the microbiological quality of raw milk during hauling and receiving. This objective was approached from two angles: (1) An industry survey was conducted to characterize milk hauling and receiving practices, and (2) a database that represented 2-yr of differences in raw (IBC) and PI (PIC) counts between receivers and producers (n = 23,285 tanker loads) was analyzed to identify and quantify hauling situations that have a negative impact on milk quality. Dairy processing facilities (n = 14) were asked to participate in the survey, of which 10 responded (78% response rate). The majority of facilities (10/14) utilized repeated tanker use per 24 h; however, facilities that only receive a few tankers a day washed after each load (n = 4). Frequency of CIP system validation greatly varied among facilities (daily to annually). This suggests that facilities that do not frequently validate could potentially have underlying CIP issues that could have a negative impact on tanker cleaning efficacy. For the database analysis, negative impact was defined as the top 2.5% of instances (n = 583) where the tanker and producer load average difference was ³ 7.67 IBC/mL and ³ 61.5 PIC/mL. Negative impact was more pronounced in PI counts. There was not an identifiable trend in seasonality. The analysis demonstrated that in instances of negative impact, the load typically included milk from a producer with historically high counts. This study suggests that CIP validation frequency and route management may need increased attention to minimize the impact hauling and receiving practices have on raw and downstream product quality.

Key Words: raw milk, quality

0532 Comparing fluorescent and light-emitting diode (LED) retail lighting effects on consumer acceptability of fluid milk. S. Duncan*, H. Potts, and K. N. Amin*, Virginia Tech, Blacksburg.*

The objective was to assess the effect of fluorescent and light-emitting diode (LED) lighting under retail storage conditions on consumer acceptability of milk. Little is known about the effect of retail light exposure on consumer acceptability of milk, especially for LED light. Packaging materials designed to interfere with light wavelengths may be needed to maintain milk quality and consumer acceptability. Consumer acceptability (two studies; *n* = 150+ in each) was assessed using a 9-point hedonic scale (1 = dislike extremely; 9 = like extremely) for overall milk acceptability and acceptability of attributes (appearance, aroma, flavor, mouthfeel, aftertaste, freshness). Just-about-right (JAR) scale (5-point scale; 3 = just about right) characterized the influence of flavor and mouthfeel on consumer acceptability. Analytical measures of milk oxidation included dissolved oxygen content and riboflavin retention. Study 1 evaluated milk stored in high density polyethylene (HDPE) packages for 4 h under LED (about 960 lux). HDPE package treatments included white (low titanium dioxide (TiO_2,), yellow, designed (high TiO_2) and controls: natural HDPE (0% TiO_2) with a light-blocking foil overwrap and without foil (both LED and fluorescent light exposure). Study 2 evaluated polyethylene terephthalate (PET) packages for 4 h under fluorescent and LED (about 1460 lux) light. PET package treatments included two experimental treatments (medium

TiO_2; high TiO_2) and four controls: light-exposed HDPE (fluorescent), light-exposed PET (fluorescent and LED), and light-protected control. Acceptability (overall, attributes) and JAR attributes were analyzed by Fisher's LSD and Penalty Analysis function, respectively, using XLSTAT (a = 0.05). Analytical measures were analyzed by ANOVA and Tukey's HSD (a = 0.05) for mean separation as appropriate. Overall mean acceptability of milk ranged from 5.7 to 6.7 (< like moderately to < like very much), with a significantly lower acceptability for milk exposed to fluorescent light in natural HDPE and clear PET packages. All PET and HDPE packages protected milk flavor from LED lighting; packages with higher TiO_2 had the most optimum performance as indicated by overall acceptability and attributes. JAR flavor evaluation illustrated penalties to overall acceptability for all HDPE packages except the designed package. Only the fluorescent light condition (both PET and HDPE in fluorescent lighting) diminished overall acceptability in study 2 based on JAR flavor evaluation. Changes in dissolved oxygen content, as an indication of oxidation, supported the observed differences in consumer acceptability in fluorescent and LED light. Acceptability in milk quality decreases over short (4 h) light exposure, especially under fluorescent lighting, without appropriate packaging.

Key Words: milk, oxidation, sensory

0533 Effect of various storage conditions on the stability of Sulphonamides in raw milk. M. Chen[1,2], F. Wen[1,3], H. Wang[4], N. Zheng[1,3], and J. Q. Wang[*1,2], *[1]Ministry of Agriculture Laboratory of Quality and Safety Risk Assessment for Dairy Products, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, [4]College of Animal Science and Technology, Yangzhou University, China.*

Sulphonamides (SAs) are synthetic compounds that are widely used in veterinary field to treat bacterial and protozoan infections in dairy cattle, due to its low cost and broad spectrum against common bacterial infections. However, improper use of SAs may lead to SAs residues in milk. Therefore, maximum level limits (MRLs) are established and raw milk is compulsory to be detected for antibiotics, including sulphonamides, by many countries and authorities. Before confirmation experiments are performed, raw milk may be preserved under different conditions. To guarantee the scientific risk assessment of SAs in raw milk and find the optimal storage condition for analytical method, this study was performed to investigate the stability of 8 SAs, including sulfaguanidine (SGD), sulfapyridine (SPD), sulfadiazine (SDZ), sulfamonomethoxine (SMM), sulfamethoxazole (SMX), sulfadimethazine (SMZ), sulfachlorpyridazine (SPDZ) and trimethoprim (TMP), in raw milk under various conditions. Storage conditions included different storage temperature/time (4°C for 4, 8, 24, and 48 h; −20°C for 1, 7, and 30 d; −80°C for 1, 7, and 30 d), thawing temperature (25°C, 40°C and 60°C), freeze–thaw cycle times (once, twice and three times), and addition of different preservatives (odium thiocyanate, sodium azide, potassium dichromate, bronopol and methanal). Raw milk collected from a local farm in Beijing was transported to our lab immediately, spiked with SAs at the MRLs level, kept under the above conditions and then analyzed by UHPLC-MS. Results showed that most SAs were quite stable (recovery = 90% ~ 120%) under 4°C, −20°C, −80°C within 48 h, 30 d, 30 d respectively, thawed at 25°C, 40°C and 60°C, and thawed at 40°C for 1 and 3 times. But most SAs of interest degraded when raw milk was thawed 5 times and preserved with preservatives added. What's more, sulfachlorpyridazine (SPDZ) seemed to be the most labile sulphonamide under these storage conditions. Preservatives seemed to be the most influential factor that affected the stability of sulphonamides in raw milk.

Key Words: raw milk, storage stability, sulphonamides

0534 Effect if pH on the hydrolysis of sodium polyphosphates in different dairy matrices. W. H. Viotto* and A. P. Barth, *University of Campinas, Brazil.*

Sodium polyphosphates are essential ingredients in processed cheese production. These salts are mainly used for their calcium-binding ability and also to control pH, which further aids in protein dispersion and hydration. Hydrolysis of polyphosphates may occur as a function of pH, temperature and chemical environment, altering the composition of salts and their action on cheese. The objective of this work was to investigate the effect of pH (5.2, 5.6, 6.0, 6.4, 6.8) on the hydrolysis of a commercial polyphosphate salt in water, milk and calcium caseinate. Aqueous solutions of polyphosphate were prepared by dissolving the commercial sodium polyphosphate blend in distilled water at 2.3% (w/w). Milk and calcium caseinate were prepared by dissolving skim milk powder (10%, w/w) and calcium caseinate powder (10.5%, w/w), respectively, in distilled water. The same concentration of polyphosphate was used for all the dairy matrices. The hydrolysis of samples was obtained by integration and normalization of the ^{31}P nuclear magnetic resonance spectra (NMR). Dual probe resonance was used, equipped with field gradient in the Z direction, coupled with spectrometer Bruker AVANCE III®. Spectra were obtained at 25°C, 90°C and 10°C to mimic the thermal processing to which the cheeses are subjected. In water, the hydrolysis rate increased as the pH decreased (4.2% for pH 6.8 to 7.59% for pH 5.2), increasing orthophosphate concentration. The same trend was observed in milk, but the rate of hydrolysis was higher (7.85% for pH 6.8 to 17.02% for pH 5.2), probably due to the presence of calcium ions. Calcium

caseinate hydrolysis was similar to that observed in water and milk, except at pH 5.2, where the hydrolysis rate was lower (8.19%) than that observed in milk. This can be explained by the lower mobility of the particles since the protein matrix is more aggregate at this pH. Small variations in pH influenced the hydrolysis of polyphosphate which could result in changes of processed cheese properties. Acknowledgment: São Paulo Research Foundation (FAPESP), grant no. 14/07291–3

0535 NIR technology as a process analytical tool for cheese inspection. W. H. Viotto*, D. F. Barbin, and C. Karaziack, *University of Campinas, Brazil.*

The chemical composition of cheese is significantly related to quality, as it is responsible for its shelf life, yield and texture. However, conventional methods for determination of chemical composition are laborious and time-consuming. Fast assessment tools such as NIR spectroscopy and spectral imaging could be used for the quality control of cheeses. The advantage of this technique is that it allows several constituents to be measured simultaneously in a quick and nondestructive way. The objective of this work was to investigate spectral imaging combined with principal component analysis (PCA) for assessment of cheese samples. Spectral information of six varieties of cheese (Cheddar, coalho, Minas, mozzarella, prato and block processed cheese) were obtained using a spectral imaging system, between 928 and 2524 nm, with 6 nm intervals, resulting in 256 analyzed wavelengths. The first two principal components were responsible for 98.2% of the variation among samples, and the score plot presented good separation among samples of coalho cheese, mozzarella and Minas cheese. Loadings show that some peaks are strongly influenced by wavebands, associated to chemical bonds related to protein and fat. Spectral imaging combined with multivariate analysis can be a potential tool for fast cheese quality assessment.

Key Words: PCA, quality control, spectral imaging

0536 Extraction of phospholipids from procream using supercritical carbon dioxide and ethanol as a modifier. B. Li*[1], Z. Linghu[1], F. Hussain[1], S. J. Smith[2], and J. K. Amamcharla[1], *[1]Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan, [2]Kansas State University, Manhattan.*

Procream is a co-product obtained during manufacture of whey protein isolate. It mainly contains whey proteins (63%–72%), fat (12–20%), and approximately 20% of phospholipids (PLs) in total fat. The interest in PLs as functional ingredients is increasing in recent years. PLs affect several cell functions, such as growth, molecular transport system, memory processing, stress responses, and central nervous system myelination. Neutral lipids can be successfully extracted using supercritical carbon dioxide (SCO_2). However, the solubility of PLs is limited in SCO_2 and therefore a modifier such as ethanol is often needed to increase the solubility of PLs. The objective of present study was to use SCO_2 and ethanol as a modifier to extract PLs from procream. For this purpose, the central composite rotatable design based on response surface methodology was used to optimize extraction conditions. The pH of procream (4-8) and extraction pressure (300–550 bar) were used as independent factors. The CO_2 flow rate (5 mL/min), extraction time (1 h), and ethanol flow rate (0.033 mL/min) were kept constant. The extractions were performed in a supercritical extraction system supplied by Applied Separations Inc., PA. Procream was procured from a commercial manufacturer and stored at −20°C until use. A two-step extraction process was followed. In the first step, 10 g of procream was mixed with glass beads in the ratio 1:1 (v:v) and placed in the extraction vessel. Neat supercritical CO_2 was allowed to pass through the extraction vessel to remove all the neutral lipids. In the second step, SCO_2 and ethanol as a modifier was used to extract phospholipids. The remaining lipids from spent solids after the second extraction were extracted using the solvent extraction method. All the lipid fractions were analyzed by high performance lipid chromatography (HPLC) with kinetex™ HILIC (150 × 4.6mm, 5 µm) column. The amount of lipids extracted from after the second stage was significantly ($P < 0.05$) affected by pH of procream. However, pressure was found be not significant ($P > 0.05$). Only Sphingomyelin was found in the lipid fractions obtained after the second extraction step and it was found to be at higher concentrations at pH 7.4. On the other hand, phosphatidylcholine and phosphatidylethanolamine were not detected in lipids obtained after second extraction. Ethanol as a modifier was not able to improve the solubility of phospholipids in SCO2.

Key Words: supercritical fluid extraction, procream, ethanol as a modifier

0537 Evaluation of Sol-Gel non-stick surface modification in dairy thermal processing. Z. Liu*[1], J. K. Amamcharla[1], and L. Metzger[2], *[1]Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan, [2]South Dakota State University, Brookings.*

Fouling is a common problem in the dairy industry across many types of processing equipment. It necessitates regular and frequent cleaning, which leads to increased down-time and reduced operating efficiency. One way to achieve a reduction in milk fouling is to modify the surface characteristics of stainless steel (SS) surfaces. This study examines the potential viability of Thermolon™, an environmental friendly and food safe surface modification on SS, in dairy thermal processing. SS 316 L coupons (1 inch × 1 inch) with 2 B finished surface (cold rolled, annealed, and pickled) were used in

this study. Sol-gel (Thermolon™) surface modification of SS coupons were provided by Porcelain Industries Inc. (Dickson, TN). The surface properties of the modified and control coupons were characterized by contact angle measurement. The measurements showed that the modified surface gave a higher contact angle at 105.5 ± 0.5°, while the control stainless steel had 82.9 ± 2°, indicating a more hydrophobic surface after modification. Control stainless steel coupons and Thermolon™ modified coupons were then inserted into a benchtop plate heat exchanger (bPHE) and raw milk was pumped through the bPHE to an average temperature of 85°C for 8 h to create milk fouling. Triplicate tests were conducted and significant reductions of milk deposit on modified surfaces was observed ($P < 0.05$). An average of 0.1231 ± 0.0145g of fouling was observed on the control coupons, while 0.0017 ± 0.0018 g of deposit on the modified surfaces. Fouling was reduced by over 90% on the modified surfaces under the same fouling condition. Overall, the Thermolon™ modified surface which has a non-stick property showed fouling resistance and potential to be used in thermal processing of milk.

Key Words: milk fouling, surface modification, Sol-gel

0538 Foaming and baking properties of MPC and egg white protein mixtures. V. Hor* and B. Vardhanabhuti, *University of Missouri, Columbia.*

Egg white protein is the major foaming ingredient used in baked goods. With the Avian flu outbreak that caused a shortage in eggs and an increase in egg prices, egg alternatives have been explored for baking applications. Milk protein concentrate (MPC) is a primary ingredient in many food products due to its functional and nutritional properties; however, its foaming properties are still underutilized. This goal of this study was to determine the effects of MPC to egg white protein isolate (EWI) ratio on foaming properties and baking properties of angel food cake.

Foam of EWI and preheated (55°C) MPC solutions were prepared by beating protein solutions for 20 min in a KitchenAid mixer. Foaming properties were observed by measuring overrun and drainage 1/5 life. Baking properties were determined by measuring the volume of angel food cakes using rapeseed displacement method, textural properties using TA-XT2 Texture Analyzer, and color using a Hunter Colorimeter. Yield stress of cake batter was measured using a Kinexus Pro rheometer.

Results showed that foam overrun and drainage significantly decreased with 20% EWI replacement. No change in overrun was observed with increasing MPC ratio ($P > 0.05$) while drainage increased. Similar trend was observed with yield stress of cake batter. When used in angel food cake, replacing 20% EWI did not significantly affect cake volume, chewiness or gumminess ($P > 0.05$) though hardness decreased by 12% and springiness increased by 14%. At 40% replacement cake volume significantly decreased and continued to decrease at higher %MPC. Largest changes in TPA attributes were observed at 40% replacement. At higher MPC ratios, the cakes were too dense such that hardness and gumminess started to increase. Replacing EWI with MPC did not affect cake color.

In conclusion, using 20% replacement yields the closest results to the traditional angel food cake especially in terms of baking properties. Modification of protein properties or addition of other ingredients to improve foaming properties are needed to improve foaming and baking properties of MPC.

Key Words: angel food cake, milk protein concentrate, egg white protein, texture, volume, foam, overrun, drainage, rheology

0539 The effect of emulsifying salts on the turbidity of a diluted milk system with varying pH and protein concentration. M. Culler*, Y. Saricay, and F. M. Harte, *Pennsylvania State University, University Park.*

Casein micelles' stability has been shown to be dependent on the surrounding environmental conditions. In the dairy industry, salts are frequently used as functional additives to tailor stability and melting properties for various applications. Thus, there is a clear need to understand the role that salts can have on the milk system, particularly their effect on the casein micelles. The aim of this study was to examine the effect of various salt types and concentrations on the turbidity of a diluted milk system at different pH's and protein concentrations to draw conclusions about the aggregation and dissociation of the casein micelles.

Solutions of 10 commonly used emulsifying salts listed in the Code of Federal Regulations for pasteurized process cheese were made by mixing the salts in a 1-in-20 dilution of water in skim milk ultrafiltrate (3 kDa MWCO) to obtain salt concentrations from 0 to 248 mM. The effect of the salts at different pH's was also examined by using salt solutions buffered to 4.8, 5.8, 6.8, 7.8 or 8.8. The turbidity of diluted skim milk (40 uL) in a given salt concentration and pH (1960 uL) was measured by UV-Vis spectroscopy at 400 nm at t = 0, t = 30 s and t = 30 m. Measurements were completed in duplicate. For experiments with varying protein contents, ultrafiltration retentate and permeate were used in differing ratios to obtain concentrations of 1.4, 2.8, 4.2, and 5.6% casein.

At pH values 5.8 and above, an increasing salt concentration resulted in a decrease in the turbidity of the diluted milk system, however salts at pH 4.8 exhibited upward trends as concentration increased. Each salt's effect on the turbidity of the system changed with varying pH and salt concentration. At pH 6.8 and t = 0, 1 mM of sodium hexametaphosphate caused a decrease in absorbance from 0.597 absorption units (AU), while 100 mM of monosodium phosphate caused only a 0.116 AU decrease for the same pH and time. Absorbance decreased slightly (> 2 AU) between t = 0 and t = 30s, however a larger decrease (1- 4 AU) was observed for t = 30 m at

pH 6.8. When the effect of varying protein concentration was tested on trisodium phosphate, the slope of the turbidity curve did not change with increasing protein concentration, but the extent of the decrease in turbidity was more pronounced at higher protein concentrations.

Key Words: casein, salt, turbidity

0540 Effect of high pressure jet processing on the rheological properties of ice cream mix. M. Tran*, D. R. Roberts, and F. M. Harte, *Pennsylvania State University, University Park.*

Homogenization is a general term that describes a process that reduces the heterogeneity of a system. In the dairy industry, two-stage valve homogenization (< 20 MPa) is used to prevent milk creaming by reducing the fat globule particle size and to homogenize ice cream mix before freezing. Advances in material science and engineering enabled high pressure jet technology (HPJ) to achieve processing pressures up to 600 MPa. The HPJ contains a diamond nozzle (75 to 400 μm diameter) which forces liquid into a jet stream, differing from high pressure homogenization that uses a valve (HPH). The HPJ is able to induce higher shear stress, temperature, cavitation, turbulence, and friction as compared with conventional homogenization. The objective of this study was to evaluate the rheological properties of conventionally processed ice cream mix processed through HPJ at 0 to 500 MPa (125 MPa increments) to understand the impacts of this technology on the physical properties of mix. The mix was evaluated for changes in density and rheological behavior. Density of the mix decreased with increasing pressure, from 1.045 g/mL at 0 MPa (control) to 0.785 g/mL at 500 MPa. All samples exhibited shear thinning behavior consistent with the Power Law model. Consistency index (k) of mixes dramatically increased to 0.788 at 500 MPa, compared with mix processed at 250 MPa (k = 0.117). The flow behavior index (n) dropped from 0.643 to 0.425 for control samples vs. ice cream mix processed at 500 MPa. Rheological properties of ice cream mix are highly affected by HPJ processing with increasing pressures, indicating structural changes within the mix. The results from this study will provide further information on the implications of HPJ processing on ice cream mix, as well as other dairy systems.

Key Words: pressure, ice cream, rheology

0541 Fat reduction in ice cream and its effect on physical structure and consumer acceptability. M. L. Rolon*, A. J. Bakke, J. N. Coupland, J. E. Hayes, and R. F. Roberts, *Pennsylvania State University, University Park.*

Fat reduction is often pursued as a way to reduce the overall energy density of food products. Ice cream is a complex food where removal of one ingredient may affect not only physical properties but also multiple sensory characteristics that are important to consumers. Fat, in particular, plays a role in structuring ice cream, contributing to the characteristic smoothness, dryness and melting rate. Removal of fat from ice cream without replacement of solids has been shown to decrease sensory quality indicators. Previous work evaluating fat removal strategies has focused on changes in key sensory descriptors, with surprisingly little information being collected on consumer acceptability of reduced-fat products. Here, we evaluated the effect of replacing fat with maltodextrin (MD) on consumer acceptability and on selected physical properties of ice cream simultaneously. Vanilla ice creams were formulated with 6, 8, 10, 12, and 14% fat and 8, 6, 4, 2, and 0% maltodextrin, respectively. A series of sensory tests were conducted in the Sensory Evaluation Center at Penn State, each with ~100 participants, to measure liking and intensity of various attributes. Physical measures included fat particle size, fat destabilization, hardness and melting rate. The experiment was replicated three times. Data were analyzed using mixed model ANOVA and correlation to assess relationships between consumer acceptability, physical variables and sensory attributes. Additional sensory testing was conducted after 19 wk of storage at −18°C. Fat particle size and fat destabilization significantly decreased with fat reduction, but consumer acceptability did not significantly differ with fat content for fresh or stored ice cream. Overall liking was correlated with slower melting rate in fresh ice cream. Following storage, ice creams with 6, 12, and 14% fat did not change in consumer acceptability compared with fresh ice cream. However, ice creams with 8 and 10% fat (and 6 and 4% MD) each showed a significant drop in liking score following storage. Collectively, the changes on the physical structure of ice cream caused by the reduction in fat from 14 to 6% did not show evidence of gross changes in consumer acceptability for either fresh or aged ice cream, although storage altered liking for some formulations but not others.

Key Words: ice cream, consumer acceptability, fat reduction

0542 Inactivation of *Listeria innocua* on cheddar cheese by supercritical fluid CO_2. S. Padilla Antunez*[1], and R. Jimenez-Flores[2], [1]*California Polytechnic State University, San Luis Obispo,* [2]*Dairy Products Technology Center, California Polytechnic State University, San Luis Obispo.*

Hard cheeses contaminated with *L. monocytogenes* and potential illness in consumers are unacceptable risks in today's commercial environment. Novel methods, such as supercritical fluid extraction with CO_2 (SFE), could potentially reduce the risk of microbial contamination and increase the safety of cheeses. The aim of this study was to evaluate the efficacy of SFE in reducing the population of *Listeria innocua* (a surrogate for *L. monocytogenes*) on the surface of cheddar cheese.

The effects of SFE on the pH, water activity, and appearance of cheddar cheese were also evaluated. Cheddar cheeses were inoculated with *L. innocua* (10^6 log CFU/g) and incubated overnight at 4°C to emulate post pasteurization contamination. The treatment with SFE was measured at two pressure and temperature combinations (120 bar at 40°C and 150 bar at 50°C) for 30 min. Treated and untreated samples were analyzed for *L. innocua*, coliforms, pH, and water activity immediately after treatment. Counts results were analyzed and compared using ANOVA. *Listeria innocua* in cheddar cheese decreased approximately 2.0 and 4.0 log CFU/g after SFE treatment at 120 bar and 40°C and SFE treatment at 150 bar and 50°C for 30 min, respectively. The water activities and pH were 0.9640 and 5.35 for treated and untreated cheddar cheeses. Cheddar cheeses showed some signs of deformation, such as some openings and splits in the surface after SFE treatment, because treatment was done in unrestrained cubes. These data suggest that SFE could potentially be used to reduce *L. monocytogenes* in cheese products.

Key Words: supercritical fluid extraction with CO_2, *Listeria innocua*, *L. monocytogenes*, hard cheeses, cheddar cheese

0543 Evaluation of the effect of cavitation on biofilm forming ability of sporeformers. T. Almalki*[1], and S. Anand[2], [1]*Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings,* [2]*South Dakota State University, Brookings.*

Thermoduric sporeformers survive heat treatment and lead to the formation of contact surface biofilms. These biofilms are difficult to clean and cause cross-contamination of milk and dairy products during milk processing. To inactivate the thermoduric sporeformers, a novel technique based on the cavitation effect is being studied in our lab. In addition to inactivating sporeformers, the cavitation may also lead to surface modifications of any surviving cells and their endospores. It is hypothesized that cavitation would result in their reduced ability to attach to contact surfaces and form less biofilms on their recovery. The present study is thus focused on the effect of cavitation on the biofilm-forming ability of three dairy related sporeformers: *Geobacillus stearothermophilus*, *Bacillus licheniformis*, and *Bacillus sporothermodurans*. Individual organisms were spiked in to sterile skim milk samples at a rate of 6.0 log CFU/mL. For the cavitation effect, the spiked samples were treated by ultrasonicator processor (VC 505; Sonics and Materials Inc., CT) at 20 kHz frequency, 500 W power, and 80% amplitudes for 10 min each. The pre- and post-ultrasonicated spiked samples were used to develop biofilms on stainless steel (SS) coupons under static conditions. The respective biofilm counts were taken after 72 h of incubation by standard microbiological techniques. Scanning electron micrographs were also taken to visually observe the developed biofilms. The replicate data from 3 trials for each organism were statistically analyzed and means were compared using the Student *t* test. The pretreatment counts in spiked milk samples were 7.2, 8.0, and 7.7 logs, respectively, for the three sporeformers. After the cavitation treatment, the counts got reduced significantly to 3.4, 4.2, and 3.7 logs, respectively. Further studies indicated that within biofilm matrices on SS coupons, the pretreatment counts for the three sporeformers were 5.35, 6.42, and 6.5 logs, respectively, while the biofilms of cavitated cells revealed significantly ($P < 0.05$) lower counts of 4.39, 5.44, and 5.82 logs, respectively, for the three organisms. Of the three organisms tested, *Geobacillus stearothermophilus* formed the least biofilms after cavitation. The results obtained in the study thus support the hypothesis that the cavitated sporeformers would form lower biofilms.

Key Words: cavitation, sporeformers, biofilm

0544 The effect of *Lactobacillus brevis* and fibrolytic enzymes on fermentation of switchgrass silages. L. Jingjing*, *State Key Laboratory of Animal Nutrition, Engineering Technology Research Center of Raw Milk Quality and Safety Control, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

The objective of this study was to determine the effect of *Lactobacillus*, enzymes, and a *Lactobacillus* + enzymes mixture on fermentation characteristics, nutritive value, and microbial diversity of switchgrass silage. Switchgrass (*Panicum virgatum* L.) was harvested at vegetable stage and treated with distilled water (control), *Lactobacillus brevis*, fibrolytic enzymes, and *Lactobacillus brevis* + fibrolytic enzymes (denoted C, LB, E, and LB+E, respectively) before ensiling. Treated switchgrass was ensiled in sealed 1.0-L plastic jars. Jars of each treatment were opened after 3, 10, 20, and 30 d for chemical and microbial analyses. Inoculation accelerated the decline of silage pH. Compared to other treatments, LB+E had the most rapid decline ($P < 0.05$) in pH during the first 3 d of ensiling. After 30 d, for C, LB, E, and LB + E, pH declined to 5.3, 4.6, 4.8, and 3.7, respectively. There was no butyric acid detected in LB and LB+E. The lactic acid concentration of LB and LB+E increased by 5.53 times and 21.75 times compared to that of C, respectively. Acetic acid concentrations of LB and LB+E decreased by 36.34% and 9.40%, respectively. NH_3–N concentrations of LB, LB+E, and E decreased by 67.7%, 74.55%, and 69.88%, respectively. Treatments with enzymes (E, LB+E) effectively ($P < 0.05$) decreased neutral detergent fiber (NDF) and acid detergent fiber (ADF) concentrations. NDF concentrations in E and LB+E decreased by 8.09% and 8.43%, respectively. ADF concentrations in E and LB+E decreased by 3.03% and 10.88%, respectively. Crude protein (CP) content of C, LB, E, and LB+E was 77.6, 96.2, 88.0, and 97.0 g/kg DM, respectively, suggesting that inoculation increased the CP content of switchgrass silage significantly ($P < 0.05$). The

16S rRNA gene-based pyrosequencing was used to analyze the community of the 30-d silage, and results indicated that the diversity of microorganisms differed among treatments significantly ($P < 0.05$). Microbial diversity was lower in treated switchgrass silages than that in the control switchgrass silage. *Enterobacter* was the dominant species in C, and the relative abundance of *Enterobacter* was 53.60%. *Enterobacter* was the dominant species in E, although the relative abundance of *Enterobacter* decreased to 40.67%, and that of *Lactobacillus* increased to 26.13% in E. In LB and LB+E, *Lactobacillus* was the advantageous species (91.19% and 96.89%, respectively), and *Enterobacter* was inhibited effectively. In conclusion, the addition of bacterial and enzymatic additives can improve switchgrass silage fermentation quality to different extents. Adding a mixture of *Lactobacillus brevis* and fibrolytic enzymes worked more effectively than either adding *Lactobacillus brevis* or fibrolytic enzymes, respectively.

Key Words: switchgrass silage, fermentation characteristics, nutritive value, microbial diversity, *Lactobacillus brevis*, fibrolytic enzymes

0545 Influence of flax seed on the bile tolerances of *Lactobacillus acidophilus*, *Lactobacillus bulgaricus*, and *Streptococcus thermophilus*.

M. Theegala[*1], R. Chiguila Arevalo[1], V. Viana[1], D. Olson[2], and K. J. Aryana[2], [1]*Louisiana State University, Baton Rouge,* [2]*Louisiana State University Agricultural Center, Baton Rouge.*

Consumption of flax seed provides health benefits such as lowering blood glucose and cholesterol levels. Bile tolerance is an important probiotic characteristic allowing survival of probiotics in the intestinal tract. This experiment was conducted to determine whether or not flax seed enhances the bile tolerance of *Lactobacillus acidophilus, Lactobacillus bulgaricus*, and *Streptococcus thermophilus*. Control (no flax seed) and experimental (62 g flax seed/L) broths were prepared for each culture. The broths were sterilized, cooled, inoculated, and plated for 8 h. The MRS broth contained 0.3% oxgall for *Lactobacillus acidophilus* LA-K and 0.3% oxgall with 0.2% sodium thioglycolate for *Lactobacillus bulgaricus* LB-12. The M17 broth contained 0.3% oxgall and 5% lactose for *Streptococcus thermophilus* ST-M5. MRS agar, MRS agar pH 5.2, and M17 agar containing 5% lactose were used for plating *Lactobacillus acidophilus* LA-K, *Lactobacillus bulgaricus* LB-12, and *Streptococcus thermophilus* ST-M5, respectively. *Lactobacillus acidophilus* LA-K plates and *Lactobacillus bulgaricus* LB-12 plates were incubated anaerobically at 37°C for 48 h and for 72 h, respectively. *Streptococcus thermophilus* ST-M5 plates were incubated aerobically at 37°C for 24 h. For *Lactobacillus acidophilus* and *Lactobacillus bulgaricus*, the log counts in the absence of flax seed significantly decreased from 0 to 8 h while no significant difference was observed in the presence of flax seed. However, no significant difference in log counts of *Streptococcus thermophilus* between 0 and 8 h for the broth either with or without flax seed was observed. Therefore, flax seed improved the bile tolerance of *Lactobacillus acidophilus* and *Lactobacillus bulgaricus* but not of *Streptococcus thermophilus*.

Key Words: flax seed, bile tolerance, dairy cultures

0546 Characterization of *Lactobacillus wasatchensis* from aged cheeses showing late-gas defects.

C. J. Oberg[1], M. D. Culumber[*1], T. Allen[2], T. S. Oberg[3], B. Villalba[4], and D. J. McMahon[5], [1]*Department of Microbiology, Weber State University, Ogden, UT,* [2]*Utah State University, Logan,* [3]*Department of Nutrition, Dietetics, and Food Sciences, Western Dairy Center, Utah State University, Logan,* [4]*Vivolac Cultures Corp., North Logan, UT,* [5]*Western Dairy Center, Utah State University, Logan.*

Lactobacillus wasatchensis WDC04, a nonstarter lactic acid bacterium, was isolated from aged cheddar cheese that had late gas formation. Subsequent studies have demonstrated that *Lb. wasatchensis* can produce gas in culture and in experimental cheeses. This organism has also been isolated from five other geographically distant production facilities (UT, WI, WA) in cheese samples with late gas defects. It has not been found in normal cheeses that exhibit no late gassy defect. The objective of this study was to characterize and compare *Lb. wasatchensis* strains isolated from the different cheese samples. Strains from each cheese were compared using 16S rRNA gene sequencing, rep-PCR, and the API® 50CH carbohydrate metabolic assay. The strains have 100% sequence identity to WDC04 based on the alignment of approximately 1200 bp of the 16S rRNA gene. However, rep-PCR analysis indicates that the strains are related but not identical. This might suggest multiple geographical sources for contamination. In addition, several primer sets specific for *Lb. wasatchensis* have been designed and tested for specificity against other *Lactobacillus* and NSLAB species. A specific primer set will allow more rapid, and possibly quantitative, detection of *Lb. wasatchensis* in cheese. Further, these primers will help to identify sources of the contaminant in the environment and to monitor critical steps in the production process, such as the incoming milk and pasteurization effluent, as possible sources of *Lb. wasatchensis*.

Key Words: lactobacilli, gassy defect, cheese

0547 Determination of antagonism between NSLAB strains and *Lactobacillus wasatchensis* WDC04 using the agar-flip method. C. J. Oberg*[1], M. Walker[2], M. D. Culumber[1], and D. J. McMahon[3], [1]*Department of Microbiology, Weber State University, Ogden, UT,* [2]*Weber State University, Ogden, UT,* [3]*Western Dairy Center, Utah State University, Logan.*

Lactobacillus wasatchensis WDC04, a new obligatory heterofermentative nonstarter lactic acid bacteria (NSLAB), was recently isolated from "gassy" cheddar cheese. Evidence indicates WDC04 may be an important cause of late gassy defect in aged cheese. One way to control WDC04 may be to incorporate other NSLAB strains into cheese that inhibit its growth. Experiments were performed to determine if inhibition occurs between common NSLABs and WDC04 utilizing the agar-flip method. A lawn of WDC04 was swabbed on MRS agar with 1.5% ribose (MRS-R) and incubated anaerobically at 25°C for 2 d or 4 d. Agar was then aseptically flipped over and individual NSLAB challenge cultures swabbed on the exposed surface. Plates were incubated anaerobically at 30°C or 37°C (for *Lb. helveticus*) for 5 d. Growth of NSLAB cultures was compared to their growth on MRS-R plates without a WDC04 lawn (controls). In a second experiment, the same procedure was utilized, except the media contained 4% NaCl and pH 5.2 to mimic the cheese environment. In a third experiment, MRS-R (4% NaCl, pH 5.2) was also used, but the NSLAB cultures were initially swabbed as the lawn, incubated, and then WDC04 was streaked on the opposite side of the agar. In the first and second experiments, *Lb. curvatus* WSU1 showed the greatest inhibition by WDC04 while *Lb. paracasei* Lila and *Lb. rhamnosus* 7469 were the least inhibited. All challenge NSLAB strains showed decreased levels of growth compared to their control plates. In both experiments, most NSLAB cultures showed more inhibition by WDC04 grown for 4 d compared to 2 d before the culture challenge. Results from the third experiment suggest that some NSLAB strains can affect growth of WCD04 under cheese-like conditions with *Lb. casei* F19, *Lb. paracasei* Lila, and *Lb. rhamnosus* 7469 exhibiting inhibition. Since there was no direct contact between WDC04 and each NSLAB challenge strain, any inhibition was due to secretion of inhibitory compounds. Examining the antagonism between NSLABs and WDC04 allows for the selection of NSLAB strains that could inhibit this problematic bacterium during cheese ripening.

Key Words: *Lactobacillus wasatchensis*, nonstarter lactic acid bacteria, late gas defect

0548 Determination of treatments to reduce late gassy defect in cheese due to *Lactobacillus wasatchensis* WDC04 contamination. C. J. Oberg*[1], I. Bowen[2], M. D. Culumber[1], and D. J. McMahon[3], [1]*Department of Microbiology, Weber State University, Ogden, UT,* [2]*Weber State University, Ogden, UT,* [3]*Western Dairy Center, Utah State University, Logan.*

Lactobacillus wasatchensis WDC04 is a recently discovered lactic acid bacterium isolated from gassy cheddar cheese. Previous research associated WDC04 with late gassy defect in aged cheese, which results in serious commercial losses. Experiments were performed to determine its salt tolerance at pH 5.2 and 6.5, resistance to HTST pasteurization, and pH tolerance. Understanding these characteristics of WDC04 could allow manipulation of the cheese environment to control it. MRS with 1.5% ribose (MRS-R) was prepared at either pH 5.2 or 6.5 with salt concentrations ranging from 0.0% to 10.0%. Two mL of each MRS-R media was added to wells in a 24 micro-well plate and an absorbance reading taken (600 nm). Immediately, 100 mL of WDC04 was inoculated into each well, and the plate incubated at 25°C for 3 d (pH 6.5) or 2 d (pH 5.2). Plates were then placed in a Teacon Infinite 2000 with absorbance readings (A_{600}) taken every 4 h for 24 h. Results showed that WDC04 grew best at 3.0% salt (pH 6.5) and 2.0% salt (pH 5.2) but showed some growth up to 6% at either pH. Further testing was performed using a narrower salt range (5.25%–6.75%) to determine if a salt concentration used in cheese could suppress WDC04 growth. Above 6.0% salt, WDC04 was inhibited. Using this methodology, the pH range (2–8) for WDC04 was also determined. Results confirmed WDC04 grows best at pH 5–6 (cheese pH) but not below pH 4 or above pH 7. To model HTST pasteurization, WDC04 was grown in MRS-R broth for 2 d, diluted, then heat shocked at 72°C for 15 sec and plated. With an initial count of 10^8 CFU/ml, results showed a decrease of 10^5 CFU/ml in survival of WDC04, indicating WDC04 could be contaminating cheese by surviving pasteurization if it is at high levels in the raw milk. Results suggest that using a higher salt/moisture ratio in cheese and increasing pre-pasteurization sanitation to remove biofilms would decrease the likelihood of *Lb. wasatchensis* WDC04 in ripening cheese, thus, reducing the possibility of late gassy defect.

Key Words: lactobacilli, cheese, gas

0549 Regional milk sourcing impact on non-starter lactic acid bacteria (NSLAB) in raw milk and cheddar cheese during aging. L. Goddik*, C. Baird, and J. Waite-Cusic, *Oregon State University, Corvallis.*

Non-starter lactic acid bacteria (NSLAB), which include lactobacilli, are found at low levels in fresh raw milk. Lactobacilli are important to the dairy industry because of their potential impact on the flavor and texture of yogurt, sour cream,

and cheese. The objective of this study was to investigate the contribution of lactobacilli from raw milk on the microbiological profile of cheddar cheese during aging (0–6 mos). Using a standardized recipe, cheddar cheeses were made with raw milk sourced from dairies on the Oregon Coast (n = 4) and in the Willamette Valley (n = 2) and aged up to 6.5 mos at 53°C. Lactic acid bacteria counts (LAB) were determined in raw milk and cheese samples using standard serial dilution and spread plating techniques on Lactobacilli MRS Agar with anaerobic incubation at 30°C for 48 h. Isolates (n = 5–10/sample) were selected for preliminary speciation using high resolution melt analysis (HRM) PCR assay targeting the V1 region of the 16S rDNA. Strains were further subtyped using a second HRM repetitive sequence-based PCR (rep-PCR). *Lactobacillus curvatus* and *L. paracasei* were identified in raw milk sourced from the Oregon Coast. *Lactobacillus paracasei* was also identified in the Willamette Valley cheeses. Species diversity decreased throughout aging in all cheeses with the exception of cheese made from milk sourced from a single dairy on the southern Oregon Coast. After 6.5 mos of aging, the predominant species across all cheeses was *L. paracasei* (40.8% of the identified isolates). Strain diversity was highest in milk sourced from the northern Oregon Coast, with six unique strains of *L. paracasei*. Evidence suggests that milk sourcing impacts the strain diversity of NSLAB present in raw milk and cheddar cheese.

Key Words: lactobacilli, rep-PCR, HRM-PCR

0550 Effect of rate of cooling and ripening temperatures on non-starter lactic acid bacteria in cheese. D. I. Khan*, and S. Anand, *Midwest Dairy Foods Research Center, South Dakota State University, Brookings.*

Non-starter lactic acid bacteria (NSLAB) play a major role in influencing cheese flavor and quality. These bacteria increase during the ripening process, and many of the heterofermentative lactic acid bacteria could lead to some typical cheese defects. Rate of cooling to different temperatures and the corresponding ripening temperatures could also affect their counts. To study this, a set of cheese samples was fast cooled to 3°C and compared with another set that was slow cooled to 10°C. These two treatment sets were each ripened at 3°C and 10°C for a period of 2 mo. Samples drawn were microbiologically analyzed using standard techniques. The selective media used included Rogosa selective *Lactobacillus* agar for NSLAB, deMan Rogosa and Sharpe (MRS) agar for specific *Lactobacillus* sp., MRS-V agar with 20 µg/ml of vancomycin for *Leuconostoc* spp., and MRS-VR agar with 2 µg/ml vancomycin and 1.5% ribose for *Lactobacillus wasatchensis*. Isolated colonies on the selective media were further identified using matrix assisted laser desorption ionization mass spectrometry-time of flight. The data were statistically analyzed, and the means were compared by a t test. Significance was declared at $P < 0.05$. At the start of the study, the NSLAB were lower ($P < 0.0001$) in samples cooled to 3°C (5.87 logs) as compared to 10°C (6.19 logs). This trend of lower NSLAB counts was maintained in samples cooled to 3°C, on further ripening at 3°C, and reached an average count of 6.00 logs at the end of 2 mo. While under similar ripening duration, the counts were 6.21 logs in the samples cooled to 3°C but ripened at 10°C. In comparison, the samples cooled to 10°C and ripened at 3°C for 2 mo showed higher counts of 6.58 logs. Similar higher counts (6.49 logs) were observed in 10°C cooled samples, which were ripened at 10°C. The predominant heterofermentative isolates included *Lactobacillus paracasei* and *Lactobacillus rhamnosus* in addition to others such as *Pediococcus acidilactici*, *Streptococcus salivarius* ssp. *thermophilus,* and *Lactococcus lactis*. None of the samples, however, showed the presence of *Lactobacillus wasatchensis* and *Leuconostoc* spp. In conclusion, fast cooling treatments to 3°C, followed by aging at 3°C would lead to lower NSLAB counts and is likely to result in a better cheese quality. This information would help cheese manufactures to choose the appropriate rate of cooling and ripening temperatures.

Key Words: cheese, ripening, NSLAB, heterofermenters

0551 Efficient removal of spores from skim milk using microfiltration: spore size and surface property considerations. E. R. Griep*, Y. Cheng, and C. I. Moraru, *Cornell University, Ithaca, NY.*

The presence of spores in milk can cause numerous quality and shelf life issues for dairy products. Microfiltration (MF) using a 1.4 µm pore size can effectively remove vegetative bacterial cells from milk and is used in commercial applications. However, this pore size may not be equally effective in spore removal. The objective of this study was to determine the effectiveness of MF using a 1.4 µm and a 1.2 µm pore size for removing spores of *Bacillus licheniformis* (BL) and *Geobacillus spp.* (GEO) from skim milk. Cell sizes of both spores and vegetative cells were evaluated by scanning electron microscopy (SEM), surface charge by zeta potential analysis, and surface hydrophobicity by contact angle measurements, in triplicate. Commercially pasteurized skim milk was inoculated in a sterilized feed tank with a spore suspension at about 10^6 spores/mL and was then treated by MF (in triplicate) using ceramic Isoflux membranes at 6°C, cross-flow velocity of 4.1 m/s, and transmembrane pressure between 69 and 74 kPa. Total aerobic plate count and spore count of the permeate were conducted. An unpaired t test was used to determine significant differences between samples at the $P < 0.05$ significance level. Vegetative cell length ranged between 2.40 and 3.82 µm and the width between 0.39 and 0.64 µm. Spores were shorter and wider, averaging 1.39–1.58 µm in length and 0.63–0.88 µm in width, thus having a higher probability to pass through a 1.4 µm membrane. Indeed, for BL (1.39 µm length by 0.63

μm width), an average spore reduction of only 2.17 log was achieved by 1.4 μm pore size. For the 1.2 μm membrane, a 4.57 log reduction was achieved. For GEO spores, their larger spore size (1.58 μm length by 0.81 μm width) allowed a practically complete removal using both pore sizes (spore counts in permeate below the detection limit). The surface properties of BL and GEO indicated that they may interact differently with the membrane. Both spore species and the ceramic membrane had negative surface charge at the milk pH, indicating slight electrostatic repulsion between them. GEO spores were hydrophilic, while BL spores were slightly hydrophobic; the ceramic membrane surface changes from hydrophilic (in unfouled state) to hydrophobic after adsorption of caseins during MF. Consequently, BL spores may experience slight attractive force to the membrane through hydrophobic interactions, which will facilitate their passage through the membrane. A good understanding of all factors that affect the removal of spores using MF can lead to the production of milk with lower spore count, higher quality, and increased shelf life.

Key Words: microfiltration, spore removal, skim milk

0552 Evaluation of microbial enzymes for degradation of exopolymeric substances (EPS) within biofilm matrices for more effective cleaning. N. Garcia-Fernandez[*1,2], A. Hassan[3], and S. Anand[2,4], *[1]Dairy Science Department, South Dakota State University, Brookings, [2]Midwest Dairy Foods Research Center, Brookings, SD, [3]Daisy Brand, Garland, TX, [4]South Dakota State University, Brookings.*

This study was conducted to determine whether biofilms on reverse osmosis (RO) membranes could be disrupted by natural crude enzymes (CE) obtained from microorganisms with the ability to degrade exopolymeric substances (EPS). The first enzyme extract (termed CE1) was obtained from a bacteriophage with infectivity for the EPS producing *Lactococcus lactis* ssp. *cremoris* strain JFR. The phage was isolated from a dairy plant environment and propagated overnight in liquid cultures of its host. The pH was then neutralized (pH 7.0) and phage particles were removed by centrifugation (75,600 × *g* for 60 min). The second extract (CE2) was obtained from supernatants of JFR cultures in 10% whey protein concentrate (WPC35), showing a reduction in its viscosity after 72 h incubation (suspected to produce hydrolases to degrade its own EPS). The third extract (CE3) was derived from supernatants of overnight tryptic soy broth (TSB) cultures of *Bacillus mojavensis* strain Bc, which hydrolyzed amylopectin and reduced viscosity of milk fermented with ropy yogurt cultures. All supernatants were microfiltered (0.22 μm) and then concentrated by ultrafiltration (10 KDa). Standard static biofilm assays were conducted by developing biofilms on 2 by 2 cm pieces of RO polyamide membrane for 24 h. The CE1 preparation was applied to JFR biofilms that were formed using M17 as the suspension medium. The CE2 was applied to biofilms formed on membranes by slime producing *Bacillus* cultures (*B. mojavensis* strain Bc and *B. licheniformis* strain K1) using TSB. The CE3 was applied to biofilms formed by a ropy strain of *Streptococcus thermophilus* (ST3534) with M17. The biofilms were treated with CE at 1% (v/v) in phosphate buffer saline (PBS) or just PBS as control at 37°C for 30 min under agitation. The viable cell counts were determined by standard culture techniques after detaching cells with stomacher. All experiments were repeated 3 times. The CE extracts obtained from the bacteriophage (CE1), JFR (CE2), and Bc (CE3) cultures reduced the counts of the respective single species biofilms by 0.5 log CFU/cm^2 (JFR), 0.3 and 0.7 log CFU/cm^2 (Bc or K1), and 0.2 log CFU/cm^2 (ST3534), respectively. These results provide an early indication that natural crude enzymes from microbial sources have the potential to selectively degrade the resistant biofilms matrices. This work also suggests that cleaning applications must contain a diverse mixture of hydrolytic enzymes to degrade the complex matrix of multiple species biofilms of dairy separation membranes.

Key Words: biofilms, enzymes, membranes

0553 Comparison of biofilm formation on stainless steel and modified surface milk plate heat exchangers. S. Jindal[*1], S. Anand[1], J. K. Amamcharla[2], and L. Metzger[1], *[1]South Dakota State University, Brookings, [2]Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan.*

Flow of milk through the plate heat exchanger (PHE) results in denaturation of proteins, resulting in fouling. This also accelerates bacterial adhesion on the PHE surface, eventually leading to the development of biofilms. In the case that milk is processed further through the fouled plates, it would result in shedding of bacteria cross-contaminated from biofilms into the product, which ultimately limits the duration of production runs. Altering surface properties, such as surface energy and hydrophobicity of the pasteurizer plates, could be an effective approach to solve this issue. This study was conducted to evaluate and compare the extent of biofouling on native stainless steel (SS) and modified surface PHEs. Raw milk was pasteurized through both the PHEs for 17 h. For microbial studies, raw and pasteurized milk samples were aseptically collected from inlets and outlets of both PHEs at various time intervals to examine the shedding of bacteria in the milk. The 3M quick swabs and ATP swabs were used for sampling from all sections of the pasteurizers (regeneration, heating, and cooling) at the end of the run, with the latter being effectively used to estimate the efficiency of Cleaning in Place. The data was statistically analyzed for analysis of variance, and means were compared. Modified PHE experienced lower mesophilic and thermophilic attachment and biofilm formation (average 1.0 and 0.99 log CFU/cm^2) in the regenerative section of the pasteurizer than those of SS PHE (average 1.49 and 1.47 logs). Higher relative light units (RLUs) were also observed

for SS PHE, as compared to the modified PHE, illustrating the presence of more organic matter on the surface of the SS PHE. In addition, at the 17th hour, milk collected from the outlet of the SS PHE experienced a sudden increase in the plate counts (5.44 log CFU/cm^2). These counts were significantly higher than those for pasteurized milk collected from modified PHE (4.12 log CFU/cm^2). This also provided evidence in favor of the modified PHE in achieving better microbial quality of pasteurized milk in long process runs. Moreover, since cleaning the SS PHE involves an acid treatment step, while only an alkali treatment step is sufficient for the modified PHE, use of the latter is both cost and time effective, making it a more ideal surface for milk processing.

Key Words: biofilms, stainless steel, modified

0554 Improved functionality of fermented milk is mediated by the symbiotic interaction between *Cudrania tricuspidata* leaf extract and *Lactobacillus gasseri* strains. N. S. Oh*, J. Y. Lee, J. Y. Joung, S. G. Kim, and Y. K. Shin, *R&D Center, Seoul Dairy Cooperative, Ansan, South Korea.*

This study was designed to investigate the cooperative effect of selected *Lactobacillus gasseri* strains and *Cudrania tricuspidata* leaf extract (CT) in enhancing the health-promoting activities of fermented milk. Addition of CT increased total bacterial counts and proteolysis during fermentation of milk with *L. gasseri* strains. Antioxidant capacities were determined by measuring the ABTS, DPPH, and peroxyl radical scavenging activities and ferric reducing power. The antioxidant capacity of CT-supplemented milk was greater than that of milk without supplementation; moreover, the antioxidant activity of CT-supplemented milk was synergistically improved by fermentation with *L. gasseri* strains. In particular, CT-supplemented milk fermented by *L. gasseri* 505 showed the highest antioxidant activity. The phenolic compounds in CT, such as neo-chlorogenic, chlorogenic, and caffeic acid, were metabolized during fermentation with *L. gasseri* strains, and 3,4-dihydroxy-hydrocinnamic acid was produced as a fermentation metabolite. Moreover, the liberation of bioactive peptides of fermented milk was increased by the proteolytic activity of *L. gasseri* strains. In particular, six peptides, which were mainly derived from β-casein, were newly identified in this study. These findings suggest that *L. gasseri* strains metabolize the phenolic acids in the CT and the bioactive peptides released through this interaction improve the antioxidant activity of fermented milk.

Key Words: *Lactobacillus gasseri*, *Cudrania tricuspidata*, milk peptide

0555 Influence of proteolytic *Bacillus* spp. on sour cream characteristics. D. Mehta*[1], L. Metzger[1], A. Hassan[2], and B. Nelson[2], [1]*South Dakota State University, Brookings,* [2]*Daisy Brand, Garland, TX.*

Bacillus spp. are frequently found as spoilage-causing microorganisms in milk and dairy products due to their heat resistant enzymes and spore formation. Hydrolysis of protein by *Bacillus* spp. has been reported in various milk and dairy products. However, limited information is available on the impact of such microorganisms on fermented dairy products. The objective of the current study was to evaluate the influence of proteolytic *Bacillus* spp. isolated from the dairy environment on physicochemical, rheological, and textural properties of sour cream during storage. *Bacillus subtilis* and *Bacillus licheniformis* were inoculated at 10^{3}cells/mL separately or together in the sour cream mix before fermentation, while mix without added *Bacillus* served as a control. The sour cream mix was fermented at 26°C using a commercial sour cream starter culture to a pH value of 4.6, followed by storage at 4°C for up to 30 d. The pH and bacterial count were monitored during fermentation and storage. Water holding capacity, rheological characteristics, and proteolysis were measured at 0, 15, and 30 d of storage. The *Bacillus* count increased by about one log during fermentation until pH 5.2, followed by a reduction in the count with a decrease in pH toward the end of fermentation. The sour cream containing *Bacillus* showed significantly ($P < 0.05$) higher viscoelastic moduli, hysteresis loop, viscosity, firmness, and proteolysis while water holding capacity and flow behavior index were lower than the control. In conclusion, this study shows that proteolysis caused by *Bacillus* during the fermentation of cultured dairy products can impact their rheological and textural properties.

Key Words: sour cream, *Bacillus*, proteolytic, texture

556 Heat tolerance of *Leuconostoc mesenteroides* as influenced by prior subjection to mild heat. I. Osorio*, and K. J. Aryana, *Louisiana State University Agricultural Center, Baton Rouge.*

Leuconostoc mesenteroides is recognized for its contribution to flavor and aroma of some cultured dairy products. Among its therapeutic benefits, it has proved to be an extremely potent cytokine producer. The anti-inflammatory effects could aid in the treatment of inflammatory conditions such as irritable bowel syndrome. In the manufacture of health beneficial new dairy products, such as probiotic cheese dips, survival of this mesophile *L. mesenteroides* would depend on its ability to tolerate high processing temperatures. The hypothesis was whether prior exposure to mild heat would enhance the heat tolerance of *L. mesenteroides.* The objective was to evaluate the effect of prior exposure to various mild temperatures for various times on the growth of *L. mesenteroides*. *Leuconostoc mesenteroides* subspp. *cremoris* Vivolac Cremosa CIT/

FPC samples were subjected to mild heat of 25°C, 35°C, or 45°C for 10 or 20 min. Samples were subsequently incubated for 24 h at 30°C followed by subjecting them to 60°C for 20 min. MRS Agar was used for plating in duplicate. Plates were incubated aerobically at 30°C for 48 h. Each experiment was conducted in triplicate. Results were analyzed using analysis of variance and Tukey mean separation. Average counts observed after subjecting mild-heat treated *L. mesenteroides* to 60°C for 20 min were 7.6 Log at 25°C for 10 min, 8.7 Log at 25°C for 20 min, 7.9 Log at 35°C for 10 min, 8.3 Log at 35°C for 20 min, 7.9 Log at 45°C for 10 min, and 8.3 Log at 45°C for 20 min. No growth was obtained when culture was not subjected to prior mild heat. Exposure of *L. mesenteroides* to mild heat enhanced its tolerance to subsequent higher heat.

Key Words: mesophile, heat tolerance

0557 *Lactobacillus plantarum* ameliorates inflammation in LPS-induced RAW 264.7 cells and DSS-induced colitis animal model.

S. H. Choi[1], S. H. Lee[1], H. J. Lee[2], and G. B. Kim[*1], [1]*Department of Animal Science and Technology, Chung-Ang University, Anseong, South Korea,* [2]*Department of Food Science and Technology, Chung-Ang University, Anseong, South Korea.*

The purpose of this study was to screen lactic acid bacteria (LAB) for anti-inflammatory activities using RAW 264.7 cells and a dextran sulfate sodium (DSS)-induced colitis animal model. Among 150 lactic acid bacteria strains isolated from healthy human feces, eight LAB strains showing excellent nitric oxide (NO) inhibitory activities were selected for further study. Peptidoglycan extracts of these strains were conducted in NO assay, western blot, and enzyme-linked immunosorbent assay (ELISA). Peptidoglycan extracts of four LAB strains significantly inhibited the production of NO related enzyme activities, such as inducible nitric oxide synthase (iNOS) and cyclooxygenase 2 (COX-2), and key cytokine levels, such as tumor necrosis factor-α (TNF-α) and interleukin 6 (IL-6), in RAW 264.7 cells. These four isolates were identified as *Lactobacillus plantarum* based on biochemical and molecular biological characterization. Additionally, the oral administration of the four LAB strains inhibited dextran sulfate sodium (DSS)-induced loss of body weight, colon shortening, and damage of colon tissue in ICR mice. Important protein level in their colon tissue, including iNOS, COX-2, TNF-α, and IL-6, were significantly reduced in the *L. plantarum* treated group. Therefore, these isolates could be used as candidate probiotic strains for the prevention and treatment of inflammatory bowel disease (IBD). We need to further investigate the mechanisms of interaction between peptidoglycans of the *L. plantarum* strain and the upstream cellular signaling mediators.

Key Words: *Lactobacillus plantarum*, anti-inflammatory, RAW 264.7 cells, dextran sulfate sodium

0558 Composition and antioxidant activity of full-fat cheese fortified with (+)-catechin, and recovery of (+)-catechin after simulated in vitro digestion.

A. Rashidinejad[1], J. Birch[2], and D. W. Everett[*3], [1]*Riddet Institute, Palmerston North, New Zealand,* [2]*University of Otago, Dunedin, New Zealand,* [3]*California Polytechnic State University, San Luis Obispo.*

(+)-Catechin, the principal catechin in green tea, was incorporated into a full-fat hard cheese at concentrations from 125 to 500 ppm to determine the extent of retention in the cheese matrix, the total cheese antioxidant activity, and recovery of catechin after in vitro digestion. Cheeses were ripened for 90 d at 8°C and digested in a gastrointestinal simulated digestion model. Measurement of pH, proximate composition, total phenolic content (TPC), and antioxidant activity after manufacture and ripening showed that the addition of (+)-catechin significantly ($P \leq 0.05$) decreased the pH of both whey and curd during cheese manufacture and ripening, but there were no significant ($P > 0.05$) differences found for moisture, protein, and fat content between the cheeses. (+)-Catechin increased TPC and antioxidant activity (measured by ferric reducing antioxidant power and oxygen radical absorbance capacity assays), although the increase was not proportional with an increasing concentration of added (+)-catechin. The retention coefficient of (+)-catechin in the curd and recovery from the mature cheese after digestion were determined by HPLC. Between 57 and 69% of (+)-catechin was retained in the cheese curd, and 19–39% (depending on the concentration) was recovered from the cheese digesta. Transmission electron micrographs showed that the ripened control cheese had a homogeneous pattern of milk fat globules with regular spacing entrapped in a homogenous structure of casein proteins, whereas the presence of (+)-catechin disrupted this homogenous structure. Evidence for interaction between (+)-catechin and cheese fat globules was provided by Fourier transform infrared spectroscopy. Association between catechin and fat globules should be taken into account when incorporating polyphenolic compounds, such as (+)-catechin, into functional cheese products to maximally retain catechin and maintain the required level of antioxidant activity without disrupting the microstructure of the cheese.

Key Words: catechin, antioxidant, digestion

0559 Prediction of fat globule particle size in homogenized milk using mid-FTIR.

D. M. Barbano[1], L. di Marzo[*1], and P. Cree[2], [1]*Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY,* [2]*Delta Instruments, Drachten, Netherlands.*

Our objectives were to develop partial least squares (PLS) prediction models using data from Fourier transform MIR (mid-FTIR) spectra to predict the particle size distributions

d(0.5) and d(0.9), surface volume mean diameter D[3,2], and volume moment mean diameter D[4,3] of milk fat globules and to validate the models. Five in-line IR homogenizers with different homogenization efficiencies were used to homogenize pasteurized modified unhomogenized milks and farm raw bulk tank milks. Homogenized milks were collected from the homogenizer outlet and then run through a mid-FTIR milk analyzer without an in-line homogenizer to collect infrared spectra of the homogenized milks for modeling. A separate portion of each homogenized milk was analyzed with a laser light scattering particle size analyzer to obtain particle size reference values. The study was replicated 3 times with 3 independent sets of modified milks and farm raw bulk tank milks. Validation of the models was done with a set of 34 milks that were not used in the model development. The PLS model factors, standard error of cross validation (SECV), and R-square for d(0.5), d(0.9), D[3,2], and D[4,3] were factors (12, 10, 12, 10), SECV (0.03, 0.12, 0.02, 0.09), and R-square (0.93, 0.88, 0.92, 0.68), respectively. The validation mean difference (MD), standard deviation of the difference (SDD), and relative standard deviation (RSD) for d(0.5), d(0.9), D[3,2], and D[4,3] were MD (−0.024, 0.019, −0.012, −0.029 μm), SDD (0.036, 0.148, 0.022, 0.110 μm), and RSD (5.47, 9.10, 4.32, 12.67%). The basis for the ability to model particle size distribution of milk fat emulsions was hypothesized to be the result of the PLS modeling detecting absorbance shifts caused by light scattering in mid-FTIR spectra of milk fat due to the Christiansen effect. The independent sample validation of particle size prediction models found that there was more variation in d(0.9) and D[4,3] predictions than the d(0.5) and D[3,2] predictions relative to laser light scattering reference values, and this may be due to variation in particle size among different pump strokes. The accuracy of the d(0.9) prediction would be fit-for-purpose for routine quality assurance to determine if the homogenizer within a mid-FTIR milk analyzer was near the failure level (i.e., d(0.9) > 1.7 μm) and needed to be replaced. This could be done as a monitoring for the daily average of the particle size performance (i.e., d(0.9)) of a homogenizer based on the mean for the day.

Key Words: particle size, homogenization, mid-FTIR

0560 Impact of mid-FTIR homogenizer performance on repeatability and predicted values for major milk components. D. M. Barbano, and L. di Marzo*, *Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

Our objective was to determine the impact of Fourier transform mid-infrared (mid-FTIR) in-line homogenizer efficiency on the repeatability and accuracy of mid-FTIR predicted fat, true protein, and anhydrous lactose determination given by traditional filter and partial least squares (PLS) prediction models. Before the experiment, the slopes and intercepts for fat, true protein, and anhydrous lactose were adjusted by running modified milk calibration samples through a mid-FTIR milk analyzer with an in-line homogenizer that produced homogenized milk with about 1.4 μm for a d(0.9). Five two-stage in-line homogenizers with different homogenization efficiencies (i.e., produced d(0.9) from 1.35 to 3 μm on unhomogenized milk) were used to homogenize unpreserved, pasteurized, externally homogenized whole milk and unhomogenized whole milk. Homogenizer selection was based on performance determined in advance using laser light scattering particle size analysis. Milk that was externally homogenized and unhomogenized milk were each tested 18 times in sequence, producing predicted values for fat B, fat A, fat PLS, true protein, true protein PLS, anhydrous lactose, and anhydrous lactose PLS. Repeatability and accuracy of fat, true protein, and anhydrous lactose determination using traditional filter models and PLS models were determined. Component predictions on externally homogenized milks (d(0.9) = about 1.0 μm) had excellent repeatability and accuracy on all components when pumped through both efficient and inefficient homogenizers. Variation in homogenizer performance on unhomogenized milks had a much larger impact on accuracy of component testing than on repeatability. The largest absolute impact was on fat measurements, producing a lower fat B test by about 0.16% at a d(0.9) of 3 μm. The fat A and fat PLS predictions were low by 0.08 and 0.07% fat, respectively, at a d(0.9) of 3 μm. Variation in homogenization had very little impact on true protein measured using the traditional filter approach but did have a larger impact on true protein predicted with a PLS model (low by 0.1% at a d(0.9) of 3 μm). Effects of variation in homogenization on anhydrous lactose predictions were small. The USDA Federal Milk Market laboratories use a d(0.9) value of 1.7 μm as a criteria to make the decision to replace the homogenizer in an IR milk analyzer. In our study, a d(0.9) of 1.8 μm produced a change in reading of < 0.04% fat and < 0.02% true protein. Both traditional filter and PLS mid-FTIR component prediction models were influenced by homogenizer performance.

Key Words: component accuracy, homogenization, mid-FTIR

0561 Lipolysis effect on milk fat and protein analysis by infrared spectroscopy using filter and Fourier transform infrared (FTIR) methods. R. M. Longo[1], L. F. Ferreira[1], F. D. A. C. Feijo[1], R. S. Conrrado[2], M. E. R. Costa[1], M. M. O. P. Cerqueira[1,2], M. O. Leite[1,2], and L. M. Fonseca[*1,2,3], *[1]Universidade Federal de Minas Gerais (School of Veterinary Medicine), Belo Horizonte, Brazil, [2]Laboratory of Milk Quality/UFMG/FUNDEP, Belo Horizonte, Brazil, [3]CNPq-Produtividade em Pesquisa, Brasilia, Brazil.*

Normal composition is an important aspect of milk quality. Infrared spectroscopy (IR) is used by most laboratories

worldwide to determine milk composition. However, the results obtained by this method may be affected if reactions, such as lipolysis, occur in milk. The objective of this work was to quantify the effect of lipolysis on milk fat and protein measurement by IR spectroscopy using filter and FTIR (Fourier transform infrared) methods. Ten liters of high quality raw milk was collected and immediately pasteurized (LTLT). This volume was aliquoted into 40-mL samples containing bronopol as a preservative. Lipolysis was induced using *Pseudomonas fluorescens* Lipase (Sigma Aldrich®; 20.000 U/g; EC number 232-619-9) added at three concentrations (100 U, 300 U, 600 U) and was followed by incubation at 7°C, 20°C, 30°C, and 40°C. Samples without enzyme addition were used as a control. Incubation periods were 0, 3, 6, 24, 48, and 96 h. IR spectroscopy methods included filter (Bentley® 2000 CombiSystem) and FTIR (CombiScope® FTIR) equipment. The experiment was a split plot design, with treatments as factorial 4 × 4 × 6 × 2 (enzyme concentrations, temperatures, incubation periods, and IR methods). ANOVA with the Duncan test (P = 0.05) were used to detect differences among treatments. There was a significant effect of milk lipolysis on milk components measured by both IR spectroscopy methods, with reduction of up 27% (2.87 g/100g to 2.08 g/100g) of fat, and increase of up to 15% (3.40g/100g to 3.92 g/100g) of protein readings for the treatments with the highest enzyme concentration and incubation at temperatures of 20°C, 30°C, and 40°C. Although component analysis in both infrared methods was affected by milk lipolysis, FTIR spectroscopy was more robust than the filter method for fat measurement ($P < 0.05$). It is concluded that lipolysis can have a significant effect on fat and protein contents measured by both IR spectroscopy methods. This is of particular concern in dairy herd improvement programs in tropical regions, where samples are usually transported and stored for long periods without refrigeration before arriving to the official laboratories. These results indicate the need for better sample management to obtain compositional results like the original samples of milk.

0562 Complimentary calcium fractionation techniques to increase coproduct solids value and utilization.

R. Singh[*1], M. Molitor[2], and J. A. Lucey[1,2], *[1]University of Wisconsin-Madison, Madison, [2]Wisconsin Center for Dairy Research, Madison.*

Soluble and precipitated calcium can be fractionated from other solids by utilizing complimentary techniques. Our research is focused on combinations of cross flow filtration together with mechanical separation via a sanitary hydrocyclone. We hypothesize that larger CaP particles are more abrasive for dairy equipment than the smaller particles. Hydrocyclones can remove large (> 50 µm) particles of CaP precipitate, before utilizing high temperature compatible, large MWCO ultrafiltration and microfiltration elements to purify and concentrate the smaller sized CaP precipitate from acid whey coproducts. Deproteinized acid whey (UF permeate) was subjected to nanofiltration (NF) to reduce the volume and impurities (lactic acid, simple sugars, and monovalent ions), which increased the calcium and phosphate concentrations. Optimal conditions for the precipitation of calcium phosphate by a combined heating/neutralization step were established as temperature 60–70°C and pH 7.0. CaP precipitates were fractionated on the basis of particle size using a sanitary hydrocyclone. We studied the impact of hydrodynamic conditions (vessel shape, agitation) on CaP precipitate size range and separation efficiency of hydrocyclone. It was observed that when neutralization/heating was done in vessels with less turbulence, the CaP particle size was bigger, which increased the hydrocyclone separation efficiency. Another significant finding was that hydrocyclone overflows from both low turbulence and high turbulence tanks have very similar particle size profiles. Apex nozzle size of the hydrocyclone did not impact separation efficiency. The small CaP particles classified into the hydrocyclone overflow were purified and concentrated using various wide pore membrane sizes of high-temperature-compatible UF and MF elements (Microdyn DS-UV200-3838 (200 kDa), DS-MP005-3838 (0.050 µm), and DSMP020-3838(0.20 µm)) membranes. It was found that the separation efficiency of CaP by either UF or MF was much better than centrifugation, as the total Ca contents in the centrifugal supernatant and MF permeate were 47.9 and 16.7 mg/100 g, respectively. Milk mineral concentrate with a small, and relatively narrow, particle size range and high CaP purity was obtained using this process (composition: 76.7% ash, 30.2% calcium, and 16.1% phosphorus (solids basis)). Study of the abrasiveness of CaP precipitate in relation to its particle size is currently in progress.

Key Words: coproducts, hydrocyclone, milk minerals, acid whey

0563 Impact of controlling the lactose to casein ratio of concentrated milks on the properties of cheddar cheese.

R. A. Ibáñez[*1], S. Govindasamy Lucey[2], J. J. Jaeggi[2], M. E. Johnson[2], and J. A. Lucey[2], *[1]University of Wisconsin-Madison, Madison, [2]Wisconsin Center for Dairy Research, Madison.*

Final pH value in cheese is determined by the amount of lactic acid in the curd as well as its buffering properties, which are determined by the concentration of casein and residual insoluble calcium phosphate. The use of concentrated milks requires the adjustment of cheesemaking parameters to achieve similar cheese composition and pH values compared with unconcentrated milks. We believe that the final pH value of cheese made from concentrated milk could be better controlled by maintaining a constant lactose-to-casein (L:CN) ratio in the milk. The objective of this study was to investigate

the effect of three casein concentrations (2.3, 2.9, and 3.2%) in milks that were standardized to a constant L:CN ratio of 1.3, on the composition, texture, functionality, and sensory properties of milled-curd cheddar cheese through 9 mo of ripening. Whole milk was concentrated by ultrafiltration, and the composition was standardized by combining retentate, permeate, and/or water to obtain appropriate CN levels while maintaining a constant L:CN ratio. Preliminary work demonstrated that increasing the CN content of milk resulted in cheeses with lower moisture content ($P < 0.05$). To keep the moisture contents similar between all CN levels, modifications to cheese manufacturing procedure (such as increasing curd particle size, depth of the milled-curd, and the salting regimen) were necessary for the milks containing higher CN levels. Cheese functionality during ripening was assessed using texture profile analysis and dynamic low-amplitude oscillatory rheology. Sensory Spectrum® and quantitative descriptive analysis were conducted with 9 trained panelists to evaluate texture and flavor attributes using a 15-point scale. Increasing the CN content of milks resulted in cheeses with lower pH, higher buffering capacity, and higher residual lactose and lactic acid concentrations ($P < 0.05$). Hardness obtained from texture profile analysis showed no differences between treatments; however, treatments made from milks with higher CN contents exhibited lower maximum loss tangent (meltability). Sensory results indicated that acidity was higher in cheeses made with increased CN ($P < 0.05$). This study suggested that to maintain similar pH values in cheeses made from concentrated milks, the L:CN ratio would need to be varied. Adjustment of the L:CN ratio of milk is a promising technique to improve the control of the final pH in cheeses made from concentrated milks.

Key Words: higher casein milk, lactose, cheddar cheese functionality

0564 Enhanced dairy membrane operations through control of deposit formation on membrane surfaces. U. Kulozik*, *Technical University of Munich, Freising-Weihenstephan, Germany.*

The objective is to present recent developments and insights on novel ways to operate dairy membrane operations at higher levels of efficiency and predictability. Boundary layer phenomena at the surfaces of membranes, in particular, adsorption, retention, and deposit formation are still not fully understood. Hence, adverse effects reducing flux and unpredictable permeation of components cannot reliably be prevented. Deposits reduce flux and in many cases dominate the system's retention characteristics. Deposit formation is dependent on the position along the membrane surface, which is a result of the pressure drop in crossflow situations. These aspects will be discussed with particular regard to whey concentration and milk protein fractionation by means of microfiltration as possibly the most challenging example. The related phenomena were investigated experimentally and theoretically in terms of assessing deposit properties (casein micelle multi-layers, in this case), such as thickness and porosity, as a function of position along the membrane. For this purpose, special membrane prototypes were constructed enabling the measurement of flux and convective transport of material through the membrane pores in four sections along a tubular, industrially sized ceramic membrane. Similarly, the effect of membrane length has been studied for spiral wound modules (SWM), which are the dominating membrane type in dairy installations. Deposit amounts and structures were assessed by means of chemical analysis and synchrotron-based X-ray analysis, using the novel GISAXS technique (grazing incidence small angle X-ray scattering). This way, casein micelle deformation was found to occur as a result of elongational flow of the filtrate stream toward the membrane surface. Further, a method for improved whey ultrafiltration performance as a result of a pre-microfiltration step is presented. The removal of protein aggregates in whey increases flux levels considerably, and a reduction of the microbial load is achieved. Novel cascade-like combinations of UF and RO/NF are discussed as a means to achieve high levels of concentration for whey and, for comparison, milk. The UF step removes the protein, such that the RO step has only to cope with osmotic pressure and remains unaffected by deposit formation. Thus, higher concentration levels and an increased flux can be achieved as well as concentration in shorter times at reduced energy levels. UF was assessed in the form of various processing concepts, namely conventional polymeric spiral-wound and ceramic crossflow systems as well as dynamic rotating ceramic membranes, which are able to produce and to cope with high protein concentration levels.

Key Words: membrane technology, microfiltration, milk protein fractionation, milk protein concentration

---

0565 Constant permeate flux microfiltration of liquid whey protein concentrate for the separation of whey proteins from fat. S. L. Beckman*[1], and L. Metzger[2], [1]*Midwest Dairy Foods Research Center, South Dakota State University, Brookings,* [2]*South Dakota State University, Brookings.*

Value added whey protein concentrates (WPC) are often processed by membrane filtration to fractionate valuable components. One such application is microfiltration (MF) applied to cheese whey to separate proteins from fats before the protein-rich fraction can be further concentrated into products containing > 80% (wt/wt) total nitrogen on a dry basis. The objective of this research was to evaluate protein recovery into permeate during MF of reconstituted WPC 50% protein on a dry basis by using constant permeate flux (CF) operation compared to conventional constant pressure (CP) operation. Typically, MF is started and operated at low (e.g., 27 to 138 kPa) and constant pressures (baseline and differential), which

could affect the long term fouling and throughput of the filter. An alternative is to maintain a constant permeate flux by modulating applied pressure during MF to modify the initial fouling, hopefully increasing protein permeation and recovery. Approximately 400 kg of liquid WPC 50% (10% solids) was made by mixing whey permeate, pure water, and liquid WPC 80%. A 200-kg aliquot was MF (0.5 µm, 6.0× mass concentration factor, 150% water diafiltration [wt/wt on a feed mass basis], 60°F) using either CP or CF operation. This was replicated three times, using different lots of WPC 50% for each replicate. During CF MF, flux (L/m^2 per h) was initially controlled by adjusting a permeate outlet valve to achieve the desired flow. As product in the recirculation loop became concentrated, flux was maintained by opening the permeate valve and then increasing the differential pressure and, thus, the inlet pressure. Pressures during CP MF were maintained at 27.6 kPa baseline and 82.7 kPa differential, giving an inlet of 110.3 kPa. Inlet pressure during CF MF increased to 172.4 kPa when the solids in the recirculation loop increased, whereas baseline pressure remained steady at 27.6 kPa. Protein (total nitrogen) recovery from feed into permeate was 63.2 ± 1.1 and 71.8 ± 4.4% for CP and CF MF, respectively. Average permeate flux during MF was 19.4 ± 3.7 and 17.4 ± 3.2 L/m^2 per h, for CP and CF MF, respectively. These results indicate that CF operation during whey MF can increase the amount of protein recovered without greatly affecting the throughput of the filtration. This research could help whey processors improve the efficiency and value of their products by implementing relatively minor changes to their processes.

Key Words: whey, microfiltration, constant permeate flux

0566 Critical factors for evaluation of cheese yield performance and fat loss in large cheese factories.

D. M. Barbano, and B. Margolies*, *Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

Our objectives were to develop a data analysis system that utilized existing data within a cheese factory to evaluate cheese yield performance and fat loss using yield formulae for cheddar and mozzarella cheese manufacturers, to determine the accuracy of input data, and determine the sensitivity of the performance evaluation results to uncertainty in the accuracy of input data. Daily cheese manufacturing and analysis data on an individual vat basis were collected (for 1 yr) from cheddar and mozzarella cheese factories that each processed about 900,000 kg of milk per day. The source and quality of all input data was identified and evaluated during repeated site visits. Observed outcomes (based on data collected in the cheese plants) for cheese yield and fat recovery were found to be very sensitive to the quality of input data for milk weight, milk fat and protein in the vat, and the moisture, fat, and salt content of the cheese. Different types and the placement of flow meters were evaluated. Milk analysis was done by mid-FTIR and cheese analysis was done with near-IR in both factories. Proficiency evaluations of the accuracy of milk and cheese analysis were conducted in comparison to physical and chemical reference methods. Observed bias differences in analytical results were used to establish ranges for sensitivity analyses. Cheese moisture and fat sensitivity analysis ranges were +0.5% and salt was +0.25% daily based on proficiency test results. This variation in moisture, fat, and salt uncertainty produced a deviation of (+)450 kg cheese/day and 225 kg cheese/day for salt. It was clear that as cheese factories have increased greatly in weight of cheese produced per day, the uncertainty in sampling and analytical accuracy of milk and cheese analysis that was adequate previously has a level of uncertainty that allows a large margin for error in controlling the financial performance of the business. A bias error in moisture with the factory laboratory being high by 0.5% moisture on cheddar was equated to a missed opportunity in 1 yr of 175,000 kg more cheese. It was concluded that given the impact on economic performance of the factory, better cheese sampling approaches and cheese analytical systems are needed to optimize and control the financial performance of the cheese manufacturing process.

Key Words: cheese yield, fat loss, cheese analysis

0567 Kinetics studies of chemical reactions in conjugated linoleic acid (CLA) enriched milk treated with high-pressure sterilization.

S. I. Martinez-Monteagudo*, *South Dakota State University, Brookings.*

Conjugated linoleic acid (CLA), a bioactive lipid naturally found in milk, is degraded through oxidation during thermal processing. Application of pressure-assisted thermal processing (PATP) reduces the thermal exposure during processing, protecting a variety of bioactive compounds. This study evaluated the impact of PATP on the CLA content at conditions where commercial sterilization has been achieved. In addition, the effect of PATP on some quality indicators was evaluated, including lactulose formation, inactivation of alkaline phosphatase, and retention of CLA during storage. At 600 MPa and 120°C for 15 min, ~78% of the CLA was retained while only ~20% was retained at 0.1 MPa and 120°C. The Weibull model was used to predict the retention kinetics of CLA. Temperature and pressure accelerated the formation of lactulose, with a maximum value of 650 mg L^{-1} at 120°C, 600 MPa, and 15 min. The PATP conditions needed to reduce 7-log of *B. amyloliquefaciens* endospores in inoculated milk were determined as well as the effect of adding nisin (4–64 mg L^{-1} milk). A reduction of 7-log was obtained after 5 min at 600 MPa and 120°C in milk with nisin added. Milk treated at 600 MPa and 120°C for 5 min was selected to evaluate the impact of PATP on the CLA retention and formation of hydroperoxides during storage. Milk with nisin added and

treated with PATP delivered higher CLA retention and a lower hydroperoxide concentration compared with the UHT equivalent process. The kinetic information obtained was used to build pressure-temperature diagrams for CLA retention and lactulose formation. The outcomes of this study are considered a step further for the development of shelf-stable milk processed by PATP.

Key Words: conjugated linoleic acid, kinetics, modeling,

0568 Impact of shear, heat and pH on the conformation, digestibility and antigenicity of lactoglobulin.
M. T. Rahaman, L. Ramchandran, and T. Vasiljevic*, *Victoria University, Melbourne, Australia.*

Processing-induced conformational changes can modulate the digestibility of food allergens and their antigenicity. Effects of pH (3, 5, 7), temperature (80, 100, 120°C), and shear (100, 500, and 1000 s^{-1}) on conformational changes (monitored by surface hydrophobicity, total thiol content, FTIR, and gel electrophoresis) and their relation to antigenicity (determined by indirect enzyme-linked immunosorbent assay) of β-lactoglobulin (β-lg) were investigated. Overall, heating at low pH (3) caused the unfolding of proteins and fragmentation by partial acid hydrolysis and thereby exposed β strands that contributed to the appearance of some hidden epitopes resulting in higher antigenicity. Heating at pH 5 and 7 decreased allergenic response due to covalently bonded molecular polymerization and aggregation, which destroyed and/or masked some epitopes. Shear alone had no effect on the antigenic response of β-lg but could have an influence in combination with pH and/or temperature. Overall, heating β-lg solutions to 120°C at pH 5 with shearing (100–1000 s^{-1}) resulted in minimal antigenicity. Structural modifications of β-lg via denaturation or SS/SH-mediated interactions can either enhance or decrease its antigenicity. Based on these results, effects of different pH (3, 5, or 7), temperature (room temperature or 120°C), and shear (0 s^{-1} or 1000 s^{-1}) on the gastrointestinal digestibility of β-lg and post digestion antigenic characteristics were further studied. Regardless of pH, unheated β-lg showed resistance to peptic digestion with high antigenic value while it was fairly susceptible to pancreatin with moderate reduction in antigenicity. Heating at 120°C significantly improved both peptic and pancreatic digestion attributed to structural alterations and resulted in much lower antigenicity; the level of reduction was pH dependent and the lowest antigenicity was recorded at pH 5. High shear (1000 s^{-1}) slightly reduced digestibility and, thereby, enhanced antigenicity of unheated β-lg at pH 5 and 7 but reduced at 120°C irrespective of the pH. Thus, treatment at pH 5, 120°C, and 1000 s^{-1} could potentially reduce post digestion antigenicity of β-lg.

Key Words: processing, shear, heat, pH, β-lactoglobulin, digestibility, antigenicity

DAIRY FOODS DIVISION SYMPOSIUM: ADVANCES IN SUSTAINABILITY WITHIN THE DAIRY PROCESSING INDUSTRY

0569 New packaging and strategies to enhance your sustainability plan.
E. Comere*, *Tetra Pak Inc., Denton, TX.*

Tetra Pak is the world's leading food processing and packaging solutions company. Working closely with our customers and suppliers, we provide safe, innovative, and environmentally sound products that each day meet the needs of hundreds of millions of people in more than 170 countries around the world. With more than 23,000 employees based in over 80 countries, we believe in responsible industry leadership and a sustainable approach to business. Technical development in the packaging industry is intense today, and everyone is trying to crack the code of sustainable packaging introducing new base materials (e.g., renewable, plant based, biodegradable, etc.), processes, and strategies. Driving innovations that address environmental impacts and designing products with the environment in mind will deliver a new competitive edge that can't be ignored. We have already seen multiple innovations in packaging over the last few years. After light weighting and recycling, the next stage of evolution and innovation is around raw material selection, with companies acknowledging our natural resource challenges and rethinking what their packaging is made of. At the same time, new packages have to meet stakeholder demands and offer good convenience while winning environmental arguments in an increasingly competitive business environment and circular economy context. It also highlights how predominant the role of packaging is in the food and drink supply chains (beyond ensuring food contents are delivered safely to consumers, it helps reduce food waste). This session will focus on packaging trends and new sustainable material options, sustainable sourcing, i.e., expanding focus from the end of life of the package (reuse/recycling) to the beginning of a package's life cycle and increasing use of renewable materials responsibly sourced, and understanding the nature of consumer knowledge (including gaps) surrounding sustainable packaging practices

Key Words: sustainable, environment, renewable

0570 Life cycle environmental assessment of yogurt production and consumption in the USA.
Y. Wang*[1], G. Thoma[2], D. Kim[2], and J. Burek[2], *[1]Innovation Center for U.S. Dairy, Rosemont, IL, [2]University of Arkansas, Fayetteville.*

The innovation Center for U.S. Dairy commissioned and jointly conducted a life cycle assessment (LCA) of the yogurt supply chain focused on defining potential environmental

impacts with the University of Arkansas. The system boundaries for this study include milk production, yogurt processing, filling and packaging, retail, and finally consumption of the yogurt including disposal of the packaging material. Estimated impacts in various unit processes (milk production, processing, packaging, transport, retail, and consumption) including product losses at each stage are reported and discussed. The functional unit is 1 kg of yogurt products consumed by U.S. consumer as sold at retail, for the year 2013. LCA data were analyzed using stochastic methods (Monte Carlo simulation) to quantify and characterize uncertainty. The impact categories used in the evaluation include climate change, photochemical oxidant formation, cumulative energy demand, freshwater eutrophication, freshwater depletion, water eutrophication, human toxicity, and marine eutrophication, ecosystems, and ecotoxicity. Here, the environmental profile is defined as the comprehensive set of inventory and impact assessment results. The report also provides interpretation and evaluation of the results to help identify the potential risks and opportunities in the yogurt production value chain. The overall cradle-to-grave GHG emissions for set, stirred, and nontraditional Greek yogurt as sold at retail were found to be 6.03, 4.98, and 7.65 kg CO_2e per kg of yogurt consumed, respectively. Using a simulated traditional Greek yogurt plant for production LCI, the cradle-to-grave greenhouse gas emissions were estimated to be 8.92 kg CO_2e per kilogram consumed. In the cradle-to-grave assessment, production of milk is the dominant contributor to most environmental impacts, and thus ongoing industry efforts to improve milk production will lead to improvements in the yogurt manufacturing sector as well. In the farm-gate-to-retail-gate analysis, yogurt transport was the single largest GHG emission contributor followed by ingredients, electricity, and packaging materials. The results suggest that careful optimization of the transport distances and the selection of transport refrigeration system using low-GWP refrigerants could reduce environmental impacts.

Key Words: yogurt, LCA, environmental impact

0571 Using big data to drive sustainable CIP. J. Curran*, *Ecolab, St. Paul, MN.*

The promise of big data as a means to drive process consistency and conformity is alluring to many industries; however, the execution often falls short of the desired outcome due to a lack of analytical resources or an inability to capture the key metrics that help drive decisions. In food and beverage processing, much of this data is already captured using existing plant instrumentation. Further, the trend has been toward recording this information electronically to allow for more data points and faster analysis; however, this data is rarely used to its fullest potential. It is stored as required, and reviewed as necessary. In the development of a new platform, Ecolab has created a method of transforming this data into actionable information, allowing customers to utilize their own data around Clean in Place, coupled with new devices to more accurately measure chemical concentration. This data is captured and utilized in process-specific algorithms to drive sustainability, profitability, and product quality. The result has been a dramatic reduction in water, energy, chemistry, and time consumed for CIP, while at the same time achieving a quantifiable increase in product quality. This is often achieved simply due to the increased process visibility, enhanced analysis, and the increased consistency and conformity that results from the analytical process and does not require large capital investment. Using big data in food and beverage processing facilities to drive sustainability has proven itself as a concept. It does, however, require process understanding and a focus on the drivers within each facility to ensure that change is made in a way that positively impacts both sustainability and product quality, food safety, and brand protection.

Key Words: CIP, analytics, sustainability

0572 Processing sustainability: ideas to create a comprehensive effort. D. Skidmore*, *Hilmar Cheese Company, Inc., Hilmar, CA.*

Hilmar Cheese Company, Inc. was recognized with the 2015 Outstanding Dairy Processing & Manufacturing Sustainability award by the U.S. Dairy Sustainability Awards. The company's Headquarters & Innovation Center was designated LEED Platinum® (Leadership in Energy and Environmental Design) in 2014. The company has produced an annual commitment to sustainability report since 2010 documenting progress and improvements and sharing this information with customers and consumers. The publicized report follows the Stewardship and Sustainability Guide for U.S. dairy, a voluntary framework for tracking and communicating progress. It also incorporates some of the methodologies outlined in the Global Reporting Initiative. The company tracks and improves in four key areas: environment, employees, economic value, and community engagement. The conference presentation will highlight activities in each key area, including water recycling and reuse, solid waste reduction, employee engagement, and community education.

Key Words: corporate responsibility, environmental stewardship, economic value, social responsibility, water reclamation

DAIRY FOODS DIVISION SYMPOSIUM: INCREASING UTILIZATION OF DAIRY CO-PRODUCTS

0573 Consumer demand, innovation, and opportunity for co-products. B. Graves*, and R. Kapoor, *Dairy Management Inc., Rosemont, IL.*

Due to their superior nutritional quality, dairy ingredients and co-products can play a key role to meet the unmet consumer demand for production of healthy, convenient, and great tasting dairy and dairy-based products that fit the way people live today. The successful introduction of new dairy products, such as Greek yogurt, as well as the increasing production of milk and whey protein concentrates has driven the creation of new co-products like Greek yogurt whey, milk and whey permeates, delactosed-whey, and milk minerals. These co-products need to have value-added utilization to increase the value of farmer's milk, improve sustainable nutrition, and decrease the carbon footprint of dairy products. There are opportunities to develop novel technologies to enhance the utilization co-products to advance our Nation's ability to produce dairy ingredients that cannot only be used in applications such as food aid, nutritional beverages, meal replacers, infant formula, and medical foods but also help food companies fulfill the current consumer trends related to high protein, clean label, and health and wellbeing.

Key Words: whey, permeate, co-products

0574 Permeate use as a sodium replacer/flavor implications. M. Drake*, *Southeast Dairy Foods Research Center, North Carolina State University, Raleigh.*

Whey and milk permeates are co-products of high-protein powder manufacture. Permeates are comprised of minerals, lactose, and organic acids. Permeates contain sodium, but potassium and organic acids contribute salty taste enhancement. As such, permeates provide value added opportunities for solids as well as sodium replacement in many foods. Sensory and chemical properties of permeates from different whey and milk sources and ingredient applications will be addressed.

Key Words: permeate, sodium reduction, dairy foods

0575 Fractionating acid whey into value-added ingredients. K. E. Smith*, *University of Wisconsin-Madison, Madison.*

There has been a huge expansion in acid whey production due to the rapid growth in Greek yogurt manufacture. Acid whey is difficult to process for many reasons, and whey from Greek yogurt manufacture is no exception. Traditionally, recovery of the whey protein has provided an economic incentive to process whey; however, Greek yogurt whey is especially low in protein as compared to other sources of acid whey, and therefore, it is more difficult to justify the expense of converting the whey into dairy ingredients as opposed to disposal. The objective of our research is to find economical methods to recover/convert the nonprotein components in Greek yogurt acid whey into value added ingredients. Membrane filtration has been used for many decades in the dairy industry to fractionate components. Our focus is on reducing the calcium content of the UF permeate from Greek yogurt acid whey through the use of novel nanofiltration membranes. Calcium can interfere with the production of ingredients, such as crystalline lactose and hydrolyzed lactose syrups. Excessive calcium incorporation into the lactose crystal results in crystalline lactose that does not meet specifications for U.S. food grade lactose, and hydrolyzed lactose syrups with high mineral contents may taste salty. Nanofiltration membranes traditionally are able to permeate monovalent ions like chloride, while retaining divalent ions such as calcium. The membranes evaluated in our study had been modified such that calcium could also permeate. Our results indicated lactose and calcium permeated the novel NF membranes to differing degrees as compared to the control NF membrane that did not permeate either component. Varying temperature, pressure, and concentration of the starting permeate during NF resulted in changes in the relative permeation of lactose and calcium. Using a modified NF membrane, we were able to concentrate permeate from Greek yogurt acid whey to approximately 25% total solids. A lactase enzyme with an acidic pH optimum was then added to produce a dairy syrup with enhanced sweetness and a reduced salty flavor as compared to a control made with a traditional NF membrane. The ability to economically remove calcium from the UF permeate should enable processors to recover value from the permeate of products like Greek yogurt acid whey.

Key Words: acid whey, membrane processing, nanofiltration

0576 Demineralization of delactosed permeate and acid whey. J. K. Amamcharla*, *Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan.*

The dairy industry is continuously working on novel technologies for producing value added products or ingredients with superior functional and nutritional qualities. Consequently, a coproduct that is relatively low in value is also being produced. It is equally important to look for new ways to increase the market for these coproducts. For example, delactosed permeate (DLP), a coproduct, is obtained after recovering milk proteins and most of the lactose from milk or whey permeate. Milk proteins are removed by using ultrafiltration processes, and lactose is separated by crystallization processes. DLP does not have a standard of identity or a defined composition. The

high moisture content (60 to 75%) and presence of organic acids poses a challenge to use it as a food ingredient without further processing. Researchers have studied the thermodynamics of moisture migration in DLP. Greek yogurt whey is compositionally different from cheese whey and, thus, poses economic and environmental challenges to the dairy industry. Greek style yogurt in the United States is one of the largest growing sectors in the dairy industry. Greek yogurt is produced by removing a part of water and water-soluble components from yogurt. Consequently, a large quantity of Greek yogurt whey (GYW) is being produced as a co-product. The objective of the present work was to present a review of newer knowledge on the manufacture and utilization of dairy co-products. It includes evaluations of the use of magnetic fluid treatment (MFT) and addition of clay minerals as alternative methods for separating valuable DLP and GYW components.

Key Words: demineralization, delactosed permeate, Greek yogurt whey

0577 Advancements in drying lactose and acid whey.
J. G. Ronckers*, *Relco, Willmar, MN.*

Aspects involved in the drying of whey and its lactose containing co-products will be highlighted, including lactose crystallization and its influences on lactose crystallization rates and drying efficiency. Glass transition, thermo plasticity, and the sticky line will be defined and discussed in relation to post crystallization in the dryer. Challenges with the Maillard reactions (nonenzymatic browning) and caking of the powder will be discussed. Drying of crystallized lactose, for instance, and the application of the "CrystaLac," a lactose crystallizing evaporator that helps increase yields, will be discussed. Methods of crystal separation and refining will be covered. Details will be shared about how lactose drying is conducted in 2 stages, using a primary attrition dryer with built in powder moisture and size classifier and a secondary stage for after drying and cooling with a fluid bed. Drying of permeate and sweet whey will be covered, including the "HiCon," a high concentration evaporator, the "CCC" Cooling, Concentration, and Crystallizing unit, and the dryer. The influences of lactose crystal sizes on drying efficiency will be covered. Finally, challenges of drying acid whey will be discussed. We will also discuss the crystallization of lactose and sticky components in acid whey and the challenges that we face when drying acid whey. The history of drying acid whey will be summarized. Future possible solutions will be proposed, such as increased crystallization by higher solids, small crystal sizes, membranes to filter out sticky components, humidity control of dryer exhaust air to prevent sticky powder, and the use of a desiccator for decreasing and controlling drying air humidity to be able to dry at lower temperatures.

Key Words: lactose, whey, crystallization, drying, co-products

0578 Lactose derivatives and GOS as prebiotic fibers.
T. C. Schoenfuss*, *University of Minnesota, Department of Food Science and Nutrition, St. Paul.*

Lactose is a disaccharide in dairy ingredients and co-products that can be polymerized by both chemical and enzymatic reactions into soluble dietary fiber. Products of each of these manufacturing processes can also be prebiotics if they have demonstrated benefits such as the positive modulation of gut microbiota and improvements in other indicators of digestive health. The enzymatic reaction involves incubating the enzyme β-galactosidase with lactose under specific concentration and temperature conditions to favor the polymerization reaction over hydrolysis. The polymerized product of this reaction is called galactooligosaccharides (GOS). The source of the β-galactosidase enzyme greatly affects the temperature requirements for polymerization, the products of the reaction (the amounts of branching and degree of polymerization), and temperature stability of the enzyme. Polymerization of lactose can also be achieved through reacting acid with lactose during heating. This can be achieved under vacuum or pressure during heating either in batch or continuous processes. The degree of polymerization and branching can vary greatly depending on the reaction conditions. The products of this reaction are called polylactose. This seminar will provide an overview of the production of both types of products and an evaluation of these fibers for prebiotic activity.

Key Words: fiber, polymerization, GOS

EXTENSION EDUCATION

0579 S survey of serum trace mineral concentrations in weaned Montana ram lambs.
C. M. Page*[1], M. Van Emon[1], S. Spear[1], T. W. Murphy[2], J. G. P. Bowman[1], and W. C. Stewart[1], *[1]Montana State University, Bozeman, [2]University of Wisconsin-Madison, Department of Animal Sciences, Madison.*

Clinical and subclinical trace mineral deficiencies can limit productivity in western sheep production systems. The objective of the study was to quantify trace mineral status among Montana ram lambs post weaning. Based on prior research investigating forage trace mineral concentrations and trace mineral status in cattle, we hypothesized that clinical and subclinical deficiencies would be most prominent with Zn and Se. To test this hypothesis, serum samples (n = 201) were collected from ram lambs 8 to 10 mo of age (BW 52.8 ± 16 kg) at 21 locations throughout Montana and analyzed for Co, Cu, Fe, Mn, Mo, Se, and Zn. The average concentration and range for each trace mineral analyzed in the serum samples were Co (1.00 ± 0.079 ng/mL, 0.09–6.22 ng/mL), Cu (0.84 ± 0.016 µg/mL, 0.3–1.61 µg/mL), Fe (154.85 ± 3.682 µg/dL, 26–350 µg/

dL), Mn (2.56 ± 0.225 ng/mL, 0.7–31.3 ng/mL), Mo (40.14 ± 5.001 ng/mL, 2.8–456.5 ng/mL), Se (111.42 ± 3.31 ng/mL, 16–197 ng/mL), and Zn (0.73 ± 0.015 µg/mL, 0.3–1.74 µg/mL). The two most deficient and marginally deficient minerals across Montana were Se (19% of ranches deficient and 24% of ranches marginally deficient) and Zn (14% of ranches deficient and 52% of ranches marginally deficient). All Se deficient samples were obtained from western Montana. There was considerable variation in serum trace mineral concentrations within individual flocks. Descriptive statistics were analyzed using SAS. Given that Se and Zn play major roles in growth, fertility, and immunity, results suggest opportunities for more effective supplementation strategies. Producers and nutritionists alike can use these results to identify mineral deficient areas and develop cost effective mineral supplementation management practices.

Key Words: trace minerals, zinc, selenium, Montana, sheep, ram lambs

0580 Breakfast on the farm event is an effective learning activity and improves consumer perceptions of dairy production.

J. M. Smith[*1], and T. A. Ferris[2], *[1]University of Vermont, Burlington, [2]Michigan State University, East Lansing.*

Educational farm tours, such as Breakfast on the Farm, provide the public an opportunity to learn firsthand, ask questions of farmers and other professionals, and give feedback about modern food production. Vermont held its first Breakfast on the Farm event on a dairy farm in August 2015. Patterned after the Breakfast on the Farm events in Michigan, the event was designed to educate consumers on key areas of concern: animal care, environmental protection, and food safety. Educational stations, coordinated by UVM Extension, were placed along a walking tour of the farm facilities allowing visitors to see cow and calf housing, milking facilities, and how feed is produced and fed. An exit survey instrument consisting of pre-post questions evaluated what participants learned and their change in perceptions of several agricultural practices. Of 550 visitors, 227 who were at least 18 yr old completed the questionnaire. Almost half of respondents had visited a working dairy farm fewer than 3 times before this event. On a 5-point scale from very little to very much, respondents indicated how much was learned about how cows are housed (4.08), what cows eat (3.91), how cows receive health care (3.38), how antibiotics are kept out of the food supply (2.87), how technology is used in dairy production (4.33), how farmers protect water quality (3.34), how calves are cared for (3.76), and how crops are grown and stored (3.60). First-time visitors gained the greatest knowledge about how technology is being used and how cows are being housed. On a 5-point scale where 1 is strongly disagree and 5 is strongly agree, first-time visitors had an average score increase of 0.56 between their before and after tour ratings of their agreement with statements that dairy farmers are treating animals humanely, protecting water quality, using pesticides responsibly, and using antibiotics responsibly. The greatest change in beliefs was about dairy farmers treating animals humanely with a mean increase of 0.74 and 0.51, respectively, among first-time visitors and all respondents. The percentage of first-time visitors agreeing or strongly agreeing that farmers treat animals humanely increased from 61% to 91% after touring the farm. Before and after differences were significant at $P < 0.005$ (paired t test) for all questions. This event improved consumer knowledge and impressions about modern dairy farms and management practices.

Key Words: educational farm tour, consumer perception, modern dairy production

---

0581 Breakfast on the farm, an educational farm tour, improves consumer trust in animal care, food safety, and modern conventional dairy production.

T. A. Ferris[*1], J. M. Smith[2], E. M. Richer[3], M. Welker[3], J. Stechschulte[3], M. A. Dunckel[4], and A. E. Kuschel[5], *[1]Michigan State University, East Lansing, [2]University of Vermont, Burlington, [3]Ohio State University Extension, Wauseon, [4]Michigan State University Extension, Alpena, [5]Michigan State University Extension, Clinton Twp.*

In 2015, five Breakfast on the Farm (BOTF) educational dairy tours were held in Michigan (MI) with 12,068 participants, one in Ohio (OH) with 3009 participants, and one in Vermont (VT) with 550 participants. Exit surveys were collected from 1406, 578, and 220 participants from MI, OH, and VT, respectively, to determine the impact of educational farm tours on consumer trust in animal care, food safety, and modern food production. Thirty-seven, 60, and 25% of participants from MI, OH, and VT, respectively, had not visited a working dairy farm in the past 20 yr (first-time visitors). Upon exiting the tour, participants were asked about their level of trust on topics "before" and "after" the tour on a 5-point scale from 1 being very low to 5 being very high trust. The mean (± SD) for before, after, and change (after–before) for first-time visitors' level of trust in modern food production were, respectively, 3.60 (± 1.14), 4.50 (± 0.75), and 0.90 (± 0.94) for MI; 3.68 (± 1.13), 4.44 (± 0.89), and 0.76 (± 0.86) for OH; and 3.96 (± 1.02), 4.59 (± 0.80), and 0.63 (± 0.89) for VT. First-time visitors' level of trust that dairy farmers will do the right thing in caring for food-producing animals for before, after, and change, respectively, were 3.94 (± 1.07), 4.69 (± 0.59), and 0.75 (± 0.93) for MI; 4.00 (± 1.04), 4.64 (± 0.68), and 0.64 (± 0.89) for OH; and 3.88 (± 1.03), 4.57 (± 0.73), and 0.69 (± 0.88) for VT. First-time visitors' level of trust that dairy farmers will do the right thing to safe-guard milk for before, after, and change, respectively, were 4.02 (± 1.03), 4.75 (± 0.53), and 0.73 (± 0.95) for MI; 4.11 (± 1.01), 4.71 (± 0.58), and 0.60 (± 0.91) for OH; and 4.24 (± 0.82), 4.73 (± 0.53), and 0.49 (± 0.64) for VT. All mean increases (after–before)

were significant at $P < 0.005$ using a paired-*t* test. Forty-five, 44, and 41% of MI, OH, and VT participants, respectively, rated farmers' efforts to prevent milk from cows treated with antibiotics from being sold to the consumer as a major factor for increasing their trust, and 42, 44, and 65% of MI, OH, and VT participants, respectively, rated their comfort with how animals are housed and managed as a major factor. Exit surveys show educational farm tours increase the level of trust consumers have for animal care and housing, food safety, and modern dairy farms.

Key Words: educational farm tours, consumer trust, modern food production

0582 Creation, delivery, and assessment of the livestock education and certification for agricultural law enforcement extension program. C. Wickens*[1], M. J. Hersom[2], R. G. Easterly III[1], E. Jennings[1], B. Myers[1], J. Shuffitt[1], B. Stice[1], and J. Weir[1], [1]*University of Florida, Gainesville,* [2]*Department of Animal Sciences, University of Florida, Gainesville.*

Many law enforcement and government agencies have dedicated law enforcement officers (LEOs) who respond to agricultural crime, agricultural inspection, urban/rural interface issues, and potential livestock neglect cases. These LEOs are potential Extension clients with educational needs. We partnered with Farm Bureau and Florida Department of Agriculture and Consumer Services to develop and implement a training and certification program for Florida LEOs in the field of animal science. The accompanying certification program adds credibility to this clientele group when they present testimony in court and make difficult decisions in cases. Using backward design methodology, a curriculum relevant to the needs of LEOs was developed and delivered by subject matter experts. A pilot program was delivered to a group of veteran LEOs in July 2014. Survey and focus group data obtained from pilot participants were used to modify program content. Three classes were offered to 52 individuals in March and December 2015 and in March 2016. Instruction used a combination of classroom and experiential learning sessions utilizing applicable equipment and live animals. Daily homework assignments and quizzes were administered to enhance retention. Final assessment to achieve certification included six hands-on exercises to demonstrate proficiency and a written, multiple-choice examination. Statistical analysis of survey data was performed using the UNIVARIATE procedure in SAS (v9.2). 94% of the participants passed the certification requirements of the program, and overall subject matter knowledge increased by 36%. Likert scale responses (1 = very little, 2 = little, 3 = some, 4 = much, 5 = very much) regarding knowledge of 14 subject matter topics before (2.89 ± 0.11) and after (3.83 ± 0.07) indicated a mean increase of 0.91 ± 0.09 units. Subject matter knowledge with a > 1 unit increase included cattle (1.40 ± 0.15) and equine (1.43 ± 0.14) body condition scoring, equine behavior (1.00 ± 0.15) and learning lab (1.07 ± 0.12), and animal nutrition (1.13 ± 0.11). Likert scale responses (1 strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly agree) indicated the usefulness of information to participants when working in the field (4.20 ± 0.10), whether participants feel better prepared to respond (4.20 ± 0.08), and whether instructors presented the material clearly (4.34 ± 0.07). The LECALE program addresses specific core curriculum to improve LEOs knowledge and skills. Utilization of the LECALE program by Florida LEOs could result in a savings of nearly $2,500 per client compared to other national certifying services.

Key Words: law enforcement, livestock, training

0583 Benchmark demographics of the Mississippi feeder calf board sale program. E. A. Caldwell*[1], B. B. Karisch[1], J. M. Riley[2], and J. A. Parish[3], [1]*Mississippi State University, Mississippi State,* [2]*Oklahoma State University, Stillwater,* [3]*Mississippi State University, Prairie.*

The semi-annual Mississippi feeder calf board sale program serves as an opportunity for beef cattle producers to build a more successful marketing strategy in the feeder cattle sector. The board sales encourage more uniform load-lots in addition to reduced shrink, handling, and comingling before shipping due to the off-site marketing of calves. Established in 2008, the program has recorded 309 total lots sold consisting of nearly 25,000 heads of cattle, with the receipts from these sales exceeding $19 million. To examine benchmark values of the board sale program, lot demographics of each sale were analyzed using the Proc Means procedure of SAS. Frequencies of hide color characteristics reveal that 92.6% of all lots sold advertised some percentage of black-hided cattle, followed by 47.2% of lots with smoke color, 43% with red, and 18.1% with white color. Specifically, 64% of all lots consisted of at least 75% black cattle, 36.6% of lots contained less than 25% red cattle, and 34% contained less than 25% cattle with smoke hide color. Lots marketed with Brahman influence represent 14.2% of lots sold. The mean weighted average lot body weight per calf across all years was 315.3 ± 4.4 kg. Results show that 0.3% of lots had a weighted average body weight per calf of less than 226.8 kg, 5.9% weighed 226.8 to 271.2 kg, 47.6% weighed 272.2 to 317.1 kg, 30.6% weighed 317.5 to 362.4 kg, 15.3% weighed 362.9 to 407.8 kg, and 0.3% weighed more than 408.2 kg. Mixed gender lots comprised 45.3% of all lots sold, followed by steer-only lots at 33.7% and heifer-only lots at 21%. Use of growth-promoting implants was advertised for 12.6% of total lots, whereas 20.4% of lots marketed cattle produced without growth promotants. Participation results indicate fewer lots per sale since 2008 accompanied by a slight increase in number of heads per sale due to increased number of heads per lot sold. Furthermore, price trends of the board sale program indicate a steady increase in selling price

throughout its history. In summary, the Mississippi feeder calf board sale program continues to provide producers a viable alternative marketing strategy. The specific attributes of each lot are central to its selling value, as consistent and industry-recognizable lot characteristics may bring premiums at sale.

Key Words: board sale, feeder calf, marketing

0584 The show-me-select replacement heifer program: adding value to beef herds in Missouri.

J. W. C. Locke*, J. M. Thomas, B. E. Bishop, J. M. Abel, S. E. Poock, D. S. Brown, J. E. Decker, and D. J. Patterson, *University of Missouri, Columbia.*

The Missouri Show-Me-Select Replacement Heifer Program was designed to improve reproductive efficiency of beef herds in Missouri and increase individual farm income. During the past 18 yr, 822 farms enrolled 122,970 heifers in the program. Regional extension livestock specialists work closely with the 243 veterinarians involved with the program state wide. State specialists provide program support to regional extension field staff and participating veterinarians. The marketing component of the program facilitated the sale of 30,539 heifers in 141 sales from 1997 through sales in 2015. These sales generated interest from 9484 prospective buyers that formally registered to buy heifers and 3366 individuals that purchased heifers from the various sales. Heifers from the program have now sold to farms in 19 states. Collectively, 141 sales have generated $42,984,650 in gross sales. A Tier Two classification was created recently that distinguishes heifers from genetically superior high accuracy sires. Using data from the Fall 2015 sales, in which Tier Two heifers sold, we may consider opportunities for producers to add value to their heifers as a result of improvements in genetic merit. Using the average sales price of Show-Me-Select qualified heifers carrying a natural-service sired pregnancy as a baseline sale average, we can make the following comparisons to determine the relative added value that resulted from improvements in genetics of the heifer and/or the pregnancy the heifer was carrying: Show-Me-Select heifers carrying natural-service sired pregnancies sold for an average sale price per heifer of $2,242; Show-Me-Select heifers carrying AI-sired pregnancies sold for an average sale price per heifer of $2,437, adding $195 per heifer; Tier Two Show-Me-Select heifers carrying natural-service sired pregnancies sold for an average sale price per heifer of $2,371, adding $129 per heifer; and Tier Two Show-Me-Select heifers carrying AI-sired pregnancies sold for an average sale price per heifer of $2,664, adding $422 per heifer. The Missouri Show-Me-Select Replacement Heifer Program is the first statewide on-farm beef heifer development and marketing program of its kind in the U.S. Impact on Missouri's economy that resulted from the past 18 yr of the Show-Me-Select program now exceeds $110M.

Key Words: added value, beef heifer, extension program

0585 Perceived mastitis costs and milk quality management practices among Southeastern United States dairy producers.

D. T. Nolan*[1], C. Blakely[2], P. D. Krawczel[2], C. S. Petersson-Wolfe[3], G. M. Pighetti[2], A. Stone[1], S. Ward[4], and J. M. Bewley[1], *[1]University of Kentucky, Lexington, [2]University of Tennessee, Knoxville, [3]Virginia Tech University, Blacksburg, [4]Mississippi State University, Mississippi State.*

Researchers from four universities in the southeastern United States completed 175-question surveys on 282 farms in TN (n = 83), KY (n = 96), VA (n = 96), and MS (n = 7) from June 22, 2014 to June 21, 2015 as a part of the Southeast Quality Milk Initiative project. The objective of this study was to analyze questions focusing on the costs associated with milk quality management and to quantify dairy producer estimates of mastitis costs. The MEANS procedure in SAS 9.3 (SAS Institute, Cary, NC) was used to summarize costs of pre- and post-milking teat disinfectants, intramammary antibiotics for mastitis treatment, vaccinations, and producer estimates of subclinical and clinical mastitis costs. The average costs associated with specific management practices and producer estimates of mastitis costs are presented in Table 1. One hundred twenty-four and 126 producers provided enough information to allow the researchers to calculate the costs of pre- and post-milking teat disinfectants per cow per day, respectively. Two hundred seventeen producers provided the researchers enough information to determine the cost of intramammary antibiotics per mastitis case. Only 52 and 3 producers provided enough information to calculate the costs of environmental and contagious mastitis vaccines per cow, respectively. When estimating the cost of clinical and subclinical mastitis, 241 and 208 producers provided a numerical estimate, respectively. Remaining producers either did not know or did not provide an estimate. These results provide new insights into producer perception of mastitis and milk quality economics.

Key Words: costs, mastitis, milk quality, SQMI

0586 Development of a web-based calendar tool f or scheduling beef cow management activities.

D. Poddaturi[1], S. Johnson*[2], G. R. Dahlke[1], D. A. Blasi[3], and G. Hanzlicek[4, 1]*Iowa State University, Ames, [2]Kansas State University, Colby, [3]Department of Animal Science and Industry, Kansas State University, Manhattan, [4]Kansas State Veterinary Diagnostic Laboratory, Manhattan.*

Extension efforts often remind producers of timely management practices and their value. Recommendations must

revolve around presumed average time of activities, such as calving and weaning. The objective of the current project was to develop a web-based cow/calf management tool to create a customizable yearly production calendar. The Management Minder (MM) was designed for beef cattle producers to facilitate the timely implementation of routine management steps to optimize health, nutrition, reproduction, and general management. The MM helps beef producers schedule routine activities based on default intervals from the appropriate date category (calving/breeding, weaning, grass turnout, and receiving cattle), and communicate these events to other members of the management team. An automatic portion adds all of the activities in a particular category and a check box is used to eliminate those not needed. Activities can also be added one at a time in a manual build portion. The program emails an ics file of user selections that can be imported by OUTLOOK™, GOOGLE™, and YAHOO™ calendar systems. Thus automatic reminders are put in place so that adequate time is allowed for cow weight gain in the third trimester, AI breeding programs can be planned, or all needed supplies can be obtained in advance of processing days. Users register on the website http://cowweb.exnet.iastate.edu/CowWeb/faces/ with a unique farm/ranch name. The application provides an option to register multiple users under the same operation. Other family/team members, consultants, or veterinarians can be given access to add events to the same farm/ranch calendar. Veterinarians can set up health programs in a calendar form for individual clients. The calendar showing the upcoming activities can be used for planning and to improve communication among team members. A dynamic database stores events for each particular farm/ranch so they can be automatically advanced to the next year, minimizing the time needed for set-up in subsequent years. Supporting information or references regarding best management practices for the selected activities are provided as web links and can be easily updated. Since the program was first made available in January 2016, user suggestions have been incorporated to improve the tool. The concept is applicable to many areas of plant and animal management that function in biological and environmental cycles. Users of this free tool have the opportunity to improve the timeliness of management activities, improve communication with partners, and reduce costs associated with forgotten or delayed management.

Key Words: calendar, cow/calf, extension

0587 Comparing the Penn State and NRC 2001 heifer ration programs. L. K. Mitchell*, and A. J. Heinrichs, *Pennsylvania State University, University Park.*

Formulating dairy heifer rations is an often overlooked aspect of farm feeding programs. The Penn State dairy heifer diet formulator (PSU-HDF) was originally developed to design and evaluate diets used in heifer research. The current objective was to evaluate differences between the PSU-HDF and the 2001 NRC program. Drawing from fundamental heifer studies at Penn State, the basis for diet formulation in PSU-HDF is N intake (g/kg of metabolic body weight) with a target of 1.67 g of N/kg $BW^{0.75}$. In contrast, the NRC emphasizes the intake of crude protein (CP) and its fractions. Furthermore, the NRC recommends dairy heifer diets to meet certain dry matter intakes (DMI) in addition to meeting metabolizable energy (ME) requirements. Research at Penn State has demonstrated that varying DMI can produce similar average daily gains (ADG) provided the diet precisely meets the ME requirements. Therefore, PSU-HDF places more emphasis on meeting ME needs and adjusts DMI as necessary. For a heifer at 6 mo weighing 200 kg targeting an ADG of 800 g, the NRC recommends a diet with 14.2% CP, 11.9 Mcal/d ME, and 5.2 kg/d DMI. Using PSU-HDF, the same heifer had her needs met by a diet with 13.6% CP, 11.7 Mcal/d ME, and 4.3 kg/d DMI. A heifer at 14 mo weighing 400 kg targeting an ADG of 800 g was recommended by the NRC to receive a diet with 11.3% CP, 20.1 Mcal/d ME, and 8.8 kg/d DMI. The diet for the same heifer using PSU-HDF was 13.1% CP, 19.7 Mcal/d ME, and 7.1 kg/d DMI. Comparing the output of these two models, we find that the NRC model often predicts 20% more DMI and 60 to 155 more g CP intake. The NRC recommends 0.2238, 0.2247, and 0.2247 Mcal/kg $BW^{0.75}$ of ME for heifers at 200, 300, and 400 kg, respectively, when targeting an ADG of 800 g. These values are consistently higher than PSU-HDF recommendations of 0.2199, 0.22, and 0.22 Mcal/kg $BW^{0.75}$ of ME for heifers with the same parameters. These results show consistent overestimation of nutrient requirements by the NRC program. According to our research trials using precision and ad libitum formulation, the PSU-HDF model will allow nutritionists to formulate diets to meet dairy heifer needs and reduce feed cost by feeding less protein and dry matter.

Key Words: dairy heifer, diet formulation

0588 Motivations of calf care workers for sick calf identification and treatment decisions. C. Crudo[1], D. A. Moore*[2], J. A. Afema[1], and W. M. Sischo[1], *[1]Washington State University, Pullman, [2]Department of Veterinary Clinical Sciences, Washington State University, Pullman, WA.*

On large dairy farm operations and calf rearing facilities, identification and treatment of sick pre-weaned calves is in the hands of employees. Understanding the motivation behind why and how calf care workers make treatment decisions could help Extension educators and dairy advisors create more tailored messages about judicious antimicrobial use. The purpose of this project was to better understand decision making on these operations by assessing employee motivation using a standardized survey tool. Western United States dairy farms and calf ranches with > 200 pre-weaned calves were contacted through their veterinarian to participate in the study. A sample

Table 0585.

Table 1: Average cost estimates among dairy producers for mastitis control practices and perceived costs of mastitis cases.

	Mean	Standard Deviation	Median
Pre-dip cost/cow/d	$0.04	$0.04	$0.03
Post-dip cost /cow/d	$0.06	$0.05	$0.04
Intramammary antibiotic cost/mastitis case	$14.85	$10.84	$12.67
Environmental vaccine cost/cow/lactation	$3.43	$4.60	$3.00
Contagious vaccine cost/cow/lactation	$3.30	$1.98	$3.60
Cost estimate of clinical mastitis[1]	$288.00	$520.25	$175.00
Cost estimate of subclinical mastitis[2]	$301.00	$746.83	$150.00

[1]Cost estimate made by producer for a clinical case of mastitis

[2]Cost estimate made by producer for a subclinical case of mastitis

size of 96 individuals was estimated based on a prevalence of 0.5 for the dominant motivation type with a precision of 0.1 and 95% confidence. The survey tool was adapted from the Motivations Sources Inventory and included 10 questions on motivation for specific aspects of calf care with response categories referring to the five motivation types: 1. External, motivated by recognition from supervisor or coworkers; 2. Extrinsic, motivated by bonuses or other monetary means; 3. Intrinsic, motivated by one's belief system; 4. Internal, motivated by task enjoyment; and 5. Goal Internal, motivated by a desire to meet the organization's goals. Additional questions included job title, training, communication, and information seeking. One-hundred seven individuals from 28 farms participated in the personal interviews. Most were calf feeders (47%), who had worked in that position for more than 5 yr. The most common motivation type was Intrinsic (41 ± 12%), and there were none of the Extrinsic type (0%). The majority of farms (79%) had calf care workers of a variety of motivation types. Six farms had employees of all the same type. Calf Feeders were predominantly Goal Internal (36 ± 13%). Calf managers and calf treaters were predominantly Intrinsic (40 ± 18% and 44 ± 23%). The dominant motivation type for sick calf identification questions was Intrinsic (32 to 50%). The dominant motivation type for questions dealing with calf treatment was Goal Internal (37 to 51%). There is a great deal of variation in calf care worker motivation types, but overall, messages and training programs to address prudent antimicrobial use could benefit by addressing belief systems for sick calf identification and the reinforcement of goals and protocols when addressing treatment.

Key Words: calf care, motivation, treatment

0589 Developing a feed allocation model to maximize income over feed cost considering farmer risk preferences. D. Liang*, T. F. Rutherford, B. L. Jones, R. D. Shaver, and V. Cabrera, *University of Wisconsin-Madison, Madison.*

We developed a nonlinear programming model that selects the optimal cropping plan and diet formulation to maximize farm income over feed cost (IOFC) in a representative 200-lactating cow, 100-ha south-central Wisconsin farm. Nutrition requirements for 6 cow-groups were formulated according to National Research Council equations. Then, the model selected the group production level toward maximum IOFC, which included milk and surplus feed sale, feed production cost, and feed purchasing cost. Yearly farm-produced feed, forage quality (NDF), and feed production costs were simulated with the integrated farm system model (IFSM, USDA, 2014) using 25-yr daily weather data (1986 to 2010). Farm-produced forage was priced according to its quality. The farm could purchase feed and sell surplus feed at 90% of market price. Feed prices were collected from the Understanding Dairy Market website (http://future.aae.wisc.edu) or predicted using FeedVal v6.0 (http://DairyMGT.info). Purchased feed and milk prices reflected 2015 market conditions, and cost of feed production was calculated aggregating resource inputs according to weather year. The optimal solution maximized the total IOFC across 25 weather years, considering the influences of farmer risk preferences toward decision-making through expected utility theory. Hence, the model also proposed an optimal cropping plan to maximize IOFC. Average IOFC across 25 yr was $8.07/cow per d with the original cropping plan of 57.1 ha of corn and 42.9 ha of alfalfa. The model chose to lower milk production for higher IOFC in some years. The farm's IOFC increased with higher milk production and varied from year-to-year because of crop yield and quality. The difference between the highest and lowest yearly IOFC was 27% on low milk production farms (5 kg per cow per d below Wisconsin average) and decreased to 17% on high milk production farms (5 kg per cow per d above Wisconsin average). Diet formulation and purchasing strategies changed for each weather year to maximize IOFC according to farm-grown feed quantity and quality. Results showed that planting corn and harvesting corn silage were favored. The model would choose to plant alfalfa only if alfalfa production cost was decreased by 8% or corn production cost was increased by 6%. A farmer with higher risk tolerance would prefer to purchase more feed from outside than a farmer with less risk tolerance.

Key Words: income over feed cost, feed allocation, whole-farm optimization

0590 A qualitative assessment of perception and communication barriers that interfere with the transfer of knowledge to dairy farmers.
M. E. Woolpert*[1,2], C. E. Morse[1], and D. M. Barbano[3], [1]*University of Vermont, Burlington,* [2]*William H. Miner Agricultural Research Institute, Chazy, NY,* [3]*Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

Efficient sharing of knowledge between consultants and dairy farmers is critically important to the success of the dairy industry. Awareness of how and where dairy farmers seek expert information when making farm management decisions is essential to understanding the communication network of scientists, agricultural experts, and farmers. This study investigated dairy farmer decision-making and communication networks as part of a larger research project on the relationships between farm management practices and milk fat and protein production on dairy farms in the Northeastern United States. Communication networks and barriers to successful information transfer were described by a subset of the farmers enrolled in the larger study. As managing a dairy farm involves complex decision-making processes across diverse knowledge areas, it was hypothesized that dairy farmers seek information from many sources and that barriers exist that are specific to the source and type of information. This research is framed within the "communication for innovation theory," which acknowledges that a person's experiences influence how he/she perceives and reacts to new information and that information transfer frequently encounters obstacles. Semistructured interviews were conducted with a heterogeneous subsample of farmers (n = 9) to collect detailed, diverse, and in-depth perspectives and experiences on decision-making and information transfer. To investigate the cooperative's role in information transfer, additional interviews were conducted with two cooperative employees. Interviews were audio-recorded, transcribed, and coded to identify common themes expressed by farmers or cooperative employees. Farmers identified the cooperative (which communicates via the internet and field technicians), expert consultants (nutritionist, veterinarian, and agronomists), financial advisors, print publications, and other farmers as principal sources of information. However, barriers to the transfer of information include farm management and family dynamics, lack of access to high speed internet, and difficulties evaluating divergent recommendations from experts. Several farmers expressed an incorrect perception of their farms' fat and protein production compared with cooperative averages, which reduced their motivation to incorporate management changes. Recommendations to overcoming these barriers were suggested by interview participants and include integrating management team meetings and facilitating informal discussion groups between farmers. Knowledge about improving milk fat and protein does not easily find its way to individual dairy farmers due to barriers within their communication network, and the proposed recommendations may aid in overcoming these barriers.

Key Words: decision making, extension education, information networks

EXTENSION EDUCATION SYMPOSIUM: GROWING EXTENSION'S IMPACTS WITH CHANGING BUDGETS AND PERSONNEL

0591 Work-life balance for extension professionals: maybe it should be redefined as 'work-life effectiveness'.
G. P. Lardy*, *North Dakota State University, Fargo.*

The literature is littered with articles related to work-life balance for a variety of professions. Do extension professionals experience work-life balance any differently than other professional or academic careers? Should we redefine work-life balance to instead be referred to as work-life effectiveness as some writers have proposed? Let's start with the first question. One can make the case for both sides of this argument. The case for being different includes the situations where we expect a considerable amount of night and weekend work from extension professionals. Many have split appointments with expectations in research and/or teaching, which tends to increase the expectations of their supervisor(s). However, the case against it includes the fact that many professionals in academia and industry have careers that require travel and many have multiple job duties, similar to split appointments in academia. While there may be some differences, there are likely more similarities. Let's evaluate the second question, should we redefine work-life balance as work-life effectiveness as some writers have proposed? In many cases, I would argue that we should be looking for work-life effectiveness rather than balance. Balance may imply some sort of notion of equal time at work and outside of work. In reality, there are likely few times when that is the case. Effectiveness, however, denotes a system or situation that produces the intended result. So, how does an extension professional (or any other professional) enhance work-life effectiveness? Here are a couple of suggestions. 1. Define what success looks like. What does being an effective extension professional look like? This should be done in concert with your supervisor. As for your personal life, perhaps asking 'What does an effective spouse, mother, father look like?' is an appropriate question to ask. 2. Set boundaries/maintain control. This includes various aspects of your career, including your schedule. If there are important family events that you want to be there for, be sure you get them on the calendar. Schedule time for personal time. Don't schedule every available minute. 3. Find time to ensure that your physical, emotional, and spiritual well-being are nurtured in addition to your professional development. In summary, I believe we should be discussing this topic as work-life effectiveness rather than work-life

balance. In addition, by asking some key questions, extension professionals may be able to better define what that looks like for them as individuals.

Key Words: extension, effectiveness, success

0592 Enhancing your extension program through a strong research program and vice versa.
W. Powers*, *Michigan State University, East Lansing.*

Faculty members with split appointments are successful in conducting joint research and Extension programs. Successful integration of research and Extension responsibilities may appear daunting at first; however, issue relevance provides a strong foundation for both resulting impact and funding alike. Thus, a well-funded research program contributes to impact-driven Extension programming. Similarly, an Extension program that is based on solid needs assessments integrates seamlessly into research support to develop and implement solutions. Perhaps the biggest challenge is finding a balance between research and Extension efforts. Expectations can appear overwhelming in that each responsibility, research, and Extension could be a full-time effort. Without clear goals and objectives, faculty can spend considerable time on Extension activities that don't result in measureable impact at the expense of demonstrating a research trajectory and scholarship needed for promotion. To avoid this pitfall, faculty should carefully and deliberately plan their time and activities such that the research and Extension programs complement each other and build on the other. This begins with an assessment of stakeholder needs and how identified needs tie to fundable research questions that translate into implementable solutions. Through constant and deliberate focus on the interconnectedness of a research and Extension program, faculty can balance a split appointment and achieve intended outcomes and scholarly outputs that lead to promotion in the academic system.

Key Words: impact, outcome, output, scholarship

0593 Culturing and leveraging allied industry support for academic programs.
M. W. Overton*, *Elanco Animal Health, Greenfield, IN.*

The mission of public universities includes undergraduate, graduate, professional, and continuing education, basic and applied research, and dissemination of information via extension programing. State-supported funding for academic positions has eroded, but its reductions usually pale relative to the cuts realized by extension departments. Delivery methods used by extension have changed dramatically in the last 30 yr concurrent with the changing structure of the dairy industry (fewer herds but more cows per herd), educational media, access to information, corporate industry support, and shrinking state economic support. One area of potential support for consideration is allied industry; however, universities are under increasing scrutiny from the public pharmaceutical companies with whom they interact. How does academia experience productive relationships with industry representatives without appearing to "be bought and paid for"? Academic and extension programs should consider the synergistic potential that exists for collaborative efforts with allied industry and pharmaceutical companies. Both industry and academia want to conduct rigorous scientific studies to help improve the level of knowledge and to develop new products or technologies. Unfortunately, many faculty members see their corporate industry allies only as potential cash cows, ready to donate or pay for product promotion. However, this viewpoint is problematic and limited in scope. Consider how many former academics are employed in the corporate world. Many were hired away from universities specifically because of their talents and abilities. Some formerly advised graduate students, taught classes, and ran research programs of their own. There is a wealth of knowledge available to help team-teach portions of courses or to serve as adjunct faculty on graduate committees. Specific collaborative efforts experienced by the authors include the teaching of specialty courses in undergraduate, graduate, and veterinary medicine courses, guest authoring for university publications, serving on Masters or PhD committees as subject matter experts, partnering with faculty members to conduct and publish scientific work unrelated to any specific product or technology, speaking at animal health conferences sponsored by universities, and working with a core faculty group at a university on an annual basis for the purposes of simply brainstorming and sharing potential research ideas. Pre-established boundaries around product highlighting or advertising and an agreement around preserving the ability to publish negative research findings are both key to high integrity collaborative efforts. However, there are many additional opportunities to be experienced through healthy collaborative efforts between academia/extension and their corporate or allied industry.

Key Words: industry support, extension, collaboration

0594 Developing regional and multi-state extension collaborations.
A. J. Young*, *Utah State University, Logan.*

The new norm for extension includes smaller budgets, fewer individuals tasked with greater job duties, and rapidly changing clientele wants and needs. Consequently, historical state boundary- based extension personnel and programs don't make as much sense as they did previously. In many situations, regional and multi-state programs provide a viable alternative to meet the needs of clientele and state universities. Many extension programs recognize this and provide short-term multi-state conferences and workshops, which have been successful in attracting individuals from not only the participating

states but regionally and nationally. However, much less common are regional or multi-state programs where individuals are identified to provide direct support to commodity-based clientele in states other than their own. Utah State University has experience with this type of programming through MOUs developed to provide dairy extension expertise for Montana, Wyoming, and Nevada, which lack dairy specialists but were getting requests from clientele for support. The MOU for each state specified the amount of time spent within the state as well as other activities to be made available. In return, specialist time was bought by the participating state. Our experience provides evidence that these programs can be successful, providing that there is appropriate support from administrators, specialists from the host state, and local county agents. County agent support is critical for achieving the greatest success. Alternatively, there may be opportunities for agreements between states on a county-basis, rather than a state-basis because of proximity of a specialist to localized clientele. Our experience suggests that it works best if money is paid by the state receiving the support to the state that is providing the expertise; it is much cheaper than hiring a new specialist. If a state wants to provide support but doesn't want to provide in-state visits, training workshops via electronic media are an easy option. With the advent of internet audio and video capabilities, extension programming can also be accomplished faster and more economically than physically traveling to that site. Sharing extension expertise across state borders makes sense in many situations, allowing for support of underserved clientele; however, the development of agreements and sharing of a specialist's time requires administrators who are willing to work under a different extension model.

Key Words: extension, multi-state, programs

0595 Extension faculty navigating the tenure and promotion process. N. E. Cockett*, *Utah State University, Logan.*

Decisions of tenure and promotion are a critical mechanism by which a university shapes its future. In addition, each tenure and promotion decision directly affects a faculty member's future in academia. It is imperative that there is clarity in expectations for a faculty position as well as the availability of "best practices" so that a faculty member can be successful in achieving those expectations. Utah State University has developed documents that articulate expectations for Extension faculty (the role statement) and a framework for success (the roadmap). These documents are used not only by faculty members and their direct supervisors to set goals and review performance but also by others, such as the university's central tenure and promotion committee, who are not familiar with the Extension specialist role. The major areas of expectation for Extension faculty include programming and scholarship. Expectations for programming include the identification of needs and issues that lead to the development of programs that disseminate information and address the issues. Extension specialists should emphasize long-term programs with measurable outcomes and impacts and strong working relationships with Extension county agents. The value of Extension programs can be assessed by the number of participants or contacts and the resulting impacts, such as change in behavior, dollars saved, or dollars generated. At Utah State University, specialists demonstrate scholarship through the dissemination of materials, such as journal articles, fact sheets, web sites, curriculum materials, and presentations and abstracts at professional meetings. All materials should be peer reviewed. The value of scholarship can be determined using standard measurements, such as journal impact factors, citations, invitations for presentations or participation on working groups, and recognition through awards. However, the value of Extension scholarship can also be measured by the uptake or adoption by Extension peers. At USU, Extension specialists are tenured within the academic college, whereas Extension county agents are tenured within USU Extension. While the USU Vice President for Extension does not have direct authority over the decisions of tenure and promotion for Extension specialists, there are annual performance review meetings that include the Extension administration, the department head, and the academic dean. This review provides the academic administration with insight on the performance of the specialists in his or her Extension assignment. A single letter is returned to the faculty member so as to avoid mixed messages on performance.

Key Words: extension, faculty, tenure, promotion, expectations

FOOD SAFETY

0596 Monitoring of pesticide residues in animal feeds from the republic of Korea. H. Park*, H. J. Kim, M. S. Jeong, C. R. Kim, E. S. Choe, Y. S. Youn, J. K. Kim, and J. H. Lee, *Experiment and Research Institute, National Agricultural Products Quality Management Service (NAQS), Ministry of Agriculture, Food, and Rural Affairs (MAFRA), Kimcheon, South Korea.*

Animal feeds can be contaminated with pesticides due to the large number of different ingredients from diverse origins. Safe animal feed is important for both animal health and the safety of foods of animal origin. To ensure the safety of animal feeds, the Ministry of Agriculture, Food, and Rural Affairs (MAFRA) regulates the amount of each pesticide that

may remain in and on animal feeds. To strictly control the pesticide residues in animal feeds, the MAFRA expanded the number of the maximum residue limits (MRLs) in a wide variety of animal feeds from 27 pesticides to 121 pesticides in 2015. Therefore, the aim of this study was to investigate the amount of pesticide residues in various complete feeds and feed ingredients (corn, barley, wheat, oat, and roughage) from the Republic of Korea as a part of an official control. A total of 126 samples were collected in 2015 and monitored for 105 pesticides from diversified chemical classes, including organochlorines, organophosphates, carbamates, triazoles, pyrethroids, and others using a validated multi-residue pesticide analysis method. According to the pesticides monitoring results, no residue was found in 84.1% of the samples, whereas 15.9% of samples contained pesticide residues below the MRLs. Pirimiphos-methyl and cyproconazole were the two most frequently found pesticides. The results revealed that all commercial animal feeds monitored in 2015 were safe and below the Korean MRLs. The low levels of residues of pesticides found in animal feeds were not considered to be serious threats to human or animal health. However, continuous monitoring with tighter regulation for pesticide residues in animal feeds is recommended.

Key Words: pesticide residues, monitoring, animal feeds, MRLs, official control

0597 *Bacillus amyloliquefaciens* from UHT organic milk produces biofilm and demonstrates virulence potential. J. L. McKillip*, A. Grutsch, E. R. Wagner, and C. Klug, *Ball State University, Muncie, IN.*

This investigation identified an isolate of biofilm-producing *Bacillus* spp. present in ultra-high temperature (UHT) pasteurized organic whole milk. The overall goal of this project was to genotypically and phenotypically characterize thermoduric *Bacillus* bacteria for virulence potential from a UHT dairy environment. Virulence determinants present in this species were detected, and virulence gene expression over time was quantified in a model food (UHT milk) system compared to *B. cereus* ATCC 14579, a known type strain containing the virulence genes of interest. Pure cultures of UHT organic dairy milk were obtained following nonselective enrichment, were biochemically identified to the species level using the Microgen *Bacillus* ID system (Hardy Diagnostics), and were validated further using fatty acid profiling and 16S rDNA sequencing (MIDI Labs Inc.) as *Bacillus amyloliquefaciens*. To confirm the presence of the virulence and regulator genes, DNA was extracted from TSB-grown pure cultures and used in real-time (SYBR Green-based) PCR with primers specific for each of the target genes. PlcR is a pleiotrophic extracellular virulence factor regulator, CodY is a flagellar repressor, NheA and HblC are well-characterized enterotoxins, and 16S served as the housekeeping gene standard. Results revealed that all gene targets were present in the UHT *B. amyloliquefaciens*. Biofilm production was quantified and determined to be produced in amounts that exceeded levels from the *B. cereus* ATCC type strain control. For virulence gene expression measurements, *B. amyloliquefaciens* was inoculated (10^2 CFU/mL) into sterilized organic milk and incubated at ambient temperature (23°C) for 72 h. Every 2 h, samples were removed for standard plate count (SPC)-based density determination and RNA extractions. mRNA for each gene target noted above were amplified with real-time NASBA and transcript-specific primers, revealing relative levels of expression of hblC, nheA, and plcR to be tightly correlated with density during late-log-to-stationary phase growth in the milk system. Dot-blot assays with anti-PlcR will be used to confirm the presence of this regulator protein in the *B. amyloliquefaciens* during incubation at the same time points used for RNA extractions. These data indicate that *Bacillus* spp. present in UHT milk harbor and express the same virulence determinants that are familiar to microbiologists in their psychrotrophic *Bacillus* counterparts, including biofilm potential. These results necessitate that the guidelines on proper storage and shipment of UHT

Table 0596.

Table 1. Summary of the Animal Feed Samples Analyzed for Pesticides

Pesticide	Use	Total # of Samples	Quantifiable Samples	Feeds	Range (ppm)	Median (ppm)	MRL (ppm)
Azoxystrobin	Fungicide		2	Oat, Roughage	0.66~1.05	0.86	15
Chlorpyrifos-methyl	Insectcide		2	Barley, Oat	0.41~0.84	0.63	6
Cyproconazole	Fungicide		5	Corn	0.58~0.95	0.65	2
Piperonyl butoxide	Insectcide synergist	126	1	Complete feed	0.30	0.30	24
Pirimiphos-methyl	Insectcide		5	Complete feed	0.12~0.30	0.14	5
Propiconazole	Fungicide		3	Roughage	0.10~1.48	0.12	2

0598 Occurrence of aflatoxin M1 in UHT, pasteurized, and powdered milk marketed in Hubei province (central China). J. L. Xiong[1], H. L. Zhou[2], L. Y. Wu[*1], and F. T. Meng[1], *[1]Hubei Key Laboratory of Animal Nutrition and Feed Science, Wuhan Polytechnic University, Wuhan, China, [2]Xiangyang Engineering Research Center of Animal Medicine, Xiangyang Vocational and Technical College, Xiangyang, China.*

Aflatoxin M1 (AFM1), a strong carcinogenic derivate of aflatoxin B1 (AFB1), occurs in milk from dairy cows fed an AFB1-contaminated diet and subsequently contaminates dairy products. This survey was conducted to evaluate the occurrence of AFM1 in UHT, pasteurized, and powdered milk available in Hubei province (central China) and to compare these milk AFM1 levels with the maximum AFM1 limits of 50 and 500 ng/L set by the European Commission (EU) and China's Ministry of Health, respectively. A total of 271 samples, composed of UHT milk (120 samples), pasteurized milk (121), and powdered student formula (30) from two major dairy brands available in Hubei province were collected from November 2014 to February 2015 (winter season). Milk AFM1 was detected by using a commercial ELISA method (RIDASCREEN® Aflatoxin M1 test kit; R-Biopharm AG, Darmstadt, Germany) with the detection limit of 5 ng/L. Differences in the concentration of milk AFM1 were statistically analyzed by Mann–Whitney comparisons using SPSS version 19.0 software. The results showed that the mean of AFM1 concentration in positive samples of pasteurized milk was significantly higher ($P < 0.05$) than that in UHT milk (133.4 vs. 20.5 ng/L), and there were significant differences ($P < 0.05$) in AFM1 concentration in milk samples among two dairy brands. In addition, AFM1 was detected in 61 samples of UHT milk (50.8%) with concentrations of 5.5–62.3 ng/L and in 115 samples of pasteurized milk (95.0%) with concentrations between 5.2 and 346.2 ng/L. Moreover, 2 samples of UHT milk (3.4%) and 77 samples of pasteurized milk (63.6%) were found to contain AFM1 above the European tolerance limit, but all samples were below China's legal limit. All samples of powdered student formula were negative at the AFM1 detection limit. The findings of the study are as follows: 1) the content of AFM1 in all milk samples was below China's national legal limit though the incidence of AFM1 in UHT and pasteurized milk was high, 2) powdered student formula was free from AFM1 contamination and thus can be considered the safest milk product tested, and 3) the incidence and concentration of AFM1 in pasteurized milk was higher compared to other dairy products. To maintain milk safety, strict monitoring systems are recommended.

Key Words: aflatoxin M1, milk, Hubei province

0599 An aptamer-based biosensor for detection of aflatoxin M1. X. Guo[1,2,3,4], F. Wen[1,3], N. Zheng[1,2,3], S. Li[1,5], M. L. Fauconnier[4], and J. Wang[*1,2,5], *[1]Ministry of Agriculture-Milk and Dairy Product Inspection Center (Beijing), Beijing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]Ministry of Agriculture-Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Beijing, China, [4]Chimie générale et organique, Gembloux Agro-Bio Tech, Université de Liège, Gembloux, Belgium, [5]Ministry of Agriculture Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Aflatoxin M_1 (AFM_1), one of the most toxic mycotoxins, imposes serious health hazards. AFM_1 had previously been classified as a group 2B carcinogen and has been classified as a group 1 carcinogen by the International Agency for Research on Cancer (IARC) of the World Health Organization (WHO). Determination of AFM_1 thus plays an important role for quality control of food safety. In this work, a sensitive and reliable aptasensor was developed for the detection of AFM_1. The immobilization of aptamer through a strong interaction with biotin-streptavidin was used as a molecular recognition element, and its complementary ssDNA was employed as the template for real-time quantitative polymerase chain reaction (RT-qPCR) amplification. Under optimized assay conditions, a linear relationship (ranging from 1.0×10^{-4} to 1.0 μg L^{-1}) was achieved with a limit of detection (LOD) down to 0.03 ng L^{-1}. In addition, the aptasensor developed here exhibits high selectivity for AFM_1 over other mycotoxins and small effects from cross-reaction with structural analogs. The method proposed here has been successfully applied to quantitative determination of AFM_1 in infant rice cereal and infant milk powder samples. Results demonstrated that the current approach is potentially useful for food safety analysis, and it could be extended to a large number of targets.

Key Words: aflatoxin M_1, aptamer, RT-qPCR.

0600 Individual and combined cytotoxicity assessment of zearalenone and ochratoxin A/α-zearalenol by full factorial design. N. Zheng[1,2,3], Y. Gao[1,2,3], H. Wang[4], and J. Wang[*2,3,5], *[1]Ministry of Agriculture-Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Beijing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]Ministry of Agriculture-Milk Risk Assessment Laboratory, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [4]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China, [5]Ministry of Agriculture Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

The co-occurrence of zearalenone (ZEA) and ochratoxin A (OTA) is commonly found in cereals. These mycotoxins can be metabolized after livestock feeding and can then co-occur in later food products in the form of ZEA, α-zearalenol (α-ZOL), and OTA. However, toxicological data concerning the combined effects among these mycotoxins by full factorial analysis design are sparse. In the present study, the combined cytotoxic effects and oxidative damage of ZEA and OTA/α-ZOL on a human hepatoma cell line (Hep G2) were evaluated by 3 × 3 full factorial analysis design and the estimated marginal means plot. Nine groups were adopted to investigate the combined effects of three levels of ZEA (0 μM, 30 μM, and 60 μM), three levels of OTA (0 μM, 6 μM, and 12 μM), and three levels of α-ZOL (0 μM, 15 μM, and 30 μM) after 48 h of exposure. Statistical analysis of the data was performed using the SAS 9.2 statistical software package. For the individual mycotoxin, our results demonstrated that Hep G2 cells were more sensitive to OTA than α-ZOL, and α-ZOL was more cytotoxic than ZEA. For the combined mycotoxins, the cytotoxicity, intracellular superoxide dismutase (SOD), and glutathione peroxidase (GSH-Px) activities as well as malonaldehyde (MDA) and glutathione (GSH) contents showed antagonism in combination of ZEA + OTA, whereas the combination of ZEA + α-ZOL behaved from antagonism to synergism as the concentration of ZEA was increased on the overall interaction. There is a significant correlation between cytotoxicity and oxidative damage in the combinations of ZEA + OTA/α-ZOL ($P < 0.05$), indicating that oxidative damage plays an important role in inducing cytotoxicity.

Key Words: mycotoxins, zearalenone, ochratoxin A, α-zearalenol, combined effect, full factorial design

0601 Distribution and genetic characterization of the top clinically-relevant Shiga toxin-producing *Escherichia coli* in feedlot cattle. J. Hallewell[*1], K. Stanford[2], T. Reuter[2], L. Chui[3], R. Johnson[4], T. A. McAllister[5], E. Topp[6], and T. W. Alexander[1], *[1]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Alberta Agriculture and Forestry, Lethbridge, AB, Canada, [3]Provincial Laboratory for Public Health, Edmonton, AB, Canada, [4]Public Health Agency of Canada, Ottawa, ON, Canada, [5]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, [6]Agriculture and Agri-Food Canada, London, ON, Canada.*

Shiga toxin-producing *Escherichia coli* (STEC) are causative bacterial agents for severe gastrointestinal illness in humans that include the potentially fatal hemolytic uremic syndrome. Cattle shed STEC in their feces, and collectively, seven serogroups of STEC, including O26, O45, O103, O111, O121, O145, and O157, have been implicated as the main serogroups associated with human disease from contaminated beef. Consequently, screening and characterization of these top serogroups is important for mitigating STEC in the human food chain. The objectives of the current study were to characterize the distribution and genetic diversity of clinically-relevant STEC in feedlot cattle. Isolates that were PCR-confirmed as belonging to serogroups O26 ($n = 116$), O103 ($n = 74$), and O111 ($n = 20$) were obtained from the feces of cattle originating in five regions (southwest Alberta, southeast Alberta, central Alberta, Saskatchewan, and British Columbia) in western Canada over a 2-yr period. Isolates were subtyped by pulsed-field gel electrophoresis (PFGE) and compared to human strains from Alberta ($n = 47$) to assess the distribution of potential clinically relevant strains. O26 isolates from cattle were generally diverse, but isolates from southwest Alberta or British Columbia were more closely related ($P < 0.05$) than isolates from other locations and were most uniform in spring and summer seasons ($P < 0.05$). Isolates of O103 ($n = 74$) from southwest or central Alberta were genetically similar ($P < 0.05$) and more closely related in spring ($P < 0.05$). O111 was not frequently isolated from feces but had location-specific and season-specific PFGE profiles ($P < 0.05$), although isolates from southwest Alberta or those collected in spring were diverse. Human isolates within each serogroup were closely related ($P < 0.05$), but cattle isolates of six O26 strains and ten O111 strains from different seasons and locations were > 90% similar to human isolates of their respective serogroups. The results from this study showed that serogroups O26 and O103 were highly diverse in cattle, but certain strains persisted in geographic regions, with the least genetic diversity among O26 and O103 strains during the spring season. Some O26 and O111 cattle strains had > 90% similarity with human isolates, suggesting human pathogens are present in cattle. However, the diverse nature of the cattle isolates implies

that STEC are readily evolving and that only a fraction of cattle isolates are closely related to those causing human disease.

Key Words: Shiga toxin-producing *Escherichia coli*, non-O157, pulsed-field gel electrophoresis

0602 Isolation and characterization of listeriaphages for control of growth of *Listeria monocytogenes* in dairy foods.

S. H. Lee[1], H. S. Lee[1], S. Heo[1], C. R. Lee[1,2], and G. B. Kim[*1], [1]*Department of Animal Science and Technology, Chung-Ang University, Anseong, South Korea,* [2]*Feed Industry Research Institute, Korea Feed Association, Seoul, South Korea.*

In this study, two lytic bacteriophages (LMP1 and LMP7) targeting *L. monocytogenes* were isolated from the intestinal content of healthy chickens to identify those with the greatest potential in reducing *L. monocytogenes* in dairy foods. The host specificity of these bacteriophages was determined with different serotypes of *L. monocytogenes* strains by the formation of lytic zones and plaques on host lawns. Genomic and morphological analyses of these phages were also performed to investigate their potential as a means of biocontrol of *L. monocytogenes* in the dairy industry. Lytic activity of *Listeria* bacteriophages was assessed in tryptic soy broth inoculated with *L. monocytogenes* ATCC 7644 or ATCC 19114 and incubated at 30°C for 24 h. Phage lytic activity was also evaluated at 10°C for 5 d in the same composition. LMP1 and LMP7 were able to inhibit the growth of *L. monocytogenes* ATCC 7644 and ATCC 19114 compared with the untreated control both at 30°C and 10°C. LMP1 was more effective than LMP7 against *L. monocytogenes* ATCC 19114; contrary to this, LMP7 was more effective than LMP1 against *L. monocytogenes* ATCC 7644. Morphological characterization from electron microscopy reveals that both LMP1 and LMP7 belong to the *Siphoviridae* family. Bacteriophage genome sequences were determined by next-generation sequencing, and they contain about 40 kb and 47 kb with 69 and 67 coding sequence genes, respectively. Comparative genome analyses could provide some evidence of their different host specificity. The effectiveness of phage cocktail (LMP1 and LMP7) on the growth of *L. monocytogenes* in milk samples was investigated at 30°C and 10°C. The growth of *L. monocytogenes* in milk was effectively inhibited by using the phage cocktail. In conclusion, two listeriaphages (LMP1 and LMP7) exhibiting different host specificity were isolated and further characterized; a phage cocktail with these phages could serve as a tool of biocontrol of *L. monocytogenes* in dairy foods.

Key Words: *Listeria monocytogenes*, phages, biocontrol, dairy foods

0603 Effects of feeding NaturSafe on foodborne pathogens in finishing beef heifers.

K. M. Feye[1], K. L. Anderson[1], M. F. Scott[*2], K. L. Dorton[2], D. L. Henry[2], C. R. Belknap[2], B. E. Depenbusch[3], and S. A. Carlson[1], [1]*Department of Biomedical Sciences, Iowa State University, Ames,* [2]*Diamond V, Cedar Rapids, IA,* [3]*Innovative Livestock Services, Inc., Great Bend, KS.*

With more judicious use of antibiotics in the future, the beef industry will need new science-based strategies to mitigate foodborne pathogens, especially as standard industry technologies are removed from the diet. In this study, cross-bred heifers (N = 1495; 359 ± 3.4 kg) were utilized in a randomized complete block design at a commercial feedlot to determine the effects of a *Saccharomyces cerevisiae* fermentation product (NaturSafe; Diamond V, Cedar Rapids, IA) on foodborne pathogens when monensin, tylosin, and direct fed microbials (DFM) were not included in the diet. Upon arrival, heifers were allowed ad libitum access to water and long-stemmed hay. During processing, they received a feedlot tag and growth implant and were vaccinated and treated for parasites. Heifers were then blocked by arrival BW and randomly assigned to one of 2 treatments (10 pens/treatment, approximately 75 heifers/pen). Treatments consisted of a diet containing 1) monensin, tylosin, and Bovamine Defend (positive control, PC), or 2) NaturSafe at 18 g/head/d without monensin, tylosin, and the DFM. Diets were fed twice daily with heifers receiving half of the daily dose of treatment in the TMR at each feeding. Cattle were harvested on d 125 and 146 (5 pens per treatment per day). At the abattoir, fecal swabs and subiliac lymph nodes were obtained from 400 animals (200/treatment, 20/pen). Fecal samples were subjected to selective culture for *Salmonella* and *E. coli* O157:H7 enumeration. Only *Salmonella* were enumerated from the lymph nodes. *Salmonella* isolates from feces and lymph nodes were analyzed for virulence (in vitro assay) and antibiotic (ceftiofur, enrofloxacin, and florfenicol) susceptibility. Statistical analyses were performed using ANOVA with Tukey's test for multiple comparisons. Compared to PC, cattle fed NaturSafe had a lower ($P < 0.05$) concentration of *Salmonella* in the feces (74%) and lymph nodes (86%). The fecal concentration of *E. coli* O157:H7 was decreased ($P < 0.05$) by 58%. *Salmonella* isolates from feces and lymph nodes were less ($P < 0.05$) virulent (68% and 66%, respectively) and associated with a decreased expression of *hil*A, a genetic regulator of *Salmonella* invasion into eukaryotic cells. *Salmonella* resistance to select antibiotics was decreased by 17 to 100% (fecal isolates) and 42 to 75% (lymph node isolates). Results from this study indicate that NaturSafe can be used as a pre-harvest food safety intervention in beef cattle when standard industry technologies like monensin, tylosin, and DFM are removed from conventional production diets.

Key Words: *Saccharomyces cerevisiae* fermentation product, cattle, pathogens

0604 Moxidectin residues in tissues of lambs submitted to three programs of gastrointestinal endoparasite control. A. L. G. Monteiro[1], C. H. E. C. Poli*[2], M. A. M. Fernandes[3], F. G. Reyes-Reyes[4], C. J. A. Silva[5], M. D. Bianchi[4], S. Gilaverte[1], and M. T. Peres[1], *[1]UFPR-Universidade Federal do Paraná, Curitiba, Brazil, [2]USU-Utah State University, Logan, [3]UFPR, Curitiba, Brazil, [4]Universidade Estadual de Campinas-UNICAMP, Campinas, Brazil, [5]Instituto Federal de SC, Camboriú, Brazil.*

Moxidectin (MOX) has been reported to induce parasite resistance promoted by frequent drug utilization. To determine dynamic concentrations of drug residues in different sheep tissues according to a gastrointestinal endoparasite control program, two experiments were performed. The first one aimed to determine the time it takes for the MOX concentration to reach the maximum residue limit (MRL) in lamb leg muscles (near the site of drug application (50 μg/kg)) and fat (500 μg/kg). For that, twenty-two lambs were slaughtered on 2, 4, 7, 14, 28, and 42 d after treatment (DAT) with a single dose of MOX (0.2 mg kg^{-1}/body weight). The second experiment aimed to quantify MOX residue in serum, muscle (near and far to the application site), fat, liver, and kidneys of suckling lambs subjected to three programs of endoparasite control: (T1) preventive treatment every 28 d, (T2) treatment when egg count per gram feces (EPG) was equal or higher than 700, and (T3) selective treatment by FAMACHA method (FMC). The experiment was performed in a completely randomized design. The lambs were slaughtered when they reached an average of 30 kg body weight, respecting the time of minimum withdraw period of 28 d. Before slaughtering, blood was collected. Two grams of each tissue was sampled. MOX extraction was based on QuEChERS method. MOX residue was determined using HPLC with mass spectrometry (LC-MS/MS). The depletion curve of MOX for muscle showed a high drug concentration at 2 DAT (1854.2 μg/kg ± 495.0) followed by rapid absorption of the drug at the site of administration, reaching a concentration below MRL at 5 DAT. Longer persistence of MOX was noted at the high concentration, reaching values below the MRL at 17 DAT. Only one sample of fat from the selective treatment group (FAMACHA) showed a concentration of MOX (586.3 $mL \cdot kg^{-1}$) above the MRL. No sample of serum showed MOX residue levels. Significant correlation was observed between MOX residue in fat and omental fat weight ($P < 0.05$; $r = 0.5310$), suggesting that animals with higher fat deposition may have increased residue persistence in their body. The production of suckling lambs with control of gastrointestinal endoparasites by selective (OPG and FAMACHA) or preventive methods (application every 28 d), considering the 28 d withdraw period, presents a low risk of incidence (less than 1%) of high concentration of MOX in muscle, fat, kidney, and liver.

Key Words: FAMACHA, EPG, sheep

0605 Shiga toxin-producing *Escherichia coli* on cattle hides and bacterial transfer from hides to carcasses in Midwestern commercial beef slaughter operations. A. McKiearnan*, N. Cernicchiaro, and M. Sanderson, *Kansas State University, Manhattan.*

Shiga toxin-producing *Escherichia coli* (STEC) are foodborne pathogens that carry Shiga toxin genes (*stx*1 or *stx*2) and can cause serious illnesses in humans. These bacteria, which are mainly shed in the feces of cattle, can contaminate beef carcasses during the hide removal and evisceration processes at harvest. Coliforms, including *E. coli*, are utilized as indicator organisms of fecal contamination of beef carcasses during in -plant processing. The objectives of this study were to determine the frequency of the major seven STEC O serogroups and their associated virulence genes on hide-on beef carcass samples and to determine the distributions of *E. coli* and coliform concentrations from cattle hides and carcasses in commercial slaughter operations. Samples were collected from four large commercial processing plants (two in the northern region and two in the southern region of the Midwestern U.S.), which were visited three times each during summer and fall of 2015. Twenty surface swabs were collected at each sampling station (hide-on, pre-wash, pre-evisceration, post-evisceration, and final product) during each plant visit. Hide-on samples were enriched in *E. coli* broth, subjected to immunomagnetic separation, plated on STEC selective media, and confirmed by PCR. Dilutions from hide-on and carcass samples were plated on *E. coli*/coliform 3M Petrifilm plates. The proportion of positive hide-on samples during summer months was 1.3% for STEC O26, 2.1% for STEC O103, 0.4% for STEC O145, and 21.7% for STEC O157, and no positive samples for STEC serogroups O45, O111, and O121. The proportion of positive fall hide-on samples was 0.8% for STEC O26, 0.8% for STEC O45, 0.4% for STEC O103, 0.8% for STEC O145, and 5.0% for STEC O157, and no positive samples for STEC serogroups O111 and O121. There was a greater number of hide-on samples with higher *E. coli* and coliform concentrations compared to pre-wash samples, demonstrating potential transfer of fecal-origin contamination to the carcasses during hide removal. For pre-evisceration and post-evisceration samples, the number of enumerable samples and the distributions of *E. coli* and coliform concentrations varied by region; the role of evisceration in carcass contamination is unclear and possibly due to plant-to-plant variation. There were few enumerable samples for the final product (before split carcasses enter the cooler), which indicates successful application of

interventions by the processing plants. These data will be inputted into a quantitative microbial risk analysis to model the risk of human illnesses due to STEC along the beef chain.

Key Words: STEC

FOOD SAFETY SYMPOSIUM: THE SPECTRUM OF FOOD SAFETY IMPROVEMENT IN FOODS OF ANIMAL ORIGIN

0606 Have we improved food safety in live cattle?

K. Stanford*, T. Reuter, and D. Niu, *Alberta Agriculture and Forestry, Lethbridge, AB, Canada.*

A number of technologies for reducing food-borne pathogens have been evaluated in live cattle, such as direct-fed microbials, vaccines, bacteriophages, and bactericidal feed ingredients. Many of these have been targeted to *E. coli* O157:H7, but efficacy in some cases has been variable, while regulatory approval of others has been less than forthcoming. As strategies to control *Salmonella* in live cattle have been even less successful, different approaches may be needed. For *E. coli*, Shiga-toxins are primary causative factors for human disease and are carried on prophages integrated into the bacterial genome. As transfer of these Shiga-toxin phages can convert previously nonpathogenic *E. coli* to pathogens and as these phages can be carried by other bacterial species, such as *Citrobacter freundii*, should we direct more future live animal food safety efforts to better controlling these endogenous phages? Fight phages with phages? Having a phage already integrated in the bacterial genome has been shown to block lysogeny by *stx*-carrying phages of the same species. Alternatively, as *E. coli* are commensal organisms in the bovine gastrointestinal tract and *E. coli* compete within the microflora for access to nutrients and valuable real estate, would it be possible to utilize the strategies of highly-competitive *E. coli* to suppress the growth of other *E. coli* with Shiga toxins? Could the safety of a direct-fed microbial containing a nonpathogenic but highly competitive strain of *E. coli* ever be assured? The CRISPR system evolved to protect prokaryote DNA from integration of viruses and plasmids. Could CRISPR-cas be used to block possible integration sites for Shiga-toxin phages in a highly-competitive nonpathogenic strain of *E. coli*? Should CRISPR-cas be used in this way? As contamination of hides is the primary route leading to contamination of meat; more emphasis on the control of pathogens on hides is warranted. A bacteriophage-based hide wash for control of *E. coli* O157:H7 has been approved by the USDA, but research data have been limited. However, a recent study by our laboratory demonstrated that non-O157 *E. coli* outweigh the pathogenic potential of O157 in feces of slaughter cattle, as serogroups such as O103 and O45 were relatively ubiquitous year-round and 55 to 65% of isolates of these serogroups carried Shiga toxins. New pre-harvest approaches that will more successfully control the gamut of current and potential bacterial pathogens in live cattle are warranted.

Key Words: Shiga toxins, *E. coli*, cattle

0607 Improving food safety in live swine.

T. R. Callaway*, *USDA-ARS, College Station, TX.*

Swine can be colonized by a variety of foodborne pathogens that can be harmful to humans who consume contaminated pork products or who are exposed to waste from swine facilities. The most common foodborne pathogenic bacteria that are associated with swine and pork are *Salmonella* and *Campylobacter*. Illnesses in humans attributed to pork products have declined in recent years due to a tremendous effort put forth by the industry; however, the record is still not perfect. While illnesses still occur, steps such as implementing on-farm biosecurity procedures, reducing exposure to pathogens during transport, and lairage have reduced the horizontal spread of these important pathogens in live swine. The economic and public health significance of intervening to reduce pathogen incidence and transmission will be discussed along with methods under development and future research avenues. Actual and theoretical interventions, such as segregated early weaning, group housing, social stresses, reducing transport stress, limiting lairage exposure, bacteriophage, colicins, and sodium chlorate applications will be described. While challenges indeed remain, work to reduce pathogen carriage in live swine holds promise to reduce human pathogen exposures and resultant illnesses.

Key Words: human pathogen exposure, foodborne pathogens, health

0608 Characterization of zoonotic bacteria from dairy cattle in the era of genomics.

J. A. S. Van Kessel*, S. W. Kim, J. S. Karns, and B. J. Haley, *USDA-ARS, Beltsville, MD.*

Dairy farms are well-documented reservoirs for zoonotic pathogens. *Salmonella* spp., *Listeria monocytogenes*, Shiga-toxigenic *Escherichia coli*, and *Campylobacter* spp. are often excreted in the feces of cows, and it is common for infected cows to show no signs of illness and not be recognized as sources of human health risks. Historically, comparisons of bacterial isolates from animals and humans were made using molecular genotyping tools, such as pulsed-field gel electrophoresis and rep-PCR, or targeted sequencing techniques, like multilocus sequence typing. The discriminatory power of these tools has been exploited for strain differentiation and epidemiology tracing, the most widespread example being PulseNet. Decreased costs have made whole genome sequencing (WGS) a viable means of comparing the genomes of large numbers of bacterial isolates. Here, we describe several examples where we have used comparative genomics and

metagenomics to describe relationships between dairy-associated isolates and isolates from other sources and elucidate the ecology of pathogens in dairy farm environments. Genome analysis of 118 *Salmonella enterica* serotype Kentucky (*S.* Kentucky) isolates from dairy, poultry, and humans identified some of the poultry and bovine isolates as sequence type (ST) 152, but there was a phylogenetic distinction between the poultry and bovine isolates. The human isolates were primarily distantly related ST198 strains. Three of the dairy isolates were ST198, suggesting that dairy animals are a potential reservoir of this human pathogen. We further compared the fecal microbial communities of *S.* Kentucky-shedding and non-shedding cows to search for potential shifts in community composition associated with *S.* Kentucky carriage. No significant differences between the two groups were observed, suggesting that *S.* Kentucky is a transient commensal gut inhabitant. For *L. monocytogenes*, we sequenced the genomes of 128 isolates from dairy cows and bulk tank milk and compared them to human-associated *L. monocytogenes* isolates. Phylogenetic inference revealed a high level of diversity among the isolated strains. Multiple sequence and virulence types were identified, including at least four virulence types known to be responsible for large outbreaks. Based on a whole genome phylogenetic analysis, several isolates were closely related to human clinical isolates, such as the strain isolated in the 2011 cantaloupe outbreak that was responsible for multiple deaths. Decreased cost and increased access to WGS is radically changing the understanding of the ecology of bacterial populations. With WGS data, much more subtle changes are readily accessible compared with historic methods of distinguishing strains.

Key Words: *Salmonella*, *Listeria*, dairy

FORAGES AND PASTURE II

0609 Influence of forage diversity on feeding behavior and diet digestibility in lambs. S. Lagrange*[1,2], and J. J. Villalba[2], [1]*INTA EEA, Bordenave, Argentina,* [2]*Utah State University, Logan.*

Diverse combinations of forages with different nutrient profiles and classes of plant secondary compounds (PSC; tannins, saponins) may improve intake and nutrient utilization by herbivores. We tested the effects of increasingly diverse combinations of PSC-containing legumes on intake and diet digestibility in lambs. Freshly-cut birdsfoot trefoil (TRE), sainfoin (SAN), and alfalfa (ALF) at the early flowering stage were offered in ad libitum amounts to forty-two lambs in individual pens assigned to 7 treatments ($n = 6$): single species, a choice of all possible 2-way combinations, or a 3-way choice of the legumes. Composited forage and fecal samples and acid detergent lignin were used to determine in vivo DMD. The change in concentration of BUN from the beginning to the end of the study (24 d) (ΔBUN) was also assessed. Dry matter intake (DMI) and digestible DMI (DDMI) were analyzed as repeated measures designs with lambs (random effect) nested within treatments. A complete random design was used for the remaining variables with treatment as a fixed factor. Lambs preferred ALF > SAN > TRE in 70:30 and 50:35:15 ratios for 2- and 3-way combinations, respectively ($P < 0.05$). Average DMI and DDMI were 10% greater for 2- and 3-way choices than for single species (Table 1). Digestibility values of tannin-containing legumes (SAN and TRE) and their combination were greater than those recorded for the saponin-containing legume (ALF) or ALF/TRE (Table 1). Feeding SAN in a single diet or in combination had lower ΔBUN and greater fecal N/N consumed ratio (Table 1) than ALF, TRE, or ALF/TRE, suggesting a shift in the site of N excretion from urine

Table 0609.

0610 Nutritive quality and forage yield of three *Brassica* varieties for use in livestock grazing systems.

S. L. Dillard*, A. I. Roca-Fernandez, M. D. Rubano, and K. J. Soder, *USDA-Agricultural Research Service, University Park, PA.*

Brassicas are gaining popularity as high-quality forage for pasture-based livestock producers due to their use to extend the fall grazing season and during the summer forage slump. Little research has been conducted to evaluate forage yield and nutritive value of brassica species. A study was designed to compare forage yield and nutrient composition of 'Barsica' rapeseed (*Brassica napus*), 'Inspiration' canola (*B. napus*), 'Appin' turnip (*B. rapa*), and 'KB Supreme' annual ryegrass (*Lolium multiflorum*). The study was conducted as a completely randomized block (n = 4) design at The Pennsylvania State University Russell Larson Agricultural Research Farm in Rock Springs, PA. Plots were drilled (Wintersteiger Plotseed XL, Salt Lake City, UT) into a prepared seed bed in August 2015 and fertilized with 71 kg N/ha. Potash, P, and lime were added according to soil tests. Forages were sampled biweekly during October and November using a 0.1-m^2 quadrat and clipped to 4 cm. Samples were dried at 60°C using a forced-air oven for 48 h, ground to 1 mm using a Willey Mill (Thomas Scientific Inc., Philadelphia, PA), and submitted to Dairy One Laboratories (Ithaca, NY) for wet chemistry analysis. Statistical analysis was conducted using Proc GLIMMIX (SAS Inc., Carey, NC) with $\alpha = 0.05$. Forage yield was not different among brassicas (1023 ± 108.5 kg DM/ha), which were greater ($P \leq 0.0001$) than ryegrass (242 ± 108.5 kg DM/ha). Although CP was greater ($P < 0.032$) in ryegrass than the brassicas (33.1 vs. 29.2 ± 1.44%), degradable and soluble protein fractions were lower ($P < 0.032$) in ryegrass than all brassicas (76 vs. 84 ± 0.71% and 49 vs. 53 ± 1.12%, respectively). Brassicas contained similar NDF and ADF concentrations (18.7 ± 0.94 and 14.4 ± 0.77%, respectively) but were lower ($P < 0.0001$) than ryegrass (35.4 ± 0.94 and 17.5 ± 0.77%, respectively). Both canola and rapeseed had greater ($P < 0.001$) NE_M and NE_L (1.65 ± 0.02 and 1.72 ± 0.01 Mcal/kg, respectively) than turnip or ryegrass (1.45 ± 0.02 and 1.54 ± 0.01 Mcal/kg, respectively). Inclusion of brassicas in a cool-season pasture rotation has the potential to increase animal productivity and reduce the need for stored feed during periods of perennial cool-season forage shortages, including mid-summer and late fall.

Key Words: *Brassica*, forage, grazing

0611 Effect of early intensive grazing of Kentucky bluegrass on animal performance.

F. A. Brummer*[1], B. Patton[1], and R. Limb[2], [1]*North Dakota State University, Central Grasslands Research Extension Center, Streeter,* [2]*North Dakota State University, Fargo.*

Kentucky bluegrass (*Poa pratensis* L.), a perennial, cool-season grass, is increasingly dominating pastures in the northern Great Plains, compromising pasture quality due to declining forage quality in the summer months when compared with native forages. Timed grazing can impact plant species and can shift plant communities to a more desired state. A grazing study was conducted at the Central Grassland Research Extension Center, North Dakota, to compare the effect of early-intensive grazing with season-long grazing on Kentucky bluegrass production and on grazing animal performance. Six pastures were assigned to one of two treatments: early intensive grazing and season-long grazing. All pastures were stocked with yearling beef heifers (340 ± 35 kg) at a moderate stocking rate before Kentucky bluegrass reaching the two-leaf stage. The early intensive treatment was grazed for 1.2 mo with a stock density of 0.39 animal units per hectare (AU · ha^{-1}), equivalent to a stocking rate of 0.46 animal unit months per hectare (AUM · ha^{-1}). The season-long treatments were grazed for 4 mo with a stock density of 0.12 AU · ha^{-1}, which is also equivalent to a moderate stocking rate of 0.46 AUM · ha^{-1}. Heifers were removed from the early-intensive treatment when 30% of native vegetation had received some grazing. Due to the shortened grazing time period, stocking density was more than three times higher on the early-intensive treatment. Heifers gained more ($P \leq 0.05$) in season-long pastures, with a corresponding weight loss on the early intensive treatment (0.16 vs. −0.45 kg · d^{-1}, respectively) in 2015. Results from this study show that early intensive grazing negatively influenced animal performance through weight loss and overall lower average daily gains when compared with season long grazing. The production of *P. pratensis* can vary widely in the northern Great Plains, depending on soil and spring moisture conditions; therefore, additional research on utilizing yearling beef cattle to spring graze *P. pratensis* will continue to document animal performance in response to this grazing treatment.

Key Words: early intensive grazing, grazing, heifer, invasive, Kentucky bluegrass, yearling

0612 Frequency of feeding distillers dry grain with solubles as a supplement to beef cows grazing corn residue.

S. M. Gross*, B. W. Neville, F. A. Brummer, and M. Undi, *NDSU Central Grasslands Research Extension Center, Streeter.*

This study was conducted to evaluate the effects of delivery frequency of distillers dried grains with solubles (DDGS) as a supplement to cows grazing corn residues in the northern

Great Plains. The 36-d study was conducted in the fall of 2015, with 80 first and second calf cows (520 ± 34.5 kg BW). Ten cows were assigned to one of eight paddocks (4 ha each) of corn residue. Four applied treatments with two replications per treatment were no DDGS supplementation (control), DDGS fed daily, DDGS fed every third day, and DDGS fed every sixth day. The DDGS was fed at 0.35% BW per day. Body weight and body condition scores were recorded on two consecutive days at the beginning and end of the study. All cows had ad libitum access to water and a mineral supplement. After corn harvest, corn grain drop was estimated by counting the number of ears on the ground in three 30.5 m rows. Gusty winds in excess of 90 km · h^{-1} before harvest resulted in approximately 1004 kg · ha^{-1} of corn grain on the ground. Above normal temperatures were encountered through the six week course of the study. Average daily gain was greater ($P < 0.05$) following daily (1.57 ± 0.12 kg) and every third day supplementation (1.62 ± 0.12 kg) relative to control (1.22 ± 0.12 kg) or every sixth day supplementation (1.19 ± 0.12 kg). Body condition score change was greater ($P < 0.05$) following daily supplementation (0.7 ± 0.08) relative to every sixth day supplementation (0.4 ± 0.08). There was no difference ($P > 0.05$) in BCS change among control cows and cows supplemented daily or every third day. These results show that under certain conditions, such as mild weather and high grain drop, cows grazing corn residue may not require supplementation. Dried distillers grains with solubles can be supplementally fed every third day to reduce winter labor costs, with no detrimental effects to animal performance.

Key Words: beef cattle, corn residue, dried distillers grains with solubles

0613 Development of an automated system for measuring supplement intake of grazing animals.

R. Reuter*[1], S. Zimmerman[2], and M. Billars[2], *[1]Oklahoma Agricultural Experiment Station, Stillwater, [2]C-lock, Inc., Rapid City, SD.*

The objective of this research was to develop and test an automated supplement intake measurement system (SmartFeed, SF), which can be used to measure individual animal supplement intake, behavior, and allow for control of supplement intake to grazing animals. The SF was developed by C-lock Inc., Rapid City, SD, and was designed using a stainless steel feed bin (79 by 71 by 86 cm) that included two weigh cells suspending the bin at two points, an RFID reader and antenna, an adjustable metal framework to limit access to animals at one time, and a data acquisition system that recorded RFID tags and feed bin weights at 1 Hz. A locking door can be added to future SF to control access for individual animals, but the prototype tested in this research did not limit supplement intake. The SF weighs about 100 kg and is self-contained and portable. Over a 14-d test period, 16 RFID-tagged steers (256 ± 31 kg mean BW) grazing dormant native range pasture in Oklahoma had ad lib, 24-h access to SF. The supplement provided in SF was 55% supplements (80% soybean meal and 20% soybean hulls, as-fed basis) and 45% fine mixing salt (as-fed basis) as an intake limiter. During testing, it was determined that SF must be placed on level ground and firmly anchored because the animals will move it if possible. The herd tended to visit SF as a group and exchanged places at the feeder frequently rather than spacing visitation over the day and/or consuming supplement in series. The major considerations for data processing included accounting for rapid animal exchanges at the feeder and weigh scale noise that resulted from animals pushing on the feed bin. Mean daily supplement intake was 1.15 ± 0.50 kg per animal (as-fed basis). The high CV (43%) indicated that considerable variation in daily supplement intake among group-supplemented steers exists. However, the Pearson correlation coefficient between mean daily intake during wk 1 vs. 2 was 0.84, indicating that the ranking of supplement intake was somewhat consistent between weeks. Overall, SF has the potential to measure and, in the future, control individual animal supplement intake in grazing experiments. These capabilities can improve design flexibility and statistical power of experiments, and may have application in nutritional management of range livestock.

Key Words: automation, grazing, supplement intake

0614 Sampling corn silage in bags from the sides.

P. Turiello*[1], M. Ruiz de Huidobro[1], H. Garcia[1], L. Forcone[1], and C. Celaye[2], *[1]Facultad de Agronomia y Veterinaria, UNRC, Rio Cuarto, Argentina, [2]Garay SRL, Recreo, Argentina.*

Because composition variation in silo bags is expected along the tube, and as nutritionists need to know forage composition before it is consumed, it is necessary to collect representative samples from the sides of the tube. The aim of the study was to determine if the composition of the side samples was similar to that of the face samples. Seven corn silage bags in dairy farms in Cordoba and Santa Fe provinces (Argentina) were sampled. Duplicate samples were taken from 5 different areas of the face of the bag (F1) with a core sampler. Then, 2 to 4 samples from both sides, 2 m forward in the bags, were taken (S). When the front achieved the same place where the side samples were taken, the newly exposed face was sampled again as in F1 (F2). After sampling, samples were stored in a refrigerated box for the rest of the day and sent to the same commercial laboratory to determine percentages of DM, NDF, ADF, CP, and ash by NIR. Nutrient composition of corn silage in F2 and S was compared using a mixed procedure of InfoStat, with silage bag as a random effect and sampling site as a fixed effect. Mean DM percentage (31.8 ± 4.0%) was inside the recommended range for corn silage, although the 80% range is lower than recommended, indicating early cuttings compared to optimum. The other nutrients were in accordance to typical values of corn silage. When evaluating different areas in both F1 and F2, no

Table 0614.

Table 1: Effect of sampling site on nutrient composition in corn silage

Nutrient	F2		S		*P*-value
	Mean	SE	Mean	SE	
DM (%)	32.0[a]	1.65	31.7[a]	1.66	0.3241
NDF (%)	46.6[a]	2.02	46.3[a]	1.94	0.7690
ADF (%)	27.6[a]	1.48	28.1[a]	1.53	0.4415
CP (%)	8.2[a]	0.46	7.8[b]	0.47	0.0001
Ash (%)	5.6[a]	0.27	5.6[a]	0.28	0.8948

Means within rows followed by the same letter are not significantly different (P ≥ 0.05).

differences were found for nutrient composition accounting for the silage bag and type of face (F1 and F2) as random effects. No differences between F2 and S were found in DM, NDF, ADF, and ash content, although CP levels showed different values in the side samples (Table 1). Our results showed that side samples are representative comparing them with the front of the bag regarding most nutrients. Nevertheless, more research is needed to determine a complete side sampling methodology for bagged silage.

Key Words: bagged corn silage, nutrient composition, sampling

0615 Survey of temporal variation in pasture mineral concentrations and total dietary mineral intake in pasture-based dairy herds. F. Curran*[1,2], D. Wall[3], P. Lonergan[2], and S. Butler[1], *[1]Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Co. Cork, Ireland, [2]School of Agriculture and Food Science, University College Dublin, Dublin, Ireland, [3]Teagasc Crops, Environment and Land Use Program, Johnstown castle Co., Wexford, Ireland.*

In grass-based dairy production systems, grazed pasture represents the sole feed for long periods. Mineral concentrations in pasture vary depending on region, season, plant variety, and fertilization strategy. The objectives of this study were to: (i) benchmark the seasonal variation in pasture mineral concentrations, and (ii) determine the mineral nutritive value of both grazed grass and the total diet for lactating dairy cows. Spring calving dairy farms (n = 44) were selected based on region and soil type and enrolled on the study. Each farm was visited once in March, May, August, and October 2013. These visits were selected to coincide with expected changes in the grass morphology and growth rate from the start (March) to the end (October) of the grazing season. During the week before each visit, pre-grazing grass samples were cut daily for 7 d to a stubble height of 4 cm. At each visit, the grass samples and samples of any other feeds being consumed (silage, concentrate, and other miscellaneous feedstuffs) were collected, and the proportion of each feedstuff in the diet was recorded. The daily grass samples were then mixed to form one composite sample, representative of grass offered to the herd during the preceding week. All samples from each farm were analyzed for mineral concentrations using inductively coupled plasma mass spectrometry (ICP–MS). The mean, range, and standard deviations for each sample analyzed were calculated across the study farms at each time-point. Pasture mineral concentrations did not vary greatly over the four sampling points, with the exception that mean Se concentration was greater at the first sampling time point (0.21 ± 0.18 mg/kg) compared with all other sample collection times (0.04 ± 0.03, 0.07 ± 0.04, 0.03 ± 0.04 mg/kg on visits 2, 3, 4, respectively). On average (range in parentheses), a pasture-only diet would have provided 90% (45–130), 80% (30–125), 50% (8–190), 65% (30–77), and 30% (3–108) of the requirements for lactating cows (National Research Council, 2001) for P, Cu, I, Zn, and Se, respectively. When total dietary mineral intakes were estimated, on average, the diet provided 96%, 153%, 359%, 109%, and 58% of the lactating cow requirements for P, Cu, I, Zn, and Se, respectively. We conclude that, on average, pasture grown on Irish dairy farms is inadequate for P, Cu, I, Zn, and Se to meet cow requirements when fed as the sole feed.

Key Words: minerals, pasture, dairy

0616 Observations of forage yield and steer average daily gain when double cropped forage following crop harvest. K. M. Ulmer*[1], R. G. Bondurant[1], J. L. Gramkow[1], G. W. Lesoing[2], M. E. Drewnoski[1], and J. C. MacDonald[3], *[1]University of Nebraska, Lincoln, [2]University of Nebraska, Auburn, [3]University of Nebraska-Lincoln, Lincoln*.

Two experiments were conducted to evaluate yield of annual forages planted after harvest in cropping systems and to determine the grazing potential. In Experiment 1, a brassica-based 5-species mix was drilled following wheat harvest on August 17 in yr 1 and August 15 in yr 2. Aboveground forage production measured in late October was 2,257 ± 270 and 3,991 ± 270 kg DM/ha in yr 1 and 2, respectively. In both years, land was split into three 2-ha paddocks and stocked according to aboveground forage yield at 909 kg DM per steer. In yr 1, 15 steers (initial BW = 205 kg [SD 16]) were divided into 5 hd groups and grazed for 48 d. In yr 2, 26 steers (initial BW = 266 kg [SD 4]) were divided into 8 to 10 hd groups and grazed for 52 d. Grazing began in mid November and ADG was 1.00 ± 0.019 and 0.70 ± 0.073 kg/hd in yr 1 and 2, respectively. In Experiment 2, half of a corn field was harvested as corn silage (CS) and half as high-moisture corn (HMC). In yr 1, a mix of oats and turnips was drilled on September 9 after CS harvest yielding 1,047 ± 65 kg/ha, and on September 18, the same mix was drilled after HMC yielding 487 ± 117 kg/ha in late October. In yr 1, there was no grazing of the oat–turnip mixture due to herbicide restrictions. In yr 2, oats were drilled on September 3 after CS harvest yielding 3,200 ± 93 kg DM/ha whereas oats drilled on September 17 after HMC harvest yielded 586 ± 95 kg DM/ha. In yr 2, grazing began in mid November with 2 groups of 10 steers per treatment (initial BW = 212 kg [SD 74]) grazing for 62 d. Steers grazing after CS were allocated 795 kg oat forage DM/hd. Steers grazing after HMC were allocated 181 kg oat forage DM and 1,229 kg corn husk and leaf DM per hd. Steer ADG did not differ ($P = 0.27$, SEM = 0.12) among treatments, 0.50 and 0.33 kg for CS and HMC, respectively. Gain per hectare of HMC (109 kg) and CS (153 kg) did not differ ($P = 0.15$, SEM = 1.07). Fall forage production after grain harvest is sufficient to provide cover and adequate forage for growing calves.

Key Words: average daily gain, brassicas, cover crop forages

0617 Banana tree (*Musa sapientum*) forage in sexed Guinea pig (*Cavia porcellus*) fattening. A. R. Sanchez*, *Universidad Tecnica Estatal de Quevedo, Quevedo, Ecuador*.

This research was performed in La Mana canton, in the southeast of Cotopaxi province, whose geographical location is 0°45′35″ S and 7°09′32″ W at an altitude of 240 m above the sea level. The objectives were 1) to determine the effect of Savoie grass (*Panicum maximum* Jacq.) and banana tree leaves (*Musa sapientum*) consumption on guinea pig productive behavior, 2) to determine the effect of sex on guinea pig productive behavior, and 3) to determine treatment yield. A factorial arrangement 2 (forages) × 2 (sexes) within a complete randomized block design with six repetitions was applied. To determine rate differences, a Turkey test ($P \leq 0.05$) was applied and the cost–benefit relationship served as a basis for the economic analysis. Forage consumption, food consumption, live weight (LW), weight gain (WG), food conversion index (FCI), carcass weight (CW), carcass yield (CY), and rent were evaluated. The highest forage consumption (55.40 g MS animal^{-1} d^{-1}), LW (841.11 g.), WG (8.78 g. animal^{-1} d^{-1}), FCI (7.96), CW (598.06 g), and CY (71.0%) were registered for savoie-based treatments. The male guinea pig reported the highest LW (826.00 g.), WG (8.57 g animal^{-1} d^{-1}), FCI (7.96), and CW (576.25 g.), whereas differences among treatments ($P < 0.05$) were shown: savoie per male interaction was significant ($P < 0.05$) for LW (881.0 g.), WG (9.63 g animal^{-1} d^{-1}), FCI (7.01), CW (639.00 g.), CY (72.5%), and 48.3% profitability. Results demonstrate that using tropical forage resources contributes to guinea pig fattening in the studied zone.

Key Words: forage, grasses, feeding, nutrition, guinea pigs

0618 Effect of frame size and season on enteric methane (CH_4) and carbon dioxide (CO_2) emissions in Angus brood cows grazing native tallgrass prairie in central Oklahoma. J. P. S. Neel*, K. E. Turner, P. H. Gowda, and J. L. Steiner, *USDA-ARS-PA-GRL, El Reno, OK*.

A reduction in enteric CH_4 production in ruminants is associated with improved production efficiency. Enteric CH_4 and CO_2 production associated with the livestock industry is of interest due to the impact these emissions might have on global climate change. Our objective was to evaluate the effect of cow frame size (FS) and season on enteric CH_4 and CO_2 production in cattle grazing during summer and fall. Twenty-eight Angus cows (545 ± 49 kg BW) of either medium ($n = 14$) or large FS ($n = 14$) and grazing simultaneously within a native tallgrass prairie pasture in central Oklahoma were used to estimate individual animal enteric CH_4 and CO_2 production daily (via a commercially available breath analyzer) over the summer and fall seasons. Cow FS was categorized based on frame scores generated from individual hip heights. Summer and fall season designations were based on summer and winter solstices and the fall equinox. Statistical analyses were conducted using GLM of SAS. The model included class effects of FS and season and their interaction. As measured at the beginning of the experiment, large-FS cows were heavier ($P < 0.001$) and had a greater frame score ($P < 0.001$) compared with medium-FS cows (609 vs. 480 kg and 6.8 vs. 4.6, respectively). As measured during the experimental period,

large-FS cows produced calves with heavier ($P < 0.01$) 205-d adjusted weaning weights (261 vs. 222 kg). There were no frame size × grazing season interactions with regard to enteric gas production. Large-FS cows produced greater ($P < 0.001$) enteric CH_4 (280 vs. 248 g/d) and CO_2 (9,065 vs. 8,021 g/d) than medium-FS cows. Cows produced higher ($P < 0.001$) amounts of enteric CH_4 and CO_2 in summer than in fall (292 vs. 236 g/d and 9,065 vs. 8,021 g/d, respectively). When expressed as total production (over the entire summer and fall seasons) of CH_4 or CO_2 per weight unit of weaned calf, enteric gas production did not differ between large- and medium-FS cows (0.20 vs. 0.21 kg/kg and 6.4 vs. 6.6 kg/kg, respectively). Further research is needed to relate enteric gas production to herbage nutritive value and animal DMI.

Key Words: beef cows, enteric methane, native prairie

0619 Grazing management: milk production and composition of dairy cows grazing elephant grass.

C. D. A. Batalha, G. F. D. S. Congio, A. C. A. Krol, S. Crestani, M. B. Chiavegato, S. C. Da Silva, and F. A. P. Santos*, *University of Sao Paulo, Piracicaba, Brazil*.

The objective of this experiment was to evaluate the effects of strategies of rotational grazing management on milk yield and composition of dairy cows grazing elephant grass (*Pennisetum purpureum* Schum. cv. Cameroon) from December 2015 to February 2016. Treatments corresponded to management strategies characterized by the pregrazing targets of 95% and maximum canopy light interception during regrowth (equivalent to 100 and 135 cm; $LI_{95\%}$ and LI_{Max}, respectively). The postgrazing target was the same and corresponded to 50% of the pregrazing height. Midlactation Holstein × Jersey cows were separated into two groups according to BW, days in milk, age, lactation number, and daily milk yield. The 2.5-ha experimental area was divided up into two sets of 18 paddocks (700 m^2). Twenty-two cows (487.5 ± 13.1 kg) were used as testers and a variable number was used to adjust stocking rate. Milking was performed twice a day at 0500 and 1530 h, milk yield was measured in a daily basis, and milk composition was measured at 10-d intervals. The amount of concentrate mix fed to cows was based on the average milk production for the groups (1 kg of concentrate:3 kg of milk) and offered in two daily individual meals just before milking. The effective values of pre- and postgrazing heights were 100.8/50.5 and 135.6/68.6 cm with average stocking rates of 9.2 and 6.0 cows/ha for $LI_{95\%}$ and LI_{Max}, respectively. The results were analyzed using the PROC MIXED of SAS ($\alpha = 0.05$). Management based on the $LI_{95\%}$ target resulted in an 18.5% increase in milk production (19.2 vs. 16.2 kg of 3.5% fat corrected milk cow^{-1} d^{-1}), lactose (854 vs. 710 g d^{-1}), protein (578 vs. 519 g d^{-1}) and fat yield (677 vs. 569 g d^{-1}), despite no difference in fat content. Protein content was higher for LI_{Max} (3.28 vs. 3.07%) and urea N was higher for $LI_{95\%}$ (13.17 and 11.83 mg dL^{-1}). The results suggest that the $LI_{95\%}$ pregrazing target correspond to a better management strategy because it resulted in increased milk and milk solids production per cow and stocking rate, resulting in increased productivity.

Key Words: light interception, tropical grass, grazing management

0620 Performance and rumimal metabolism are not changed in lactating dairy cows offered spring available annual forage crops during a short-term grazing experiment. K. A. Juntwait*, A. F. Brito, K. S. O'Connor, R. G. Smith, K. M. Aragona, C. P. Ghedini, and A. B. D. Pereira, *University of New Hampshire, Durham*.

Spring available annual forage crops (AFC) can potentially be used to extend the grazing season by increasing pasture production. We aimed to determine the impact of spring available AFC on pasture production and animal performance during a short-term grazing experiment. Fourteen multiparous and 2 primiparous lactating organically certified Jersey cows were randomly assigned to either a traditional legume–grass pasture mix (control treatment; $n = 8$ cows) or a spring AFC mix of wheat, triticale, barley, cereal rye, and hairy vetch strip-tilled into a traditional pasture (SpAFC treatment; $n = 8$ cows). The botanical composition (DM basis) for the control averaged 70% grasses, 17% legumes, and 13% other (broadleaf, weeds, and dead), whereas that for SpAFC averaged 60% grasses, 14% legumes, 13% AFC grasses, 4% AFC legumes, and 9% other. Cows averaged 433 ± 48 kg of BW and 83 ± 50 DIM for the control group and 416 ± 46 kg of BW and 86 ± 43 DIM for the SpAFC group. A 14-d adaptation period was followed by a 7-d sampling period. Pasture nutrient composition during the sampling period averaged 16.0 and 15.1% CP, 53.3 and 56% NDF, and 34.6 and 32.1% ADF for the control and the SpAFC, respectively. Pasture biomass averaged 3,038 ± 303 and 4,052 ± 353 kg of DM/ha for the control and SpAFC, respectively. Cows were fed a total mixed ration (TMR) and milked twice daily and had access to a new strip of pasture after the afternoon milking. Pasture intake was estimated using chromium oxide and IVDMD. Ruminal fluid was sampled using an esophageal tube immediately after the morning milking with samples analyzed for VFA. Results are shown in Table 1. There were no significant differences in pasture and TMR intake comparing the control with SpAFC, but a trend ($P = 0.08$) was observed for increased total DMI (+0.8 kg/d) in cows fed the control treatment. Contents and yields of milk and milk fat and protein and ADG did not differ between treatments. A trend ($P = 0.06$) for greater MUN was observed with feeding the SpAFC rather than the control treatment. No significant differences were observed in the plasma concentrations of urea N and NEFA or in the ruminal concentration of total VFA. Strip-tilling spring available AFC into a perennial grass–legume pasture mix increased herbage biomass production and did not affect animal performance of lactating Jersey cows in the Northeastern United States.

Key Words: annual forage crops, dairy cows, grazing

0621 Performance and ruminal metabolism in lactating dairy cows offered summer available annual forage crops during a short-term grazing experiment. K. A. Juntwait*, A. F. Brito, K. S. O'Connor, R. G. Smith, K. M. Aragona, C. P. Ghedini, and A. B. D. Pereira, *University of New Hampshire, Durham*.

Summer available annual forage crops (AFC) have the potential to increase pasture production during times of heat and drought in the Northeastern United States. The objective of this study was to determine the impact of summer available AFC on pasture production and animal performance during a short-term grazing experiment. Sixteen multiparous and 4 primiparous organically certified lactating Jersey cows were randomly assigned to 1 of 2 treatments: traditional legume–grass pasture mix (control; $n = 10$ cows) or a summer AFC

mix of millet, teff, buckwheat, oats, and chickling vetch strip-tilled into a traditional pasture (SuAFC; n = 10 cows). The botanical composition (DM basis) for the control averaged 69% grasses, 11% legumes, and 20% other (broadleaf, weeds, and dead), whereas that for SuAFC averaged 61% grasses, 13% legume, 1% AFC grasses, 2% AFC legumes, 12% AFC broadleaf, and 11% other. Cows averaged 434 ± 46 kg of BW and 146 ± 61 DIM for the control and 449 ± 53 kg of BW and 140 ± 57 DIM for the SuAFC. A 14-d adaptation period was followed by a 7-d sampling period. Pasture nutrient composition during the sampling period averaged 12.9 and 14.8% CP, 53.1 and 50.1% NDF, and 35 and 38.8% ADF for the control and SuAFC, respectively. Pasture biomass averaged 2,774 ± 275 and 2,588 ± 272 kg of DM/ha for the control and SuAFC, respectively. Cows were fed a total mixed ration (TMR) and milked twice daily and had access to a new strip of pasture after the afternoon milking. Pasture intake was estimated using chromium oxide and IVDMD. Ruminal fluid was sampled using an esophageal tube immediately after the morning milking with samples analyzed for VFA. Results are shown in Table 1. There were no significant differences in pasture, TMR, total DMI, ADG, and milk yield between the control and SuAFC. Milk fat and protein concentrations and yield were all significantly greater in cows offered SuAFC than in cows offered the control. A trend (P = 0.09) for lower MUN in cows fed SuAFC vs. cows fed the control treatment was observed. Cows offered SuAFC had less (P < 0.01) concentration of plasma urea N than those offered the control. Ruminal concentrations of total VFA and plasma NEFA did not differ between treatments. Strip-tilling summer available AFC into perennial grass–legume pasture mix did not change pasture biomass production compared with the control but increased the concentrations and yields of milk fat and protein.

Key Words: annual forage crops, dairy cows, grazing

0622 Fluctuation of soil carbon dioxide emission in agrosilvopastoral system managed with sheep.

F. O. Alari, A. C. Ruggieri*, T. Silva do Nascimento, E. B. Malheiros, P. P. Spasiani, L. F. Brito, R. A. Reis, and A. S. Cardoso, *Sao Paulo State University, Jaboticabal, Brazil*

The burning of fossil fuels and the misuse of land in the agricultural sector has been raising the concentration of carbon dioxide (CO_2), which causes global temperature rise causing climate imbalance. The use of integrated systems such as agrosilvipastoral is vitally important in mitigating this gas. This research aimed to evaluate the CO_2 in soils intercropped with corn and Massai grass with subsequent implementation of a silvopastoral system with sheep grazing. The experiment was performed at Sao Paulo State University in Brazil from April to May 2012 and February 2013 to September 2014. Carbon dioxide emissions were assessed weekly from soil on intercropping corn and Massai grass 15 d before the corn harvest and 1 mo after. Carbon dioxide assessments were also performed every 15 d in three different treatments: silvopastoral Massai grass with eucalyptus spacing by 6.0 by 1.5 m with grazing assess, silvopastoral Massai grass with eucalyptus spacing by 12.0 by 1.5 m, and Massai grass without eucalyptus system with grazing assess in a completely randomized design with repeated measures with two longitudinal factors (2 yr of evaluations and two seasons: dry and rainy season). The CO_2 emission on intercropping corn and Massai grass remained constant a week after harvesting of maize with an average of 2.43 μmol CO_2 $m^{-2}{\cdot}s^{-1}$. Two weeks after the harvest, there was reduction in CO_2 emissions of 34.98% or 0.85 μmol CO_2 $m^{-2}{\cdot}s^{-1}$. The average flux of CO_2 emission in the silvopastoral system did not differ between treatments (P > 0.05). In the summer (rainy season), there were higher CO_2 emission values compared with the winter (dry season) (P < 0.05), with a reduction of 44.46%, or 2.33 μmol $m^{-2}{\cdot}s^{-}1$, in the CO_2 emissions. Comparing the years of measure, we can denote that in the first year, there was the highest values of CO_2 emissions compared with the second year of measure (P < 0.05), with a reduction of 16.44%, or 0.73 μmol CO_2 $m^{-2}{\cdot}s^{-1}$. Therefore, the corn harvest reduces the emission of CO_2 in the soil. However, the introduction of trees in the pastoral system did not change the CO_2 emissions. The CO_2 emission was modified only by climatic factors. These results can be explained because the silvopastoral system was in an implementation phase when the eucalyptus trees had an average height between 1.7 and 4.7 m in first and second year, respectively, and were not providing the expected shading as the silvopastoral system.

Key Words: intermittent stocking, climatic changes, tropical pasture

0623 Yield and quality evaluation of ensiled Johnsongrass as a potential forage for beef cattle.

M. L. Bass*[1], D. D. Harmon[2], J. M. Lourenço[3], D. Hancock[2], and R. L. Stewart Jr.[3], *[1]University of Georgia, Athens, [2]Dep. of Crop and Soil Sciences, University of Georgia, Athens, [3]Dep. of Animal and Dairy Science, University of Georgia, Athens*.

Johnsongrass (*Sorghum halepense*) is a nonnative invasive species that is commonly used for hay production. Johnsongrass could be ensiled to avoid long drying times associated with hay production. The objective of this study was to examine the nutritive value and digestibility of Johnsongrass conserved as silage when harvested at four maturity levels: 3-wk, boot, flower, and dough. A preexisting stand of Johnsongrass was split into 16 plots in May 2015 at the J. Phil Campbell Research Station at the University of Georgia in Watkinsville, GA. Each plot was then randomly assigned to one of the four treatments. After reaching the proper stage, botanical separation and growth stage data were collected before harvesting to obtain DM yield. During the growing season, two harvests were designated for ensilage. After these harvests, forage was allowed to

wilt to approximately 50% DM. Wilted forage was packed into mini-silos constructed with 90-cm lengths of 10-cm diameter polyvinyl chloride pipe. Forage was packed to a density of 2.4 kg/L. The silos were sealed and allowed to ferment for 10 wk. After fermentation, all samples were frozen until subsequent nutritive value and fermentation characteristics could be determined. Statistical analysis was performed in JMP (SAS Inst. Inc., Cary, NC) with treatment as a main effect and harvest date as a random variable. Treatment did not have a significant effect on DM yield ($P = 0.09$). Neutral detergent fiber, ADF, and lignin increased ($P < 0.001$) as maturity at harvest increased from 3-wk (52, 35, and 6.0%, respectively) to dough (62, 41, and 7.9%, respectively). However, CP and relative forage quality decreased ($P < 0.01$) as maturity at harvest increased from 3-wk (108 and 14.9%, respectively) to dough (86 and 12.2%, respectively). Forage maturity did not affect nonstructural carbohydrates ($P = 0.06$). After fermentation, pH was similar ($P = 0.06$) across maturities; however, total VFA and ammonia was greater ($P < 0.03$) for forage harvested at 3 wk (7.7 and 1.4%, respectively) compared with dough (5.7 and 0.9%, respectively). These data indicate that Johnsongrass can provide high-quality forage if not allowed to mature past the boot stage and can be ensiled, providing an alternate method of conservation.

Key Words: Johnsongrass, silage, digestibility

0624 Evaluation of warm-season annual forages on forage production and stocking rate.

D. D. Harmon*[1], M. L. Bass[2], J. M. Lourenço[2], C. D. Teutsch[3], J. R. Segers[4], A. M. Stelzleni[2], R. L. Stewart Jr.[2], and D. Hancock[1], *[1]Dep. of Crop and Soil Sciences, University of Georgia, Athens, [2]Dep. of Animal and Dairy Science, University of Georgia, Athens, [3]Dep. of Crop and Soil Environmental Sciences, Virginia Polytechnic Institute and State University, Blacksburg, [4]Dep. of Animal and Dairy Science, University of Georgia, Tifton*.

A 2-yr study was conducted to evaluate four warm-season annual forages in a southeastern forage-finishing beef production system. Forage treatments were brown midrib sorghum × sudangrass (*Sorghum bicolor* var. *bicolor* × *bicolor* var. *sudanense*) (BMR; Honey Graze/AS6201), sorghum × sudangrass (SS; Sugargrazer/AS5201), pearl millet [*Pennisetum glaucum* (L.) R. Br.] (PM; Tifleaf III), or pearl millet planted with crabgrass [*Digitaria sanguinalis* (L.) Scop.] (PMCG; Tifleaf III + Red River) planted at a seeding rate of 22.4, 22.4, 16.8, and 11.2 + 5.6 kg ha^{-1}, respectively. Sixteen pastures (0.81 ha) were assigned to one of four forage treatments in a randomized complete block design. Pastures were subdivided into two 0.405-ha paddocks for rotational grazing. British-cross beef steers ($n = 32$; 438 ± 49 kg) were stratified by weight and randomly assigned to 1 of the 16 pastures for forage finishing. Put-and-take grazing was used to maintain a forage allowance of 1,600 to 4,500 kg ha^{-1}. Pastures were grazed in 2014 and 2015 for 70 and 63 d, respectively. Forage yield was measured by clipping, in triplicate, a 4.3-m^2 area with a plot harvester on d 0 and every 14 d thereafter, whereas metabolic BW were measured on d 0 and every 34 d thereafter until termination of the trial. Statistical analysis was conducted using the MIXED procedure in SAS 9.4 (SAS Inst. Inc., Cary, NC) with main effects of treatment, year, and the interaction. Analysis of main effects revealed that DM yield in 2014 was greater for BMR and SS compared with PM and PMCG at d 0 ($P < 0.05$; 1,657, 1,958, 1,205, and 1,297 kg h^{-1}, respectively) and at d 14 ($P < 0.05$; 4,007, 4,670, 3,485, and 2,962 kg h^{-1}, respectively). In 2015, DM yield was greater at d 0 for BMR, SS, and PM compared with PMCG ($P < 0.05$; 2,548, 2,755, 3,016, and 2,039 kg h^{-1}, respectively) and at d 42 for BMR compared with SS, with PM and PMCG as intermediates ($P < 0.05$; 2,880, 1,577, 2,294, and 2,219 kg h^{-1}, respectively). Average daily gain was significantly ($P < 0.05$) higher for steers grazing BMR (0.90 kg/d) compared with steers grazing SS and PMCG (0.68 and 0.62 kg/d, respectively) but did not differ from steers grazing PM ($P > 0.05$; 0.79 kg/d). These findings suggest that BMR, SS, PM, and PMCG may all be used in beef cattle production systems but BMR may outperform SS, PM, and PMCG on the parameters of forage yield and animal performance.

Key Words: warm-season annual forages, beef, performance

0625 Microbiota attachment and structural components of *Lolium perenne* L. and *Festuca arundinacea* Schreb. during in vitro fermentation.

H. A. Zavaleta-Mancera*[1], D. Trujillo-Gutierrez[1], S. S. Gonzalez-Muñoz[2], M. Cobos-Peralta[1], J. E. Ramirez-Bribiesca[3], and J. L. Bórquez-Gastelim[4], *[1]Colegio de Postgraduados, Montecillo Texcoco, Mexico, [2]Colegio de Postgraduados, Montecillo Estado de Mexico, Mexico, [3]Colegio de Postgraduados, Montecillo, Mexico, [4]Universidad Autónoma del Estado de México, Toluca, Mexico*.

The objective of this research was to evaluate the effect of lignin aggregation in *Lolium perenne* and *Festuca arundinacea* on microbiota attachment and cell wall components during in vitro degradation. Stages of senescence (0, 30, and 60%) were measured in summer and winter. Leaf tissue structure and cell wall components were studied using histochemistry technique. An in vitro fermentation test was performed during 72 h, and microbiota attachment to grass residues was studied using scanning electron microscopy. The experimental design was split plot, and PROC MIXED of SAS was used to evaluate the stage effect, whereas means were compared with a Tukey test. The central vein (CV) of 0% senescence showed higher lignified tissue in summer than in winter, whereas for 30 and 60% senescence, lignified tissue was higher in *Lolium* compared with *Festuca* ($P < 0.05$). The extension of the vascular

bundle sheath (EVBS) of the CV contributed the most to leaf lignification ($P < 0.05$). Senescence affected IVDMD, and total VFA production of *Lolium* and *Festuca* at 30% senescence was lower in winter, but in summer, is was higher compared with 60% senescence leaves ($P < 0.05$). Microbiota cell wall attachment was higher in 0% senescent leaves in both grasses, but in 30 and 60% senescent leaves, microbiota was reduced and attached to lignified walls of fibers and vessels of xylem ($P < 0.05$). It is concluded that leaves cell aging of *Lolium* appears as lignification of the EVBS with higher values in summer, whereas no differences were found in *Festuca*. The oldest leaves of *Festuca* showed higher NDF and ADF, which affected in vitro response and fermentative variables of the ruminal inoculum and microbiota attachment. As far as we know, this is the first contribution about tissue identification during leaf lignification of *Lolium* and *Festuca* in winter and summer.

Key Words: leaf structure, lignified tissue, microbiota attachment

0626 Correlation of fermentation characteristics with intake and digestibility of alfalfa silage in gestating ewes. V. Niyigena*[1], K. P. Coffey[2], W. K. Coblentz[3], A. N. Young[1], D. Philipp[2], H. L. Bartimus[4], and R. T. Rhein[1], *[1]Department of Animal Science, University of Arkansas Division of Agriculture, Fayetteville, [2]University of Arkansas, Division of Agriculture, Fayetteville, [3]U.S. Dairy Forage Research Center, Marshfield, WI, [4]Department of Agriculture and Environmental Sciences, Lincoln University, Jefferson City, MO*.

Baled silage production provides benefits to farmers because it reduces leaf losses and requires a shorter wilting time, thereby limiting risks of exposure to rain compared with making hay. Our objective was to investigate the correlation of alfalfa silage fermentation parameters with intake and digestibility in gestating ewes. Alfalfa from 3 field blocks was baled in large round bales at a mean moisture concentration of 59.1 ± 4.30% and then wrapped with plastic on the day of baling or 1, 2, or 3 d after baling; this resulted in considerable variability in silage fermentation measurements. Following approximately 5 mo of storage, the alfalfa was chopped and then offered for individual ad libitum consumption by 16 gestating ewes (63.5 ± 1.71 kg average BW) where total feces were collected for 7 d following a 10-d dietary adaptation in each of 3 different periods. Diets were rerandomized to different ewes for each period such that ewes were not offered the same treatment in any period. Data were analyzed using PROC CORR of SAS to determine the correlation between alfalfa fermentation parameters with intake and digestibility measurements. Dry matter and OM intakes were positively correlated ($P < 0.05$) with silage moisture and lactic acid and propionate concentrations and negatively correlated ($P < 0.05$) with ADF concentrations. Dry matter and OM digestibilities were positively correlated ($P < 0.05$) with proportion of lactic acid to total acids (mol/100 mol) but negatively correlated ($P < 0.05$) with ADF concentration, and OM digestibility was also positively correlated ($P < 0.05$) with silage pH. Digestibility of ADF was positively correlated ($P < 0.05$) with silage pH but negatively correlated with water content, lactic acid, total acids, and propionate. Digestible DM and OM intakes (g/kg BW) were positively correlated ($P < 0.05$) with water content of silage, total silage acids, lactic acid, propionate, and butyrate. Therefore, managing alfalfa silage to ensure more desirable fermentation should also result in greater intake of digestible OM, which should improve overall energy status of ruminants. The study was supported in part by USDA-ARS specific cooperative agreement 58-3655-4-052.

Key Words: alfalfa, digestibility, fermentation

0627 A Bayesian approach to unmixed diet composition. N. Vargas Jurado*, K. M. Eskridge, and R. M. Lewis, *University of Nebraska-Lincoln, Lincoln*.

Accurately measuring diet composition is key to delineating feed efficiency, but under grazing conditions, doing so is challenging. Plant-wax markers can be used to estimate the composition of diet mixtures. However, traditional methodologies such as nonnegative least squares (NNLS) ignore variability in and relationships (covariances) between such markers. More recently, Bayesian hierarchical models for linear unmixing (BHLU) have been successfully used for estimating mixing proportions in hyperspectral image analysis

Table 0627.

Table 1. Efficiency of BHLU under four specifications and NNLS

Plant mixture	BDU	BDG	BCU	BCG	NNLS
NMSE					
2	14.4	52.2	11.0	34.0	23.2
3	25.3	66.1	25.1	45.7	39.2
8	321.1	417.1	210.4	463.3	431.8
CP					
2	0.97	0.74	0.91	0.76	0.72
3	0.98	0.89	0.98	0.85	0.73
8	0.18	0.16	0.12	0.17	0.17

and could be applied to estimate diet composition. The objective of the present study was to determine the efficiency of BHLU under five scenarios: 1) BHLU with no covariance and uniform priors, 2) BHLU with no covariance and Gaussian priors, 3) BHLU with covariances and uniform priors, 4) BHLU with covariances and Gaussian priors, and, for completeness, 5) NNLS. A simulation study was performed using *n*-alkane and long-chain alcohol concentrations measured on eight forage species in western rangelands: *Bouteloua gracilis*, *Bromus tectorum*, *Amorpha canescens*, *Schizachyrium scoparium*, *Hesperostipa comata*, *Bouteloua curtipendula*, *Melilotus officinalis*, and *Pascopyrum smithii*. Three mixtures were formed: 1) the two plants *M. officinalis* and *B. tectorum*; 2) the three plants *M. officinalis*, *B. tectorum*, and *B. gracilis*; and 3) all eight plants. For the two- and three-plant mixtures, proportions were drawn from a Dirichlet distribution. The eight-plant mixture reflected the composition of a field in spring. Covariances between markers were specified based on observed correlations. In each case, 900 samples were drawn. Efficiency was assessed through normalized mean squared error (NMSE) and coverage probability (CP). Accounting for covariances between markers increased efficiency of estimation, as shown by lower NMSE and increased CP (Table 1). Gaussian priors increased errors and reduced coverage. Although not entirely comparable with Bayesian methods, NNLS performed reasonably well in terms of NMSE but achieved lower CP. In the eight-plant scenario, all methods performed poorly, suggesting that delineating individual plants grazed in complex swards will be difficult.

Key Words: diet composition, plant-wax markers, Bayesian inference

0628 Dry matter yields and nutritional composition of corn and sorghum for silage in Florida.

G. Ferreira*[1], C. R. Staples[2], and J. D. Wasdin[3], *[1]Virginia Polytechnic Institute and State University, Blacksburg, [2]Dep. of Animal Sciences, University of Florida, Gainesville, [3]University of Florida, Gainesville*.

The objective of this retrospective study was to determine the effect of forage type and planting season on DM yield and nutritional composition of corn and sorghum for silage. Data were obtained from hybrid test trials performed by University of Florida. Evaluated forages included corn, forage sorghum (FS), and sorghum Sudan (SS) planted during spring and summer of each year from 2008 to 2014. Plantings occurred on March 17 (±13 d) and July 17 (±3 d) for corn and April 16 (±9 d) and July 18 (±2 d) for sorghum species during spring and summer seasons, respectively. Nutritional composition of harvested and nonensiled samples was determined using NIRS (Dairyland Labs, WI). Data were analyzed using Proc MIXED of SAS. The statistical model included the effects of year (random; df = 6), the treatments (fixed; df = 5), and the residual error (df = 30). Orthogonal contrasts were used to test the effect of planting season (contrast 1), corn vs. sorghum (contrast 2), interaction of season and corn vs. sorghum (contrast 3), FS vs. SS (contrast 4), and the interaction of season (FS vs. SS; contrast 5). Dry matter yield was greater ($P <$??) for corn than for sorghum. Summer planting resulted in 30 to 35% lower ($P <$??) DM yields than spring planting in all forages. Dry matter yields did not differ ($P >$??) between sorghum species. Corn had lower ($P <$??) concentrations of NDF, greater ($P <$??) concentrations of starch, and greater ($P <$??) NDF digestibility than sorghum species. Sorghum Sudan had greater ($P <$??) concentrations of NDF than FS. In conclusion, spring season forages yielded more DM of better nutritional quality than summer season forages. Also corn yields more DM of better nutritional quality than sorghum forages.

Key Words: corn, sorghum, silage.

0629 Influence of plant population, maturity and ensiling time on fermentation profile, nitrogen fractions, and starch digestibility in earlage.

L. F. Ferraretto*[1], R. D. Shaver[2], J. G. Lauer[3], L. Brown[4], R. Lutz[4], J. Kennicker[4], R. Schmidt[5], and D. M. Taysom[6], *[1]University of Florida, Gainesville, [2]University of Wisconsin-Madison, Madison, [3]University of Wisconsin, Madison, [4]Monsanto, St Louis, MO, [5]Lallemand Animal Nutrition, Milwaukee, WI, [6]Dairyland Laboratories Inc., Arcadia, WI*.

The objective of this study was to evaluate the effect of plant population, maturity at harvest, and ensiling time on

Table 0628.

fermentation profile, N fractions, and ruminal in vitro starch digestibility (ivSD; 7 h incubations on dried and 4-mm ground samples) in earlage (contains husks, kernels, and cob). Samples from 4 hybrids (used as experimental unit), each planted at 4 different plant populations (64,000 [64K], 79,000 [79K], 94,000 [94K] or 109,000 [109K] plants/ha) and harvested at 2 maturities (one-half kernel milk line [1/2ML] or black layer [BL]), were collected at harvest, inoculated (Buchneri 500; Lallemand Animal Nutrition, Milkwaukee, WI), and ensiled in vacuum-sealed bags for 30, 60, 120, and 240 d. Ensiled and fresh samples were analyzed at Dairyland Laboratories Inc. (Arcadia, WI). Data were analyzed using Proc Mixed of SAS with the fixed effects of ensiling time, plant population, maturity, and their interactions. Regressions to determine linear relationships were performed using Proc Reg in SAS. Except for greater (P = 0.01) DM content for 64K than for 94K and 109K or slightly greater ivSD for 94K than for other treatments (P = 0.04; 65.5 vs. 63.3% of starch, on average), no effects of plant population were observed (P > 0.10). Although contents of DM, CP, starch, and sugars were greater (P > 0.01), lactate, acetate, 1,2-propanediol, ethanol, and total acid concentrations were lower and, thus, pH was greater in BL earlage. Furthermore, soluble CP and ammonia N concentrations and ivSD were reduced by 5.5, 1.0, and 8.3 percentage units, respectively, in BL than in 1/2ML. Measurements of pH were greater (P = 0.001) for 30 d than the other ensiling times in relationship to a shift in fermentation from lactate (P = 0.001) toward acetate and 1,2-propanediol (P = 0.001) as fermentation progressed. Gradual increases were observed (P < 0.001) from 30 to 240 d for soluble CP (40.6, 47.6, 49.7 and 69.5% of CP) and ammonia N (4.3, 5.4, 5.9, and 9.6% of N). Likewise, the ivSD measurements increased with ensiling time (P < 0.001; 57.9, 59.9, 67.8, and 69.9% of starch). Both ammonia N (R^2 = 0.42, P = 0.001) and soluble CP (R^2 = 0.45, P = 0.001) were positively related to ivSD. Fermentation profile, N fractions, and ivSD of earlage were influenced to a greater extent by ensiling time and maturity than by plant populations. Ammonia N and soluble CP were both good indicators of ivSD in earlage.

Key Words: earlage, ensiling time, starch digestibility

0630 Replacing alfalfa silage with birdsfoot trefoil silage varying in tannin content in lactating cow diets. U. C. Hymes Fecht*, *USDA ARS Dairy Forage Research Center, Madison, WI.*

Silages made from birdsfoot trefoil (BFT) containing 3 levels of condensed tannins (CT) were compared with alfalfa silage (AS) as the principal forage in the diets of lactating dairy cows. Thirty-five multiparous and 15 primiparous Holstein cows were fed a covariate diet for 2 wk and then blocked by parity and DIM and randomly assigned to 1 of 5 diets in a trial of randomized complete block design. Experimental diets were fed as total mixed ration for 12 wk and contained 48% (DM basis) AS or 16% AS plus 32% BFT with low CT (BFTL), normal CT (BFTN), or high CT (BFTH) or a mixture with equal DM from all 3 BFT silages. The BFTL, BFTN, and BFTH contained 5.1, 8.4, and 14.8 g CT/kg DM, respectively. The balance of dietary DM was fed as corn silage, high-moisture shelled corn, soybean meal, soy hulls, Energy Booster, and macro- and trace minerals plus vitamins A, D, and E. Diets were formulated to 16.5% CP and 30% NDF. Statistical analyses were performed using the mixed procedures of SAS. Intake and yield of milk, ECM, true protein, lactose, and SNF were greater (P < ??) on BFTL and BFTN than on AS and BFTH, whereas the BFT mix was intermediate. Apparent N efficiency also was numerically higher (P > ??) on BFTL and BFTN than on the other 3 diets; MUN was lower (P < ??) on all BFT diets than on AS. These results suggest that CT concentrations of approximately 5 to 8 g/kg DM in BFT improve utilization of forage nutrients for milk production.

Key Words: birdsfoot trefoil, condensed tannins, milk production

0631 Bacterial and fungal community structure of conventional and brown midrib corn hybrids ensiled with or without a combo inoculant at high dry matter concentrations. J. J. Romero*[1,2], Y. H. Joo[3], Y. Zhao[4], J. Park[3], M. A. Balseca-Paredes[1], E. Gutierrez-Rodriguez[5], and M. S. Castillo[1], *[1]Department of Crop Science, North Carolina State University, Raleigh, [2]Animal and Veterinary Sciences, University of Maine, Orono, [3]Division of Applied Life Science (BK21Plus, Inst. of Agri. & Life Sci.), Gyeongsang National University, Jinju, the Republic of Korea,[4]Department of Animal Nutrition and Feed Science, China Agricultural University, Beijing, P. R. China, [5]Department of Food, Bioprocessing, and Nutrition Sciences, North Carolina State University, Raleigh*.

The objective was to evaluate the effects of a combo inoculant on the microbial community structure of 4 corn hybrids ensiled at high DM. Treatment design was the factorial combination of 4 corn types (HYB) ensiled with (INO) and without (CON) inoculant. Corn hybrids were TMF2R737 and F2F817 (A and B; 44.0 and 38.1% DM, respectively; from Mycogen) and P2089YHR and P1449XR (C and D; 42.0 and 41.3% DM, respectively; from Pioneer). F2F817 and D were brown midrib mutants. The inoculant added contained *Lactobacillus buchneri* and *Pediococcus pentosaceus* (4×10^5 and 1×10^5cfu/g of fresh corn). Experimental design was a complete randomized design with treatments replicated 6 times (silos). Corn was chopped, treated or not with inoculant, packed into 7.6-L bucket silos, and stored for 100 d. At d 0, neither HYB nor INO affected the relative abundances of Enterobacteriaceae (61.4 ± 4.54%) and Brucellaceae (3.8 ± 1.24%) bacterial families. F2F817 had more abundance ($P \leq 0.05$) of Rhizobiaceae (5.2 vs. 2.41 ± 0.48%) and Pseudomonadaceae (3.3 vs. 1.8 ± 0.17%) families, compared with A and C. For fungi, 45% (±4.17) consisted of unidentified fungal sequences followed by unidentified sequences of the Tremellales order, which were more abundant in C vs. the others (21.4 vs. 9.5; $P \leq 0.05$). At d 100, a HYB × inoculation effect was observed for the Lactobacillaceae and Leuconostocaceae bacterial families ($P < 0.02$). For the former, INO increased its abundance in all HYB (99.1 vs. 58.9 ± 5.3%) but to a larger extent for B (98.3 vs. 34.3%), and for the latter, INO reduced its abundance in all HYB (0.1 vs. 11.3 ± 3.58%), except C (0.06 vs. 6.67), and to a larger extent in B (0.7 vs. 28.7). INO decreased ($P < 0.01$) the Enterobacteriaceae (0.6 vs. 23.5 ± 1.16%), Streptococcaceae (0.1 vs. 4.6 ± 0.54%), Aeromonadaceae (0.01 vs. 0.55 ± 0.03%), and Brucellaceae (0.01 vs. 0.39 ± 0.05%) families. For fungi, INO had less abundance ($P < 0.01$) of Pichiaceae (6.5 vs. 47.3 ± 5.19%) but more of the Debaryomycetaceae (63.1 vs. 17.3 ± 4.1%) and Mucoraceae (2.7 vs. 0.8 ± 0.53%) families when compared with CON. The results indicate that epiphytic microbial composition differ depending on HYB and that after ensiling, INO favors the dominance of the Lactobacillaceae and Debaryomycetaceae families compared with a more diverse microbial community in the CON.

Key Words: corn silage, bacterial and fungal diversity, combo inoculant

0632 Bacterial and fungal community structure of oats ensiled with or without a combo inoculant. J. J. Romero*[1,2], Y. Zhao[3], M. A. Balseca-Paredes[1], Y. H. Joo[4], J. Park[4], E. Gutierrez-Rodriguez[5], and M. S. Castillo[1], *[1]Department of Crop Science, North Carolina State University, Raleigh, [2]Animal and Veterinary Sciences, University of Maine, Orono, [3]Department of Animal Nutrition and Feed Science, China Agricultural University, Beijing, P. R. China, [4]Division of Applied Life Science (BK21Plus, Insti. of Agri. & Life Sci.), Gyeongsang National University, Jinju, the Republic of Korea, [5]Department of Food, Bioprocessing, and Nutrition Sciences, North Carolina State University, Raleigh*.

The objective was to evaluate the effects of a combo inoculant on the microbial community structure of oats ensiled at high DM concentrations (44.0%). From each of 6 sections in a field, whole oats at heading stage were mowed, wilted for 21 h, chopped, treated (INO) or not (CON) with inoculant, packed into 19-L plastic bucket silos, and ensiled for 217 d. The inoculant added contained *Lactobacillus buchneri* and *Pediococcus pentosaceus* (4×10^5 and 1×10^5 cfu/g of fresh oats). The V4 region of the 16S rRNA gene and the ITS-1 region were amplified and sequenced using an Illumina MiSeq platform for describing the bacterial and fungal communities, respectively. Experimental design was a complete randomized design replicated 6 times (silos). At d 0, there were no differences due to INO for the relative abundance of the Leuconostocaceae (82.9 ± 4.27%), Enterobacteriaceae (15.2 ± 3.52%), Streptococcaceae (0.5 ± 0.10%), and Pseudomonadaceae (0.2 ± 0.13%) bacterial families. For fungi, most of the total relative abundance consisted of unidentified sequences (56.9 ± 6.46%). INO had a higher abundance of the Davidiellaceae family (34.3 vs. 19.6 ± 4.47%) and a lower abundance of unidentified sequences of the Pleosporales order (1.5 vs. 3.2 ± 0.40%) vs. CON ($P \leq 0.05$). No differences between INO and CON were observed for the Pleosporaceae (5.1 ± 2.08%), Nectriaceae (1.9 ± 0.51%), and Debaryomycetaceae (0.6 ± 0.35%) families. At d 217, INO had a lower relative abundance of Leuconostocaceae (42.3 vs. 95.8 ± 4.64%) and a higher relative abundance of Lactobacillaceae (57.4 vs. 3.9 ± 4.65%) bacterial family vs. CON ($P < 0.01$). No effects of INO were observed on the Enterobacteriaceae family (0.05 vs. 0.03 ± 0.02%). For fungi, there were no differences between INO and CON for the relative abundance of Pichiaceae, Trichocomaceae, and Debaryomycetaceae (0.33 ± 0.22%) families and unidentified sequences of the Saccharomycetales order (13.9

± 11.4%), Ascomycota phylum (5.9 ± 4.0%), and Fungi kingdom (1.46 ± 0.96%). However, there was a large numerical decrease of Pichiaceae (41.2 vs. 82.5 ± 20.68%) and increase of Trichocomaceae (14.0 vs. 1.9 ± 6.71%) families in INO vs. CON ($P < 0.23$). In conclusion, INO had only a relative minor influence on the epiphytic fungi but not on the epiphytic bacterial composition. After ensiling, INO favored the dominance of Lactobacillaceae compared with Leuconostocaceae bacterial family in CON. No effects of INO were observed on the fungal community at d 217, but a large numerical decrease was observed in Pichiaceae and increase in Trichocomaceae fungal families vs. CON.

Key Words: oats haylage, bacterial and fungal diversity, combo inoculant

0633 Microbial count, fermentation, and aerobic stability of regular and brown midrib corn hybrids ensiled with or without a combo inoculant at high moisture concentrations. J. J. Romero*[1,2], J. Park[3], M. A. Balseca-Paredes[1], Y. Zhao[4], Y. H. Joo[3], A. Heitman[1], E. Gutierrez-Rodriguez[5], and M. S. Castillo[1], *[1]Department of Crop Science, North Carolina State University, Raleigh, [2]Animal and Veterinary Sciences, University of Maine, Orono, [3]Division of Applied Life Science (BK21Plus, Insti. of Agri. & Life Sci.), Gyeongsang National University, Jinju, the Republic of Korea,[4]Department of Animal Nutrition and Feed Science, China Agricultural University, Beijing, P. R. China, [5]Department of Food, Bioprocessing, and Nutrition Sciences, North Carolina State University, Raleigh*.

The objective was to evaluate the effects of a combo inoculant on microbial count, fermentation, and aerobic stability of 4 hybrids of corn ensiled at high moisture concentrations. Treatment design was the factorial combination of 4 corn types ensiled with (INO) and without (CON) inoculant. Corn types (HYB) were TMF2R737 and F2F817 (A and B, respectively; from Mycogen) and P2089YHR and P1449XR (C and D, respectively; from Pioneer). F2F817 and D were brown midrib hybrids. The inoculant added contained *Lactobacillus buchneri* and *Pediococcus pentosaceus* (4×10^5 and 1×10^5 cfu/g of fresh corn). Experimental design was a complete randomized design with 6 replicates (silos). Corn was chopped, treated or not with inoculant, packed into 7.6-L bucket silos, and stored for 100 d. At d 0, there were differences due solely to hybrids ($P \leq 0.05$). The percent DM was 30.5, 26.3, 31.1, and 31.5 for A, B, C, and D, respectively; lactic acid bacteria (LAB) count (log cfu/g of fresh corn) was similar for C and D (8.4) and both were greater than A and B (7.7 ± 0.23); yeast count was greatest in C (6.8 vs. 6.0 ± 0.14) and mold count was lowest in D vs. the others (4.6 vs. 5.2 ± 0.15; $P \leq 0.05$). At opening, INO increased ($P \leq 0.05$) LAB (9.3 vs. 7.1 ± 0.29), acetic acid (3.44 vs. 1.32 ± 0.35% of DM), and 1,2-propanediol for all HYB (0.7 vs. 0.0) except D (0.3 ± 0.11% of DM; INO × HYB, $P < 0.01$); decreased yeast (3.1 vs. 4.6 ± 0.45) and molds (1.5 vs. 3.0 ± 0.61); and extended the aerobic stability (582 vs. 111 ± 128 h) vs. CON. However, INO decreased ($P \leq 0.05$) DM recovery (95.6 vs. 97.4 ± 1.05%) and lactic acid for all HYB (4.2 vs. 7.6) except A (4.9 ± 0.59% of DM; INO × HYB, $P < 0.01$) and WSC (1.2 vs. 2.3 ± 0.17% of DM) vs. CON. Also, INO increased pH for all HYB (4.1 vs. 3.9) except D (3.9 ± 0.03; INO × HYB, $P < 0.01$) and decreased ethanol only for D (0.8 vs. 1.3) but not for the others (0.6 ± 0.08% of DM; INO × HYB, $P < 0.01$). The results indicate that the inoculant used consistently improved aerobic stability across HYB by increasing acetic acid and reducing fungal counts but reduced DM recovery of the corn ensiled at high moisture.

Key Words: corn silage, microbial counts, combo inoculant

0634 Forage quality of two different pasture systems incorporating warm and cool season forages for grazing organic dairy cattle. K. E. Ruh*[1,2], B. J. Heins[1], and J. Paulson[3], *[1]University of Minnesota West Central Research and Outreach Center, Morris, [2]University of Minnesota, Saint Paul, [3]University of Minnesota Extension, Rochester*.

Two pasture systems (perennial and annual grass species) with enhanced in-field and landscape-level species diversity were analyzed for forage quality characteristics across the grazing season at the West Central Outreach and Research Center organic dairy in Morris, MN, for 3 yr. System 1 was a diverse mixture of cool season grasses and legumes (perennial ryegrass, white clover, red clover, chicory, orchardgrass, meadow bromegrass, alfalfa, and meadow fescue). System 2 was a combination of perennial polycultures and annual warm-season grasses (BMR sorghum-sudangrass and teff grass). Grazing of lactating cows was initiated when forages were 20 to 30 cm tall, and strip size was adjusted to leave 7 to 13 cm of refusals. Random samples of pasture forage were sampled every other day when a group of cows moved to a new paddock. Pasture clippings were randomly collected in a 0.76-m^2 square of pasture. Forage samples were sent to Rock River Laboratory, Inc., Watertown, WI, and were analyzed with NIR spectrophotometry for DM, CP, and total tract NDF digestibility (TTNDFD). Data were analyzed using the MIXED procedure of SAS. Independent variables for analyses were the fixed effects of system (perennial [1] or perennial–annual [2]), month (June to October), forage (perennial grass pasture, oats/turnips mix, BMR sorghum-sudangrass, or teff grass), year (2013, 2014, and 2015), and their interactions, and date of harvest was a random variable. The DM was 23.3 and 22.4% for systems 1 and 2, respectively ($P = 0.44$). The CP was 23.0 and 18.0% for systems 1 and 2, respectively ($P < 0.001$). The CP for system 1 was 20.9% in 2013, 23.2% in 2014, and 24.7% in 2015 ($P < 0.05$). The CP for system 2 was

14.6% in 2013, 18.9% in 2014, and 20.5% in 2015, and 2013 was lower ($P < 0.05$) than 2014 and 2015. The TTNDFD was 54.6% and 54.9% for system 1 and system 2, respectively ($P = 0.84$). The TTNDFD was 63.8% in 2013, 48.0% in 2014, and 51.9% in 2015 for perennial grass pastures ($P < 0.01$) and 59.3% in 2013, 46.3% in 2014, and 59.0% in 2015 for warm season annual grasses. In summary, CP was greater in perennial cool-season pasture systems; however, TTNDFD and DM did not differ between pasture systems. Yearly effects and weather may affect forage quality in both pasture production systems.

Key Words: grazing, teff, sorghum-sudangrass

0635 Meta-analysis of the effect of homolactic and facultative heterolactic bacteria inoculation on silage quality II: Aerobic stability and yeast, mold and clostridia counts.

A. S. Oliveira*[1], Z. G. Weinberg[2], A. A. P. Cervantes[3], K. G. Arriola[3], I. M. Ogunade[3], Y. Jiang[3], D. Kim[3], M. C. M. Gonçalves[4], D. Vyas[3], and A. T. Adesogan[3], *[1]Universidade Federal de Mato Grosso – Sinop, Sinop, Brazil, [2]Department of Food Quality and Safety, Agricultural Research Organization, The Volcani Center, Rishon Le Zion, Israel, [3]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [4]Instituto Federal Goiano, Rio Verde, Brazil*.

Data from 120 peer-reviewed papers were summarized to evaluate the effects of homolactic and facultative heterolactic bacteria (HAB; *Lactobacillus plantarum*, *Pediococcus pentosaceus*, *Enterococcus faecium*, *Lactobacillus rhamnosus*, or their combinations) inoculation on aerobic stability and microbial profile of silages. The effects were statistically analyzed by comparing raw mean differences between inoculant and control treatment means that had been weighted by inverse variance using random models. Heterogeneity sources evaluated by meta-regression included crop species, application rate (AR; $<10^4$, 10^5 to 10^6 or $>10^7$ cfu/g, representing 3.7, 93.6 and 2.7% of studies, respectively), HAB species, and silo type (laboratory or farm-scale; 92.2 and 7.8% of studies, respectively) as covariates. Corn/sorghum, temperate and tropical grasses, sugarcane, alfalfa, other legumes, and other crops silages accounted for 22.8, 32.3, 7.8, 10.2, 4.8, 12.9, and 9.2% of the silages, respectively. High heterogeneity (I^2 statistic > 50%) was detected for all response variables. No interactions ($P > 0.05$) between the covariates were detected. Inoculation did not affect aerobic stability (2.4 h; $P = 0.33$, $n = 44$) but reduced counts (log cfu/g as fed) of Clostridia (−2.31 log cfu/g; $P < 0.01$, $n = 7$) mainly in grass silage studies ($n = 6$). Inoculation did not affect mold counts in corn/sorghum silages (0.05; $P = 0.73$, $n = 15$), but it reduced mold counts in temperate (−0.50; $P < 0.01$, $n = 10$) and tropical grasses (−1.68; $P = 0.04$, $n = 2$). Inoculation increased yeast counts (0.30; $P < 0.01$, $n = 82$). Inoculation with HAB did not affect aerobic stability, but it increased the growth of yeasts in all crops and reduced clostridia and mold populations in tropical and temperate grass silages.

Key Words: clostridia, *Lactobacillus plantarum*, mold, yeast

---

0636 Meta-analysis of the effect silage inoculation with homolactic or facultative heterolactic bacteria on the performance of dairy cows.

A. S. Oliveira*[1], Z. G. Weinberg[2], A. A. P. Cervantes[3], K. G. Arriola[3], I. M. Ogunade[3], Y. Jiang[3], D. Kim[3], M. C. M. Gonçalves[4], D. Vyas[3], and A. T. Adesogan[3], *[1]Universidade Federal de Mato Grosso – Sinop, Sinop, Brazil, [2]Department of Food Quality and Safety, Agricultural Research Organization, The Volcani Center, Rishon Le Zion, Israel, [3]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [4]Instituto Federal Goiano, Rio Verde, Brazil*.

Data from 13 peer-reviewed papers were summarized to examine the effect of silage inoculation with homolactic or facultative heterolactic bacteria (HAB) on the performance of dairy cows. The effects were compared by raw mean differences (RMD) between inoculant and control treatment means and weighted by inverse variance using random-effect models. Heterogeneity sources evaluated by meta-regression and included as covariates crop species (grass, alfalfa, corn, or mixtures of silages representing 68.8, 12.5, 6.3, and 12.5% of experiments, respectively), HAB species (*Lactobacillus plantarum* or HAB combinations were each used in 50% of the studies), diet type (total mixed ration [TMR] vs. non-TMR were used in 25 and 75% of the studies, respectively), and level of milk yield of control cows (<22 or >22 kg/d were produced in 56.3 and 43.7%, respectively, of the studies). All studies had HAB application rates of 10^5 to 10^6 cfu/g fed. High heterogeneity was detected for DMI (I^2 statistic = 71.5%), milk yield ($I^2 = 81.6\%$), and milk protein concentration ($I^2 = 88.7\%$), whereas moderate heterogeneity was detected for milk fat concentration ($I^2 = 49.1\%$). No interaction ($P > 0.10$) was detected between the covariates. Inoculation with HAB increased DMI (RMD = 0.66 [0.22, 1.10] kg/d; $P < 0.01$, $n = 11$), did not affect milk yield in cows producing <22 kg of milk/d (RMD = −0.89 [−1.93, 0.13] kg/d [$P = 0.09$]; milk yield for control cows = 19.60 ± 1.88 kg/d; $n = 9$), but increased milk yield in cows producing >22 kg/d (RMD = 1.07 [0.26, 1.88] kg/d [$P < 0.01$]; milk yield of control cows = 29.92 ± 8.64 kg/d; $n = 6$). Inoculation with HAB tended to increase milk fat concentration (RMD = 0.06 [−0.004, 0.11] % milk; $P = 0.07$, $n = 15$) and increased milk protein concentration (RMD = 0.10 [0.05, 0.15] % milk; $P < 0.01$, $n = 13$, $n = 2$ outliers). However, there was a trend for inoculation with a mixture of HAB species to give a higher milk protein response (RMD = 0.15 [0.02, 0.25] % milk; $P = 0.02$, $n = 6$)

than inoculation with *L. plantarum* alone (RMD = 0.04 [0.01, 0.07] % milk; $P < 0.01$, $n = 7$). Inoculation with HAB with improved the performance of dairy cows producing more than 22 kg of milk/d but did not affect that of those producing lower quantities of milk.

Key Words: forage conservation

0637 Screening of microorganism and effects of different bacterial additives on fermentation quality of rye silage harvested at dough stage.

S. S. Lee*[1], Y. H. Joo[1], H. J. Lee[1], J. W. Jang[2], O. K. Han[3], J. H. Kim[2], and S. C. Kim[1,2], *[1]Division of Applied Life Science (BK21Plus, Insti. of Agri. & Life Sci.), Gyeongsang National University, Jinju, the Republic of Korea, [2]Department of Animal Science, Gyeongsang National University, Jinju, the Republic of Korea, [3]National Institute of Crop Science, Rural Development Administration, Suwon, the Republic of Korea*.

This study was investigated to select a new inoculant and estimate its effects on rye silage harvested at dough stage. Twenty-four rye silages were collected from the commercial beef cattle farms. A total of 180 dominant microorganisms from these rye silages were selected and identified as *Lactobacillus* spp. Those were confirmed the antimicrobial activities against such as mycotoxigenic fungi through antagonism screening. The isolates also were analyzed for acidification ability through monitoring a change of bromophenol blue color and pH of MRS broth. Finally, the isolates were evaluated for fibrinolysis ability through the enzyme plate assay test using four enzymes (cellulase, xylanase, esterase, and chitinase). Eight isolates among 180 isolates indicated antimicrobial activities against *Fusarium moniliforme*. Two isolates indicated strong acidification ability (R4-26 and R7-24). In enzyme plate assay test, one isolate was effective for all enzymes (R48-27). Selected isolates R48-27 (LP1) and R4-26 (LP2) were evaluated on rye silage to improve fermentation quality. Rye forage was grown at the research farm of Gyeongsang National University, Jinju, the Republic of Korea, and harvested at dough stage (46% DM). The forages were divided into five treatments: CON (distilled water at 2 mL/kg of fresh forage), LP1 (*Lactobacillus plantarum* R48-27 at 4.0×10^4 cfu/g of fresh forage), LP2 (*L. plantarum* R4-26 at 4.0×10^4 cfu/g of fresh forage), MIX (mixture of LP1 and LP2 at 1:1 ratio), and LB (*Lactobacillus buchneri* at 4.0×10^4cfu/g of fresh forage). The forage was chopped and ensiled into 10-L mini-silos with 4 replications for 100 d. The NDF concentration was higher ($P < 0.05$) in CON and MIX silages compared with the other silages, whereas ADF concentration was lower ($P < 0.05$) in LP2 silage than the other silages. The LB silage produced the lowest pH that was equated with higher lactate production ($P < 0.05$), whereas the LP2 silage produced the highest acetate and propionate ($P < 0.05$). The LB silage resulted in the highest lactate-to-acetate ratio ($P < 0.05$). Mold was not detected only in the LP2 silage. In conclusion, the new inoculant (LP2) could be suggested to improve the silage safety, which has a strong effect against mycotoxin fungi.

Key Words: rye silage, inoculant, fermentation quality

0638 Effects of cow and bag type on the undigested neutral detergent fiber after two hundred forty hours in situ incubation.

H. Yang*[1], Y. Yan[2], D. J. Undersander[3], and D. K. Combs[4], *[1]College of Animal Science and Technology, China Agriculture University, Beijing, P. R. China, [2]College of Animal Science and Technology, Sichuang Agriculture University, Chengdu, P. R. China, [3]Department of Agronomy, University of Wisconsin, Madison, [4]Department of Dairy Science University of Wisconsin, Madison*.

The effect of cow and in situ bag type on undigested NDF (uNDF) content of corn silage, wheat straw, and alfalfa silage after 240 h in situ incubation were evaluated in three rumen-cannulated Holstein cows. Two corn silages, a wheat straw, and an alfalfa silage sample were dried and ground to pass through a 2.5-mm screen. After thorough mixing, 1 , 2, and 5 g of each forage were placed into F57 Ankom bags (4 by 5 cm), Ankom 5- by 10-cm nylon bags (part number R0510), or Ankom 10- by 20-cm nylon bags (part number R1020), respectively. There were three duplicates for each treatment within each cow. Sample mass to surface area by bag was 25, 20, and 12.5 mg cm^{-2}, respectively. The residual NDF was analyzed after 240 h incubation. Data was analyzed by SPSS 19.0. Within each forage, the effect of cow and bag type on uNDF within forages was determined by ANOVA. Means were compared by Duncan's multiple range test. The contents of the uNDF significantly differed due to bag type ($P < 0.001$). The content of uNDF in F57 bags was significantly higher than in R0510 and R1020 nylon bags ($P < 0.05$) and there was no significant difference in uNDF between R0510 and R1020 nylon bags ($P > 0.05$). The uNDF differed within cow for wheat straw ($P < 0.001$). Bag type and effective surface area should be taken into consideration when measuring uNDF by in situ methods; the estimate of uNDF in relatively indigestible materials, such as wheat straw, may also be affected by cow.

Key Words: undigested neutral detergent fiber, in situ, bag type

0639 WS Immunodetection of the Cry toxin in leaves of transgenic maize hybrids. G. Balieiro Neto*[1], A. W. P. Freitas[2], R. Botelho Ferraz Branco[2], K. Maria Roncato Duarte[2], F. Porto Pela[3], and M. D. Baruffi[3], *[1]Sao Paulo State Agency Agribusiness Technology, Ribeirao Preto, Brazil, [2]São Paulo State Agency Agribusiness Technology, Ribeirao Preto, Brazil, [3]University of São Paulo, Ribeirao Preto, Brazil*.

This assay aimed to evaluate the Cry toxins concentration in the last completely expanded leaf at 7, 14, 28, 35, 70, 84, and 96 d after planting of five corn hybrids. The evaluated hybrids were Syngenta Impact TL TG, Monsanto DKB 390 VT PRO II, Monsanto AG 8088 PRO II, Biomatrix 2B655 Herculex from Dow, and Syngenta 7205 Viptera. To analyze the toxin concentrations, antibodies were produced and a PTA-ELISA was developed. The positive controls used to produce the calibration curves were Sigma-Aldrich BF412b (Cry1Ab), Sigma-Aldrich BF418b (Cry1F), and Sigma-Aldrich BF423b (Vip3Aa20). The experimental design was randomized blocks in a factorial arrangement 5 (hybrid) × 7 (samples) with five repetitions. There were a significant interaction between hybrid and sampling period. The mean concentrations of the Cry toxins in the hybrids Herculex, AG 8088 PRO II, DKB 390 VT PRO II, Viptera, and Impacto were 7.58, 13.05, 16.81, 22.67, and 34.05 µg/g of fresh tissue, respectively. The mean concentration of Cry toxins were 16.77, 15.16, 18.46, 22.87, 22.85, 20.62, and 15.98 µg/g of fresh tissue at 7, 14, 28, 35, 70, 84, and 96 d after planting. Higher concentration of Cry toxin occurred between 35 and 70 d after planting and the hybrids with the higher concentrations were Viptera and Impacto with concentrations of 34.6 and 39.6 µg/g of fresh tissue, respectively. This information can integrate selection criteria of hybrids for cultivation in different regions according to the level of infestation of pests and resistance thereof to different Cry toxin concentrations.

Key Words: corn, Cry toxin, OGM, PTA ELISA

0640 The effect of defoliation severity during late autumn–winter on herbage production, regrowth, and nitrogen uptake. G. Cun*, G. R. Edwards, and R. H. Bryant, *Lincoln University, Lincoln, New Zealand*.

Nitrate leaching is an important environmental concern in livestock production in temperate pastures with leaching losses often high in late autumn/winter. Management strategies are sought to reduce nitrate leaching by enhancing pasture growth and uptake of nitrogen (N) over the winter period. The objective of this experiment was to determine the effect of five postgrazing heights on herbage production, quality, and N uptake of a diverse pasture mixture containing *Lolium perenne* (perennial ryegrass), *Trifolium repens* (white clover), *Cichorium intybus* (chicory), *Plantago lanceolata* (plantain), and *Medicago sativa* (lucerne) during the late autumn winter season. Pasture areas were defoliated to five different residual heights (20, 30, 40, 50, and 60 mm) by a push lawn mower in a randomized block design with four replicates. All swards were allowed to regrow for 112 d and herbage accumulated over the regrowth period was measured. Swards defoliated to 20, 30, and 40 mm had greater herbage regrowth (1,884, 1,508, and 1,322 kg DM/ha, respectively) compared with those defoliated to 60 mm (1,289 kg DM/ha) over 112 d. Repeated measures analysis on N concentration of herbage showed a significant interaction ($P = 0.012$) of defoliation treatment with time. For the 20-mm defoliation, N concentration increased from 18.8 to 29.7 g N/kg whereas the 60-mm defoliation decreased from 26.1 to 24.9 g N/kg during the regrowth period. During this 112-d regrowth period, pastures defoliated to 20 mm accumulated 56.01 kg N/ha compared with 32.07 kg N/ha in plots defoliated to 60 mm. The results indicate severely grazing to postgrazing heights <40 mm may improve growth and N uptake in the late autumn/winter period.

Key Words: grazing management, nitrogen uptake, defoliation severity

0641 Tall wheatgrass biomass yield and quality after interseeding with hairy vetch. M. Menghini[1,2], H. M. Arelovich*[1,2,3], M. F. Martínez[1], R. D. Bravo[1], and M. D. Chamadoira[1], *[1]Dto. Agronomia, Universidad Nacional del Sur, Bahia Blanca, Argentina, [2]CIC, Bahia Blanca, Argentina, [3]CERZOS, Bahia Blanca, Argentina*.

Tall wheatgrass (TW; *Thinopyrum ponticum*) is a reliable perennial temperate grass frequently used as a pasture in southwest semiarid Argentina. However, grass quality and biomass yield is affected by soil fertility. Mixes with annual legumes well adapted to the area such as hairy vetch (HV; *Vicia villosa*) may affect grass biomass yield and nutritive value. The aim of this study was to evaluate the effect of interseeding HV within an existing TW pasture on the biomass yield and nutritional value measured in fall, once the life cycle of the legume is finished. The experimental site was located at 62°00′56″ W, 38°10′16″ S. Pastures arranged in plots of 9 m^2 were used as experimental units. The treatments were control, no interseeding (TWCon), and TW + HV interseeding at a density rate of 20 $kg \cdot ha^{-1}$ (TWHV) in a complete block design ($n = 3$). Interseeding dates for HV were March 20 and 22 of 2013 and 2014, respectively, with a similar biomass yield composition of 80 and 83% for HV in the spring of both years. The plots were manually clipped at 8 cm height on March 21, 2014 (Y1), and May 12, 2015 (Y2). Subsamples of 0.4 m^2 were obtained from each plot to determine forage DM content and biomass yield, CP, NDF, ADF, ADL, and in vitro DM digestibility (IVDMD). Data were analyzed as a mixed model and means were compared by Tukey ($\alpha = 0.05$). An interaction treatment by year was only apparent for CP ($P < 0.05$). Then, CP concentration was analyzed for each treatment; TWCon was 8.2 and 3.8% vs. a higher level for TWHV 13.5 and 6.8% for Y1 and Y2, respectively ($P < 0.05$). The year mean for the rest of the variables are shown in the table. Except for ADL, which was higher for TWHV, the DM, NDF, and ADF contents resulted lower for TWHV than for TWCon ($P < 0.05$), whereas for DM yield and IVDMD, the differences attributed to the interseeding were not significant. Interseeding HV into TW existing pastures improve the nutritional value of the TW regrowth.

Key Words: *Vicia villosa*, *Thinopyrum ponticum*, intercropping

0642 Effect of canopy height on the nutritive value of elephant grass silage. E. B. Alves, I. L. De Oliveira, J. R. Gervasio, M. S. Bastos, S. M. Da Silva, J. O. Gusmao, L. M. Lima, and T. F. Bernardes*, *Federal University of Lavras, Lavras, Brazil*.

The ideal canopy height (CH) to harvest elephant grass for making silage has not been determined. Therefore, the objective of this study was to evaluate the yield of elephant grass (*Pennisetum purpureum* cv. Cameroon) and the silages produced from plants harvested at five CH: 100, 140, 180, 220, and 260 cm (described as CH100, CH140, CH180, CH220 and CH260, respectively). The experiment consisted of 25 plots with four rows each. The plants used to assess forage yield and to produce the silages were cut at ground level from the two central rows of each plot every time the canopy reached the target height. To make silages, the plants were chopped with a theoretical cut length of 20 mm and packed to a wet density of 688 kg/m^3 in 15-L laboratory silos. To measure effluent production, 10 kg of sand were placed on the bottom of the silos. The silos were sealed with plastic lids, weighed, and maintained at room temperature for 60 d. At silo opening, silage was removed and subsamples were taken to determine fermentation end products, microbial counts (bacteria, yeasts, and molds), and nutritive value. The experimental design was randomized blocks with five repetitions. The data were analyzed by the mixed-model method using the MIXED procedure (SAS Institute, 2004). The means were compared by a Tukey test at 5%. Canopy height was considered a fixed effect and block was considered a random effect. CH100 and CH140 had the lowest yield (on average, 12.8 ton DM/ha) and CH260 had the highest (22.4 ton DM/ha). CH180 and CH220 showed an intermediate production (on average, 17.3 ton DM/ha). The DM concentration of the plants before ensiling ranged from 11.6 to 21.5% ($P < 0.001$). Canopy height did not affect fermentative and microbial characteristics of the silages. Effluent losses were greater ($P < 0.0001$) in silages with plants harvested at CH100 (58.4 kg/ton of fresh forage), whereas the silages from CH260 had the lowest effluent production (24.1 kg/ton of fresh forage). The in vitro digestibility of the silages produced with plants harvested at CH100, CH140, and CH180 was greater (on average, 69.9%; $P = 0.0007$) than that of the other treatments (57.1%). As no differences among treatments were observed in terms of fermentation quality, it is possible to conclude that the right CH to produce elephant grass silage range from 180 to 220 cm due to the greater balance between forage yield and silage digestibility.

Key Words: cut-and-carry system, forage harvesting, tropical forage

0643 Compost inclusion level in soil on chemical composition and in vitro dry matter digestibility of native and improved cactus forage varieties. J. A. Santos-Haliscak*[1], J. Kawas[1], H. Fimbres-Durazo[1], G. Moreno-Degollado[1], R. E. Vázquez-Alvarado[1], E. Olivares-Sáenz[1], and H. Andrade-Montemayor[2], *[1]Universidad Autonoma de Nuevo Leon, San Nicolas de los Garza, Mexico, [2]Universidad Autónoma de Querétaro, Querétaro, Mexico*.

The objective of this study was to determine DM and protein production per hectare, chemical composition, and in vitro digestibility of two cactus varieties planted in soil with three compost levels. A randomized complete block design with a

factorial arrangement of treatments, with the two cactus varieties, one with spines (WS) and one without spines (WOS), four seasons (summer, fall, and winter of 2013 and spring 2014) and three levels of compost (0, 61, and 122 tons/ha) was conducted. Compost was purchased from a local feedlot. The WS variety was Forrajero Mina and the WOS was COPENA F1. These were planted in double rows, with a spacing of 0.5 m between plants and 0.6 m between rows in 1.2-m-wide beds. The design included 5 beds (repetitions), for a total of 300 plants per variety and 600 for the entire experiment. The WS variety had higher concentrations of NDF (30.5 vs. 22.3%; $P = 0.001$), hemicellulose (17.5 vs. 7.9%; $P = 0.001$), ash in NDF (4.09 vs. 3.14%; $P = 0.005$), iron (59.8 vs. 49.8 ppm; $P = 0.020$), and manganese (41.1 vs. 34.3 ppm; $P = 0.005$), whereas the WOS variety had higher concentrations of lignin (1.4 vs. 0.7%; $P = 0.001$), ash in ADF (0.92 vs. 0.45%; $P = 0.03$), calcium (3.1 vs. 2.9%; $P = 0.001$), and zinc (44.6 vs. 39.0 ppm; $P = 0.03$). In vitro DM digestibility was higher (79 vs. 67%; $P = 0.001$) for the WOS variety. The inclusion of compost increased DM (2.8 to 4.4 tons/ha; $P = 0.018$) and CP (196 to 556 kg/ha; $P = 0.001$) production, lignin (0.83 to 1.22%; $P = 0.008$), phosphorus (0.10 to 0.23%; $P = 0.001$), and zinc (36.7 to 44.1 ppm; $P = 0.025$) while decreasing the concentration of ash in ADF (0.93 to 0.51%; $P = 0.031$). The two cactus varieties had high ash and moisture content, which may reduce the energy density of this feed for livestock. Nitrogen associated with the ADF fraction (0.65%) may reduce nitrogen availability for bacteria in the rumen.

Key Words: cactus, chemical composition, in vitro digestibility, compost.

0644 Neutral detergent fiber digestibility of diets supplemented with soy hulls, corn stover, or alkali–ethanol–treated stover in lactating dairy cows. D. M. Donnelly*[1], L. C. de Resende[2], and D. K. Combs[3], *[1]Department of Dairy Science, University of Wisconsin-Madison, Madison, [2]University of Wisconsin-Madison, Madison, [3]Department of Dairy Science, University of Wisconsin, Madison*.

The objective of this study was to evaluate the digestibility of diets supplemented with three sources of NDF: soy hulls, untreated corn stover, or corn stover treated with NaOH and ethanol. Total tract apparent DM and NDF digestibility were measured with eight lactating Holstein cows in a replicated 4 × 4 Latin square design with four 21-d periods. The diets consisted of a low-fiber control diet (25% of diet DM as NDF) and treatment diets containing the control diet supplemented with 2.1 kg of soy hulls, untreated corn stover, or NaOH/ethanol–treated stover. Treatment diets contained approximately 30% of diet DM as NDF. Feed intake, orts, and milk yield were recorded daily. During the third week of each period, 12 fecal samples were collected to cover a 24-h period and composited. Milk collected from the last four milkings of each period was analyzed for milk composition. Data was evaluated using PROC MIXED (SAS version 9.3) with cow within block and period as random effects and treatment set as a fixed effect. Milk yield, milk fat percentage, and DMI did not differ among treatments ($P > 0.05$). Intake of NDF and iNDF intake as a percentage of BW were similar across treatments. Cows fed the control diet and the diet with supplemented soy hulls had higher DM digestibility (57.7 and 60.0% DMD, respectively) compared with cows fed diets supplemented with untreated stover (52.4%; $P < 0.0001$). The DM digestibility of the diet with supplemented treated stover was similar to both the untreated stover and soy hull rations. In vivo NDF digestibility was lowest when cows were fed the untreated stover ration. Digestibility of NDF was improved when soy hulls or treated

Table 0644.

	Control	Soy Hulls	Treated Stover	Untreated Stover	SEM	P - Value
MY, kg	28.0	30.7	27.9	29.9	3.3	0.36
Fat, %	4.4	4.1	4.2	4.4	0.3	0.39

NDF Intake, %BW	1.39	1.44	1.40	1.36	0.08	0.24
iNDF Intake, % BW	0.140	0.149	0.145	0.142	0.008	0.24

stover were added to the diets ($P < 0.0001$). The NaOH/ethanol treatment process appears to improve the DM and NDF digestibility of corn stover to values similar to those of soy hulls. Supplemental fiber did not affect milk yield, DMI, or fiber intake.

Key Words: in vivo, neutral detergent fiber, NaOH

0645 Yield and nutritive value of photoperiod-sensitive sorghum and sorghum-sudangrass in central Wisconsin. E. Remick*[1], H. Su[2], W. K. Coblentz[3], and M. Akins[2], *[1]University of Wisconsin-Madison, Madison, [2]University of Wisconsin, Madison, [3]U.S. Dairy Forage Research Center, Marshfield, WI.*

A study was conducted to evaluate the yield and nutrient composition of photoperiod-sensitive (PS) and non-PS forage sorghum, sorghum-sudangrass, and sudangrass compared with corn planted on 2 dates and harvested using single- or multiple-cut harvest strategies at 2 research stations (Marshfield and Hancock), each located in central Wisconsin. At each site, treatments were arranged in a randomized complete block design with 4 replicates. The experiment was analyzed as a split-split-plot design with planting date (early or mid June) designated as the main plot, harvest strategy (single cut or multiple cut) as the subplot, and 8 forage cultivars (corn silage, PS forage sorghum, PS sorghum-sudangrass, forage sorghum, BMR forage sorghum, sorghum-sudangrass, BMR sorghum sudangrass, or PS-BMR sudangrass) designated as the sub-subplot treatment factor. Multiple-cut plots were harvested in late August and early October with single-cut plots harvested only in early October. Data were independently analyzed for each location. Overall, forage yields were numerically greater for Hancock plots compared with Marshfield plots (Table 1). At Hancock, DM yields were greater for the early compared with late planting date (16,225 vs. 12,080 kg DM/ha; $P = 0.014$), but there were no effects of planting date at Marshfield (overall mean = 8,228 kg DM/ha; $P = 0.90$). The lack of response at Marshfield was likely due to delayed germination of early planted plots following heavy rains. At both sites, the single-cut harvest (17,517 kg DM/ha at Hancock and 11,729 kg DM/ha at Marshfield) was greater ($P < 0.01$) than the multiple-cut harvest system (10,789 kg DM/ha at Hancock and 4,726 kg DM/ha at Marshfield). There were yield differences for variety as well as variety by harvest type interactions ($P < 0.01$) at both locations (Table 1). At both sites, the multiple-cut harvest strategy reduced yields of all hybrids. The sorghum-sudangrass and PS sorghum-sudangrass varieties had the greatest numerical yields among the sorghum types tested under both harvest strategies. Reduced yields of varieties harvested using multiple-cut strategies may reflect reduced tillering and regrowth capabilities of certain varieties. Using a single harvest, several sorghum forage types has similar or better forage yields compared with corn silage.

Key Words: forage sorghum, sorghum-sudangrass photoperiod sensitive

0646 Cutting interval and water application influence *Sericea lespedeza* yields and condensed tannin content. L. C. Nuti*[1], J. P. Muir[2], E. A. Duffus[1], Y. Jung[1], A. A. James[1], N. M. Cherry[3], and G. R. Newton[1], *[1]Prairie View A&M University, Prairie View, TX, [2]Tarleton State University, Stephenville, TX, [3]Texas A&M AgriLife Research, Stephenville, TX.*

Sericea lespedeza (SL; *Lespedeza cuneata*) contains tannins that may provide beneficial effects in gastrointestinal nematode suppression in small ruminants. The objective of the present work was to investigate the effect of cutting frequency and water application on forage yield, total tannin content, and active protein bound to tannins. *Sericea lespedeza* was grown in 30 raised boxes (1.5 m^2 by 0.3 m) containing a commercial potting soil mixture. Established (yr 3) SL was randomly assigned to a cutting interval of 30, 45, or 60 d over a 120-d trial period. Within each cutting frequency, boxes were randomly assigned to a watering treatment of ambient rainfall or 2.5 or 5.0 cm of applied water per week (AWW). At the designated harvest intervals, SL was cut to a height of 12.5 cm and weighed (wet weight). The effect of cutting frequency and water treatments were analyzed using SAS 9.3 general linear model procedure for repeated measure design. No interaction was detected between cutting frequencies and water application rates. Cutting interval ($P < 0.08$) and water treatments ($P < 0.03$) influenced overall wet weight yield of SL over the 120-d growing period. A 45-d cutting interval produced more SL forage ($P < 0.07$; 8.43 ± 0.39 kg) when compared with a 30-d cutting interval (7.15 ± 0.39 kg) but was similar to yields obtained on Day 60 (7.56 ± 0.39 kg). Plants supplemented with 5 cm AWW produced more SL forage (8.61 ± 0.4) than plants grown under ambient conditions (7.12 ± 0.4 kg; $P < 0.03$) or supplemented with 2.5 cm AWW (7.42 ± 0.34 kg; $P < 0.9$). *Sericea lespedeza* was then sun dried and condensed tannin (CT) and protein-bound (PB) CT were determined using 50 μg DM and the protein precipitable phenolics method of Hagerman and Butler (1978). Total CT was not influenced by water application rates ($P > 0.1$). A cutting interval of 45 d increased the amount of plant CT (153.18 ± 12.95 μg; $P > 0.01$) when compared with the 30- (100.75 ± 11.51 μg) or 60-d (107.73 ± 15.86 μg) cutting intervals. Concentrations of PB CT were not influenced by cutting interval or water application rates. Growth of SL under ambient conditions in Texas is good but can be improved with irrigation. A 45-d cutting interval maximizes plant yield and total tannin concentrations.

Key Words: *Sericea lespedeza*, growth, tannins

0647 A comparison of in vitro rumen digestibility and fermentation indices of tannin-rich chestnut meal. J. H. Park*[1], J. W. Jang[1], J. H. Kim[1], H. J. Lee[2], Y. H. Joo[2], S. S. Lee[2], I. H. Choi[3], and S. C. Kim[1,2], *[1]Department of Animal Science, Gyeongsang National University, Jinju, the Republic of Korea, [2]Division of Applied Life Science (BK21Plus, Insti. of Agri. & Life Sci.), Gyeongsang National University, Jinju, the Republic of Korea, [3]Department of Companion Animal & Animal Resources Science, Joongbu University, Geumsan, the Republic of Korea*.

This study was conducted to estimate in vitro rumen digestibility and fermentation indices of tannin rich chestnut meal probiotic using a novel wireless automated gas production system. The chestnut separated to whole chestnut (WCP), endodermis (EDP), or kernel (KNP) and then ground by cutting mill. The ground chestnuts were mixed with combo inoculant (*Lactobacillus acidophilus*, 1.0×10^6 cfu/g; *Saccharomyces cerevisiae*, 1.0×10^6 cfu/g; and *Bacillus subtilis*, 4.5×10^6 cfu/g), individually placed into 10-L mini-silos, and incubated at 39°C for 4 d to produce each chestnut probiotic. Each chestnut probiotic (0.5 g) was placed into the incubation bottles with rumen fluid mixture (40 mL), which was mixed with Van Soest medium in a 2:1 ratio. Rumen fluid was collected from cannulated Hanwoo heifers. Four replicates in each treatment with three blanks were incubated at 39°C for 48 h, and gas pressure was measured at 30 min intervals. The bottle contents were centrifuged at the end of incubation. The supernatant was used for pH, ammonia N, and VFA and the residue was used for in vitro digestibility of DM (IVDMD) and NDF (IVNDFD). The KNP (76.5 and 60.1%) had greater ($P < 0.05$) IVDMD and IVNDFD, respectively, than WCP (49.5 and 19.2%, respectively) or EDP (46.1 and 20.1%, respectively). The KNP had greatest ($P < 0.05$) concentrations of total VFA (116 m*M*/L), propionate (26.6%), and butyrate (23.4%), whereas EDP had greatest ($P < 0.05$) pH (6.60) and concentrations of ammonia N (35.9 mg N/100 mL) and valerate (52.5%). Acetate concentration and acetate-to-propionate ratio in WCP (52.6% and 2.12, respectively) and EDP (52.5% and 2.14, respectively) were higher ($P < 0.05$) than those in KNP (46.4% and 1.75, respectively). The rapidly fermentable fraction (0.72 vs. 0.28 mL/g) in KNP was greater ($P < 0.05$) than in WCP. The KNP (4.93 mL/g, 5.65 mL/g, and 0.29%/h) had greatest ($P < 0.05$) total fermentable fractions and fractional fermentable rate. The lag phases (4.69 and 4.81 vs. 3.72 h) in EDP and KNP were greater ($P < 0.05$) than in WCP. In conclusion, it is suggested that KNP could be used to improve the rumen fermentation characteristics for ruminants.

Key Words: chestnut, digestibility, fermentation characteristics

0648 Inoculant effects on bermudagrass silage nutritive value and fermentation characteristics. E. C. Freitas[1], J. M. D. Sanchez*[2], F. A. Kuhawara[3], U. Cecato[4], J. M. B. Vendramini[5], and A. Aguiar[1], *[1]DeLaval Manufacturing, Bannockburn, IL, [2]UF/IFAS Range Cattle Research and Education Center, Ona, FL, [3]Sao Paulo State University, Botucatu, Brazil, [4]UFL, Ona, FL, [5]UF/IFAS, Range Cattle Research and Education Center, Ona, FL*.

The objective of this study was to investigate the nutritive value and fermentation parameters of 'Jiggs' bermudagrass (*Cynodon dactylon* L.) silage treated with FeedTech microbial inoculants M20XC and M25AS (2×10^6 cfu/g of treated forage [as fed]) and F600 and F20 (2×10^6 cfu/g of treated forage [as fed]) or control (C). The experiment was conducted in Florida in 2014. Plots (experimental units, 3 by 2 m) were staged on August 15 at an 8-cm stubble height and fertilized with 80 kg N/ha. Forage was harvested with a 4-wk regrowth interval, immediately packed into a mini-silo at a density of approximately 382 kg fresh forage/m^3, and ensiled for 106 d. Treatments were distributed in a randomized complete block design with 5 replicates. The data were analyzed using PROC MIXED with treatment as a fixed effect and block as a random effect. There was an increase on DM recovery ($P = 0.04$; 99.7 vs. 84.4%) and IVTD ($P = 0.06$; 57.8 vs. 53.8%) on silage treated with M20XC compared with the control. No differences were detected among treatments on DM, CP, ADF, NDF, and NDFD ($P > 0.10$). Silage pH, acetic acid, propionic acid, butyric acid, and ammonia concentrations were similar among treatments ($P > 0.10$). However, there was a trend ($P = 0.14$) that M20XC had the greatest concentration of acetic acid between treatments. There was no effect ($P > 0.27$) of inoculants on mold and yeast count (mean = 1.7 and 1.3 log cfu/g, respectively) and mycotoxins (aflotoxin, vomitoxin, zearalenone, and T2) among treatments. FeedTech M20XC may be an efficient inoculant to increase DM recovery and IVTD of bermudagrass silage in the Southeastern United States.

Key Words: grass, silage, inoculants

0649 The effect of a microbial inoculant at two application rates on the aerobic stability of high-moisture corn. E. Benjamim da Silva*, R. M. Savage, S. A. Polukis, M. L. Smith, A. E. Laubach, K. M. Pacer, and L. Kung Jr., *University of Delaware, Newark*.

The purpose of this study was to evaluate the effect of a microbial inoculant at two application rates on the fermentation and aerobic stability of high-moisture corn (HMC). High-moisture corn (74% DM) was 1) untreated (control), 2) treated with *Lactobacillus buchneri* (NCIMB 30139) at an application rate of 400,000 cfu/g of fresh material (LB400), or 3) treated with *L. buchneri* (NCIMB 30139) at a rate of

600,000 cfu/g of fresh material (LB600). The inoculant was supplied by Volac Intl., Ltd., United Kingdom. Five replicated lab silos (7.5 L) for each treatment were packed (density of 658 kg DM/m^3) and ensiled for 30 and 92 d between 21 and 23°C. Data were analyzed as a 3 × 2 factorial arrangement of treatments with the main effects of treatment, day, and their interaction. High-moisture corn was analyzed for fermentation end products, number of yeasts, and aerobic stability. At 92 d, the pH of LB400 and LB600 (4.48 and 4.47) was higher ($P < 0.01$) than that of control (4.33). All treatments had similar concentrations of lactic acid at 30 d, but by 92 d, lactic acid concentrations decreased ($P < 0.01$) in LB400 and LB600 (0.36 and 0.41%) compared with untreated HMC (0.58%). At 30 d, treatment with LB400 and LB600 (0.36 and 0.30%) had higher ($P < 0.01$) concentrations of acetic acid compared with control (0.05%). At 92 d, untreated HMC (0.15%) had lower ($P < 0.01$) concentrations of acetic acid than LB400 and LB600 (0.79 and 0.86%). Treatment with LB400 and LB600 (0.32 to 0.55%) increased ($P < 0.01$) 1,2-propanediol concentrations compared with untreated HMC (0.00 to 0.09%) at both 30 and 92 d. At both ensiling times, HMC treated with LB400 and LB600 (<2.00 to 2.97 log cfu/g) had fewer ($P < 0.01$) yeasts than control HMC (4.04 to 5.93 log cfu/g). At 30 and 92 d, treatment with LB400 and LB600 (>217 h) greatly increased ($P < 0.01$) aerobic stability compared with untreated HMC (16 to 56 h). This experiment showed that inoculation with *L. buchneri* (NCIMB 30139) can improve the fermentation characteristics and the aerobic stability of HMC.

Key Words: aerobic stability, high-moisture corn, *Lactobacillus buchneri*

0650 Meta-analysis of the effect of homolactic and facultative heterolactic bacteria inoculation on silage quality: III Dry matter recovery, chemical composition and in vitro digestibility.

A. S. Oliveira*[1], Z. G. Weinberg[2], A. A. P. Cervantes[3], K. G. Arriola[3], I. M. Ogunade[3], Y. Jiang[3], D. Kim[3], M. C. M. Gonçalves[4], D. Vyas[3], and A. T. Adesogan[3], *[1]Universidade Federal de Mato Grosso – Sinop, Sinop, Brazil, [2]Department of Food Quality and Safety, Agricultural Research Organization, The Volcani Center, Rishon Le Zion, Israel, [3]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [4]Instituto Federal Goiano, Rio Verde, Brazil*.

Data from 120 peer-reviewed papers were summarized to evaluate the effects of inoculation with homolactic and facultative heterolactic acid bacteria (HAB) on DM recovery (DMR), chemical composition, and 48-h in vitro DM digestibility (IV-DMD) of silages. The effects were statistically analyzed by comparing raw mean differences between inoculant and control treatment means that had been weighted by inverse variance using random models. Heterogeneity sources evaluated by meta-regression included crop species, application rate (<10^4, 10^5 to 10^6, or >10^7 cfu/g, which represented 3.7, 93.6, and 2.7% of the studies, respectively), HAB species, and silo type (laboratory or farm-scale, which represented 92.2 and 7.8% of the studies, respectively) as covariates. Corn/sorghum, temperate and tropical grasses, sugarcane, alfalfa, other legumes, and other crops silages represented 22.8, 32.3, 7.8, 10.2, 4.8, 12.9, and 9.2% of the silages, respectively. No interactions ($P > 0.05$) between the covariates were detected. High heterogeneity (I^2 statistic > 50%) was observed for all response variables, except ADIN ($I^2 = 41.6\%$) and water-soluble carbohydrates (WSC; $I^2 = 0$). Inoculation did not affect DMR of corn/sorghum silages ($P = 0.10$, $n = 18$) but increased DMR ($P < 0.05$) of temperate grasses (2.89%; $n = 10$) and tropical grasses (2.89%; $n = 8$) and reduced DMR of sugarcane (−2.87%; $P < 0.01$). Inoculation did not affect the DM concentration of corn/sorghum silages ($P = 0.80$, $n = 45$) and sugarcane ($P = 0.11$, $n = 14$) but increased DM ($P < 0.05$) of temperate grasses (0.60%; $n = 54$), tropical grasses (0.45%; $n = 17$), alfalfa (0.31%; $n = 11$), other legumes (0.77%; $n = 30$), and other crops silages (0.86%; $n = 20$). Inoculation did not affect CP concentration ($P = 0.56$, $n = 106$), tended to reduce ADIN concentration (−0.13% nitrogen; $P = 0.09$, $n = 9$), and reduced WSC concentration (−0.32% DM; $P < 0.01$, $n = 150$) and lignin concentration (−0.28% DM; $P = 0.01$, $n = 20$), but it did not affect IV-DMD ($P = 0.24$, $n = 33$). Inoculation with HAB did not improve DMR of corn/sorghum silages, but it improved those of tropical and temperate grass silages and reduced that of sugarcane silages. Inoculation with HAB did not improve chemical composition or IV-DMD of silages.

Key Words: forage conservation, *Lactobacillus plantarum*

0651 Percentages of alfalfa and grass in fresh and ensiled binary mixtures using near infrared reflectance spectroscopy: Developing a robust calibration.

E. Karayilanlia*[1], J. H. Cherney[2], P. Sirois[3], D. Kubinec[4], and D. J. R. Cherney[2], *[1]Suleyman Demirel University, Isparta, Turkey, [2]Cornell University, Ithaca, NY, [3]Dairy One, Ithaca, NY, [4]Dairy One Forage Laboratory, Dairy One Cooperative, Inc., Ithaca, NY*.

Evaluating alfalfa and grass content of alfalfa–grass mixtures is useful for quantifying forage and diet quality. No studies have attempted to evaluate percent alfalfa content of silages and no commercial forage laboratory currently offers this service. Our objective was to develop a robust near-infrared reflectance spectroscopy (NIRS) method to estimate percent composition of binary alfalfa–grass mixtures in the Northeastern United States. Alfalfa–grass samples were collected across New York state over 4 growing seasons and hand separated, and a subset was separately ensiled. Dry samples were coarsely ground, mixed in known proportions, and reground for analysis by NIRS at Dairy One Forage Laboratory, Ithaca,

NY. Samples were mixed to range from 0 to 100% alfalfa for NIRS calibration, with a total of 741 individual samples from 2011, 2012, and 2014 used for calibration. Prediction equations were developed using three NIRS instruments. Dairy One calibrated a Foss 6500 NIRS instrument as well as two newer generation Foss XDS instruments, analyzing most samples with all three instruments. A total of 1,480 spectra were collected for calibration, with samples packed twice and scanned in duplicate. Calibration statistics were similar for the three instruments. Close agreement between R2 (0.99) and 1-VR (0.99) for all three equations indicates consistent results among the cross-validation groups and suggests that the calibration models are robust. There was no benefit in separate sample calibrations for fresh and fermented samples. Spectra from the three instruments were combined to develop and support a single calibration for use in a commercial setting across multiple platforms. Calibrations for grass and alfalfa percent worked well with all instruments and equally well with fresh versus ensiled forage. The three prediction equations had relative prediction deviation values of 4.35, 4.97, and 4.62, indicating calibrations were satisfactory. A diverse set of 98 samples from 2015 were used for validation of the equations. Mixture content was predicted with good precision and accuracy showing biases of 2.49 and SE of prediction of 5.06, with R2 of 0.972, using the equation developed across multiple instruments. These data indicate that with selection of a robust set of calibration samples over many environments, NIRS can be used to determine the botanical composition of alfalfa–grass samples, regardless of whether they are fresh or ensiled, and that replicate scans from multiple instruments can be combined to develop a single calibration that will perform with equal efficiency across different instruments.

Key Words: forage evaluation, botanical composition

0652 Comparison of dry matter measurements between three hand-held near-infrared units with oven drying at sixty degrees Celsius for forty-eight hours.

D. M. Donnelly*[1], H. Yang[2], and D. K. Combs[3], *[1]Department of Dairy Science, University of Wisconsin-Madison, Madison, [2]College of Animal Science and Technology, China Agriculture University, Beijing, P. R. China, [3]Department of Dairy Science, University of Wisconsin, Madison*.

This study compared DM predictions of three hand-held near infrared spectrophotometer (NIRS) units (Moisture Tracker, Digi-Star Inc., Fort Atkinson, WI) to conventional oven drying at 60°C using two alfalfa and two corn silages. Corn and alfalfa silages (1,500 g) obtained from the University of Wisconsin Dairy Cattle Center (DCC) and the Arlington Research Station (ARS) were analyzed for DM daily for 20 d. Three NIRS calibrations were also tested within each unit: NIRf, NIRa, and NIRb. The DM predicted from the factory-preset calibrations was NIRf. NIRa was an adjusted DM prediction, where the average difference between oven-dried forage and NIRf determined on duplicate forage samples for 3 d before the experiment was used as a bias adjustment for all subsequent DM determinations. NIRb was a bias-adjusted DM prediction based on the average difference between oven-dried forage and NIRf over the 20-d experiment. NIRb was determined on each forage sample after the experiment had been completed. Each forage was scanned 20 times by each NIRS unit. The average predicted DM from the 20 scans was recorded as the forage DM. The process was repeated three times with each NIRS unit. Two 100-g subsamples of each forage were then oven-dried for 48 h at 60°C daily. Data was analyzed using PROC MIXED (SAS, version 9.3), with method, day, feed, method × day, and method × feed as fixed effects and equipment as the random effect. Oven DM of ARS and DCC alfalfa silages was 37.34 and 48.52%, respectively. Oven DM of ARS and DCC corn silages was 34.69 and 37.41% DM, respectively. NIRf DM predictions were significantly different from their respective oven values for ARS corn silage and ARS haylage ($P < 0.0001$), and NIRf DM tended to differ from oven DM for DCC Corn Silage; $P = 0.06$). NIRf and oven DM for DCC haylage were similar ($P = 0.99$). All NIRb DM values were similar to oven-dried DM for all four forages ($P > 0.05$). The hand-held NIRS units accurately predicted DM content of the alfalfa and corn silages when the factory preset calibrations were corrected for bias.

Key Words: dairy cattle, dry matter, near-infrared

0653 Grazing intensities and season affect N_2O emissions in a tropical pastureland.

A. S. Cardoso[1], L. F. Brito[1], E. R. Janusckiewicz[1], E. S. Morgado[2], R. P. Barbero[1], J. F. W. Koscheck[1], R. A. Reis[1], and A. C. Ruggieri*[1], *[1]Sao Paulo State University, Jaboticabal, Brazil, [2]Universidade Federal de Uberlandia, Uberlandia, Brazil*.

The study assessed a tropical pasture in Brazil to determine how grazing height and season influences N_2O production and consumption. Nitrous oxide fluxes were measured over 2 yr in a Marandu palisade grass pasture with 3 grazing heights (15, 25, and 35 cm), 6 replicates, and 4 seasons (spring, summer, autumn and winter) using static closed chamber and chromatography quantification. The N_2O flux (μg N_2O-N m^{-2} h^{-1}) was integrated by linear interpolation to cumulative emissions. The patters of N_2O fluxes were displayed by using means and SEM. The data were submitted to ANOVA by using R statistical software. When significant, a polynomial orthogonal contrast was done. Nitrous oxide emissions were maximum following rainfall events and application of urea fertilizer (Fig. 1). Nitrous oxide emissions were greatest in the summers whereas lower fluxes associated with frequent instances of N_2O uptake in other seasons. The topmost rate of N_2O emissions was measured in the second week of December 2013 when mean fluxes were 469, 394, and 279 μg N_2O-N

m^{-2} h^{-1} for 15, 25, and 35 cm of pasture heights, respectively.

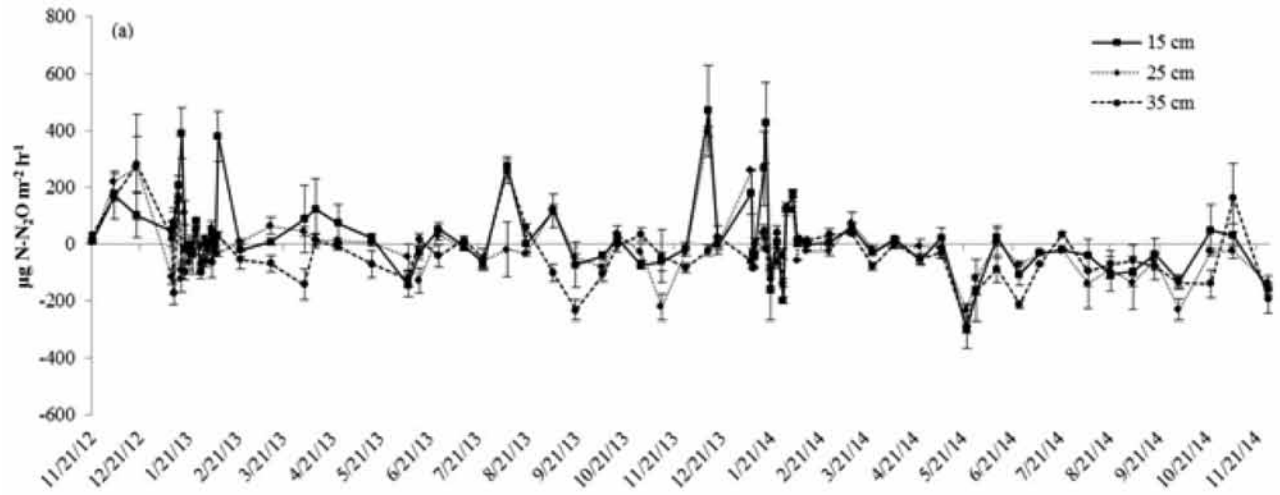

Fig 0653.

Figure 1. N_2O flux (μg N_2O-N m^{-2} h^{-1}) for three grassland intensities (15, 25, and 35 cm) during two years of evaluation (November 21, 2012 to November 26, 2014).

Negative fluxes were detected in approximately 60% of all N_2O sampling especially in the spring and autumn of the yr 2 when lower values of water-filled pore space were also recorded. The highest rate of N_2O consumption was measured on May 23, 2014, when mean fluxes were −299, −235, and −287 μg N_2O-N m^{-2} h^{-1} for pastures heights of 15, 25, and 35 cm, respectively. Grazing intensity was significantly correlated with N_2O flux during the summer. There was a linear reduction in annual cumulative N_2O emissions ($P < 0.05$) with decreasing grazing intensities for both years. The total N_2O emissions were 300.1, 41.6, and −48.3 mg N_2O-N m^{-2} in yr 1 and −153.2, −263.7, and −298.7 mg N_2O-N m^{-2} in yr 2 for 15, 25, and 35 cm of pasture heights, respectively. The greater grazing intensity had the highest levels of N_2O emissions in all seasons except for in the spring of yr 1. The grassland intensity on cumulative N_2O emissions was negatively linear in the annual analysis ($P < 0.05$) driven by the negative associations observed in the summer ($P < 0.05$) and even more so in the autumn ($P < 0.001$). There was a negative linear effect of pasture height on the amount of N_2O emitted/consumed. High stocking rates in the grazing systems influenced the increment of N_2O production, although lower grazing intensities contributes to N_2O mitigation in tropical pastures.

Key Words: continuous stocking, greenhouse gas, pasture height

0654 Impact of foliar spray on yield and chemical composition of alfalfa hay. S. Acharya* and D. P. Casper, *Dairy Science Department, South Dakota State University, Brookings*.

The study objective was to determine the response to foliar nutrient application (proprietary product) on DM yield and chemical composition of second-cutting alfalfa hay. Two fields with a total area of 38.4 ha were selected, where half of the second-cutting alfalfa hay field was sprayed as the Test and half of the field was unsprayed as the Control. The spraying rate was 23.4 L/ha. Crop was planted following established standard procedure of alfalfa, and the interval between first and second cutting was 28 d. Each field was divided into four replications, two represented by Control Plot and two by Test Plot. After harvesting alfalfa and drying in the field, hay was square baled (at moisture level of 14.2%) and weighed and samples were taken using a standard hay probe bale sampler later on. A total of eight hay samples (4 samples from each field) were sent to a commercial laboratory for analysis of nutrient composition. Dry matter yield was increased ($P < 0.01$) for Test (1.48 and 1.34 mt/ha for Test and Control, respectively) compared with Control. Similarly, digestible DM was also found improved ($P < 0.01$) for Test Plot (0.93 and 0.80 mt/ha) compared with Control. Crude protein percentage was increased ($P < 0.05$) for Test Plot (21.1 and 19.1%) compared with Control. There was a trend ($P < 0.10$) of increase in in vitro DM digestibility (62.6 and 59.8 5) and a numerical increase in NDF digestibility (52.1 and 50.8%) for Test compared with Control. This could be explained by a significantly ($P < 0.05$) lower lignin content of Test (8.07 and 8.71%) compared with Control. The nonfiber carbohydrates content was higher ($P < 0.05$) for Test (22.2 and 21.3%) compared with Control. This could further

be explained by a significant ($P < 0.01$) higher NE for lactation content for Test alfalfa (1.28 and 1.19 Mcal/kg) compared with Control. The use of foliar nutrient sprays increase DM yield and nutrient digestibility of alfalfa, thus being able to support more milk yield and feed efficiency.

Key Words: foliar spray, alfalfa, chemical composition

0655 Evaluation of in vitro gas production and energy available in low-lignin alfalfa varieties. K. P. Ortega*, G. Getachew, D. H. Putnam, and E. J. DePeters, *University of California, Davis, Davis*.

Lignin is composed of cross-linked phenolic compounds that impact forage quality. As forage plants mature, lignin concentration increases and DM and fiber digestibility decrease. Low-lignin alfalfa varieties offer potential for improved forage quality and animal production as well as increased yield by allowing for harvests at later maturity while maintaining high digestibility. Lignin synthesis in alfalfa was reduced by genetic manipulation through suppressing enzymes in the lignin biosynthetic pathway. In the current study, two genetically modified alfalfa lines (LL) and their respective controls (CL) were used to study the effect of reduced lignin content on in vitro gas production and predicted ME concentration. Sixty-four samples, that is, four alfalfa lines (two LL and two CL), four field replicates, two cuttings (cut 1 and 3), and two cutting schedules (28 and 35 d), were used. An in vitro technique was used to determine differences in in vitro gas production and predicted ME concentration between two CL and two LL varieties of alfalfa. Alfalfa samples were compared at cuttings 1 and 3 as well as cutting schedules that occurred at 28 and 35 d. Ground alfalfa samples were incubated in buffered rumen fluid using an in vitro gas technique at various time points over 72 h to determine the influence of lignin on rate and extent of in vitro gas production. Four in vitro incubations were conducted, and rate and extent of gas production were calculated using an exponential model. The ME was estimated using the 24 h gas production and CP content of each sample as described by Menke and Steingass (1988). Total ME ($P < 0.0001$) and rate of gas production ($P < 0.0001$) were higher in the LL varieties than the CL varieties, whereas no significant difference was found in extent of gas production. Low-lignin alfalfa varieties offer potential to increase the ME concentration in alfalfa, which needs to be further evaluated by animal feeding studies.

Key Words: alfalfa, low lignin, in vitro gas production, metabolizable energy

0656 WS Influence of supplement type and monensin addition on utilization of low-quality, cool-season forage by beef cattle. D. W. Bohnert*[1], M. C. Rodrigues[1], M. C. Vieira[1], K. C. Swanson[2], S. J. Falck[3], and R. F. Cooke[1], *[1]Oregon State University – EOARC Burns, Burns, [2]North Dakota State University, Fargo, [3]USDA-ARS, EOARC Burns, Burns, OR*.

Two studies were conducted to evaluate the influence of supplement composition and monensin addition on intake and digestibility of a low-quality (4.5% CP), cool-season forage as well as cow performance. Treatments included a nonsupplemented control (CON), approximately 30% CP supplements consisting of corn and urea (CU), CU + monensin (200 mg/d; CU+M), dried distillers' grains (DDGS), or DDGS + monensin (200 mg/d; DDGS+M). In Experiment 1, 5 steers were used in an incomplete 5 × 4 Latin square with four 28-d periods to compare the effects of monensin and supplement type on forage intake, digestibility, and ruminal fermentation characteristics. Forage intake tended to be greater with supplementation ($P = 0.06$), was greater with DDGS compared with CU ($P = 0.03$), and was decreased with monensin addition ($P = 0.04$). Ruminal pH was increased with monensin; however, it was increased more with monensin addition to the DDGS supplement compared with the CU supplement ($P < 0.01$). In Experiment 2, 80 late gestation cows were stratified by age, BCS, and BW and randomly allotted to treatments (20 pens; 4 cows/pen and 4 pens/treatment). Precalving and postcalving BCS change were more positive with supplementation ($P < 0.01$), whereas monensin addition to the supplements benefited precalving ($P = 0.02$) and postcalving ($P = 0.02$) BCS change a greater amount with the CU supplement compared with the DDGS supplement. Monensin addition, irrespective of supplement type, reduced forage intake while maintaining performance of beef cattle consuming low-quality forage.

Key Words: cattle, cool-season, forage, ionophore, monensin, supplementation

0657 WS Methods to increase productivity of spring calving production systems in the Nebraska Sandhills. D. Broadhead*[1], A. Stalker[1], J. A. Musgrave[2], and R. N. Funston[3], *[1]University of Nebraska-Lincoln, North Platte, [2]University of Nebraska, Lincoln, [3]University of Nebraska, North Platte*.

A 2-yr study evaluated effects of late-gestation supplementation, postpartum progestin administration, and creep feeding on productivity of March calving cows. In yr 1, 120 crossbred cows (BW 479 ± 57 kg) were assigned to 1 of 4 levels of late-gestation supplementation, 1 of 2 levels of postpartum progestin, and 1 of 2 levels of creep feed in a 4 × 2 × 2 factorial arrangement of treatments in a completely random design. The

four supplement levels fed were 1) 0 kg/d Dec. 1 to Mar. 1, 2) 0.41 kg/d DM Dec. 1 to Mar. 1, 3) 0.41 kg/d DM Jan. 15 to Mar. 1, or 4) 0.82 kg/d DM Jan. 15 to Mar. 1 while cows grazed dormant upland range. Levels of exogenous progesterone postpartum were 1) controlled internal drug release device for 7 d or 2) no progesterone administration. Creep feed levels were 1) unrestricted access by the calf to creep feed, which contained an intake limiter, or 2) no access to creep feed. The higher levels of late-gestation supplementation increased cow BW ($P < 0.05$) and increased cow BCS ($P < 0.05$) but did not affect ($P > 0.12$) reproductive measures or calf performance. Exogenous progesterone administration postpartum did not affect ($P > 0.13$) cow or calf performance. Allowing calves access to creep feed increased ($P < 0.01$) calf BW at weaning by 21 kg.

Key Words: creep feed, progesterone, supplement

0658 Performance of stocker cattle grazing 'Tifton 85' bermudagrass supplemented with dried distillers' grains on per-animal and per-area bases: A two-year summary.

W. B. Smith*[1], F. M. Rouquette[1], J. L. Kerby[1], L. O. Tedeschi[2], J. L. Foster[3], J. P. Banta[4], K. C. McCuistion[5], T. J. Machado[5], and L. A. Redmon[2], *[1]Texas A&M AgriLife Research, Overton, TX, [2]Texas A&M University, College Station, [3]Texas A&M AgriLife Research, Beeville, TX, [4]Texas A&M AgriLife Extension, Overton, TX, [5]Texas A&M University – Kingsville, Kingsville*.

The supply of dried distillers' grains (DDG) generated from the ethanol industry provides great opportunities for feed additives and supplementation of stocker cattle. The objective of this study was to evaluate performance of stocker calves grazing 'Tifton 85' bermudagrass [*Cynodon dactylon* (L.) Pers.] when supplemented daily with varying levels of DDG. Steers ($n = 96$ [4 testers pasture^{-1} yr^{-1}], 363 ± 3.7 kg initial BW, and approximately 15 mo of age) were stratified by BW and randomly allocated to each of 16 pastures (0.7 ± 0.01 ha) across 2 yr (2014 and 2015). Pastures were randomly allocated to each of 4 levels of DDG supplementation for about 110 d at 0, 0.25, 0.5, or 1% BW hd^{-1} d^{-1}. Steers were group fed daily at 0800 h and weighed every 21 d. Grazer animals were added to pastures based on visual and forage mass assessments to maintain a similar forage allowance among pastures. Data were analyzed using SAS PROC MIXED or PROC GLIMMIX. Least squares means were calculated for treatments and separated using *F*-protected *t* tests with the Tukey–Kramer adjustment. Average daily gain was greatest ($P < 0.05$) from steers offered 1% BW DDG (1.25 kg/d) and least from non-DDG steers (0.77 kg/d), with 0.25 and 0.5% BW being intermediate (1.05 and 1.12 kg/d, respectively). Additional gain from DDG supplementation was greater ($P < 0.05$) from 1% BW DDG (0.68 kg/d) than from 0.25 and 0.5% BW steers (0.47 and 0.54 kg/d, respectively). There was a trend ($P = 0.13$) toward increased supplemental feed to additional gain ratios of 4.2, 5.4, and 7.2 for 0.25, 0.5, and 1% BW DDG, respectively, indicating that higher levels of DDG supplementation resulted in substitution of forage in the diet. There was no measurable difference ($P = 0.33$) in stocking rate (318 kg = 1 steer) among treatments (overall mean = 12.4 hd/ha), whereas gain per area was greatest ($P < 0.05$) at 1,883 kg/ha from pastures offered DDG at 1% BW followed by intermediate values of 1,268 kg/ha at 0.25% and 1,399 kg/ha at 0.5% BW. Pastures receiving no supplementation had steers gaining 906 kg/ha. Supplementation of stocker calves with DDG while grazing Tifton 85 bermudagrass is a viable management strategy to optimize gain per animal or per area.

Key Words: Tifton 85 bermudagrass, dried distillers' grains, stocker, supplement

0659 Monensin effects on early-weaned beef calves grazing annual ryegrass pastures.

J. M. B. Vendramini*[1], F. Leite de Oliveira[2], J. M. D. Sanchez[2], J. Yarborough[2], D. Perez[2], J. Ralston[2], and R. F. Cooke[3], *[1]UF/IFAS, Range Cattle Research and Education Center, Ona, FL, [2]UF/IFAS Range Cattle Research and Education Center, Ona, FL, [3]Oregon State University – EOARC Burns, Burns*.

The objective of this study was to evaluate the effects of monensin on performance of early weaned beef calves grazing annual ryegrass (*Lolium multiflorium*). The experiment was conducted at the University of Florida/Institute of Food and Agricultural Sciences Range Cattle Research and Education Center, Ona, FL, from January 12 to April 14, 2015. Treatments were calves receiving monensin (20 mg/kg of estimated total DMI) or control (no monensin) distributed in a randomized complete block design with four replicates. Calves were weaned with 81 ± 6 kg BW at 84 ± 20 d of age. Calves were supplemented with 1% BW concentrate (18% CP and 78% TDN) daily. Four calves were allocated to each pastures (0.3 ha, experimental unit) in a continuous and fixed stocking rate. Herbage mass and nutritive value were evaluated every 14 d, and calf BW was recorded every 28 d. Blood samples were collected at the termination of the study. Data were analyzed using the Proc Mixed of SAS with treatment as fixed effect and block as random effect. There was no difference ($P \geq 0.05$) in herbage mass (mean = 1,450 kg/ha), CP (mean = 22.2%), and in vitro digestible OM (mean = 78.7%) between treatments. Calves receiving monensin had greater ADG (0.71 vs. 0.57 kg/d; $P = 0.003$) and tended to have greater IGF-1 (89.5 vs. 67.9 ng/mL; $P = 0.09$) but there was no difference ($P \geq 0.05$) in BUN (mean = 26.7 mg/dL), glucose (mean = 86.3 mg/dL), and insulin (mean = 2.31 uIU/mL). The incidence of coccidiosis was lesser (0.49 vs. 1.35 log count) for calves receiving monensin. Adding monensin to the concentrate supplement

is a feasible management practice to improve performance of early weaned calves grazing annual ryegrass pastures.

Key Words: supplementation, beef cattle, monensin

0660 Reduced enteric methane emissions on legume versus grass irrigated pastures. J. W. MacAdam*[1], K. A. Beauchemin[2], A. I. Bolletta[3], and L. R. Pitcher[4], *[1]Department of Plants, Soils, and Climate, Utah State University, Logan, [2]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [3]National Institute of Agricultural Technology, Bordenave, Argentina, [4]Utah State University, Logan*.

Life cycle assessment that compared the cow–calf and feedlot phases of beef production in western Canada demonstrated that the greatest source of greenhouse gas emissions, in carbon dioxide equivalents (CO_2 eq.), was enteric methane (CH_4). Furthermore, the cow–calf phase was responsible for approximately 80% of CO_2 eq. Perennial legume forages contain less fiber than grasses and are, therefore, more digestible, and condensed tannins (CT) have been reported to reduce ruminant enteric methane emissions. Our objective was to measure enteric CH_4 emissions of beef cows and heifers grazing irrigated pastures. We compared a grass with two nonbloating legumes, one that had CT and one that did not. Our treatments were meadow bromegrass (*Bromus riparius* Rehmann), CT-containing birdsfoot trefoil (*Lotus corniculatus* L.), and non-CT cicer milkvetch (*Astragalus cicer* L.). The study was a randomized complete block design with 5 replications. The experimental unit was a 0.365-ha rotationally stocked pasture containing one forage treatment and one cow in late gestation (616 ± 8 kg; 2014) or two heifers (each 439 ± 7 kg; 2015). Following a 5- (2014) or 2-wk (2015) adjustment period, enteric methane was sampled on 4 d/wk for 5 wk on 1 (2014) or 2 (2015) reps/wk using the sulfur hexafluoride method (Johnson et al., 2007). Forage disappearance from pastures was estimated from pre- minus postgrazing herbage DM, measured using a rising plate meter calibrated for each species. This value is presented as percent of BW. The herbage of the cultivar of birdsfoot trefoil used in this study, *Langille*, contained 20 to 30 mg CT/g DM whereas the CT concentration of the other two pasture species was negligible. We conclude that methane emissions were reduced by approximately half for cows grazing legumes compared with grass and by approximately one-third for heifers grazing legumes compared with grass. However, there did not appear to be an effect of CT on enteric CH_4 emissions.

Key Words: birdsfoot trefoil, cicer milkvetch, meadow bromegrass

0661 Milk production, rumination, and body condition score of organic dairy cattle grazing two pasture systems incorporating warm and cool season forages. K. E. Ruh*[1,2], B. J. Heins[2], and J. Paulson[3], *[1]University of Minnesota, Saint Paul, [2]University of Minnesota West Central Research and Outreach Center, Morris, MN, [3]University of Minnesota Extension, Rochester*.

Organic dairy cows ($n = 90$) of Holstein and crossbred genetics were used to evaluate the effect of two pasture production systems (perennial versus perennial/annual systems) over two grazing seasons (May to October of 2014 and 2015) on milk production, milk components (fat, protein, MUN, and SCS), rumination (min/d), BCS, and BW. Cows were assigned to one of two pasture systems: 1) system 1, a diverse mixture of cool season grasses and legumes (perennial ryegrass, white clover, red clover, chicory, orchardgrass, meadow bromegrass, alfalfa, and meadow fescue), or 2) system 2, the same combination of perennial polycultures and annual warm season grasses (brown midrib sorghum-sudangrass [BMRSS] and teff grass). Cows rotationally grazed pasture and moved to a new paddock every 2 d and were supplemented corn (2.27 kg/d) and provided free-choice mineral on pasture. Weekly milk production, monthly milk components, and biweekly BW and BCS were recorded for each of the six replicate groups. Activity and rumination time (daily) were monitored electronically using HR-LD Tags (SCR Engineers Ltd., Netanya, Israel) for the grazing season. The PROC MIXED of SAS was used for statistical analysis, and independent variables were fixed effects of system (1 or 2), forage (perennial grass, BMRSS, or teff) nested within system, year (2014 or 2015),

Table 0660.

Table 1. Enteric methane emissions and forage allowance on irrigated pastures

	Birdsfoot trefoil	Cicer milkvetch	Meadow bromegrass
Enteric methane (g/head/d)			
Cows, 2014	167b	159b	355a
Heifers, 2015	152b	145b	215a
Forage disappearance (kg DM/d/kg BW)			
Cows, 2014	1.63a	2.04a	2.17a
Heifers, 2015	1.99b	2.68a	1.62b

Numbers within a row followed by different letters are statistically different at $P < 0.05$.

system nested within year, and week nested within system, with replicate nested within system as a random effect with repeated measures. System 1 and system 2 cows had similar ($P > 0.05$) milk production (14.7 and 14.8 kg/d, respectively), fat percentage (3.92 vs. 3.80%, respectively), protein percentage (3.21 vs. 3.17%, respectively), MUN (12.5 and 11.5 mg/dL, respectively), and SCS (4.05 and 4.07, respectively). There was a significant yearly effect ($P < 0.05$) for milk production, MUN, and SCS for both systems. Milk production was higher ($P < 0.05$) in 2015 compared with 2014 (15.6 vs. 13.9 kg/d, respectively). There was no effect ($P > 0.05$) of forage type on milk production, fat, protein, MUN, or SCS. Cows in system 1 had greater ($P < 0.05$) daily rumination (530 min/d) compared with cows in system 2 (470 min/d). The BW (485 and 497 kg) and BCS (3.10 and 3.06) were similar ($P > 0.05$) for system 1 and 2, respectively. In summary, warm season annual forages may be incorporated into grazing systems for organic dairy cattle while maintaining milk production and quality.

Key Words: grazing, BMR sorghum-sudangrass, teff

0662 Evaluation of production, rumination, milk fatty acid profile, and profitability for organic dairy cattle fed sprouted barley fodder. B. J. Heins*[1], J. Paulson[2], and H. Chester-Jones[3], *[1]University of Minnesota West Central Research and Outreach Center, Morris, [2]University of Minnesota Extension, Rochester, [3]University of Minnesota Southern Research and Outreach Center, Waseca*.

Certified-organic cows (n = 36) were used to evaluate the effect of feeding sprouted barley fodder to dairy cows on production, SCS, BW, BCS, daily rumination, milk fatty acid profile, and profitability. Cows were assigned to one of two replicated treatment groups (4 groups; n = 9 cows each group): 1) no fodder supplementation or 2) fodder supplementation at 9.1 kg/cow per day. Supplement was fed with a total mixed ration of organic corn silage, alfalfa haylage, and an organic grain mix (corn and minerals). The fodder replaced 2.7 kg of DM of organic corn. The no-fodder cows were fed 3.6 kg of organic grain in the supplement. The study was conducted at the University of Minnesota's West Central Research and Outreach Center, Morris, MN. For 70 d during the summer of 2015, 28 fodder trays (0.6 by 1.8 m) from a FarmTek Fodder Pro system were filled with 4.1 kg of presoaked barley grain, which was soaked for 24 h, to produce sprouted barley fodder. Each tray was automatically watered three times a day for 4 min each time. Weekly milk production, monthly milk components, and biweekly BW and BCS were recorded for each of the four replicate groups. Activity and rumination time (daily) were monitored electronically using HR-LD Tags (SCR Engineers Ltd., Netanya, Israel). Data were analyzed using the MIXED procedure of SAS on a pen basis. Independent variables for analyses were the fixed effects week of study and fodder supplementation group and replicate was a random effect. Milk production and SCS were not different ($P > 0.05$) for the fodder (12.3 kg/d and 3.63, respectively) and no-fodder (13.3 kg/d and 3.55, respectively) supplementation groups. Furthermore, BW (503 kg vs. 505 kg) and BCS (3.17 vs. 3.17) for fodder and no-fodder cows were not different. The fodder cows tended ($P < 0.10$) to have less rumination (519 vs. 550 min/d) compared with the no-fodder cows. The fodder cows tended ($P < 0.10$) to have a lower omega 6:omega 3 ratio (1.16 vs. 1.40) than the no-fodder cows. Net income per cow per day was similar for fodder ($2.96 vs. $3.18 cow/d) and no-fodder cows, respectively. In summary, the results show that sprouted barley fodder may have no benefit in an organic production system.

Key Words: sprouted fodder, production, organic

0663 Effect of tillage and planting date of wheat pasture on forage production and calf performance. P. A. Beck*[1], W. Galyen[2], T. Hess[3], and D. S. Hubbell III[3], *[1]University of Arkansas SWREC, Hope, [2]University of Arkansas, Fayetteville, [3]University of Arkansas Livestock and Forestry Research Station, Batesville*.

The objectives of this experiment were to determine how fall wheat forage production and animal performance are affected by establishment method (conventional tillage [CT] vs. no-till [NT]) and timing in dedicated wheat fields (1.6 ha). No-till pastures were planted on August 15 (n = 8), September 1 (n = 8), or September 15 (n = 8) and CT pastures were planted on September 1 (n = 3) or September 15 (n = 3). Preconditioned steers (n = 236; 245 ± 21.1 kg BW) were placed on wheat pasture when forage mass reached a minimum of 1,100 kg DM/ha. Steers were destocked from pastures on 23 February 2015 and 11 February 2016. Forage mass was estimated monthly using a calibrated rising plate meter, with 20 plate readings per pasture. Data were analyzed as a randomized complete block design using the mixed procedure of SAS (SAS Inst. Inc., Cary, NC). Forage mass in November for NT did not differ (P = 0.91) between the August 15 (1,525 ± 386 kg/ha) and September 1 (1,548 ± 386 kg/ha) planting dates but was greater than (P = 0.05) the September 15 planting date (1,153 ± 386 kg/ha). November forage mass for CT planted on September 1 (1,982 ± 426 kg/ha) tended (P = 0.10) to be greater than that for CT planted on September 15 (1,444 ± 426 kg/ha) and NT planted on August 15 or September 1. No-till planting on September 15 (1,153 ± 386 kg/ha) produced less ($P \leq 0.05$) forage in November than other planting methods. The average starting date of grazing was November 26 for CT planted on September 1 or September 15 and NT planted on August 15 or September 1 whereas the average starting date of grazing was delayed ($P < 0.01$) until December 8 for the NT September 15 planting. Initial forage allowance (3.79 ± 0.93 kg forage DM/kg steer BW) did not differ ($P \geq 0.84$) among tillage methods and planting dates and, therefore, ADG (1.24 ± 0.10 kg/d) did

not differ ($P = 0.63$) among planting methods. Steer grazing days per hectare and BW gain per hectare were reduced ($P \leq 0.02$) by NT planting on September 15. Planting wheat pasture in mid August using NT did not result in improved forage production or animal gains compared with CT or NT on September 1. If planting is delayed until mid September, use of CT provides advantages over NT.

Key Words: Wheat pasture, tillage, planting date, steers

0664 Impact of high-energy forages on grass-finished steer performance and carcass merit.

R. M. Martin*[1], J. E. Rowntree[1], K. A. Cassida[1], and D. Carmichael[2], *[1]Michigan State University, East Lansing, [2]Michigan State University AgBio Lake City Research Center, Lake City*.

The research objective was to compare high-energy forage options during the finishing period for Upper Midwestern forage-finished beef production systems. Twelve 0.80-ha pastures were randomly assigned to 1 of 3 forage treatments including mixed pasture (MIX), simple cereal grain/brassica mixture (SIMP), and complex cereal grain/brassica mixture (COMP). Red Angus–influenced steers (439.99 kg ± 4.21 BW; $n = 24$) were stratified by BW and randomly assigned to 1 of 12 paddocks and were grazed for a 76-d finishing period. Steers had ad libitum access to water, free choice mineral, and supplemental hay and were allowed access to strips in each grazing treatment, which were back fenced to allow for forage regrowth. Overnight fasted BW was measured on d 0, 36, 66, and 76. At the end of the finishing period, steers were slaughtered under federal inspection and carcass data were collected 48 h postmortem. Data were analyzed using Proc Mixed (SAS version 9.4) where paddock was the experimental unit. Steers had different d 0 to 76 BW gains ($P < 0.01$), where gains were greatest for MIX (90.15 kg ± 3.32) followed by COMP (73.71 kg ± 3.32) and then SIMP (64.64 ± 3.32). Although overall BW gains were greatest for steers in MIX, there was a tendency ($P = 0.11$) for d 67 to 76 gains to be highest in COMP and least for MIX (19.28 kg ± 2.07 and 12.47 kg ± 2.07, respectively).There was a treatment × period interaction for d 76 BW ($P < 0.01$), where steers on COMP and SIMP had less BW (514 kg ± 4.7 and 505 kg ± 4.7, respectively) than those on MIX (530 kg ± 4.7), yet each had greater ($P < 0.01$) dressing percents (56.95% ± 0.44 and 59.96% ± 0.44 versus 54.67% ± 0.44, respectively).There were no differences ($P > 0.05$) among steer carcasses from all treatments for HCW, backfat, LM area, KPH, YG, and marbling score. These data indicate that steers grazing all treatments had reasonable gains and carcass merit and that these systems can be a viable component of forage-finishing systems in the Upper Midwest.

Key Words: brassicas, beef, grass finished

0665 Effect of stocking rate on performance, diet selection, and apparent total-tract digestibility among heifers grazing cover crops.

B. R. Brunsvig*, D. W. Brake, A. J. Smart, and E. E. Grings, *South Dakota State University, Brookings*.

Grazing cover crops can increase lands available for cattle production and reduce costs associated with winter feeding. Unfortunately, data are limited on stocking rates that allow optimal utilization of cover crops by cattle. We evaluated effects of stocking rate among heifers (573 ± 9.5 kg BW) grazing cover crops. Cover crop pasture (12.1 ha) consisted of a mixture of annual ryegrass (*Lolium multiflorum*; 66.5%), radish (*Raphanus sativus*; 20%), and purple top turnip (*Brassica rapa*; 13.5%). Pasture was divided into 12 paddocks. Heifers were blocked by weight before initiation of the experiment and randomly assigned to 1 of 4 BW blocks. Stocking rate treatments were designed to obtain 45, 55, or 65% forage utilization and were achieved by randomly assigning 3, 4, or 5 heifers within each BW block to paddocks. All paddocks in 3 BW blocks contained a ruminally cannulated heifer to facilitate measures of diet selection, and heifers were allowed to graze for 48 d. Heifers were weighed on consecutive days at the beginning and end of the experiment and on d 9 to 22. Heifers were provided TiO_2 from d 14 to 23, and composite fecal samples (d 18 to 24) allowed estimates of fecal output. Estimates of DMI and diet digestibility were obtained from determination of fecal and diet acid detergent insoluble ash. Initial, intermediate, and final diet samples were collected on d 2, 24, and 46 by ruminal evacuation. Fecal and diet samples were analyzed for DM, OM, NDF, and ADF. Reductions in stocking rate tended to increase intermediate (linear effect, $P = 0.06$) and overall (linear effect, $P = 0.10$) ADG. However, estimates of DMI tended (quadratic effect, $P = 0.07$) to be less as stocking rate was reduced. Reduced stocking rate tended (quadratic effect, $P = 0.06$) to increase diet DM; however, stocking rate had no impact ($P \geq 0.15$) among diet OM, NDF, and ADF. Estimates of DM and OM digestibility decreased (quadratic effect, $P < 0.01$) with reduced stocking rate. Similarly, reduced stocking rate tended (linear effect, $P = 0.06$) to reduce NDF digestibility, but stocking rate had no effect ($P \geq 0.23$) among estimates of ADF digestibility. These data indicate that reduced stocking rate among heifers grazing cover crops tends to increase performance. It is unclear why estimates of DMI and diet digestibility decreased with reduced stocking rate.

Key Words: cattle, cover crops, stocking rate

0666 The physiological consequences of ingesting a toxic plant (*Diplotaxis tenuifolia*) and medicinal supplements influence subsequent foraging decisions by sheep. F. H. Catanese[1], J. J. Villalba*[2], and R. A. Distel[1], [1]*Universidad Nacional del Sur, Bahia Blanca, Argentina,* [2]*Utah State University, Logan*.

There is a large group of highly nutritious plants that are commonly avoided by grazing livestock due to the presence of toxic plant secondary compounds. Our hypothesis was that aversion toward toxic plants is learned and that their negative postingestive effects could be attenuated by specific nutrients. Therefore, we determined the impact of supplements on physiological parameters and feeding behavior in Merino sheep consuming *Diplotaxis tenuifolia* ("Wild rocket"), a plant with high concentration of glucosinolates (37.2 ± 3.6 μmol/g). Thirty-six sheep were randomly assigned to four feeding treatments in a split-plot design with lambs (n = 9) nested within treatment: Wild rocket (DT), Wild rocket and a protein (160 g/d) supplement (DT+P), Wild rocket and a protein supplement containing iodine (10 mg/d) and copper (40 mg/d) (DT+P+M), or alfalfa pellets (CTRL) in amounts that paired the ingestion of Wild rocket in DT. Toward the end of a 35-d exposure period, sheep in DT showed the lowest intake of Wild rocket (P = 0.04) as well as reduced concentrations of plasma thyroid hormones (T3 and T4; P < 0.001 and P = 0.05, respectively) and the enzyme alanine aminotransferase (P = 0.02) and a trend toward reduced hemoglobin concentration (P = 0.07) relative to sheep in DT+P and DT+P+M, which, in turn, showed concentrations of hormones and hepatic enzymes similar to those recorded in CTRL. Total serum protein and albumin levels were greater (P = 0.03 and P = 0.04, respectively) in supplemented than in unsupplemented sheep fed Wild rocket, which could have elicited a protective effect on glucosinolate ingestion. Foraging behavior was evaluated in an experimental arena where animals could select among randomly distributed buckets containing a fixed amount of Wild rocket or variable amounts of barley grain. Regardless of barley grain availability, sheep in DT showed lower intake and lower time spent eating Wild rocket than sheep in DT+P or in DT+P+M (19.0 vs. 48.5 and 43.2 ± 6.0 g [P = 0.007] and 26.8 vs. 54.4 and 48.9 ± 4.78 s [P = 0.005], respectively). Sheep in CTRL showed intake levels of Wild rocket and behavioral responses similar to those observed in supplemented sheep. In conclusion, nutritional supplements have the potential to attenuate the negative postingestive effects of glucosinolates in Wild rocket and enhance the utilization of the plant at pasture. A negative feeding experience with Wild rocket is needed for animals to display the typical pattern of aversion commonly observed in grazing conditions.

Key Words: feeding behavior, food aversions, glucosinolates

0667 Lining bunker wall with oxygen barrier film reduces nutrient losses of corn silages. L. M. Lima, J. P. Dos Santos, I. L. De Oliveira, J. O. Gusmao, M. S. Bastos, S. M. Da Silva, E. B. Alves, J. R. Gervasio, and T. F. Bernardes*, *Federal University of Lavras, Lavras, Brazil*.

Spoiled silage at the shoulders of bunker silo is common. The objective of this study was to evaluate the effect of two systems for covering corn silage in bunker silos. The first system comprised a sheet of 45-μm-thick oxygen barrier film (OB; polyethylene + ethylene-vinyl alcohol) placed along the length of the sidewall before filling, with approximately 2 m of excess draped over the wall. After filling, the excess film was pulled over the wall, and a sheet of polyethylene was placed on top. The second system involved using a standard sheet (ST) of 180-μm-thick polyethylene film. Eight commercial bunker silos were divided into two parts lengthwise so that half of the silo was covered with OB and other with ST system. During the filling, three bags with chopped corn were buried in the central part of the bunkers (CORE) in three 10-m-apart sections. After filling, 18 bags (9 per covering system) were buried in the upper layer of the three sections. These bags were placed at three distances from the bunker walls (0 to 50, 51 to 100, and 101 to 150 cm). During unloading, the bags were removed from the silos to determine the DM losses, fermentation end products, and nutritive value. The Milk2006 spreadsheet was used to estimate milk per ton of DM. The experiment was set up as randomized blocks with eight replicates (silos). Two orthogonal contrasts were tested to compare silages under the two covering systems with that in the CORE (OB versus CORE and ST versus CORE). Three orthogonal contrasts compared the distances from the bunker walls (OB50 versus ST50, OB100 versus ST100, and OB150 versus ST 150). Variables were analyzed with the PROC MIXED procedure of the SAS at 5%. The OB method produced well-fermented silages, which were similar to the CORE, whereas the PE system showed less lactic acid and greater pH and mold counts compared with the CORE. The PE method had 116.2 kg of milk/ton less than the CORE (P = 0.0016), as the OB system and the CORE were similar (1,258.3 and 1,294.0 kg/ton, respectively). Regarding the distances from the walls, the effects were more pronounced in the corner zones (0 to 50 cm). OB50 silages had better fermentation profile and lower spoiled microorganisms and DM losses than ST50. Corn silage at the shoulders has quality similar to the CORE when the OB system is used.

Key Words: aerobic deterioration, bunker silo, silage covering

0668 Effects of method and storage time on the nutritive value of sugarcane for dairy cattle.
F. T. Fonseca[1], L. M. Lima[1], R. M. De Oliveira[1], F. N. Domingues[2], and T. F. Bernardes*[1], [1]*Federal University of Lavras, Lavras, Brazil,* [2]*Federal University of Para, Belem, Brazil*.

Fresh chopped sugarcane is an important forage source for dairy cattle in tropical environments; however, daily harvest has been a major constraint for producers. Therefore, the objective of this study was to evaluate two storage methods (stem and whole plant) in different times on the nutritive value, microbial counts, and DM losses to extend the intervals between harvests. Two experiments were performed for 2 yr (Experiment 1 and 2). In both experiments, 288 plants of sugarcane were manually collected during the crop harvesting window. Leaves were removed from 144 plants and other part remained intact (whole plants). Sugarcane stems and plants were split into 18 bunches (8 stems or plants per bunch) and placed on the ground in a barn at ambient temperature for 0, 2, 4, 6, 8, and 10 d. For each day of evaluation, three bunches of each treatment were weighed to determine DM losses. Afterward, bunches were chopped to assess nutritive value and microbial counts (bacteria, yeasts, and molds). In experiment 2, additionally to these parameters was assessed the leaf carbon balance (CO_2 uptake during photosynthesis minus CO_2 loss during respiration) in sugarcane plants. Treatments were arranged in a completed randomized design with repeated measurements over time. The data were analyzed by the mixed-model method using the MIXED procedure (SAS Institute, 2004). The means were compared using a Tukey test at the 5% probability. In both experiments, DM and NDF concentrations and in vitro DM digestibility were lower in stems compared with whole plants. Storage time had an inconsistent effect on chemical composition and microbial counts. Only DM losses were affected by the interaction between method and storage time. Whole plants reached losses more than 90 kg MS/ton at 6 and 8 d in the experiment 1 and 2, respectively. On the other hand, stems showed the maximum DM losses at 10 d (55.1 and 35.0 kg MS/ton for experiment 1 and 2, respectively). The carbon balance of leaves in whole plants was negative due to respiration losses from 2 d storage, which might explain the rise in DM losses. Overall, sugarcane stems is the most effective method to store forage under a cut-and-carry system because stems have greater nutritive value and take up less space in the barn with a long duration of aerobic stability (10 d).

Key Words: cut-and-carry system, forage harvesting, tropical forage

0669 Bunk heating of rations containing corn silage with various inoculants, a stabilizer, or wet grain byproducts: A field survey.
B. Powel-Smith, L. Nuzback*, F. Owens, S. Dennis, B. Mahanna, and W. Rutherford, *DuPont Pioneer, Johnston, IA*.

Inoculation of corn silage with *Lactobacillus buchneri* (LB) retards yeast growth and delays heating of corn silage exposed to air. The objective of this survey was to quantify the effects of LB inoculation of corn silage on temperature stability of total mixed ration (TMR) containing corn silage with or without added wet feeds (12 with whey, 9 with wet distillers' grains, and 5 with wet corn gluten). Effects of adding a feed stabilizer ($n = 6$) to the TMR also were monitored. Samples of 57 TMR as delivered to the bunk at 55 dairies in the Upper Midwest were obtained during June of 2015. These TMR samples were exposed to air at room temperature and TMR temperatures were recorded after 6, 12, 24, 36, 48, 60, and 72 h of air exposure by an individual not familiar with the silage treatments or TMR additions. Although 9 different silage inoculants were used, only one of the inoculants contained LB. When compared with the TMR containing corn silage with other inoculants, TMR containing corn silage treated with LB had TMR temperatures that were 2, 5, and 7°C lower ($P < 0.05$) at 6, 12, and 24 h. Temperature responses differed among the various wet feeds that were added. Including wet distillers' grains in the TMR resulted in a 6°C greater ($P < 0.05$) temperature by 24 h but differences thereafter were not significant ($P > 0.10$). Including wet gluten or whey in the TMR resulted in temperatures that were 7°C and 5°C greater ($P < 0.05$), respectively, at 12 h than TMR not containing these wet feeds. Total mixed rations containing wet grains plus corn silage treated with LB had temperatures that were 3, 7, and 8°C lower ($P < 0.02$) at 6, 12, and 24 h than those TMR containing wet grain plus corn silage not treated with LB. Addition of the feed stabilizer failed to significantly alter the TMR temperature at any time. In conclusion, LB inoculation of corn silage that was included in the TMR reduced heating of the TMR as delivered to lactating cows for 24 h whether or not wet feeds were included in the TMR.

Key Words: corn silage, inoculants, temperature stability

0670 The effect of *Lactobacillus brevis* and fibrolytic enzymes on fermentation of switchgrass silages.

J. Liu[1], Y. Wang[1], X. Wang*[2], Z. Cao[1], S. Li[1], and Z. Cui[2], [1]*State Key Laboratory of Animal Nutrition, Beijing Engineering Technology Research Center of Raw Milk Quality and Safety Control, College of Animal Science and Technology, China Agricultural University, Beijing, P. R. China,* [2]*Center of Biomass Engineering, College of Agriculture and Biotechnology, China Agricultural, Beijing, P. R. China*.

The objective of this study was to determine the effect of *Lactobacillus*, enzymes, and *Lactobacillus* + enzymes mixture on fermentation characteristics, nutritive value, and microbial diversity of switchgrass silage. Switchgrass (*Panicum virgatum* L.) was harvested at vegetable stage and treated with distilled water (control), *Lactobacillus brevis*, fibrolytic enzymes, and *L. brevis* + fibrolytic enzymes (denoted C, LB, E, and LB+E, respectively) before ensiling. Treated switchgrass was ensiled in sealed 1.0-L plastic jars. Inoculation accelerated the decline of silage pH. Compared with other treatments, LB+E had the greatest decline ($P < 0.05$) in pH during the first 3 d of ensiling. After 30 d, for C, LB, E, and LB+E, pH declined to 5.3, 4.6, 4.8, and 3.7, respectively. There was no butyric acid detected in LB and LB+E. Lactic acid concentration of LB and LB+E increased by 5.53 times and 21.75 times than that of C, respectively. Acetic acid concentration of LB and LB+E decreased by 36.34 and 9.40%, respectively. NH_3–N concentration of LB, LB+E, and E decreased by 67.7, 74.55, and 69.88%, respectively. Treatments with enzymes (E and LB+E) effectively ($P < 0.05$) decreased NDF and ADF concentration. Neutral detergent fiber concentration of E and LB+E decreased by 8.09 and 8.43%, respectively. Acid detergent fiber concentration of E and LB+E decreased by 3.03 and 10.88%, respectively. Crude protein content of C, LB, E, and LB+E was 77.6, 96.2, 88.0, and 97.0 g/kg DM, respectively, suggesting that inoculation increased CP content of switchgrass silage ($P < 0.05$). The 16S rRNA gene-based pyrosequencing was used to analyze the community of the 30-d silage, and results indicated that the diversity of microorganisms differed among treatments ($P < 0.05$). *Enterobacter* was the dominant genus in C, and the relative abundance of *Enterobacter* was 53.60%. *Enterobacter* was the dominant species in E, although the relative abundance of *Enterobacter* decreased to 40.67% and that of *Lactobacillus* increased to 26.13% in E. In LB and LB+E, *Lactobacillus* was the advantageous species (91.19 and 96.89%, respectively), and *Enterobacter* was effectively inhibited. In conclusion, the addition of bacterial and enzymatic additives can improve the switchgrass silage fermentation quality at different extent. Adding the mixture of *L. brevis* and fibrolytic enzymes worked more efficient than adding either *L. brevis* or fibrolytic enzymes, respectively.

Key Words: switchgrass silage, fermentation characteristics, nutritive value

0671 Effects of wrapping time delays on fermentation characteristics of baled alfalfa silages.

W. K. Coblentz*[1], K. P. Coffey[2], and E. A. Chow[3], [1]*U.S. Dairy Forage Research Center, Marshfield, WI,* [2]*University of Arkansas, Division of Agriculture, Fayetteville,* [3]*Kuraray America, Inc., Pasadena, TX*.

Baled silage is an attractive forage conservation approach for small and mid-sized dairy or beef producers, partly because it limits the risks associated with baling dry hay during wet or unstable weather conditions. Our objectives were to test the effects of delayed wrapping on silage fermentation and the storage characteristics of baled alfalfa silages. A secondary objective was to evaluate a prototype bale wrap containing an O_2–limiting barrier, against an identical polyethylene wrap without the O_2 barrier. Sixty-four 1.19- by 1.25-m round bales of alfalfa were made from 4 field blocks at a mean moisture concentration of 59.1 ± 4.3% and a mean initial wet bale weight of 473 ± 26.4 kg. Large-round bales were wrapped in plastic film within 4 h of baling (d 0) or after delays of 1, 2, or 3 d and then stored for 97 d. All bales were wrapped with 7 polyethylene layers. At wrapping, internal bale temperatures were greater for all bales with wrapping delays compared with bales wrapped on d 0 (54.9 vs. 34.9°C; $P < 0.01$) and linearly increased ($P < 0.01$) to a maximum of 63.9°C after a 3-d delay. No internal bale temperature for any treatment combination exceeded 30°C by 23 d after baling. Concentrations of water=soluble carbohydrates linearly declined with bale temperature at wrapping ($y = -0.039x + 6.5\%$; $r^2 = 0.634$); conversely, the buffering capacity of pre-ensiled forages linearly increased with bale temperature ($y = 2.98x + 316$ mEq/kg DM; $r^2 = 0.759$). Total silage fermentation acids were greatest when bales were wrapped on d 0 compared with bales wrapped with 1-, 2-, or 3-d time delays (4.64 vs. 2.26%; $P < 0.01$) and declined with both linear ($P < 0.01$) and quadratic ($P < 0.01$) effects of time delay. Similar responses were observed for lactic acid but without the quadratic effect of time ($P = 0.18$). Butyric acid also was detected and was greatest within bales wrapped on d 0 compared with those wrapped after 1, 2, or 3 d (0.99 vs. 0.38%; $P < 0.01$), and a similar response (0.68 vs. 0.52%; $P < 0.01$) was observed for NH_3–N (% of DM). Bale wrap had no effect on any silage fermentation response ($P \geq 0.07$), likely because of the conservative (7-layer) wrapping protocol. Silage fermentation characteristics deteriorated with time delays before wrapping, but responses were exacerbated when delays exceeded 1 d.

Key Words: alfalfa, baled silage, fermentation

0672 Effects of wrapping time delays on the nutritive value of baled alfalfa silages. W. K. Coblentz*[1], K. P. Coffey[2], and E. A. Chow[3], [1]*U.S. Dairy Forage Research Center, Marshfield, WI,* [2]*University of Arkansas, Division of Agriculture, Fayetteville,* [3]*Kuraray America, Inc., Pasadena, TX.*

Baled silages are an attractive forage conservation option, especially for small and mid-sized beef and dairy producers. Our objectives were to test the effects of delayed wrapping on the nutritive value of baled alfalfa silages on a pre- and post-storage basis. A secondary objective was to evaluate a prototype bale wrap containing an O_2–limiting barrier against an identical polyethylene wrap without the O_2 barrier. Sixty-four 1.19- by 1.25-m large-round bales were wrapped in plastic film within 4 h of baling (d 0) or after delays of 1, 2, or 3 d. All bales were wrapped with 7 polyethylene layers. The internal bale temperature for all bales declined to <30°C by 23 d after baling, regardless of wrapping time delay. Internal bale temperatures ranged from 34.9 to 63.9°C, 38.1 to 66.7°C, and 29.7 to 39.6°C when determined at the time of wrapping, as the maximum temperature during storage, and as mean for the initial 23 d of storage, respectively. In each case, these responses were explained by linear ($P < 0.01$) effects of time delay; a quadratic ($P = 0.01$) effect of time also was observed for the 23-d mean temperature. After completing a 97-d storage period, NDF concentrations could be linearly related to internal bale temperature at wrapping ($y = 0.14x + 40.5\%$; $r^2 = 0.67$). Concentrations of neutral-detergent insoluble CP ($y = -0.0009x^2 + 0.16x - 1.3\%$ of DM; $R^2 = 0.84$) and acid-detergent insoluble CP ($y = -0.0003x^2 - 0.014x + 2.1\%$ of DM; $R^2 = 0.70$) both quadratically increased with internal bale temperature at wrapping. Energy density calculated as TDN with the summative approach declined in a quadratic relationship with internal bale temperature at wrapping ($y = -0.0039x^2 + 0.31x + 51.2\%$ of DM; $R^2 = 0.61$), which represented a loss of approximately 3 TDN units when wrapping was delayed by 3 d. Generally, responses were less clear when samples of unfermented forage were obtained immediately before bales were wrapped in polyethylene. The type of bale wrap had no effect ($P \geq 0.32$) on any aspect of forage nutritive value, likely because of the conservative (7-layer) wrapping protocol. The nutritive value of fermented round-bale silages deteriorated with time delays before wrapping, but responses were exacerbated with delays longer than 1 d.

Key Words: alfalfa, baled silage, nutritive value

0673 Effects of corn planting density and maturity on yield and nutritional quality of corn silage. G. Ferreira* and C. L. Teets, *Virginia Polytechnic Institute and State University, Blacksburg.*

The objective of this study was to determine the effects of planting density and maturity on yield and nutritional quality of corn for silage in a double-crop rotation system. The study was performed at an 800-cow dairy farm located in southern Virginia. Corn was planted in experimental plots within 2 cornfields, one of which was irrigated with a central-pivot irrigation system. Planting densities were 55, 70, 85, and 100 seeds/ha (× 1,000) in 4 replicates per cornfield (2 fields × 4 densities × 4 replicates = 32 plots total). Plots were twelve 50-m-long rows separated by 76 cm. The irrigated cornfield was watered with approximately 100 mm of water before silking. At one-fourth and three-fourths milk-line stages of maturity (early and late, respectively), 10 plants from each plot were cut (15 cm above ground), weighed, chopped, mixed, and analyzed using wet chemistry. Additionally, 200 to 400 g of chopped material were placed into mini-silos and analyzed after 60 d. Data was analyzed as a completely randomized design with repeated measures. The statistical model included the fixed effects of density (D) and irrigation (I), the interaction of D × I, the whole-plot error, the fixed effect of maturity (M), and the interactions of M × D, M × I, and M × D × I. Dry matter yield linearly increased ($P < 0.01$) when increasing planting density at both maturity stages. Concentrations of CP, NDF, and starch of the fresh material were not affected ($P > 0.13$) by planting density at any maturity stage. Maturity did not change CP ($P > 0.20$) and NDF ($P > 0.54$) concentrations but increased starch ($P < 0.01$) and decreased ($P < 0.01$) sugars concentrations in the fresh materials. The decrease in sugars concentration with maturity was greater ($P < 0.05$) for

Table 0673.

Effect of corn planting density (plants/ha x 1000; D), irrigation (I) and maturity (M) on yield and nutritional quality of corn silage.

nonirrigated than for irrigated corn (6.8 and 3.5 percentage units, respectively). A cubic effect ($P < 0.01$) of planting density on sugars concentration was observed for fresh samples. Planting density did not affect silage pH ($P > 0.11$) but late maturity silages had greater pH ($P < 0.01$) than early maturity silages (3.81 vs. 3.67, respectively). The concentrations of NDF, starch, and sugars of silages did not change with planting density ($P > 0.14$). In conclusion, increasing planting density increased DM yields while minimally affecting the nutritional composition of corn silage at any maturity stage.

Key Words: planting density, corn silage, nutritional quality

9674 Effect of homolactic bacteria inoculation and aerobic stress during ensiling on the nutritional and fiber digestibility characteristics of spring triticale. L. C. Solórzano*[1], L. L. Solorzano[2], A. A. Rodriguez[1], and J. A. Teisberg[4], *[1]University of Puerto Rico, Mayagüez, [2]Lankin, Fitchburg, WI, [3]Nurealm, LLC, Hutisford, WI.*

Silage is often aerobically stressed during storage due to improper management, weather, or mechanical issues, resulting in diminished silage quality. The effect of homolactic bacteria inoculation (HBI; supplying >9.1 × 10^{10} cfu/g containing *Lactobacillus plantarum*, *Enterococcus faecium*, *Lactococcus lactis*, *Pediococcus pentosaceus*, and *Pediococcus acidilactici*) and aerobic stress during ensiling on fresh whole plant spring triticale (x Triticosecale spp.) was evaluated. Triticale was fermented for 120 d at a temperature of 20 to 23°C using 3-L capacity PVC mini-silos fitted with two-way mechanics to vent gas. Sixteen mini-silos were filled with about 2 kg of the crop at about 35% DM and 5.2% soluble carbohydrates (DM basis). Four treatments were A) no HBI with gas vent closed, B) HBI with gas vent closed, C) no HBI with gas vent open during the ensiling period, and D) HBI with gas vent open during the ensiling period. Upon opening, nutritional characteristics and fiber digestibility were determined at a commercial lab (Rock River Lab, Watertown, WI). Statistical analysis was performed using a completely randomized designs. Treatment had no effect ($P > 0.05$) on the content of the following characteristics, which averaged (%) CP (16.9), ADICP (0.61), fat (3.54), aNDF (55.9), lignin (2.04), starch (0.17), sugar (1.73), NFC (11), ash (14), total tract NDF digestibility (49.2), or NDF K_d (4.25%/h). Treatment C (31.4%) had a lower ($P < 0.05$) DM content compared with treatment D (33%) but did not differ ($P > 0.05$) from treatments A (31.3%) or B (31.8%). The digestibility of NDF was lower ($P < 0.05$) for treatments C (52.8%) and D (52.5%) compared with that of treatments A (54.1) and B (57.5%). The content of uNDF240 was higher ($P < 0.05$) for treatment D (13.2%) compared with treatment B (12%) but it was similar ($P > 0.05$) to treatments A (13%) and C (12.7%). Silage that was inoculated and kept in anaerobic storage conditions resulted in lower uNDF240 and may help explain the numerically higher NDF digestibility observed. Aerobic stress (treatments C and D) during the ensiling period decreased fiber digestibility. Inoculating silage that was aerobically stressed resulted in DM content higher compared with that of silage kept under aerobic conditions but not inoculated. Therefore, it is recommended to inoculate silage to prevent DM content and fiber digestibility losses in case of aerobic exposure during the storage period.

Key Words: silage, inoculation, fiber digestibility

0675 Effect of homolactic bacteria inoculation and aerobic stress during ensiling on the fermentation characteristics, dry matter recovery, and aerobic stability of spring triticale. L. C. Solórzano*[1], L. L. Solórzano[2], A. A. Rodriguez[1], and J. A. Teisberg[3], *[1]University of Puerto Rico, Mayagüez, [2]Lankin, Fitchburg, WI, [3]Nurealm, LLC, Hutisford, WI.*

On farm silage storage is often aerobically stressed due to slow ensiling, improper chop length, and packing or poor covering. The effect of homolactic bacteria inoculation (HBI; supplying >9.1 × 10^{10} cfu/g containing *Lactobacillus plantarum*, *Enterococcus faecium*, *Lactococcus lactis*, *Pediococcus pentosaceus*, and *Pediococcus acidilactici*) and aerobic stress during ensiling on fresh whole plant spring triticale (x Triticosecale spp.) was evaluated. Triticale was fermented for 120 d at a temperature of 20 to 23°C using 3-L capacity PVC mini-silos fitted with two-way mechanics to vent gas. Sixteen mini-silos were filled with about 2 kg of the crop at about 35% DM and 5.2% soluble carbohydrates (DM basis). Four treatments were A) no HBI with gas vent closed, B) HBI with gas vent closed, C) no HBI with gas vent open during the ensiling period, and D) HBI with gas vent open during the ensiling period. Upon opening, DM recovery and fermentation characteristics were determined at a commercial lab (Rock River Lab, Watertown, WI). Aerobic stability (AS) was determined by monitoring temperature at 6 h intervals during 7 d. Statistical analysis for fermentation characteristics and DM recovery was performed using a completely randomized design (CRD). Statistical analysis for AS data was performed as a CRD with 4 treatments by 29 time point factorial arrangement of treatments. Treatment B increased ($P < 0.05$) the content of lactic acid (5.33%) and total VFA (9.19%) compared with treatments A (3.71 and 8.18%, respectively), C (3.57 and 8.59%, respectively), and D (3.78 and 8.37%, respectively). Treatment B decreased ($P < 0.05$) pH (4.87) and acetic acid (3.56%) compared with treatments A (5.07 and 4.20%, respectively), C (5.07 and 4.65%, respectively), and D (4.96 and 4.31%, respectively). Treatment C (66%) had lower ($P < 0.05$) DM recovery compared with treatments A (88.6%), B (79.6%), or D (87.1%). Silage that was inoculated and aerobically stressed (treatment D) yielded an additional 24% DM recovery compared with noninoculated silage that was aerobically stressed (treatment C). All silages, regardless of treatment, were

aerobically stable and averaged 18.7°C. Inoculating triticale silage improved the DM recovery when the silo was aerobically stressed to levels comparable to that of anaerobic silages. Inoculating silage stored in anaerobic conditions improved fermentation characteristics. Therefore, it is recommended that silages be inoculated as protection against aerobic stresses due to suboptimal management, whether controllable or not.

Key Words: silage, aerobic stress, inoculation

0676 Effects of inoculant application on chemical composition, fermentation indices, and microbial counts of corn silage.

S. S. Lee*[1], H. J. Lee[1], Y. H. Joo[1], D. H. V. Paradhipta[1], I. H. Choi[2], O. K. Han[3], and S. C. Kim[1], *[1]Division of Applied Life Science (BK21Plus, Insti. of Agri. & Life Sci.), Gyeongsang National University, Jinju, the Republic of Korea, [2]Department of Companion Animal & Animal Resources Science, Joongbu University, Geumsan, the Republic of Korea, [3]National Institute of Crop Science, Rural Development Administration, Suwon, the Republic of Korea*.

This study was performed to determine the effect of inoculant application on chemical composition, fermentation indices, and microbial counts of corn silage and changes of microbes after the silo was opened. Two corn hybrids (Kwangpyeonok [KP] and Pioneer1543 [PI]) were harvested at 29.7 and 29.7% of DM, respectively. The harvested corn forage was chopped to 4 to 6 cm lengths and treated with 2 inoculants at the ratio of 1.2×10^5 cfu/g of *Lactobacillus plantarum* (LP) and 1.2×10^5 cfu/g of *Lactobacillus buchneri* (LB) on a fresh-weight basis. Treatments had a 2 × 2 factorial arrangement with three replications. The chopped corn forage (10 kg) was ensiled in a 20-L mini-silo for 100 d. After the silo was opened, a sample (5 kg) was collected for analyses of chemical compositions, fermentation indices, and microbial counts. The remained silage was stored in a mini-silo under aerobic condition and subsampled on 1, 2, 4, and 8 d of opening the silo to analyze the microbial counts. Data were analyzed with a model including hybrid, inoculant, and the interaction using the GLM procedure of SAS. The KP silage had higher ($P < 0.05$) DM (28.4 vs. 26.7%), crude ash (6.85 vs. 5.96%), in vitro DMD (71.4 vs. 64.3%), and in vitroNDFD (50.2 vs. 45.2%) but lower CP (8.62 vs. 9.61%) and ADF (25.9 vs. 27.1%). The LP silage had higher ($P < 0.05$) CP (9.24 vs. 8.99%) than LB silage. The PI silage had higher ($P < 0.05$) ammonia N (0.11 vs. 0.09%) and acetate (1.00 vs. 0.88%) and lactate-to-acetate ratio (4.22 vs. 3.51) than KP silage. The LP silage had higher ($P < 0.05$) lactate (3.12 vs. 2.07%) but lower acetate (0.76 vs. 1.12%). The LP silage had higher ($P < 0.05$) lactic acid bacteria (6.15 vs. 4.50 log10 cfu/g) and yeast (6.08 vs. 5.21 log10 cfu/g), whereas mold was not detected. During aerobic exposure, PI silage had higher ($P < 0.05$) mold count than KP silage. The counts of LAB, yeast, and mold were lower ($P < 0.05$) in silages treated with LB than in silages treated with LP. Therefore, the KP hybrid with LB application could improve the silage quality not only in the front end phase but also in the feedout phase to the farmers.

Key Words: corn silage, fermentation indices, inoculant

0677 Impact of temperature after defrosting on fermentation of high-moisture corn.

L. F. Ferraretto*[1], E. Lynch[2], J. P. Goeser[1,2], and R. D. Shaver[3], *[1]University of Wisconsin, Madison, [2]Rock River Laboratory, Inc., Watertown, WI, [3]University of Wisconsin-Madison, Madison*.

Late harvest of high-moisture corn (HMC) into late fall and winter months during 2014/2015 raised concerns among northern Wisconsin dairy farmers about fermentation of frozen HMC. Although silage maintains fermentation capacity on defrosting, low temperature may inhibit fermentation. Therefore, the objective of the present study was to evaluate the effect of temperature on fermentation profile of defrosted HMC stored frozen for a longer period. An unfermented HMC sample obtained from the University of Wisconsin – Madison Agricultural Research Station (Arlington, WI) on October 2013 was immediately frozen and stored at −20°C until March 2015. Sample was defrosted, homogenized, and divided into 33 subsamples of 250 g each. Three subsamples were randomly selected as fresh samples whereas the remaining 30 subsamples were vacuum-sealed in plastic bags and randomly assigned to 10 treatments (3 reps per treatment). Treatments were mini-silos fermenting in the dark either in a warm (at room temperature 20°C; WR) or cold (in the refrigerator set for 3°C; CD) temperature and allowed to ferment for 1, 3, 7, 14 or 28 d. All samples were analyzed for DM, fermentation profile, and ammonia N (% DM). Data were analyzed using Proc Mixed of SAS with the fixed effects of temperature, ensiling time, and their interaction. Content of DM was slightly greater for CD than for WR ($P = 0.01$; 71.5 vs. 71.1%, respectively). A temperature × ensiling time interaction was observed ($P < 0.001$) for pH, ammonia N, lactate, acetate, ethanol, and total acid concentrations. All parameters followed a similar pattern with gradual reduction in pH (6.27, 5.40, 4.97, 4.93, and 4.72, respectively) or increases in ammonia N (0.00, 0.01, 0.01, 0.02, and 0.02% of DM, respectively), lactate (0.12, 0.24, 0.39, 0.45, and 0.43% of DM, respectively), acetate (0.00, 0.11, 0.15, 0.17, and 0.19% of DM, respectively), ethanol (0.00, 0.09, 0.17, 0.20, and 0.20% of DM, respectively), and total acid (0.12, 0.35, 0.54, 0.68, and 0.72% of DM, respectively) concentrations as fermentation progressed from 1 to 28 d in WR. In contrast, except for a difference in pH for 28 d compared with 1 d (6.41 vs. 6.48, respectively) of fermentation, ensiling time did not affect other fermentation parameters in CD. These findings suggest that although HMC maintains fermentation capacity on defrosting

even after frozen for a prolonged period in storage, fermentation will not occur until warm temperature is reached. Future research is warranted to elucidate at which temperature fermentation progresses normally.

Key Words: high-moisture corn, fermentation

0678 The effect of two microbial inoculants on the aerobic stability of high-moisture corn. S. A. Polukis*, M. L. Smith, R. M. Savage, E. Benjamim da Silva, A. E. Laubach, A. M. Gray, and L. Kung Jr., *University of Delaware, Newark*.

The objective of this study was to evaluate the effect of two microbial inoculants on the fermentation characteristics and aerobic stability of high-moisture corn (HMC). High-moisture corn (71% DM) was 1) untreated (control) or 2) treated with *Lactobacillus hilgardii* (LH) (600,000 cfu/g of fresh material), 3) treated with *Lactobacillus buchneri* 40788 (600,000 cfu/g), or 4) treated with *L. hilgardii* + *L. buchneri* 40788 (LH+LB) (300,000 cfu/g). Inoculants were supplied by Lallemand Animal Nutrition, Milwaukee, WI. Five individually replicated lab silos (7.5 L) for each treatment were packed (packing density of 669 kg DM/m^3) and ensiled for 10, 30, and 92 d between 21 and 23°C. Data were analyzed using the Fit Model in JMP (SAS Inst. Inc., Cary, NC) as a 4 × 3 factorial arrangement of treatments with the main effects of treatment, day, and their interaction. The numbers of lactic acid bacteria were greater for LH (8.91 log cfu/g) than the control (8.41 log cfu/g) at 30 d, whereas all inoculated treatments had higher numbers (7.91 to 8.03 log cfu/g) than the control (7.18 log cfu/g) at 92 d ($P < 0.01$). At 10 d, all treated HMC had lower numbers of yeasts (3.53 to 4.18 log cfu/g) than the control (5.68 log cfu/g). The same occurred at 30 d (<2.00 to 2.26 vs. 5.18 log cfu/g) ($P < 0.01$). At 92 d, LH (4.30 log cfu/g) was numerically lower than the control (4.91 log cfu/g) and LH+LB and LB (both < 2.00 log cfu/g) had lower numbers of yeasts ($P < 0.01$). There were lower ($P < 0.01$) concentrations of lactic acid for treated HMC compared with the control at both 30 (0.74 to 0.80 vs. 1.04%) and 92 d (0.68 to 1.15 vs. 1.45%). All treated HMC had higher ($P < 0.01$) concentrations of acetic acid than the control at 30 (0.47 to 0.57 vs. 0.13%) and 92 d (0.98 to 1.16 vs. 0.23%). Concentrations of ethanol for treated HMC were lower ($P < 0.01$) than the control at 92 d (0.39 to 0.48 vs. 0.73%). All inoculated HMC were more ($P < 0.01$) aerobically stable than the control at 10 (42 to 56 vs. 22 h), 30 (>250 vs. 31 h), and 92 d (>250 vs. 49 h). The inoculants used in this study altered the fermentation characteristics and improved the aerobic stability of HMC.

Key Words: aerobic stability, *Lactobacillus buchneri*, *Lactobacillus hilgardii*

0679 Investigating the relationship between corn silage fiber digestibility and rainfall, growing degree days, and soil type. S. A. Flis*[1], T. P. Tylutki[2], and P. Sirois[1], [1]*Dairy One, Ithaca, NY,* [2]*AMTS LLC, Cortland, NY*.

The relationship of rainfall, growing degree days (GDD), and soil type on aNDFom and aNDFom digestibility (aNDFdom) measured at 30, 120, and 240 h was evaluated on corn silage harvested in New York in the fall of 2015. Five fresh corn silage samples were taken from four different fields at three different farms in New York during the 2015 harvest (n = 60). Samples were analyzed for DM, aNDFom, aNDFdom30, aNDFdom120, aNDFdom240, and K at a commercial laboratory. Farms are located in Saratoga County, NY; Cayuga County, NY; and Livingston County, NY. Farm records of daily rainfall, daily temperature, GDD50, planting dates, corn hybrid, harvest dates, soil type, and nutrient applications from manure and fertilizer were collected from each farm. Data was analyzed using JMP by correlation and regression. Total rainfall (planting to harvest) and cumulative GDD50 were correlated to decreased aNDFdom30 ($r = -0.44$, $P < 0.001$) and aNDFdom240 ($r = -0.27$, $P < 0.05$). As aNDFom increased, the aNDFdom120 ($r = -0.41$, $P < 0.01$) and aNDFdom240 ($r = -0.38$, $P < 0.01$) decreased. Both aNDFdom240 ($r = -0.62$, $P < 0.001$) and aNDFdom30 ($r = -0.66$, $P < 0.001$) decreased with increased rainfall in July. August rainfall had a negative effect on aNDFom120 ($r = -0.61$, $P < 0.001$). Temperature effect (cumulative GDD) on aNDFdom30 begins with the temperatures the plant is exposed to in May ($r = -0.68$, $P < 0.001$). This effect was greater in June ($r = -0.72$, $P < 0.001$). Stepwise regression analysis found that 53% of the variation in aNDFom30 was explained by May and June GDD and May rainfall. There was a strong relationship of soil type to aNDFdom30, aNDFom120, and aNDF0m240, where soils more prone to being wet had lower digestibility ($r = -0.56$ to -0.78, $P < 0.001$). This small sample size did not allow for investigation of the relationships of aNDFdom digestibility to hybrid. Rainfall, GDD, temperature, and soil type were all found to effect aNDFdom digestibility times. Higher cumulative rainfall or rainfall in specific months decreased aNDFdom digestibility. Additional data relating aNDFom digestibility to environmental and soil characteristics could result in improved water management systems and potentially altering timing for planting and harvest.

Key Words: fiber digestibility, corn silage, rainfall

0680 Forage yield and quality of four maize cultivars sown in single and double rows. M. A. Ramirez*, *Universidad Nacional Autonoma de Mexico, FMVZ, Mexico, City, Mexico*.

Corn silage is an important component in feedlot and dairy rations. The aim of the study was to determine forage yield

and quality of four maize cultivars sown in single and double rows. Cultivars were two hybrids, Gladiator and Fog, and two natives, Red and White; single rows were 80 cm apart and double rows were a pair of rows 40 cm apart with 80 cm separation between pairs of rows. Seeding rate was 80,000 plants ha^{-1}. Experimental design was a completely random with four replicates, the experimental unit was a 4.8- by 3-m plot, and treatments were in a 4 × 2 factorial arrangement. Harvest was at one-half milk line stage. Variables measured were forage yield on DM basis and CP, NDF, and ADF contents. The cultivar × sowing method interaction did not influence ($P > 0.05$) forage yield and quality measures. There was a trend ($P = 0.10$) for native cultivars to show higher forage yield than the hybrids (25.4 vs. 21.4 t/ha, respectively), whereas double-row sowing tended ($P = 0.19$) to yield 12% more forage than single-row sowing (24.7 vs. 22.2 t/ha, respectively). Cultivar determined ($P < 0.05$) CP content; native Red showed the highest content, 9.7%, whereas hybrid Fog showed the lowest, 8.8%. Cultivar and sowing method did not influence ($P > 0.05$) NDF content; the overall mean was 66.5%. There was a trend ($P = 0.09$) for the hybrids to show a lower ADF content than natives (36.1 vs. 38.7%, respectively). The conclusion was that maize cultivar and sowing method could be important factors in forage yield and quality.

Key Words: maize, forage yield, forage quality

0681 Evaluation of genetic diversity of *Lactobacillus plantarum* isolated from alfalfa silage using the BOX-polymerase chain reaction.

M. C. N. Agarussi, O. G. Pereira*, K. G. Ribeiro, E. S. Leandro, V. P. Silva, and R. A. Paula, *Federal University of Viçosa, Viçosa, Brazil*.

The objective of this study was to evaluate the genetic diversity of isolates of *Lactobacillus plantarum* obtained from wilted and nonwilted alfalfa silage. Alfalfa was harvested at 50 d of regrowth and wilted for 6 h. Alfalfa was chopped into particles of 1.5 cm, packed in plastic bags of 25 by 35 cm, and sealed under vacuum. Lactic acid bacteria (LAB) were isolated from samples of fresh alfalfa plants without wilting, fresh forage (Day 0) wilted for 6 h, and its both nonwilted and wilted silages in different fermentation periods (1, 3, 7, 14, 28, and 56 d). The DNA of the strains of LAB was extracted by using a commercial kit (Wizard Genomic DNA Purification kit; Promega). The sequences of the 16S rRNA gene were amplified by PCR using the primers P027F and 1492R. The sequences of the isolates were compared with those available in the GenBank database and aligned using the BLASTn algorithm (basic local alignment search tool) for nucleotides. Of the 138 isolates identified, 58 were *L. plantarum*; therefore, the BOX-PCR was used to evaluate the diversity of these isolates using the primer BOX-A1. The PCR products were separated on 1.6% agarose gel at 60 V for approximately 2 h. The fingerprint of BOX-PCR was documented using the image display system (Kasvi, K33-312). Ten well-defined banding patterns of polymorphism were obtained between the evaluated isolates, with the same distributed in 10 distinct clades. In each clade, *L. plantarum* was considered to be present when clones showed a percent similarity equal to or greater than 90%. Only three *L. plantarum* strains presented no clones with a percentage of less than 90% similarity. No pattern of days of fermentation was observed and no wilting effect on the grouping of the isolates in the clades was observed. Supported by Fapemig, CNPq, and INCT-CA.

0682 Volatile organic compounds in sugarcane silage treated with chemical and microbial additives.

L. L. Cardoso[1], K. G. Ribeiro*[2], O. G. Pereira[1], M. I. Marcondes[2], and K. Weiss[3], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Brazil, [3]Humboldt University of Berlin, Berlin, Germany*.

This study aimed to evaluate the production of volatile organic compounds in sugarcane silage treated with different additives. The treatments were sugarcane silage without additive (control) and sugarcane silage with *Lactobacillus buchneri* (LB), *Lactobacillus plantarum* and *Pediococcus pentosaceus* (LPPA), *L. plantarum* and *Propionibacterium acidipropionici* (LPPA), 5 g kg^{-1} CaO (SS5CaO), 10 g kg^{-1} CaO (SS10CaO), 5 g kg^{-1} urea (SS5urea), and 10 g kg^{-1}urea (SS10urea). The contents of ethyl acetate, ethyl lactate, ethanol, and other organic acids were determined at the University of Berlin, Germany. Fifty grams of silage were weighed into glass beakers and 200 mL of distilled water and 1 mL of toluene were added to each beaker and mixed with a glass stirrer in a chemical fume hood. The beakers were immediately sealed with Parafilm and stored in a refrigerator (4°C) overnight. The next day, the solution was carefully mixed by swirling each beaker and the silage extract was obtained by filtration through a Whatman No. 54 filter paper. The extract was further filtered through a microfilter and analyzed for fermentation end products using HPLC and special GC techniques. A lower acetone concentration was verified ($P = 0.001$) for the treatment SS10urea, which did not differ for treatments LB, SS5CaO, SS10CaO, and SS5urea. In relation to methanol ($P = 0.001$), a lower concentration was also verified for the treatment SS10urea but did not differ for treatments SS, LPPP, LPPA, and SS5CaO. The propanol ($P = 0.001$) presented lower concentrations for the treatments SS5urea and SS10urea but did not differ for the treatments LPPP and LPPA. Butanol was only detected in the treatment SS10CaO ($P = 0.001$), whereas only for the treatments SS5CaO, SS10CaO, and LB was the presence of 1,2-propanediol ($P = 0.001$) observed, with the lowest concentration associated with LB. A lower concentration of ethanol was observed for

the treatment SS5CaO and SS10CaO and a greater concentration was observed for LB, but the values did not differ among LPPA, LPPP, and SS treatments. The silages treated with CaO presented lower ethyl esters and ethanol and there was a correlation between ethyl acetate + ethyl lactate and ethanol contents. The ensilage conditions strongly affect the concentrations of acids that are produced during the fermentation process, although in the present experiment, low concentrations of these acids were obtained, thereby indicating that the ensilage was satisfactorily performed. However, more research is needed to understand the role of these compounds in silages.

Key Words: ethanol, ethyl acetate, ethyl lactate

0683 Meta-analysis of the effect of homolactic and facultative heterolactic bacteria inoculation on silage quality: I – Fermentation profile.

A. S. Oliveira[1], Z. G. Weinberg[2], A. A. P. Cervantes[3], K. G. Arriola[3], I. M. Ogunade[3], Y. Jiang[3], D. Kim[3,4], M. C. M. Gonçalves[5], D. Vyas[3], and A. T. Adesogan*[3], *[1]Universidade Federal de Mato Grosso– Sinop, Sinop, Brazil, [2]Department of Food Quality and Safety, Agricultural Research Organization, The Volcani Center, Rishon Le Zion, Israel, [3]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [4]Department of Animal Sciences, University of Florida, Gainesville, [5]Instituto Federal Goiano, Rio Verde, Brazil*.

Homolactic and facultative heterolactic acid bacteria (HAB) inoculants enhance silage fermentation by rapid production of lactic acid, which decreases the pH and reduces DM and nutrient losses. Data from 120 peer-reviewed papers were summarized to evaluate the effects of inoculation with HAB on silage fermentation profile. The effects were analyzed by comparing raw mean differences between inoculant and control treatment means that had been weighted by inverse variance using random models. Heterogeneity sources evaluated by meta-regression included crop species, application rate ($<10^4$, 10^5 to 10^6 or $>10^7$ cfu/g, representing 3.7, 93.6 and 2.7% of studies, respectively), HAB species, and silo type (laboratory or farm-scale) as covariates. Inoculation did not affect the pH of corn/sorghum silages ($P = 0.34$, $n = 59$) but reduced the pH ($P < 0.05$) of temperate grasses (−0.17; $n = 60$), tropical grasses (−0.17; $n = 17$), sugarcane (−0.03; $n = 28$), alfalfa (−0.30; $n = 8$), other legumes (−0.25; $n = 29$), and other crops (−0.26; $n = 17$). Inoculation increased lactate (0.97% DM; $P < 0.01$, $n = 249$) and reduced butyrate (−0.05% DM; $P < 0.01$, $n = 56$) but did not affect propionate ($P = 0.61$, $n = 109$). Inoculation did not affect acetate in alfalfa silages ($P = 0.15$, $n = 9$) but reduced acetate in corn/sorghum (−0.10% DM; $P < 0.01$, $n = 57$), temperate grasses (−0.30% DM; $P < 0.01$, $n = 71$), tropical grasses (−0.16% DM; $P = 0.03$, $n = 19$), sugarcane (−0.34% DM; $P < 0.01$, $n = 26$), other legumes (−0.47% DM; $P < 0.01$, $n = 24$), and other crops (−0.11% DM; $P < 0.01$, $n = 12$). Inoculation did not affect NH_3–N (% total nitrogen) concentration in corn/sorghum ($P = 0.63$, $n = 22$) or sugarcane ($P = 0.33$, $n = 5$) but reduced it ($P < 0.01$) in temperate grasses (−2.17% N; $n = 49$), tropical grasses (−1.78% N; $n = 9$), alfalfa (−1.47% N; $n = 6$), other legumes (−1.77% N; $n = 18$), and other crops (−1.36% N; $n = 9$). Inoculation with HAB did not improve the fermentation of corn/sorghum silages or sugarcane silage but markedly improved those of grasses, legumes, and other crop silages independent of the HAB species.

Key Words: ammonia, forage conservation, organic acids

0684 The effects of air and heat stress on the aerobic stability of silage treated with a chemical additive.

R. M. Savage*, E. Benjamim da Silva, M. L. Smith, S. A. Polukis, K. M. Pacer, A. E. Laubach, A. M. Gray, and L. Kung Jr., *University of Delaware, Newark*.

The chemical additive Safesil (active ingredients: sodium benzoate, potassium sorbate, and sodium nitrite; Salinity, Sweden) was evaluated for its effects on the fermentation and aerobic stability of corn silage. Whole plant corn samples were harvested at 40% DM, chopped, processed, and treated with 1) no additive (control), 2) Safesil (2 L/t), or 3) Safesil (3 L/t). Silos (7.5 L; forage density of 224 kg of DM/m^3) from each treatment were stored at either 22 ± 2 or 30 ± 2°C and subjected to no air stress or a 2-h weekly air stress. After 100 d of ensiling, 5 replicate silos were opened for each treatment. Data were analyzed by ANOVA as a 3 × 2 × 2 factorial arrangement of treatments with main factors of additive, storage temperature, air stress, and their interactions. Silages were analyzed for numbers of yeasts, fermentation end products, and aerobic stability. Both application rates of Safesil resulted in silages with lower numbers of yeasts ($P < 0.01$) compared with control silage (3.96 vs. <2.00 log cfu/g). Silos that were stressed with air also had higher ($P < 0.01$) yeast counts compared with silos without air stress (3.21 vs. <2.00 log cfu/g). Treatment with Safesil at both 2 and 3 L/t lowered ($P = 0.01$) the concentration of ethanol in both unstressed and air stressed silos (0.52 to 0.70%) compared with control silages (1.27 to 1.47%). When silos were stored at 22°C, treatment with Safesil at 2 and 3 L/t increased ($P < 0.01$) aerobic stability in unstressed silos (185 and 236 h, respectively) compared with unstressed control silos (72 h). When silos were stored at 30°C, only treatment with Safesil at 3 L/t improved ($P < 0.01$) aerobic stability in silos that were both not stressed (168 h) and stressed (225 h) compared with control silos that were not stressed (79 h) and stressed (44 h). Air-stressed silos treated with Safesil 3 at L/t and stored at 30°C (225 h) had greater ($P < 0.01$) aerobic stability compared with stressed silos treated with Safesil at 3 L/t and stored at 22°C (95 h). The use of Safesil has the potential to improve aerobic stability of corn silage

in warm climates even with decreased silo integrity.

Key Words: corn silage, aerobic stability, sodium benzoate

0685 Effects of chemical additives on fermentation characteristics of high-moisture alfalfa silage.

E. Benjamim da Silva*, R. M. Savage, M. L. Smith, S. A. Polukis, A. E. Laubach, K. M. Pacer, and L. Kung Jr., *University of Delaware, Newark*.

Alfalfa is sometimes harvested with a high moisture content that increases the chances for undesirable fermentations. The objective of these experiments were to determine the effectiveness of Safesil (SF; active ingredients: 10% potassium sorbate, 20% sodium benzoate, and 5% sodium nitrite) and Safesil Challenge (SC; active ingredients: 7.5% potassium sorbate, 15% sodium benzoate, and 10% sodium nitrite) from Salinity, Sweden, on improving the fermentation of high-moisture alfalfa silage. Alfalfa was directly chopped at 23% DM and used in two experiments. In Experiment 1, we evaluated the effect of SF on the characteristics of early fermentation. Four individual 1-kg replicates of untreated alfalfa or alfalfa treated with 4 L/t of SF were ensiled in vacuumed and heat-sealed, nylon–polyethylene bags for 1, 2, 4, and 7 d. Data were analyzed as a 2 × 4 factorial arrangement of treatments, with main factors of treatment, days of ensiling, and their interaction. In Experiment 2, the long term effects of SF or SC with and without air stress during storage were determined. Replicated silos (7.5 L) were packed (density of 224 kg of DM/m^3) with the same forage described above and were untreated or treated with SF (3 and 4 L/t) or SC (2 and 3 L/t). Half of the silos were submitted to a 2-h weekly air stress. Data were analyzed by ANOVA as a 2 × 5 factorial arrangement of treatments with main factors of air stress, treatment, and their interaction. In Experiment 1, pH decreased and acids and ethanol similarly increased for untreated and treated silages as ensiling progressed. Compared with untreated silage, treated silages had fewer yeasts ($P < 0.01$) at 4 d of ensiling (4.52 vs. 2.96 log cfu/g) and less enterobacteria after 1 d (6.79 vs. 5.81 log cfu/g). Ethanol concentration was numerically lower for treated silages at all time points. In Experiment 2, for silos submitted to air stress, the DM recovery after 100 d was higher ($P = 0.04$) for SF- and SC-treated silage than for untreated silage. After 100 d, numbers of yeasts and molds were less than 2.00 log cfu/g for all treatments. These experiments showed that Safesil can quickly reduce harmful microorganisms, such as yeasts and enterobacteria, in high-moisture alfalfa and that Safesil and Safesil Challenge can improve DM recovery in silage submitted to air stress.

Key Words: alfalfa, silage, Safesil

FORAGES AND PASTURES SYMPOSIUM: GREENHOUSE GAS EMISSIONS IN PASTURE-BASED DAIRY AND BEEF CATTLE SYSTEMS

0686 Comprehensive national assessment on the sustainability of beef production.

C. A. Rotz*[1] and K. R. Stackhouse[2], [1]*USDA-ARS Pasture Systems and Watershed Management Research Unit, University Park, PA,* [2]*National Cattlemen's Beef Association, Centennial, CO*.

To develop better scientific understanding of the sustainability of beef in the United States, a national assessment is being conducted by the National Cattlemen's Beef Association, a contractor to the beef checkoff. This includes a life cycle assessment (LCA) of greenhouse gas emissions along with other environmental, social, and economic impacts. Assessments are being made for representative cattle operations in each of seven geographic regions to form the national total. Producer surveys and visits are used to characterize region-specific production systems, and the information gathered provides a basis for system simulation and a farm-gate LCA. Assessments have been completed for the central plains and midwestern regions and are in progress for the western and eastern regions of the country. Results thus far show farm-gate carbon footprints of representative production systems vary from 16 to 28 kg CO_2e/kg of carcass weight (CW) with a mean around 20 kg CO_2e/kg CW. The cow–calf operation is the source of 67 to 77% of this footprint and stocker operations contribute up to 18% of the footprint. Therefore, depending on whether cattle are backgrounded on pasture or in a feedlot, the grassland-based portion of the system can contribute 67 to 85% of the farm-gate carbon footprint of finished beef cattle. Enteric methane emission is the source of about 60% of the total greenhouse gas emissions from cow–calf and stocker operations and 35% of that from feedlot finishing operations. Nitrous oxide emissions contribute about 20% of the carbon footprint of grazing cattle. Considering post-farm gate sources (harvest, retail, restaurant, and consumer), the full carbon footprint is about 45 kg CO_2e/kg of consumed beef. Of this total, 58 to 73% can be attributed to emissions from grazing cattle and the inputs required to maintain them. A similar result is found for environmental impacts such as total reactive nitrogen loss, where 50 to 70% of the farm-gate footprint is attributed to grazing cattle. Therefore, to make substantial reductions in the environmental impacts of beef production, our analysis to this point indicates that mitigation strategies are needed to reduce greenhouse gas and nitrogen emissions from grassland systems. This provides a major challenge for beef cattle research because practical technologies or strategies for reducing these emissions are

essentially unknown.

Key Words: beef, cattle, carbon footprint

0687 Screening for forages and foraging managements that reduce nitrogen excretion and methane emissions while maintaining or increasing animal production. P. Gregorini*, P. C. Beukes, and A. J. Romera, *DairyNZ Ltd., Hamilton, New Zealand*.

Farmers face complex decisions at the time to feed animals, trying to achieve their production goals while contemplating social and environmental constraints. Our purpose was facilitating such decision-making for pastoral dairy farmers, aiming to reduce urinary N (UN) and methane (CH_4) emissions while maintaining or increasing milk production (MP). There are a considerable number of forages the farmers can choose from and combine. First, we used three grasses, three legumes, and two herbs combined in 72 mixed swards. Then, 50 feeds (forages and grains) were systematically combined in different proportions producing 11,526 binary diets. Swards and binary diets were screened, using an a posteriori approach and a Pareto front (PF) analysis of model (Molly-DairyNZ) outputs. The objective was identifying combinations with the best possible compromise (i.e., frontier) between UN, CH_4, and MP. All PF solutions are considered optimal and equally good. Using MP and low UN as objective functions, PF included seven optimal swards, with fescue, alfalfa, and plantain as key species. Adding CH_4 emissions as objective function increased the number to 23. For binary diets, the MP–UN frontier included 10, 14, 12, and 50 for nonlactating and early, mid, and late lactation periods, respectively, with cereals and beets featuring strongly. Using the same objective functions but including ryegrass as dietary base, PF included 2, 4, 8, and 4 diets for those periods. These results suggest that from a wide range of diverse diets, farmers could choose from a handful of mixed swards and binary diets to reduce UN while maintaining or increasing production. If the criterion is maintaining pasture-based systems, there are fewer suitable options. Reducing UN will simply require dilution of N supplied by pasture by either supplementing low-N forages or strategic foraging managements. The results also indicate that reducing UN may imply increments in CH_4 emission and vice versa, that is, pollution swapping. Although there is no perfect sward or diet that optimizes all the objectives at once, there are feeding options to offset pollution swapping, if the current diet is not in the frontier. Ultimately, it is up to the farmers to choose the best options, according to their farming context.

Key Words: forages, ruminant nutrition, environmental footprint

0688 Outcomes and future directions from the National Livestock Methane Program in Australia. T. M. Davison*, *Meat and Livestock Australia, Brisbane, Australia*.

The National Livestock Methane Program (NLMP) was a collaborative and coordinated research effort run by Meat and Livestock Australia. The investment in methane research was initiated by a federal government program, filling the Research Gap. This overall initiative also included other national programs of work in soil carbon, nitrous oxide, and manure management. The program aims were to provide Australian livestock producers with practical strategies and tools to help them increase productivity and profitability and at the same time lower methane emissions. The NLMP was a $33.5 million investment over 3 yr and consisted of 17 projects in 5 themes of work: 1) forages, 2) supplements, 3) beef genetics, 4) rumen microbiology, and 5) measurement. Three overarching themes linked the program of work within NLMP. First, to develop a greater understanding of the underlying mechanisms in the production and control of methanogenesis; second, to identify methods or farming practices that might apply to the federal government Carbon Farming Initiative (a scheme that offers income opportunities for carbon abatement), and third, communication products for use by partners. A variety of outcomes included knowledge of the relationship between productivity and methane emissions, identification of methane abatement from various forages, the role of supplements such as red algae and grape marc, the role of wheat in dairy diets, identification of potential plant bioactives, new bacterial species, and knowledge of rumen methane pathways. A national needs and gaps analysis that included a marginal abatement cost curve analysis was conducted to determined future priorities for research based on a range of investment criteria.

Key Words: methane research, forages, supplements, carbon schemes

0689 Greenhouse gas emissions and mitigation in the West African subregion: Challenges and opportunities. C. Antwi*, *Kwame Nkrumah University of Science & Technology, Kumasi, Ghana*.

Animal agriculture contributes to about 18% of the global greenhouse gasses (GHG), of which 3% is generated by all ruminants in sub-Saharan Africa. The methane emissions from these ruminants represent about 12% of the GE intake, which could otherwise be used as energy for maintenance. In an attempt, therefore, to reduce emissions, researchers in the West African subregion have initiated profiling GHG emissions of feed resources and selection feed with less methane emission potential. Some common feedstuffs in the subregion were assayed for their methane production using either the in vitro systems or hand-held methane analyzer. In vitro assessment of shea nut (*Butyrospermum parkii*) for methane

production indicated that including 10% of shea nut cake in finishing feedlot *Bos taurus* diets reduced 24-h in vitro methane production by approximately 20% without any significant reduction in total and individual VFA production. Methane output was also reduced during in vitro ruminal fermentation of *Brachiaria ruziziensis* when the in vitro mixture was supplemented with 20% of leaves of the browse plant *Securinega virosa*. Different fractions of Napier grass were evaluated in Ghana for methane production using a hand-held methane analyzer. The stem fraction was 2.5 times higher than that of the leaves, and as the grass advanced in age, the methane production increased. Emissions directly associated with animal production have globally increased partly because of the high demand for animal products. It is envisaged that emission intensity from animal agriculture in the West African subregion will increase due to the nature of feed they feed on. In an attempt to reduce emissions from animals, scientists adopt in vitro method of screening and selection of feed for ruminants. This, however, fails to estimate emission per feed intake, making it impossible to advance the best practices that result in GHG mitigation without any adverse effect on animal productivity. Although the global research alliance suggests to its member countries, of which Ghana is one, to focus on activities that reduce emissions intensity of livestock while increasing productivity, little is seen in terms of investment in developing research activities that reduces emissions. Several agro-byproducts including palm kennel cake and other cakes of leguminous crop exist in the subregion. Owing to their high lipids content, when supplemented to the high fibrous diet consumed by ruminants, it is certain that not only will methane emissions be reduced but that productivity will also increase.

Key Words: methane, mitigation, Africa

0690 Effects of native and tame grassland species reintroduction on carbon sequestration potential on the Canadian Prairies. A. D. Iwaasa*, B. McConkey, and H. Wang, *Agriculture and Agri-Food Canada, Swift Current, SK, Canada*.

Rising concentration of carbon dioxide in the atmosphere has prompted interest in implementing improved grassland management practices that could lead to a net accumulation of carbon in grassland soils. Converting cropland into native or tame perennial grasslands may result in substantial increase in soil C sequestration. Two studies were started in southern Saskatchewan where semiarid cropland was converted to perennial grasslands: Study 1 (2000–2014) seeded two different native pasture mixes (Simple, 7 species, and Diverse, 12 species) and Study 2 (2006–2011) seeded four different pasture types (meadow bromegrass + alfalfa [A], native grass mix [NG], NG + A, and NG + native legume). The objective of the studies was to determine the change in soil organic carbon (SOC) levels as affected by type of forage pasture mix and form of disturbance (grazing and nongrazing). In Study 1, the disturbance treatments were continuous, rotational, and nongrazing and the stocking rates were 0.8 and 1.9 animal unit (AU) ha^{-1}, respectively. In Study 2, continuous grazing occurred and the stocking rate ranged from 2.0 to 4.0 AU ha^{-1} depending on which pasture treatment was used. All pastures were grazed to a utilization rate of 50 to 60%. Soil samples from each pasture were collected from three locations and at each location, a five radial (star pattern) sampling pattern occurred. From each of the five microsites, core samples were taken at five depths (0–7.5, 7.5–15, 15–30, 30–45, and 45–60 cm). Soil sampling for study 1 occurred in 2000, 2004, 2008, 2011, and 2014, whereas in study 2, it occurred in 2008 and 2011. In study 1, no SOC level (0–15 cm) differences were observed between disturbance and pasture mix combinations and interaction after 14 production years. Soil organic C levels were affected by year ($P < 0.0001$), which was expected with the different environmental conditions experienced among the different soil sampling years. In study 2, no SOC level (0–15 cm) differences were observed for interaction or main effects after three production years. Our studies did not support our hypothesis that a more diverse native mix (higher species richness) and tame grass + alfalfa would have higher SOC level than other treatments. Detecting small SOC change is difficult due to spatial heterogeneity in initial SOC, soil texture, bulk density, and plant productivity. Using our results, we develop criteria for measurement systems to detect changes design to detect SOC change.

Key Words: grazing, soil organic carbon, native and tame forages

GENOMICS SYMPOSIUM: TRANSLATIONAL GENOMICS TO IMPROVE FERTILITY OF ANIMALS

0691 Translational genomics for improving sow reproductive longevity. D. C. Ciobanu*[1], S. D. Kachman[1], S. Olson[1], M. L. Spangler[1], M. D. Trenhaile[1], H. Wijesena[1], P. S. Miller[1], J. J. Riethoven[1], C. A. Lents[2], J. F. Thorson[2], R. Massey[3], and T. J. Safranski[3], *[1]University of Nebraska – Lincoln, Lincoln, [2]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [3]University of Missouri, Columbia*.

Approximately 50% of sows are culled annually with more than one-third due to poor fertility. Age at puberty, the earliest prebreeding indicator of reproductive longevity, can be measured early in life and has a moderate heritability. Selection for age at puberty is challenging due to labor-intensive phenotyping. Genomic selection for this trait would be a more viable option because it could increase accuracy and selection response. This study aims to identify DNA markers that

will predict, at weaning, gilts with early age at puberty and superior reproductive longevity. Our hypothesis is that genetic sources that affect age at puberty also explain variation in sow reproductive longevity. To test the hypothesis, data and tissues from a UNL resource population (n > 1,700 gilts) were integrated with genomewide association analyses, genome/RNA sequencing, and polymorphism discovery to uncover DNA variants that could predict age at puberty and reproductive longevity. A BeadArray panel of 56,424 SNP explained 25.2% of the phenotypic variation in age at puberty in a training set (n = 820). In an evaluation data set consisting of subsequent batches of similar genetics (n = 412), we compared a model based on all SNP from major 1-Mb windows with one based on SNP with the largest estimated effect. The model based on all SNP from the major windows explained more of the phenotypic variance compared with the model based on large effect SNP (12.3 to 36.8% vs. 6.5 to 23.7%). One major pleiotropic region included AVPR1A, for which the favorable genotype was associated with higher probability of the gilts to produce the first parity compared with the other genotypes (P < 0.05). Genome sequencing of 20 sires using Proton technology provided sources of genetic variation outside the limited capability of the BeadArray. Sequencing reads averaged 165 bp with a depth that varied from 16.2x to 29.7x. A substantial proportion (38%) of the total SNP discovered (140,000) were located in known genes. Transcriptome profile was evaluated by RNA sequencing of the microdissected arcuate nucleus (ARC) in pre-/postpubertal gilts (n = 12) subjected to different dietary treatments. Using a combination of Tophat and local Bowtie, the majority of the reads were aligned to the reference genome/transcriptome (>93%). This integrated knowledge accompanied by economic modeling will be evaluated in commercial populations to understand and improve expression of puberty and sow reproductive potential through genomic selection. This project is supported by Agriculture and Food Research Initiative Competitive Grant number 2013-68004-20370 from the USDA–National Institute of Food and Agriculture. The USDA is an equal opportunity provider and employer.

Key Words: age at puberty, genomic selection, reproductive longevity.

0692 Detection and selection against early embryonic lethals in United States beef breeds. J. F. Taylor*[1], R. D. Schnabel[1], B. Simpson[2], J. E. Decker[1], M. Rolf[3], B. P. Kinghorn[4], A. Van Eenennaam[5], M. D. MacNeil[6], D. S. Brown[1], M. F. Smith[1], and D. J. Patterson[1], *[1]University of Missouri, Columbia, [2]GeneSeek, a Neogen Company, Lincoln, NE, [3]Oklahoma State University, Stillwater, [4]University of New England, Armidale, Australia, [5]University of California, Davis, [6]Delta G, Miles City, MT.*

More than 3,000 bovine genomes have now been sequenced worldwide, and much of the variation within the genome of cattle has been discovered. Many variants likely to have functional effects due to their locations within annotated coding regions have been identified. However, the lack of complete annotation leads to our inability to identify variants that lie within regulatory regions, and furthermore, the phenotypic effects caused by coding variants are not well understood. Among these are the class of loss of function variants within genes that are essential for life—a gene set that is largely conserved in identity among mammals. Based on marker haplotype analyses performed primarily in dairy breeds, we postulate that several lethal variants segregate within most cattle breeds and that these variants tend to be breed specific in their identity. To identify these variants, we have designed the first generation of a bovine functional assay, the GGP-F250, to contain 34,000 common variants present on many of the genotyping assays currently used by the cattle industry and 199,000 predicted genic functional variants. The assay is publicly available from GeneSeek. These variants were discovered by analyzing whole genome sequence data for 297 cattle from 17 breeds and RNA-seq data for 159 animals and were confirmed using data from the 1000 Bull Genomes Project and dbSNP. We have genotyped 18,300 animals with this assay representing Holstein and 9 U.S. beef breeds including over 11,000 Angus animals, and these data are being used to fine map QTL underlying susceptibility to respiratory disease and feed efficiency. Data from Angus are being used to sequentially test each putative functional variant for a deficiency of homozygotes and fully penetrant lethals will manifest with a complete lack of homozygotes. Candidate lethal alleles will be migrated to assays commonly used in the beef industry such as the GGP-LD and GGP-HD platforms to genotype hundreds of thousands of animals and validate the lack of homozygotes. Mate selection software is being developed as part of the USDA National Institute of Food and Agriculture grant number 2013-68004-20364 “Identification and management of alleles impairing heifer fertility while optimizing genetic gain in Angus cattle” project to assist breeders with mating decisions based on each animal’s carrier status for defects and embryonic lethals.

Key Words: GGP-F250, fertility, embryonic lethal

-693 Genomic selection for improved fertility of dairy cows with emphasis on cyclicity and pregnancy.

G. J. M. Rosa*[1], P. J. Pinedo[2], J. E. P. Santos[3], R. C. Bicalho[4], G. Schuenemann[5], R. Chebel[6], K. N. Galvão[3], R. O. Gilbert[7], S. L. Rodrigez-Zas[8], C. M. Seabury[9], J. Fetrow[6], and W. W. Thatcher[10], *[1]University of Wisconsin, Madison, WI, [2]Colorado State University, Fort Collins, CO, [3]University of Florida, Gainesville, FL, [4]Cornell University, Ithaca, NY, [5]The Ohio State University, Columbus, OH, [6]University of Minnesota, Saint Paul, MN, [7]Cornell University College of Veterinary Medicine, Department of Clinical Sciences, Ithaca, NY, [8]University of Illinois, Urbana-Champaign, IL, [9]College of Veterinary Medicine, Texas A&M University, College Station, TX, [10]Department of Animal Sciences, University of Florida, Gainesville, FL*

The overall goal of this ongoing integrated project (research, extension, and education) is to make use of advanced genomic technologies to improve dairy cattle fertility, with emphasis on cyclicity and pregnancy. The specific aims are 1) development of a fertility database with genotypes and phenotypes based on objective and direct measures of fertility in Holstein dairy cows, 2) identification of genome regions associated with fertility traits and use of this information on prediction models that can be applied in selection of dairy cattle for improved fertility, 3) development and implementation of a comprehensive extension program on best management and genomic selection practices to improve fertility of dairy herds, and 4) development of an education component targeting the general public as well as students in animal and veterinary sciences. In this presentation we will describe the development and outcomes on Specific Aim 1 as well as some preliminary analyses and results related to Specific Aim 2. A total of 12,000 Holsteins cows from 7 states (New York, Minnesota, Wisconsin, Texas, California, Florida, and Ohio), comprising 2 to 3 farms per state, were enrolled at calving and monitored weekly until pregnancy. Main events were uterine health, metabolic disorders, cyclicity, estrus, pregnancy per AI, and pregnancy loss, together with milk yield until 305 DIM. A reproductive index, calculating the predicted probability of pregnancy at first AI after calving, was generated using a logistic regression model that included cow-level variables such as diseases incidence, anovulation, BCS, and milk yield. Within each farm, cows were stratified as pregnant on d 60 after the first AI (high-fertility population) and as nonpregnant on d 60 after 2 AI (low-fertility population). A selective genotyping approach was implemented using the reproductive index developed, with selected cows from the high-fertility pregnant (850 cows) and the low-fertility nonpregnant (1,750 cows) groups. Preliminary analyses of the phenotypic data have been implemented, including the estimation of genetic parameters of cyclicity and other fertility indicators as well as the impact of postpartum diseases on lactation curves. Heritability estimates ranged from 0.03 to 0.12 for the various traits, and many factors influencing the lactation curve have been detected. The next step of the project will include multitrait and network analyses of the fertility indicators as well as genomewide association and gene-set enrichment analyses for detection of genomic regions and sets of genes affecting fertility traits in dairy cattle.

Key Words: genomics, fertility, dairy

0694 Improving fertility of dairy cattle using translational genomics.

T. E. Spencer*[1], H. L. Neibergs[2], P. J. Hansen[3], J. B. Cole[4], J. Dalton[5], D. A. Moore[6], M. Chahine[7], and A. De Vries[3], *[1]Division of Animal Sciences, University of Missouri, Columbia, [2]Department of Animal Sciences, Washington State University, Pullman, [3]Department of Animal Sciences, University of Florida, Gainesville, [4]Animal Genomics and Improvement Laboratory, ARS, USDA, Beltsville, MD, [5]University of Idaho, Caldwell, ID, [6]Department of Veterinary Clinical Sciences, Washington State University, Pullman, [7]Department of Animal and Veterinary Sciences, University of Idaho, Twin Falls*.

Selection for higher milk production in United States dairy cattle has been very successful during the past 50 yr; however, today's lactating dairy cows exhibit a high incidence of subfertility and infertility with a national pregnancy rate of only 15%. An integrated approach is being used to improve reproductive performance and profitability of dairy cattle using recent advances in animal genomics and improved understanding of fertility. The overarching hypothesis is that lactating cow fertility can be increased through genetic selection for maternal fertility in heifers and cows and use of sires with high daughter pregnancy rate (DPR), resulting in a significant, sustainable, and profitable increase in overall herd fertility. Objectives are to 1) identify genomic loci associated with fertility in dairy heifers and cows, 2) identify functional SNP associated with DPR and early embryo development, (3) evaluate the efficiency and profitability of increasing fertility in dairy cattle using genetic selection tools, and 4) engage in technology transfer regarding novel approaches for improving fertility using genetic selection tools to dairy farmers, dairy farm personnel, and their advisors in English and Spanish using DAIReXNET and extension road shows. Each objective involves an integrated team of scientists working in animal reproduction, genomics, breeding, and extension toward a common goal. The expected outcome and impact of meeting our goal is increased sustainability, profitability and international competitiveness of the U.S. dairy industry. This project was supported by Agriculture and Food Research Initiative Competitive Grant number 2013-68004-20365 from the USDA

National Institute of Food and Agriculture.

ADSA–ASAS NORTHEAST SECTION GRADUATE STUDENT ORAL COMPETITION

0695 Survival and growth of *Listeria monocytogenes* on queso fresco cheese stored under modified atmospheres. S. R. Barnes* and D. J. D'Amico, *University of Connecticut, Storrs*.

Cheese varieties characterized by high moisture and low acidity, such as queso fresco (QF), have been shown to support the growth of *Listeria monocytogenes* to very high levels during refrigerated storage. In addition to improving quality and extending shelf life, modified atmosphere packaging (MAP) has been used to control the growth of pathogenic microorganisms in various foods. The objective of this research was to determine the effect of five MAP conditions on the survival and growth of *L. monocytogenes* as postprocessing contaminants on QF during refrigerated storage at 7°C. To test the hypothesis that MAP affects *L. monocytogenes* growth on QF during storage when compared with conventional methods of packaging (i.e., vacuum), 25-g samples of QF were surface inoculated with an eight-strain cocktail of *L. monocytogenes* to achieve 4 log cfu/g. Following microbial attachment, individual cheeses were placed in 75-µm high barrier pouches (nylon/ethylene vinyl alcohol/polyethylene), packaged under one of seven conditions (air, vacuum, 100% carbon dioxide [CO_2], 70% CO_2/30% nitrogen [N_2], 50% CO_2/50% N_2, 30% CO_2/70% N_2, or 100% N_2), and stored at 7°C. Samples were removed weekly through 28 d of storage for enumeration of *L. monocytogenes*. Data were analyzed using one-way ANOVA. Analyses identified overall effects of time and packaging treatment on the change in *L. monocytogenes* counts over 28 d ($P < 0.001$). *Listeria monocytogenes* populations increased rapidly on cheese packaged under air, vacuum, and 100% N_2, with counts significantly differing ($P < 0.001$) from the initial inoculum by Day 7. Changes in counts over time and counts on individual days did not differ between these treatments, with means exceeding 7 log cfu/g on Day 14 and stabilizing at >8 log cfu/g through Day 28. Treatments that incorporated CO_2 at any percentage significantly limited pathogen growth over time compared with treatments without CO_2, including air and vacuum controls ($P < 0.001$). Although pathogen growth was limited, the change in counts over 28 d in CO_2 treatments was significant ($P < 0.05$), reaching a mean of 5.0 log cfu/g. Pathogen growth during storage did not significantly differ between treatments with varying percentages of CO_2. These data demonstrate that vacuum packaging and conditions containing 100% N_2 do not impede the growth of *L. monocytogenes* on QF. However, packaging under anaerobic modified atmospheres containing CO_2 may be a promising control for limiting *L. monocytogenes* growth on QF and other high-moisture, low-acid cheeses during cold storage.

Key Words: packaging, *Listeria monocytogenes*, cheese

0696 The effects of poor maternal nutrition on dam and offspring inflammatory status throughout gestation. A. K. Jones*, S. M. Pillai, M. L. Hoffman, K. K. McFadden, K. E. Govoni, S. A. Zinn, and S. A. Reed, *Department of Animal Science, University of Connecticut, Storrs*.

We hypothesized that poor maternal nutrition during gestation exaggerates the inflammatory status of ewes throughout gestation and that this would be reflected in the immune profile of offspring during late gestation and at parturition. Pregnant western white-faced ewes ($n = 78$) were individually housed and fed 100 (CON), 60 (RES), or 140% (OVER) of NRC requirements for TDN beginning at d 30.2 ± 0.2 of gestation. Whole blood was collected from a subset of ewes at d 24.0 ± 0.9 and 135.0 ± 0.3 of gestation ($n = 4$ ewes per diet per day) and from 3 to 4 offspring per diet euthanized at d 135 of gestation or within 24 h of parturition. Whole blood RNA was isolated, and expression of 84 genes mediating inflammation was profiled using a real-time PCR array. Data were analyzed using PROC MIXED in SAS for main effects and interaction of diet and day of gestation for ewes and main effect of maternal diet for offspring with the PDIFF option for mean comparisons. In ewes, regardless of diet, relative to d 24, *interleukin* (*IL*) *17β*; receptors for *IL1*, *IL6*, *IL8*, *IL10α*, and *IL10β*; *colony stimulating factor* (*CSF*) *2*; *CSF3*; *tumor necrosis factor superfamily member* (*TNFSF*) *13*; *TNFSF13β*; *chemokine ligand 17*; *chemokine receptor 1*; *vascular endothelial growth factor A*; and *platelet factor 4* increased 3.8-, 1.7-, 2.1-, 2.4-, 1.5-, 1.3-, 1.9-, 2.0-, 1.6-, 1.9-, 3.7-, 1.7-, 1.7-, and 2.5-fold at d 135 of gestation, respectively ($P \leq 0.05$). In contrast, *chemokine ligand 10* decreased 4.1-fold at d 135 relative to d 24 in ewes, regardless of diet ($P = 0.02$). In OVER ewes, *TNFSF4* decreased 1.5-fold compared with CON ewes ($P \leq 0.05$). *Interleukin 1 receptor antagonist* (*IL1RN*) increased 1.8-fold in RES ewes at d 135 compared with CON ewes at d 24 ($P \leq 0.04$). In offspring, *chemokine ligand 22* increased 2.8-fold in OVER ewes compared with CON ewes at d 135 ($P \leq 0.05$). At parturition, *interferon γ* decreased 3.0- and 3.8-fold in OVER and RES ewes, respectively, compared with CON ewes ($P \leq 0.006$). In conclusion, inflammatory progression is characteristic of advancing gestation and the increased expression of *IL1RN*, an antagonist of *IL1α* and *IL1β*, in RES ewes at d 135 may be a protective mechanism suppressing proinflammatory signaling. The inflammatory profile of offspring was altered by poor maternal nutrition, which may negatively affect growth and health if persistent postnatally, thereby reducing offspring productivity.

Key Words: inflammation, maternal nutrition, sheep

0697 Effects of poor maternal nutrition during gestation on offspring prenatal muscle growth.

S. M. Pillai*, A. K. Jones, M. L. Hoffman, K. K. McFadden, S. A. Zinn, S. A. Reed, and K. E. Govoni, *Department of Animal Science, University of Connecticut, Storrs*.

Poor maternal nutrition during gestation can negatively affect offspring muscle development, thereby reducing production efficiency. We previously observed that cross-sectional area (CSA) of semitendinosus muscle fibers from offspring of ewes exposed to restricted feeding or overfeeding during gestation were increased at birth and reduced at 3 mo of age. Although the negative effects of poor maternal nutrition persist into postnatal growth, it is not well known when during gestation poor maternal diet affects offspring muscle growth. We hypothesized that restricted feeding and overfeeding ewes during gestation would alter fetal muscle fiber CSA during gestation. To test this hypothesis, 78 pregnant western white-faced ewes were individually housed and fed 100 (control fed, $n = 25$), 60 (restricted fed; $n = 27$), or 140% (overfed; $n = 26$) of NRC requirements for TDN beginning at d 30.2 ± 0.2 of gestation. For CSA analysis, a subset of ewes was euthanized at d 45 ($n = 20$) or 135 ($n = 19$) of gestation and offspring were collected ($n = 10$ to 14 per treatment per time point). Offspring from control-fed, restricted-fed, and overfed ewes are referred to as CON, RES, and OVER, respectively. From offspring, longissimus dorsi and semitendinosus muscles were excised, weighed, and frozen in optimal cutting medium. Muscle sections were cryosectioned and immunostained with wheat germ agglutinin. Images ($n = 5$ per offspring) of muscle cross-sections were taken and CSA were determined using ImageJ software. The CSA data were analyzed using the MIXED procedure of SAS, with maternal diet as the main effect. No differences ($P \geq 0.53$) due to maternal diet were observed for the BW of offspring or weight of semitendinosus or longissimus dorsi (as percent of BW) at d 45 or 135. At d 45, longissimus dorsi CSA tended to be smaller in RES and OVER compared with CON (CON: 228.8 ± 19.0 μm^2; RES: 171.0 ± 18.1 μm^2; OVER: 183.0 ± 16.1 μm^2; $P \leq 0.07$); however, no effect of maternal diet was observed for CSA of longissimus dorsi at d 135 ($P = 0.48$). There was no effect of maternal diet on CSA of semitendinosus ($P \geq 0.40$) at either time point. In conclusion, during the period of primary myogenesis (approximately d 45 of gestation) and within 15 d of the beginning of dietary treatment, poor maternal nutrition, both restricted feeding and overfeeding, during gestation caused a reduction in offspring longissimus dorsi CSA.

Key Words: maternal nutrition, muscle, sheep

0698 Effects of citral and linalool on blood neutrophil toxicity and oxidative response in dairy cows.

C. M. Scholte*[1], Y. Qu[1], M. Garcia[1], T. H. Elsasser[2], D. Biswas[1], and K. M. Moyes[1], *[1]Department of Animal and Avian Sciences, University of Maryland, College Park, [2]USDA, ARS, Beltsville, MD*.

Alternative therapies to controlling and treating mastitis are being pursued to reduce potential antibacterial resistance. Certain bioactive phytochemicals extracted from plants, such as citral and linalool, have demonstrated antimicrobial activity and may serve as acceptable alternatives for conventional mastitis treatments. It is unknown how these phytochemicals may interact with bovine polymorphonuclear cells (PMN), the predominant cell type recruited during mastitis. The objective of this study was to evaluate the effects of citral and linalool on cytotoxicity and the oxidative response of bovine blood PMN in vitro. Blood was sampled from four healthy, primiparous Holstein dairy cows in mid lactation (DIM > 90). Polymorphonuclear cells were isolated and incubated for 2 h with various concentrations of citral (0, 0.1, 0.2, 0.4, 0.8 and 10 μL/mL) and linalool (0, 0.1, 1.2, 2.4, and 10 μL/mL). Cytotoxicity was measured by nonradioactive, colorimetric assay to quantify lactate dehydrogenase production. Oxidative burst response for the PMN was measured by relative chemiluminescence of reactive oxidative species production after exposure to 1.6 μg/mL phorbol 12-myristate-13-acetate in addition to citral or linalool during incubation. Data were analyzed by ANOVA using the MIXED procedure of SAS 9.2. Each phytochemical was separately analyzed. Differences among treatments were determined using the PDIFF statements and significance was declared at $P \leq 0.05$. Citral concentrations of 0.8 and 10 μL/mL increased PMNL cytotoxicity to 33.0 and 68.3%, respectively ($P < 0.01$), relative to the control. Oxidative burst response increased at 0.01 and 0.02 μL/mL concentrations of citral, whereas 0.4 and 0.8 μL/mL concentrations decreased oxidative burst ($P < 0.01$). Linalool concentrations equal to or less than 2.4 μL/mL did not alter PMN cytotoxicity relative to the control and 10 μL/mL increased cytotoxicity to 81.2% ($P < 0.01$). Oxidative response of PMN increased for 1.2, 2.4, and 10 μL/mL concentrations of linalool ($P = 0.02$). In summary, citral and linalool do affect in vitro bovine blood PMN cytotoxicity and oxidative burst response. Concentrations less than 0.4 μL/mL of citral and 2.4 μL/mL of linalool were nontoxic to bovine blood PMN and concentrations between 0.1 to 0.2 μL/mL citral and 1.2 to 10 μL/mL linalool increased oxidative burst response. The use of citral and linalool as an alternative therapy for mastitis is promising as they may not interfere with the immune response during mastitis.

Key Words: mastitis, polymorphonuclear cell, alternative therapy

0699 In vitro screening of the anthelmintic efficacy of birdsfoot trefoil commercial varieties and cultivars against ovine *Haemonchus contortus*.

C. Barone*[1], S. Ferguson[1], A. Zajac[2], R. Brown[1], J. Reed[3], C. Krueger[3], and K. Petersson[1], [1]*University of Rhode Island, Kingston,* [2]*Virginia Polytechnic Institute and State University, Blacksburg,* [3]*University of Wisconsin-Madison, Madison*.

Some forages containing condensed tannins (CT), also called proanthocyanidins (PAC), suppress gastrointestinal nematode (GIN) infections in small ruminants. The objective of this study was to investigate the anthelmintic potential of 51 commercial varieties and cultivars of birdsfoot trefoil (BFT) against *Haemonchus contortus*. The antiparasitic activity of BFT proanthocyanidin extract (BFT-PAC) and BFT aqueous extract (BFT-AqE) was tested using the following in vitro assays: 1) egg hatching and viability of L1 *H. contortus* larvae and 2) exsheathment of L3 *H. contortus* larvae. Birdsfoot trefoil powder of each variety or cultivar was analyzed for CT content (mg/g) by the 4-(dimethylamino)cinnamaldehyde method. Birdsfoot trefoil proanthocyanidin extract was prepared by isolating PAC extract from the BFT powder using solid-phase chromatography. Birdsfoot trefoil aqueous extract was prepared by soaking BFT powder in water at room temperature for 24 h. The plant matter was then removed, leaving an aqueous extract. 1) For in vitro egg hatch and viability of L1 larvae, *H. contortus* eggs were isolated from fresh feces and exposed to varying concentrations of BFT extracts for 24 h. The percentage of hatched eggs and L1 larval mortality (based on motility) were determined. 2) For in vitro exsheathment, 2,000 *H. contortus* L3 larvae were incubated in varying concentrations of BFT extracts for 24 h followed by exsheathment using CO_2. The percentage of exsheathed larvae (based on absence of sheath) was determined. Condensed tannin content ranged between 1.5 and 63.8 mg/g across 51 varieties and cultivars. Inhibition of egg hatch and larval mortality was observed with incubation in BFT-AqE; however, the concentration at which this inhibition and mortality was most effective varied among varieties and cultivars: at 3 mg/mL, percent inhibition of egg hatch and L1 mortality spanned between 0 and 100% across 51 varieties and cultivars tested. Results for incubation in BFT-PAC and results for exsheathment are pending. Preliminary results indicate that commercial varieties and cultivars of BFT-AqE inhibited egg hatch and increased larval mortality, but the degree of inhibition and mortality varied. Additional results testing BFT-PAC and testing exsheathment will provide further information about the anthelmintic efficacy of commercial varieties and cultivars of BFT for small ruminant GIN control.

Key Words: small ruminant, sheep, condensed tannin

0700 Anti-obesity and antidiabetic properties of lactoferrin are independent of calorie intake.

R. C. Zapata*[1], A. Pezeshki[2], A. Singh[1], and P. K. Chelikani[1], [1]*University of Calgary, Calgary, AB, Canada,* [2]*Oklahoma State University, Stillwater*.

Whey proteins provide multiple health benefits to humans including promotion of weight loss and improving diabetic control. However, the bioactive components of whey that produce such benefits and the underlying mechanisms of action are poorly understood. Our objectives were to determine the effects of whey, and its components lactalbumin and lactoferrin, on 1) energy balance, body composition, glucose tolerance, and gut hormones and 2) key regulatory markers of glucose and lipid metabolism in liver and skeletal muscle of diet-induced obese (DIO) rats. The DIO rats were randomized to receive one of 5 isocaloric dietary treatments (n = 8/group; 40% fat and 4.63 kcal/g)—control (CON; 15% protein), whey (WH), lactalbumin (LA), lactoferrin (LF), and pair-fed WH to LF (PF)—for approximately 8 wk. The high-protein diets contained 15% added whey or its components. Food intake, meal patterns, energy expenditure, body composition, glucose tolerance, plasma hormone, and hepatic and muscle mRNA abundance were measured. Data were analyzed by linear mixed models, ANOVA, or ANCOVA. We found that 1) compared with CON, WH, LA, and LF reduced food intake, with LF producing a greater and sustained reduction of intake; 2) the hypophagia is partly due to reduced meal size and/or frequency, increased peptide YY mediated satiety, and decreased diet preference; 3) LF produced greater reductions in BW and fat mass, enhancement in energy expenditure, and improvement in glucose tolerance than PF; 4) LA decreased BW and fat mass, increased energy expenditure, and improved glucose tolerance compared with CON; 5) LA and LF decreased plasma concentrations of insulin and leptin relative to CON; and 6) LA increased the mRNA abundance of GLUT2, glucokinase, glycogen synthase, and carnitine palmitoyltransferase-1 and decreased fatty acid synthase and pyruvate dehydrogenase, whereas LF increased glucokinase and glucose-6-phosphate dehydrogenase and decreased phosphofructokinase and fatty acid synthase in the liver and both LA and LF increased muscle pyruvate dehydrogenase compared with CON. Together we demonstrate that the improvement in energy balance, lipid metabolism, and glucose tolerance by lactoferrin are beyond its hypophagic effects. Our findings have important implications for developing lactalbumin- and lactoferrin-based functional foods and nutraceuticals for weight loss and diabetic control. Funding by ALMA, AI-Bio, and Alberta Milk.

Key Words: diabetes, lactalbumin, lactoferrin, obesity, whey

0701 Effect of milk protein intake and casein:whey ratio in breakfast meals on postprandial glucose, satiety ratings, and subsequent meal intake. B. Kung*[1], S. Paré[1], A. J. Tucker[1], G. H. Anderson[2], A. J. Wright[1], and H. D. Goff[1], *[1]University of Guelph, Guelph, ON, Canada, [2]University of Toronto, Toronto, ON, Canada*.

Novel satiating dairy-based breakfast products have potential to reduce the risk of developing and improve management of type 2 diabetes and obesity. Whey and casein proteins may induce different physiological effects on blood glucose, induction of satiation, and satiety. Whey proteins have been associated with acute satiation, compared with the prolonged feelings of satiety from casein. The purpose of this work is to investigate the impact of breakfast meal milk casein:whey ratio and protein concentration on postprandial blood glucose, appetite ratings, and subsequent food intake. In a randomized, controlled, double-blinded study, healthy young adults ($n = 32$; 16 m/f, 23.4 ± 3.1 yr, and 22.2 ± 2.5 kg/m^2 BMI) consumed milk (250 mL) with normal (80:20) or modified (40:60) casein:whey protein ratio at normal (3.1%) or high (9.3%) protein concentration, or water (control), along with 2 servings of breakfast cereal. Following an overnight fast and up to 120 min following the breakfast meal, participants had their plasma glucose concentrations determined from fingerprick samples, completed a series of scale ratings to assess satiety, and consumed a weighed ad libitum pizza lunch. Repeated measures ANOVA followed by Tukey–Kramer's post hoc testing was performed. Incremental area under the curve (AUC) glucose values showed significant attenuations in postprandial plasma glucose concentration for all milk treatments, relative to control ($P < 0.05$). Also, the high-protein treatments (9.3%) had significantly attenuated glucose concentrations compared with those with lower-protein treatments (3.1%). However, there was no effect of casein:whey protein ratio on blood glucose. Treatments were not associated with differences in total AUC for individual scale ratings of Hunger, Desire to Eat, Fullness, and Prospective Consumption. Nor were differences observed in mean appetite score ($P = 0.86$) or subsequent lunch intake ($P = 0.06$). Therefore, because consumption of high-protein milk treatments with breakfast cereal was associated with the lowest plasma postprandial glucose concentration, new high-protein dairy breakfast products should be considered for product development. (Supported by a contribution from the Dairy Research Cluster Initiative.)

0702 Evaluation of modified stainless steel surfaces targeted to reduce biofilm formation by common dairy related sporeformers. S. Jindal*[1], S. Anand[1], J. K. Amamcharla[2], and L. Metzger[1], *[1]South Dakota State University, Brookings, [2]Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan*.

Development of bacterial biofilms on stainless steel (SS) surface of dairy equipment such as plate heat exchangers pose a great threat to the quality of milk and other dairy products, as the biofilm-embedded bacteria can survive thermal processing to a greater extent. Many of these are sporeformers that also form heat-resistant spores, leading to a long-term persistent contamination. Biofilms also offer cleaning challenges, as they are generally resistant to regular cleaning protocols. The main objective of this study was to evaluate different surface modifications (AMC 18, Durasan, Lindgren, and Magnaplate) of stainless steel for their resistance to biofilm formation. It was hypothesized that these coated surfaces would promote a lower deposit build-up and bacterial adhesion. Challenge studies, using vegetative cells of common dairy-related

aerobic sporeformers, namely *Geobacillus stearothermophilus* (ATCC 15952), *Bacillus licheniformis* (ATCC 6634), and *Bacillus sporothermodurans* (DSM 10599), were conducted to study the biofilm formation on the modified and native SS coupons under static conditions. Standard enumeration techniques were used to culture biofilm-embedded bacteria. The adherence of these organisms was observed to be influenced by surface energy and hydrophobicity but exhibited no relationship with surface roughness. Statistical analysis of the number of adhered cells of *G. stearothermophilus* to different native and modified SS surfaces, after 72 h of incubation, revealed significant differences in counts. Lindgren was observed to be most resistant to bacterial attachment (average 3.15 log cfu/cm^2), in comparison to the native SS surface that recorded a higher average bacterial adhesion of 5.11 logs. Similar results were obtained with *B. licheniformis* and *B. sporothermodurans*, the latter showing least attachment. Scanning electron microscopy provided the visual evidence of the extent of biofilm development and bacterial attachment on the surface of modified and native SS surfaces. In conclusion, Lindgren coating, being the most resistant to biofilm development, could potentially help in reducing the bacterial cross-contamination of milk and dairy products during processing.

Key Words: biofilms, sporeformers, surface modification

0703 Gelation properties of micellar casein concentrate when recombined with cream. Y. Lu*, D. J. McMahon, and A. H. Vollmer, *Western Dairy Center, Utah State University, Logan*.

Skim milk can be concentrated using microfiltration and evaporation to produce a highly concentrated micellar casein concentrate (HC-MCC), containing approximately 20% casein with approximately 70% of serum proteins removed during diafiltration. Understanding the gelation properties of HC-MCC and when mixed with cream to form a recombined concentrated milk (RCM) is important for using RCM for cheese manufacture. After concentration, HC-MCC forms a gel when cooled. Heating above the cold gelation temperature (up to 50°C) can break up the gel so that the individual casein micelles are solubilized. When examined using transmission electron microscopy, cold-gelled HC-MCC was observed to form a close-packed gel, which probably occurs when kinetic energy of the casein micelles is sufficiently reduced to inhibit their mobility in relation to adjacent casein micelles. Similar observations of cold gelation were made when HC-MCC was mixed with cream in casein to fat ratios of 0.8 or 1.2 as would be used for the manufacture of cheddar or part skim mozzarella cheese. At pH 6.6, an RCM with high protein can gel at cheese-making temperatures, whereas with 12% or less casein, it does not gel above 12°C. In micrograghs of cold-gelled RCM, casein micelles were less closely packed together and were partially dissociated. It appears that the protein strands that have been partially released from the casein micelles still entangle, restrict the mobility of each other, and form a fine stranded gel network. To understand challenges related to cheese making using an RCM that contains 4 times the level of casein than normally found in milk, its coagulation properties (rennet coagulation time and curd firmness) were studied using a rheometer. Reducing rennet amount can lengthen coagulation time of RCM but it does not affect curd firmness or firming rate. Decreased coagulation temperature can lengthen coagulation time and slow curd firming rate, but it also increases initial viscosity of RCM. Lowering pH of RCM to pH 6.0 did not solve the problem of curd firming being too rapid. Microstructure of RCM and its rennet coagulum indicated that the increased curd firmness probably results from the highly interlinked and longer protein strands in RCM curd. Overall, RCM with a casein level of 11 to 12% has potential for use in cheese making, provided its higher viscosity compared with milk and its fast curd firming rate can be overcome. Reducing rennet amount can be used to slow coagulation and curd firming.

Key Words: rheology, microstructure, casein micelle

0704 Thermal stability of microfiltered and ultrafiltered retentates. I. R. T. Renhe*[1] and M. Corredig[1,2], [1]*University of Guelph, Guelph, ON, Canada,* [2]*Gay Lea Foods, Guelph, ON, Canada*.

Membrane filtration technologies are widespread unit operations in the dairy industry and are often used to obtain ingredients of tailored processing functionalities. The objective of this work was to better understand the effect of partial removal of whey proteins by microfiltration (MF) on the heat stability of the retentates. Control retentates were obtained using ultrafiltration (UF). Pasteurized milk was microfiltered (80 kDa polysulfone membrane) or ultrafiltered (30 kDa cellulose membrane) in a plate and frame membrane system to reach two and four times concentration (based on volume reduction). Concentrates showed no differences in pH, casein micelle size, or minerals in the serum phase, before heating, as diafiltration was not used in this study. The reduced amount of whey protein in the MF retentates caused a significant increase in the heat stability of the retentates, compared with UF retentates. This difference was not due to ionic composition differences or to pH. Heat coagulation time decreased with protein concentration but significantly increased in MF retentates, containing less whey proteins than the corresponding UF controls. In 2x concentrates, retentates prepared with MF, containing 20% less whey proteins than UF control, showed an increase in the heat coagulation time of about 11 min. 4xMF retentates contained 17 ± 3 mg/mL of whey proteins, about 40% less whey proteins than the 4xUF control retentates. A 4x concentrate prepared by MF showed heat stability statistically similar to that of a 2xUF concentrates, with a heat coagulation time of about 38 min. The turbidity parameter

1/l*, measured by diffusing wave spectroscopy, increased after heating, with the UF retentates showing a higher value than the MF retentates, at the same protein concentration. In addition, 4xMF concentrates showed a 1/l* value comparable to that of 2xUF concentrates. In conclusion, this work demonstrated that partial removal of whey proteins by MF could be used as a means to increase heat stability of milk concentrates.

Key Words: heat coagulation time, milk concentrate, whey protein

0705 Effect of milk protein composition on in vivo gastric digestion of a model infant formula.

N. Rafiee Tari*, M. Z. Fan, and M. Corredig, *University of Guelph, Guelph, ON, Canada*.

The objective of this work was to determine the effect of protein composition and, in particular, the presence of whey proteins or b-casein, on the digestion behavior of a model infant formula. An in vivo piglet model was used, as this is an established model for human infants' digestion. Three formulas optimized for piglets were prepared with the same concentration of protein and same caloric content. One formula contained only whey proteins (WP) and two others contained a casein-to-WP ratio of 40:60 but differed in the amount of β-cas. To obtain modified protein ratios, microfiltration (using polyethersulfone membrane with 80 KDa of molecular weight cut-off) was conducted on skimmed milk at either 7 or 22°C. Retentates and permeates were combined with additional whey protein and other ingredients, and after heating, the formulas were used to feed 24 piglets. The piglets were housed and fed from age 3 to 21 d, and animal behavior and health conditions were investigated. The study was performed in two blocks, sacrificing the animals after 60 and 120 min from the last meal. Gastric digesta samples were collected and studied for physicochemical properties. The tests were performed on fresh samples in less than 10 min after euthanizing. There were no differences in the properties of the curd, within a treatment, between the two blocks. All curds showed a shear-thinning behavior, with a significantly higher viscosity and a higher modulus for curds obtained from casein/WP formula, compared with the curds from WP formula. Confocal microscopy showed structures with larger voids in WP digestates, compared with those from cas/WP formula, which showed a higher density throughout the matrix. Despite differences in physicochemical properties, a pH range of 4.4 to 5.8 was measured for the gastric contents, with no significant difference observed between diets or with time of digestion. There were also clear differences in animal growth between treatments. Casein/WP formulas were shown to improve growth performance, with approximately 50% higher average daily growth and increased feed efficiency, compared with the WP formula. The results bring significant advances to our understanding of the importance of different protein ratios on the digestion of dairy matrices.

Key Words: digestion, infant formula, milk proteins

0706 Differences in high-density polyethylene milk packaging performance under light-emitting diode and fluorescent retail storage.

K. N. Amin*, M. L. Johnson, J. B. Phillips, S. Duncan, H. Potts, S. F. O'Keefe, J. E. Marcy, and K. Mallikarjunan, *Virginia Tech, Blacksburg*.

The purpose of this study was to determine how commercial and designed packaging performed in the conditions of a retail dairy case with fluorescent and light-emitting diode (LED) lighting. Commercial retail cases in the Tennessee and Virginia area and the retail case used in this study were tested for light intensity (lux) within various locations on the shelf units with a hand-held light meter. Freshly processed milk (2%) was filled in high-density polyethylene (HDPE) packages with varying light protective additives (LPA). Treatments included yellow, low titanium dioxide (TiO_2; 1.3%) and high (4.9%) TiO_2; controls included translucent HDPE (0% TiO_2; light exposed [LE]) and translucent HDPE with foil overwrap (light protected [LP]). All packages were stored for 4, 8, 16, 24, 48, and 72 h under fluorescent and LED light. Riboflavin (Rb) retention and thiobarbituric reactive substances (TBARS) were measured (2 replications) as indicators of initiation and secondary oxidation products. Means were compared using ANOVA and Tukey's HSD ($\alpha = 0.05$). The polymer conducting electronic nose (eNose) analyzed headspace volatiles for milk quality for all packages under light treatments for 8 and 24 h (canonical distribution $\alpha = 0.05$) for one replication. Commercial retail cases varied from 50 to 4,700 lux, with fluorescent light having a greater variability than LED lights. The retail case used in this study fell within the light intensity range of commercial retail cases. Mean light intensity within fluorescent (1,617 ± 505 lux) and LED (929 ± 97 lux) cases were significantly different, but this difference did not affect Rb and TBARS analysis based on analysis of covariance. Light protected performed most effectively under both lights whereas LE provided inadequate protection ($P < 0.05$). Milk in yellow and high TiO_2 packages retained the highest concentration of Rb (61 and 55% retention, respectively) among LPA packages under LED through 72 h. Under fluorescent light, interactions with package and light were different from LED, suggesting light spectra and light transmittance interactions occur between light source and LPA packaging. Milk stored in the two lighting conditions each had unique volatile chemistry based on (eNose) canonical distribution. Under fluorescent light, eNose effectively separated controls from LPA packages but not under LED light, suggesting that LED does not have as much effect on volatile profile as does fluorescent light. High-density polyethylene packaging with pigments performs better under LED lights than under fluorescent lights at low lux conditions. Effective packaging should protect milk

quality regardless of light and intensity.

Key Words: light-emitting diode, milk, packaging

0707 Efficient removal of spores from skim milk using microfiltration: Spore size and surface property considerations. E. R. Griep*, Y. Cheng, and C. I. Moraru, *Cornell University, Ithaca, NY*.

Presence of spores in milk can cause numerous quality and shelf-life issues for dairy products. Microfiltration (MF) using a 1.4-µm pore size can effectively remove vegetative bacterial cells from milk and is used in commercial applications. However, this pore size may be not be equally effective in spore removal. The objective of this study was to determine the effectiveness of MF using 1.4- and 1.2-µm pore sizes for removing spores of *Bacillus licheniformis* (BL) and *Geobacillus* spp. (GEO) from skim milk. Cell size of both spores and vegetative cells was evaluated by scanning electron microscopy, surface charge by zeta potential analysis, and surface hydrophobicity by contact angle measurements, in triplicate. Commercially pasteurized skim milk was inoculated in a sterilized feed tank with a spore suspension, at about 10^6 spores/mL, and then treated by MF (in triplicate) using ceramic Isoflux membranes at 6°C, cross-flow velocity of 4.1 m/s, and transmembrane pressure between 69 and 74 kPa. Total aerobic plate count and spore count of the permeate were conducted. An unpaired *t* test was used to determine significant differences between samples at a $P < 0.05$ significance level. Vegetative cell length ranged between 2.40 and 3.82 µm and the width ranged between 0.39 and 0.64 µm. Spores were shorter and wider, averaging 1.39 to 1.58 µm in length and 0.63 to 0.88 µm in width, therefore having a higher probability to pass through a 1.4-µm membrane. Indeed, for BL (1.39-µm length × 0.63-µm width) an average spore reduction of only 2.17 log was achieved by 1.4-µm pore size. For the 1.2-µm membrane, a 4.57 log reduction was achieved. For GEO spores, their larger spore size (1.58-µm length by 0.81-µm width) allowed a practically complete removal using both pore sizes (spore counts in permeate below the detection limit). The surface properties of BL and GEO indicated that they may interact differently with the membrane. Both spore species and the ceramic membrane had negative surface charge at the milk pH, indicating slight electrostatic repulsion between them. *Geobacillus* spp. spores were hydrophilic, whereas BL spores were slightly hydrophobic; the ceramic membrane surface changes from hydrophilic (in unfouled state) to hydrophobic after adsorption of caseins during MF. Consequently, BL spores may experience slight attractive force to the membrane through hydrophobic interactions, which will facilitate their passage through the membrane. A good understanding of all factors that affect the removal of spores using MF can lead to the production of milk with lower spore count, higher quality, and increased shelf life.

Key Words: microfiltration, skim milk, spore removal

ADSA DAIRY FOODS GRADUATE STUDENT POSTER COMPETITION

0708 Unit operations before and during spray drying influence the flavor of milk protein concentrate and whole milk powder. C. Park* and M. Drake, *Southeast Dairy Foods Research Center, North Carolina State University, Raleigh*.

Flavor is a limiting factor in the application and shelf life of dried dairy ingredients. Many off-flavors are caused during ingredient manufacture, which carry through into ingredient applications and decrease consumer acceptance. The objective of this research was to investigate the effect of spray drying parameters on the flavor of milk protein concentrate (MPC) and whole milk powder (WMP). Liquid MPC70 was produced from pasteurized skim milk by ultrafiltration/diafiltration to 19% solids (wt/wt) and evaporated to 32% solids (wt/wt). Spray drying was performed with varying inlet temperature (160, 210, or 260°C) and feed solids concentration (12, 22, or 32%). Whole milk powder was produced from standardized pasteurized whole milk that was evaporated to 50% solids (wt/wt), homogenized in two stages with varying pressures (0/0, 55.1/13.8, 110/27.6, or 165/41.4 bar), and spray dried. Whole milk powder was evaluated at 0, 3, and 6 mo storage at 22°C. Sensory properties were evaluated by descriptive sensory analysis and volatile compounds were evaluated by headspace extraction (SPME) with gas chromatography mass spectrometry. Fat globule size in condensed whole milk and particle size of powders were measured by laser diffraction. Surface free fat of WMP was measured by solvent extraction. Furosine in MPC70 was analyzed by UPLC-MS. Spray drying of MPC70 at 160°C increased cardboard flavor and volatile lipid oxidation products and decreased sweet aromatic flavor and furosine concentration compared with 210 or 260°C ($P < 0.05$). Solids concentration during drying had no effect on furosine concentration ($P > 0.05$). Decreasing feed solids concentration decreased sweet aromatic flavor and increased cardboard flavor and volatile lipid oxidation products ($P < 0.05$). Increased homogenization pressure decreased cardboard flavor, volatile lipid oxidation compound concentrations, fat globule size in condensed milk, and surface free fat in WMP ($P < 0.05$). Surface free fat in powders increased cardboard flavor and lipid oxidation. These results indicate that off-flavors are decreased with increasing feed solids concentration and inlet temperature in MPC70 and with increased homogenization pressures in WMP. To decrease off-flavor intensities in WMP and MPC70, manufacturers should evaluate these parameters during ingredient manufacture.

Key Words: milk proteins, whole milk powder, unit operations

0709 The effect of bleaching agents on the degradation of vitamins and carotenoids in WPC80.

M. A. Stout*[1], C. Park[2], and M. Drake[2], [1]*North Carolina State University, Raleigh,* [2]*Southeast Dairy Foods Research Center, North Carolina State University, Raleigh*.

Previous research has demonstrated that chemical or enzymatic bleaching impact flavor and functionality of whey proteins. The role of bleaching on vitamin and carotenoid degradation is unknown. The objective of this study was to determine the effects of bleaching with hydrogen peroxide (HP), benzoyl peroxide (BP), or native lactoperoxidase (LP) on vitamin and carotenoid degradation. The role of an alternative colorant on whey protein vitamin profile was also evaluated. Colored cheddar whey (15 mL/454 L milk) was manufactured, pasteurized, and fat separated and then assigned to 250 ppm HP, 25 ppm BP, or 20 ppm HP (LP system) at 50°C for 1 h. An unbleached control (Con) as well as whey from cheese milk with an alternative colorant (AltC) were also included. The Con and AltC were also heated to 50°C for 1 h. Wheys were concentrated to 80% protein by ultrafiltration and spray dried. The experiment was replicated in triplicate. Vitamin, norbixin, and carotenoid contents were determined by HPLC and volatiles by gas chromatography mass spectrometry. A trained panel documented sensory properties of the rehydrated WPC80. Volatile compound and sensory results were consistent with previous studies on bleached and unbleached whey proteins. WPC80 that were chemically or enzymatically bleached had decreased retinol, β-carotene, ascorbic acid, α-carotene, thiamine, lutein, and α-tocopherol ($P < 0.05$) compared with Con WPC80 or AltC WPC80. Benzoyl peroxide WPC80 contained less of these compounds than HP or LP WPC80 ($P < 0.05$). Riboflavin, pantothenic acid, pyridoxine, and nicotinic acid concentrations were not impacted by bleaching ($P > 0.05$). Alternative colorant WPC80 contained 6% more β-carotene than Con WPC80 ($P < 0.05$). Bleaching to remove norbixin decreases fat soluble vitamin and carotenoid concentrations in the final spray dried whey protein.

Key Words: bleaching, vitamin degradation, alternative colorant

0710 Characterization of flavor and functional properties of liquid and dried WPC 80, WPI, MPC 85, and micellar casein concentrates.

B. Carter*[1], H. Patel[1], D. M. Barbano[2], and M. Drake[3], [1]*North Carolina State University, Raleigh,* [2]*Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY,* [3]*Southeast Dairy Foods Research Center, North Carolina State University, Raleigh*.

Traditionally most protein ingredients are sold as a powder due to its ease to transport and longer shelf life. Many high-protein powder ingredients such as MPC 85 and micellar casein concentrate (MCC) have poor rehydration properties (e.g., solubility), which might be a limiting factor for using these ingredients in end applications. Previous research suggested that the spray drying may have some adverse effects on flavor and functional properties of dried ingredients. Moreover, spray drying is the costly unit operation in the manufacture of protein ingredients. Considering this, manufacturers of dried protein ingredients are considering an option to manufacture liquid retentate, which will not only save the cost of spray drying but may provide improved flavor and functional properties. The objective of this study was to determine what effect, if any, spray drying has on the flavor and functionality of high-protein ingredients. Liquid and dried protein ingredients (WPC 80, WPI, MPC 80, and MCC) were manufactured from the same lot of milk at the North Carolina State University pilot plant. These ingredients were characterized using native PAGE, particle size, and calcium activity, and functionality differences were evaluated by measurement of foam stability, protein solubility, and heat stability. Protein solubility was measured at pH 7 before and after centrifugation by micro-bicinchoninic acid assay (micro-BCA), and heat stability by heating at 90°C for 0, 10, 20, and 30 min followed by micro-BCA and turbidity loss. Flavor was evaluated by descriptive analysis, and volatile compound analysis was conducted by GC–MS to identify key flavor differences between the liquid and spray dried protein ingredients. No differences were detected in solubility and heat stability between liquids and powders ($P > 0.05$). WPC 80 (liquid or spray dried) did not produce a foam; powder WPI produced a more stable foam as opposed to the liquid, but with milk proteins, the liquids produced a more stable foam ($P < 0.05$). This result is likely due to the particle size difference between liquid and powder being much greater in milk proteins compared with whey proteins ($P < 0.05$). All powders had higher aroma intensity and cooked flavors compared with liquids ($P < 0.05$). Powder proteins also had low but distinct cardboard flavor concurrent with higher volatile aldehydes compared with liquids. An understanding of how spray drying effects both flavor and functionality will help producers better use the ingredients they have available to them.

Key Words: milk proteins, whey proteins, flavor, functionality

0711 Effect of milk protein concentrate (MPC 80) quality on susceptibility to fouling during thermal processing.

G. Gandhi*[1] and J. K. Amamcharla[2], [1]*Department of Animal Sciences and Industry/ Food Sciences Institute, Kansas State University, Manhattan,* [2]*Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan*.

Milk protein concentrate (MPC) is incorporated into wide range of dairy beverages to improve the functional, nutritional,

and sensory properties. Various factors such as drying conditions, composition, storage, and dissolution conditions affect the overall functional characteristics of MPC. To be used for its intended purpose, it is essential to study the functional properties such as solubility, dissolution, and fouling characteristics of MPC. Fouling of the stainless steel (SS) surfaces during thermal processing of milk is a major problem in the dairy industry. It is important to understand the composition and structure of the fouling layer to minimize the fouling of the processing equipment. The objective of the present study was to understand the effect of MPC solubility on its susceptibility to initiate fouling on SS surfaces during thermal processing. Milk protein concentrate powder with 80% protein content was obtained from a commercial manufacturer, divided into two lots. To create powders with different solubility characteristics, the first lot was stored at 25°C and the second lot at 40°C for 2 wk. Immediately after the storage, the powder solubility characteristics were monitored using focus beam reflectance measurement technique and solubility index. As expected, the MPC stored at 40°C showed the slow dispersion rate of particles when compared with the powder stored at 25°C, indicating poor solubility characteristics. Fouling characteristics were studied using a custom-build benchtop heat exchanger (bPHE). The bPHE was designed to accommodate two SS coupons with 1″ by 1″ dimensions. The MPC was reconstituted to 10% (wt/wt) solution and pumped for 2 h through bPHE to an average outlet temperature of 71.9°C. Subsequently, the SS coupons were removed from the bPHE and fouled layer was characterized using weight of fouling, scanning electron microscopy, confocal laser scanning microscopy, energy dispersive X-ray spectroscopy, and SDS-PAGE. The average foulant accumulated over the SS coupons by the poor quality powder (stored 40°C) and the good quality (stored at 25°C) powder was 0.171 ± 0.031 and 0.093 ± 0.019 g, respectively. Storing the powders at 40°C significantly ($P < 0.05$) increased the amount of fouling on SS coupons. Microscopic investigations revealed the heterogeneity of the fouling layer with the discrete distribution of lipids and proteins with uniform calcium distribution. Therefore, the study will be helpful in designing effective strategies to reduce fouling during processing of high-protein dairy beverages.

Key Words: fouling, milk protein concentrate, plate heat exchanger

0712 Oxygen barrier and light interference packaging properties for controlling light-induced oxidation in milk. H. Potts*, S. Duncan, M. L. Johnson, S. F. O'Keefe, J. E. Marcy, and K. Mallikarjunan, *Virginia Tech, Blacksburg*.

A recent shift to more energy efficient light-emitting diode (LED) lights in retail dairy cases has occurred, but the effects of LED light on fluid milk in retail conditions are not known. Our objective was to determine the efficacy of polyethylene terephthalate (PET) packaging at preventing light-induced oxidation in 2% milk under LED and fluorescent retail light. Light interference effects were studied in combination with the oxygen barrier effects of PET. The extent of oxidation in 2% milk packaged in PET bottles (2 L; average wall thickness: 0.33 mm; treatments: clear with UV barrier and 2.1, 4.0, and 6.6% titanium dioxide [TiO_2]) under fluorescent and LED retail light up to 72 h was studied. Two control packages (clear PET = full light exposure and PET wrapped with foil and plastic = no light exposure) were used for comparison, creating a total of six packaging experimental treatments. Chemical measures of oxidation ($\alpha = 0.05$; ANOVA) included formation of secondary lipid oxidation products, riboflavin degradation, and headspace volatiles analysis by an electronic nose. Volatile analysis compared electronic nose smell-prints by canonical discrimination analysis. Sensory evaluation of milk (triangle test, 3 replications) compared milk from experimental packages to light-protected control milk for similarity ($\beta = 0.05$) and to light-exposed control milk for differences ($\alpha = 0.05$). Polyethylene terephthalate with 6.6% TiO_2 was an effective package for protecting fluid milk sensory quality for up to 8 h under LED light (936 ± 136 lux) but only for 4 h under fluorescent light (1,447 ± 1,072 lux). Polyethylene terephthalate with 4% or less TiO_2 could not effectively protect milk flavor from light-induced changes through 4 h fluorescent or LED light exposure. Milk stored in PET packages retained 0.90 mg/L or higher riboflavin content over 72 h retail light exposure. Electronic nose technology differentiated ($P < 0.05$) volatile profiles among fresh milk with no light exposure and milk that remained under retail lights for 8 h or more, indirectly supporting the changes in sensory quality. The results conclude that LED light is less detrimental to milk quality than fluorescent light and higher levels of TiO_2 in PET packages were more effective at preventing light-induced oxidation in 2% milk.

Key Words: milk, oxidation, sensory

0713 Use of fluorescence-based Amaltheys analyzer for studying effect of pH and heat on whey protein interactions in reconstituted milk protein concentrate. K. Sajith Babu*, Z. Liu, and J. K. Amamcharla, *Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan*.

Milk protein concentrates (MPC) are complete proteins that contain both casein and whey proteins in the same ratio as in milk. In comparison with skim milk powder or whole milk powder, MPC are higher in protein and lower in lactose and minerals. The objective of our study was to use fluorescence-based Amaltheys analyzer to study the effect of pH and heat on whey protein interactions in reconstituted milk protein concentrate. MPC85 from two different lots of same manufacturer was reconstituted into 5% solution and the pH values were adjusted between 5.5 and 7 and heated (70, 80, and 90°C) up to 20 min. The level of whey protein denaturation

and protein associations were examined for each milk sample. The level of native whey protein in the no-heat and heat-treated milk samples were determined using native PAGE. The whey protein nitrogen index (WPNI) and the FAST (fluorescence of advanced Maillard products and soluble tryptophan) index were measured by fluorescence-based Amaltheys analyzer (Spectralys Innovation, Romainville, France) and was compared with the native PAGE results. The results based on the WPNI, gives an indirect indication of the denaturation and aggregation of whey proteins. The level of denatured whey proteins was significantly dependent on the pH and thermal treatment, with high levels of interactions at pH 5.5 and low levels of changes at pH 7. Reconstituted MPC85 with no heat treatment (WPNI 1.84 ± 0.01 mg WPN·g^{-1} powder at pH 7 and WPNI 1.69 ± 0.01 mg WPN·g^{-1} powder at pH 5.5, respectively) retained most of the whey proteins in the native state. In contrast, the reconstituted MPC85 at 90°C for 20 min (WPNI 0.44 ± 0.01 mg WPN·g^{-1} powder at pH 7 and WPNI 0.21 ± 0.01 mg WPN·g^{-1} powder at pH 5.5) contained a comparatively small proportion of native whey proteins, although some α-lactalbumin was still present (shown in native PAGE). The degree of denaturation of β-lactoglobulin appeared to be crucial and could be related to the WPNI and FAST index. The amount of whey protein interactions increased with increase in temperature and decrease of pH. The results in this study indicate that the changes in whey protein induced by the heat treatment of reconstituted milk protein concentrate were affected by pH and thermal treatment time, and the Amaltheys analyzer was found to be a simple and rapid instrument for studying these interactions.

Key Words: milk protein concentrate, whey protein nitrogen index, protein denaturation and aggregation

0714 Use of ozonated water in removing *Bacillus cereus* biofilms from the dairy membranes.

R. Henderson*[1], G. Gandhi[1], N. Sevart[1], S. Gragg[2], R. Phebus[1], and J. K. Amamcharla[3], [1]*Department of Animal Sciences and Industry/Food Sciences Institute, Kansas State University, Manhattan,* [2]*Department of Animal Sciences and Industry/ Food Sciences Institute, Kansas State University, Olathe,* [3]*Food Science Institute, Animal Sciences and Industry, Kansas State University, Manhattan*.

Fouling of dairy membranes is a major problem and leads to biofilm development. This causes reduction in membrane performance and leads to premature replacement of membranes. Ozone is a potent bactericidal agent used in diverse applications. The objective of this study evaluates the efficiency of ozonated water on removal of biofilms from dairy processing membranes. To generate aqueous ozone, an ozone generator system supplied by CleanCore Technologies Inc. (Omaha, NE) was used. The system consists of six ozone generators connected to an injector that mixes ozone with water. It also houses a dissolved ozone monitor and oxidation–reduction potential sensor. The half-life of ozone in ozonated water was evaluated using a factorial design with pH (2, 4, and 7) and temperature (5, 10, and 20°C) as independent factors with two replications. Reduction in ozone concentration in ozonated water was monitored at regular intervals until the final concentration dropped below 1.0 ppm. First order rate constants (k) were calculated using a first order decay model and ozone half-life was then calculated. Temperature and pH and their interaction significantly ($P < 0.05$) affected half-life. Maximum ozone half-life was achieved with pH 4 solution at 10°C, with an average half-life of 478 min; therefore, these conditions were used to evaluate biofilm removal from dairy membranes. Ultrafiltration of skim milk was performed in a bench-top plate and frame system. Flat sheet polyethersulfone (PES) membranes (Hannifin Corp., Oxnard, CA) were fouled during 5x ultrafiltration of pasteurized skim milk. Fouled PES membranes were submerged in Luria broth inoculated with *Bacillus cereus* (ATCC 10987) and incubated for 48 h at 37°C to promote biofilm formation. Biofouled membranes were installed in the plate and frame system and exposed to ozonated water for 6 min in recirculation mode. Subsequently, residual biofilm was removed by scraping a 6.45 cm^2 of the membrane, transferred into 10 mL of 0.1% peptone water, and vortexed. Serial dilutions were plated onto mannitol egg yolk polymyxin agar, and plates were incubated at 37°C for 24 to quantify viable *B. cereus* populations, which were compared with corresponding population levels on nontreated control membranes. The *B. cereus* biofilms grown on fouled PES dairy membranes and treated with ozonated water under the described conditions were reduced by an average of 1.0 log cfu/cm^2. Data suggests ozonated water has potential as an effective and environmentally friendly means for removing biofilms from dairy membrane systems.

Key Words: ozonated water, ultrafiltration membranes, biofilms

0715 Development of a benchtop method to polymerize lactose to soluble fiber.

A. F. Kuechel* and T. C. Schoenfuss, *University of Minnesota, Department of Food Science and Nutrition, St. Paul*.

Twin-screw extrusion is used to polymerize lactose and glucose to an oligosaccharide, polylactose. However, previous research in our lab demonstrated that the lactose in permeate and acid whey could not be polymerized using our standard method. There is a lack of understanding for what inhibits the polymerization reaction; the citric acid content and extruder feed rate have been researched, yet chemical properties such as moisture and mineral contents have not. The objective of this study was to develop a benchtop method for polymerization using a CEM Mars 6 microwave reaction system so that inhibition factors could be identified before scaling up to the extruder. A heating profile needed to be established that

would consistently polymerize a blend of citric acid (6%), glucose (20%), and lactose (74%). Seven-gram samples of the sugar acid blends were added to 8 Teflon MarsXpress vessels. The set temperature, ramp time, and hold time were varied to melt the powder blend and achieve polymerization, without reaching decomposition. All vessels were continuously monitored for temperature during the reaction via an infrared thermometer. The reacted samples were cooled and dissolved in water, passed through ion-exchange resins, and then separated and detected by HPLC-ELSD. An initial heating profile with a 5-min ramp time to a 180°C target temperature imitated extrusion conditions known to result in polymerization. Even though polymerization was observed with this heating profile, the reactants did not reach the target temperature and temperature variability between vessels occurred. These challenges led to modifications of the heating profile including an increase in the ramp time (15 min) and a reduction in the temperature (140°C). Uneven heating was still a challenge so the formula was modified by adding a small amount of water (<1% wt/wt) to increase dipole rotation due to the microwave energy. The inclusion of a polar solvent resulted in consistent, even heating. Product resulting from the lower-temperature, longer-time heating profile demonstrated successful polymerization. The elevated pressure in the microwave reaction system, when compared with the open extrusion system, allowed for polymerization at a lower temperature. This benchtop polymerization method allows for experimentation of numerous formulas and the identification of inhibitors. Understanding these factors for permeate or acid whey will allow for polymerization into a value added ingredient, soluble fiber.

Key Words: lactose, polymerization, microwave

0716 Effect of microencapsulated iron salts on cheddar cheese divalent cation balance and composition.

A. Arce* and Z. Ustunol, *Michigan State University, East Lansing*.

Milk is considered an important source of macro- and micronutrients but naturally low in iron content. Cheese and other dairy products had been fortified with iron with low success due to negative changes in composition and organoleptic attributes. There is limited information about using microencapsulation of iron compounds in dairy products. Minerals have the ability to displace one another in any system; consequently, it is expected that encapsulation will avoid divalent cation displacement within the cheese matrix. The objective of this study was to analyze divalent cation balance in fortified cheddar cheese with microencapsulated ferrous sulfate. Furthermore, proximate analysis was done to provide more information about any compositional changes after fortification. Cheddar cheese was manufactured using standard cheddar cheese procedures a total of three times. Cheddar cheese was fortified with either large microencapsulated ferrous sulfate (LMFS; 0.9536 g microencapsulated ferrous sulfate/kg cheese and 700–1,000 μm diameter) or small microencapsulated ferrous sulfate (SMFS; 1.7801 g microencapsulated ferrous sulfate/kg cheese and 220 to 422 μm diameter). Iron treatment was incorporated to cheddar cheese processing in the salting step but omitted for the control. After 90 d of aging, calcium, iron, magnesium, and zinc content were analyzed using atomic absorption spectroscopy and percent recoveries were calculated. Moisture, ash, fat, and protein analysis were done using AOAC methods. All collected data was analyzed using one-way ANOVA and Tukey's HSD test ($P = 0.05$). Iron content for all treatments were significantly different ($P < 0.05$): approximately 0.030 mg Fe/g cheese for the control, 0.134 mg Fe/g cheese for LMFS, and 0.174 mg Fe/g cheese for SMFS. Results showed 81.3% iron recovery for LMFS and 90.0% iron recovery for SMFS. Proximate analysis and magnesium, zinc, and calcium content were not significantly different when comparing fortified cheeses with the control. Overall, microencapsulated ferrous sulfate caused no major changes in terms of cheddar cheese composition and successfully increased iron content. Microencapsulated ferrous sulfate with smaller diameter showed slightly better results for iron retention in cheddar cheese. The proposed fortified cheddar cheese can help increase total iron intake for children, pregnant women, vegetarians, and those whose diets are likely to be deficient in iron by providing at least 5 mg Fe (30% RDA) per serving.

Key Words: fortification, cheese, minerals

0717 Rumen development in Holstein calves.

K. E. Mitchell*, *University of California, Davis, Davis*.

Feed intake in calves is very important for future production and health, but there are many issues that can influence starter intake such as weather, rumen development, and overall calf health. The objectives of this study were to observe the interaction of starter grain intake and rumen development. Data from 122 Holstein bull and heifer calves were collected from age 2 to 69 d, time of exit from hutch including fecal scores (1–3), DMI, medication, and milk intake. Daily starter grain samples were pooled by week and analyzed for nutrient content by Analab (Agriking, Fulton, IL). Blood samples were collected from a subset of 38 calves and analyzed for glucose (mg/dL) and β-hydroxybutyrate (BHBA; mmol/L) levels with Precision Extra (Abbott Diabetes Care, Inc., Alameda, CA) blood meters. At 1, 6, and 9 wk, blood samples were also analyzed using a VetScan Large Animal Profile rotor (Abaxis Inc., Union City, CA). The rotor tested for albumin (ALB), alkaline phosphatase (ALP), aspartate aminotransferase (AST),

calcium (Ca), creatine kinase (CK), γ glutamyl transferase (GGT), phosphorus (P), magnesium (Mg), total protein (TP), and urea nitrogen (BUN). The Abaxis blood parameters indicate immune status and, indirectly, liver function (ALB, Glob, TP, and GGT), liver and bone function (ALP, Ca, P, and Mg), liver and kidney function (AST and BUN) and muscle damage (CK). Weekly outcomes, average DMI, average milk intake, and blood parameters were analyzed using the MIXED procedure of SAS with repeated measured by calf, hutch, and gender as fixed effects and the random variable week. Hutch and gender were not significant but week was significant for all comparisons. Alkaline phosphatase and Ca were all elevated whereas AST, TP, and Glob were lower than expected values. Blood urea nitrogen and CK were within the expected range for adult cows and steadily increased over the experimental period. Total protein ($P < 0.064$), AST ($P < 0.0001$), Glob ($P < 0.0076$), BHBA ($P < 0.0001$), and BUN ($P < 0.013$) increased with increasing DMI. Glucose ($P < 0.0001$), however, decreased with increasing DMI. Increases in these parameters also show changes as the rumen develops. Therefore, starter grain intake is an important factor for rumen development in a Holstein calf.

Key Words: blood parameters, calves, rumen development

0718 Milk fat secretion in lactating dairy cattle is influenced by soybean particle size and fatty acid profile. K. A. Weld* and L. E. Armentano, *University of Wisconsin – Madison, Madison*.

It is well established in the literature that when feeding free vegetable oils, oleic acid has a smaller negative effect on milk fat secretion than does linoleic acid. The objectives of these experiments were to analyze the effects of oleic and linoleic acid fed as part of full fat soybeans and to analyze the interaction between soybean particle size and fatty acid profile. Trial 1 used 63 cows (28 primiparous and 35 multiparous; 111 ± 20 d in milk [DIM]). Cows were housed in a common pen with 32 electronic feed gates and fed conventional or high-oleic (Plenish) whole raw beans for 3 wk following a covariate adjustment period. The second trial used 20 cows (10 primiparous and 10 multiparous; 88 ± 10 DIM) in a tie stall barn, using two complementary 5 × 5 Latin squares per parity. Raw Plenish or conventional beans, either ground (GP and GC) or whole (WP and WC), formed 4 iso-fat diets in a 2 × 2 factorial, plus a fifth treatment was a low-fat diet without soybeans. Diets were 55% forage and isonitrogenous and contained 2.9 to 3.9% added ether extract from soybeans (15.5–18.7% soybeans, DM basis). In trial 1, there was a parity × diet interaction ($P < 0.10$); there were no diet effects with primiparous cows ($P > 0.10$), but for multiparous cows, feeding Plenish beans increased milk fat yield ($P < 0.05$). In trial 2, when there was a significant interaction ($P < 0.10$) between bean type and particle size, we tested GP vs. GC and WP vs. WC. If the interaction was not significant ($P > 0.10$), the main effects of bean type and particle size were tested. There was a significant interaction between bean type and particle size for both milk fat yield and concentration ($P < 0.05$). GP resulted in greater milk fat yield and concentration than GC ($P < 0.05$), whereas there was no difference between WP and WC ($P > 0.10$). Diet affected milk yield with the Plenish diets resulting in lower milk yield ($P < 0.05$). In both trials, the increase in milk fat yield was due to an increase in 18-carbon milk fatty acids ($P < 0.05$) and there was not a difference in short-chain fatty acid yield ($P > 0.10$). Plenish high-oleic soybeans result in moderately increased milk fat compared with conventional soybeans, and this difference is greater when soybeans are fed ground rather than whole.

Key Words: linoleic, oleic, soybeans

Table 0718.

Variable	Trial 1			Trial 2					
	Conventional Multiparous	Plenish Multiparous	SE	Low Fat	Ground Conventional	Ground Plenish	Whole Conventional	Whole Plenish	SE
DMI (kg/d)	26.5	26.8	0.9	26.5	26.3	26.3	26.7	26.6	0.6
Milk (kg/d)	45.1	45.0	1.2	48.0	48.8	47.2	48.5	46.8	1.0

0719 Effects of heat stress and dietary zinc source on mammary tight junction of lactating dairy cows. X. Weng*[1], A. P. A. Monteiro[1], J. Guo[1], J. K. Bernard[1], J. DeFrain[2], and S. Tao[1], *[1]University of Georgia, Tifton, [2]Zinpro Corporation, Eden Prairie, MN*.

Dietary Zn has been shown to alter gut integrity in monogastrics under heat stress. However, the effect of Zn on mammary tight junction (MTJ) integrity in heat-stressed lactating dairy

cows has not been studied. Seventy-two multiparous lactating Holstein cows (2.9 ± 1.1 parity and 99.7 ± 55.5 d in milk) were randomly assigned to 4 treatments with a 2 × 2 factorial arrangement to study the effect of environment and Zn source on performance and MTJ integrity (n = 18/treatment). Treatments included two environments, cooled (CL) or not cooled (NC), and two Zn sources, 75 ppm supplemental Zn as ZnCl (IOZ) or 35 ppm ZnCl + 40 ppm Zn–methionine complex (ZMC). The experiment was divided into baseline and environmental challenge phases, 84 d each. During the baseline phase, all cows were cooled (fans and misters over the freestall and feeding areas; average temperature–humidity index = 73) and fed respective dietary treatments, whereas during the environmental challenge phase, NC cows were not cooled (average temperature–humidity index = 78). Feed intake was measured daily. Milk yield was recorded at each milking (3x/d) and composition was analyzed weekly. Vaginal temperature was measured every 5 min for 4 d/wk. Milk and plasma samples were collected weekly for analyses of milk BSA and plasma lactose. Deprivation of cooling decreased DMI ($P < 0.01$). Energy-corrected milk yield decreased ($P < 0.01$) for NC cows relative to CL cows (24.5 vs. 34.1 kg/d). An interaction between environment and Zn source ($P = 0.04$) occurred for milk fat percent as CL cows fed ZMC had lower milk fat percent relative to other groups. Relative to CL cows, NC cows had lower milk lactose and solids-not-fat percent ($P = 0.05$) but higher concentration of milk urea nitrogen ($P < 0.01$). Vaginal temperature was higher ($P < 0.01$) in NC cows relative to CL cows (39.9 vs. 39.0°C). Plasma lactose was similar between treatments at the start of the baseline phase but increased in cows fed IOZ and was unchanged in cows fed ZMC throughout the baseline phase (Zn source × day, $P = 0.06$). Relative to CL cows, plasma lactose tended to increase in NC cows over time (environment × day, $P = 0.09$), indicating increased MTJ permeability, and feeding ZMC tended to decrease plasma lactose during the environmental challenge phase relative to IOZ ($P = 0.11$). In conclusion, removing active cooling impairs lactation performance and feeding a portion of dietary Zn as ZMC improves the integrity of MTJ as evidenced by the decreased permeability of lactose through MTJ.

Key Words: heat stress, mammary tight junction, zinc

0720 Effects of feeding forage and concentrate, separately or as a total mixed ration, on ruminal methane emission, fermentation characteristics, and total tract digestibility. B. Rajaraman*[1], A. Selvaraj[2], C. H. Lee[2], and K. H. Kim[1,2], *[1]Graduate School of International Agricultural Technology, Seoul National University, Pyeongchang, the Republic of Korea, [2]Green Bio Science and Technology, Seoul National University, Pyeongchang, the Republic of Korea*.

Very little research is available on the advantages of feeding systems, specifically how forage and concentrate feeding, separately (SF) or as a total mixed ration (TMR), affects methane production from enteric fermentation of ruminant. Three experiments were performed at three different levels of daily feed intake (1.8, 2.1, and 2.6% of BW) to investigate methane production from the different feeding systems by using a quadruplicated 2 × 2 crossover design. Each experiment was conducted using eight male Holsteins with BW ranging from 230 to 570 kg. Animals were provided either SF or TMR containing 73% concentrate and 27% forage, with the same ratio of same ingredients and grasses, twice a day. Animals fed SF received the forage first for 30 to 40 min and then received the concentrate. In experiment 2, the ruminal fermentation characteristics (1.5, 3.0, and 4.5 h after morning feeding) and indirect total tract digestibilities were evaluated based on rumen fluid and fecal grab samples, respectively. Animals fed TMR in experiment 1 and 2 emitted significantly more methane (169.9 vs. 140.1 ± 6.9 L/d [$P < 0.05$] and 138.4 vs. 114.19 ± 4.2 L/d [$P < 0.01$], respectively) and lost more methane energy (7.1 vs. 5.6 ± 0.4% [$P = 0.01$] and 4.0 vs. 3.4 ± 0.2% [$P < 0.01$], respectively) compared with those fed SF. No differences ($P > 0.1$) were observed in methane emissions and methane energy losses for animals fed diets at 2.6% of BW in experiment 3, although those fed TMR emitted slightly more methane than those fed SF. Cattle that received SF exhibited significantly lower ($P < 0.05$) ruminal pH and higher ($P < 0.05$) ammonia N concentration, total VFA, and individual VFA production compared with those fed a TMR at 4.5 h after feeding. A significantly ($P < 0.05$) lower acetate:propionate ratio (2.2 vs. 2.6) in those fed SF reflected the shift in hydrogen transfer toward the formation of more propionate than in those fed TMR. Significantly higher levels of isobutyrate and isovalerate ($P < 0.05$) were observed in those fed SF compared with those fed TMR. The total tract digestibilities of CP, NDF, and OM were not affected by the feeding system. Overall, these results indicate that, compared with TMR, SF significantly reduces methane emission from ruminants and increases VFA production without affecting the total tract digestion.

Key Words: methane, rumen, separate feeding

0721 The effect of dietary fats on fatty acid composition, gene expression, and vitamins status in preruminant calves. C. Y. Tsai*, W. I. Loucks, C. M. Scholte, K. C. Ramsey, M. E. Doumit, and P. Rezamand, *University of Idaho, Moscow*.

Dietary saturated (SFA) and unsaturated fat (UFA) alters fatty acid composition of various tissues, serum, and lipid-soluble vitamins. The objective was to examine the effect of dietary SFA and UFA on adipose, liver, serum, polymorphonuclear (PMN) and peripheral blood mononuclear cells' (PBMC) fatty acid profiles, selected gene expression of inflammatory mediators, and their relation with vitamin content in preruminant calves. Twelve Holstein male calves were randomly assigned to two treatments. Starting at 3 d of age, 6 calves on SFA received 120 mL palm oil/d and 6 calves on UFA received 80 mL flaxseed oil plus 40 mL CLA. After 50 d, all animals were euthanized and samples were obtained. Gas chromatography was used to analyze fatty acid composition. High-performance liquid chromatography was used to analyze α-tocopherol and retinol in liver tissues as well as α-tocopherol, retinol, and β-carotene in serum. Liver and adipose tissue were analyzed for relative gene expression of interleukin (IL)-1β, IL-6, IL-8, IL-10, IL-12, interferon-γ, peroxisome proliferator-activated receptor-γ, TNF-α, retinol binding protein-4, and NF-κB. The PBMC were examined for gene expression of IL-1β, IL-6, TNF-α, and intercellular adhesion molecule-1; PMN were analyzed for expression of caspase-1, IL-8 receptor, and L-selectin (L-SEL). Data were analyzed using the PROC TTEST of SAS with significance declared at $P \leq 0.05$. The UFA had greater α-linolenic acid (α-LA) compared with SFA calves in (NEFA, neutral lipids [NL], and phospholipids [PL]) fractions of liver, adipose, and serum as well as PBMC and PMN. The higher content of α-LA in calves fed UFA resulted in greater EPA in all three lipid fractions of serum as well as NL and PL fractions of adipose tissue. In addition, PBMC and PMN had higher EPA in UFA calves. The UFA group, however, had lower γ-linolenic acid compared with SFA calves in all three fractions of liver as well as NL and PL fractions of serum. Dietary UFA also increased total PUFA in three lipid fractions of serum and adipose. The lipid-soluble vitamins content in serum was reduced by dietary UFA. Moreover, L-SEL expression was upregulated in calves receiving UFA. This may indicate that UFA supplementation elevated the substrate of PUFA biosynthesis but possibly degraded the lipid soluble vitamins to protect these fatty acids from oxidation. This may influence the migration of PMN from the blood to tissues, affecting overall inflammatory responses.

Key Words: calves, fatty acid composition, gene expression

0722 Effect of OmniGen-AF and heat stress during the dry period on subsequent performance of cows. T. F. Fabris*[1], J. Laporta[1], F. N. Correa[1], Y. M. Torres[1], D. J. Kirk[2], D. J. McLean[2], J. D. Chapman[2], and G. E. Dahl[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]Phibro Animal Health Corp., Quincy, IL*.

Heat stress in dairy cows during the dry period impairs milk production in the next lactation. Feeding OmniGen-AF (OG) to lactating cows during heat stress increases DMI and lowers respiration rate (RR) and rectal temperature (RT), but effects in dry cows are not known. We hypothesized that OG supplementation before, during, and after the dry period (approximately 160 d) would overcome the effects of heat stress and improve performance. Treatment groups were heat stress (HT; only shade; $n = 17$), heat stress with OmniGen-AF (HTOG; 56 g/d; $n = 19$), cooling (CL; shade, fans, and sprinklers; $n = 16$), and cooling with OmniGen-AF (CLOG; $n = 11$). Cows were randomly assigned to treatments based on previous mature equivalent milk production. Cows were dried off 45 d before expected calving and after parturition; cows were kept under the same cooling system and management until 60 DIM. Cooling cows during the dry period reduced RT (38.8 vs. 39.0 for CL vs. HT, respectively; $P < 0.01$) and RR (44 vs. 73 for CL vs. HT, respectively; $P < 0.01$). Respiration rate was also decreased by OG supplementation (56 vs. 61 for OG vs. non-OG, respectively; $P < 0.01$). There was an interaction between OG supplementation and HT ($P < 0.1$); HTOG cows had lower RT compared with HT cows. During the dry period, OG reduced DMI relative to non-OG cows ($P < 0.1$). Calf birth weight was greater in calves from CL cows (CL vs. HT; $P < 0.01$). In cows, no differences in hematocrit, total protein, and BCS among treatments were detected. Cows on CLOG had higher BW (kg) at parturition (CLOG, 794.9 kg; CL, 746.8 kg; HTOG, 762.9 kg; and HT, 720 kg). Gestation length was approximately 4 d longer for CL cows compared with HT cows ($P < 0.01$). Cows on CLOG, CL, and HTOG treatments produced more milk (5.2 ± 1.9, 4.8 ± 1.6, and 4.6 ± 1.4 kg/d, respectively) than HT cows (35.9 ± 1.5 kg/d). Body weight after parturition and DMI were evaluated up to 60 DIM and averaged DMI 19.4 ± 0.7 kg/d, with no differences observed among treatments. These results confirm that exposure of dry cows to heat stress negatively impacts milk production in the subsequent lactation. Active cooling of dry cows and OG supplementation can reduce the negative effects of heat stress in the dry period.

Key Words: cooling systems, heat stress, OmniGen-AF

0723 Feed efficiency is associated with reproductive performance in dairy cows. E. M. Bart*[1], M. D. Hanigan[2], D. M. Spurlock[3], M. J. VandeHaar[4], and R. R. Cockrum[1], *[1]Virginia Polytechnic Institute and State University, Blacksburg, [2]Virginia Tech, Blacksburg, [3]Iowa State University, Ames, [4]Michigan State University, East Lansing*.

For residual feed intake (RFI) to be used as an alternative measure of feed efficiency in the dairy industry, it must not be unfavorably correlated with fertility. Previous research in beef cattle, sheep, and pigs suggests that reproduction is impacted by RFI status. Therefore, the objective of this study was to determine the phenotypic relationship between RFI and reproductive performance in dairy cows. Feed, milk, and health data were collected on 1,513 Holstein cows in various stages of production at Virginia Tech and Iowa State University for 84 d. Daily measurements of DMI, milk yield, weekly milk composition, and monthly BW were used to calculate RFI. Cows with lower RFI were identified as more feed efficient. Four measures of reproductive performance were examined: number of services (NS; n = 1,037), previous days dry (DD; n = 760), days open (DO; n = 716), and days to first calving (DFC; n = 472). Correlation and ANOVA analyses with ad hoc comparisons using a Tukey adjustment were performed in R. For the ANOVA, cows were categorized into top 5% (high RFI; n = 50), middle 5% (medium RFI; n = 50), and bottom 5% (low RFI; n = 50). Correlations were calculated between reproductive measures and RFI. There was a weak positive phenotypic correlation (r_p = 0.18 ± 0.04, P < 0.01) between NS and DO with RFI, suggesting that feed-efficient cows may require fewer services to become pregnant and shorter periods to become bred. There was also a weak negative phenotypic correlation (r_p = −0.14 ± 0.04, P < 0.01) between DFC and RFI, suggesting increased days for feed-efficient cows to produce their first calf. Medium-RFI cows had greater DD (P = 0.046; 109.5 ± 13.9) compared with high-RFI cows (63.3 ± 11.7), but neither differed ($P \geq 0.12$) from low-RFI cows. High-RFI cows had increased NS (P = 0.016; 4.80 ± 0.54 services) compared with low-RFI cows (3.05 ± 0.33 services), but neither differed ($P \geq 0.14$) from medium-RFI cows. Low-RFI cows had lower DO ($P \leq 0.05$; 83.61 ± 10.4 d) than both medium- (126.0 ± 14.3 d) and high-RFI cows (115.9 ± 10.4 d). Therefore, feed-efficient cows had decreased NS and DO. Overall, results suggested that selection for RFI will not unfavorably impact reproduction in dairy cows.

Key Words: feed efficiency, reproductive performance, residual feed intake

0724 Use of 1,25(OH)2 vitamin D_3 to maintain postpartum blood calcium and improve immune function in dairy cows. A. Vieira Neto*, I. A. Peixoto, F. R. Lopes Jr., R. Zimpel, C. Lopera, L. D. P. Sinedino, K. N. Galvão, C. D. Nelson, and J. E. P. Santos, *University of Florida, Gainesville*.

Objectives were to determine the effects of a slow-release injectable formulation of 1,25-dihydroxyvitamin D_3 (calcitriol) on mineral metabolism and measures of immune function in recently calved Holstein cows. Cows were blocked by parity (2 vs. >2) and calving sequence and, within each block, randomly assigned to subcutaneously receive 300 µg of calcitriol (DHVD; n = 25) or vehicle (CON; n = 25) within 6 h of calving. Blood and urine were sampled before treatment application, 12 h later, and on d 1, 2, 3, 5, 7, 9, 12, and 15 postpartum. Samples were analyzed for total (tCa) and ionized Ca (iCa), magnesium (Mg), phosphorus (P), calcitriol, NEFA, β-hydroxybutyrate (BHBA), glucose, serotonin (5-HT) and crosslaps (CTX-1). Neutrophil function was evaluated in the first week postpartum. Intake of DM and production performance was evaluated for the first 42 d postpartum. Data were analyzed by ANOVA with mixed models using the MIXED procedure of SAS. DHVD increased (P < 0.01) concentrations of calcitriol within 4 h of application from 24 to 420 pg/mL, which returned to baseline within 3 d. Blood iCa and tCa took 12 and 24 h, respectively, to increase after treatment with vitamin D compared with CON. Concentrations of iCa (CON = 1.05 vs. DHVD = 1.18 mM), tCa (CON = 2.11 vs. DHVD = 2.35 mM), and P (CON = 1.51 vs. DHVD = 2.06 mM) remained elevated (P < 0.01) in DHVD until 3, 5, and 7 d postpartum, respectively. Concentration of Mg (CON = 0.76 vs. DHVD = 0.67 mM) was less (P < 0.01) in DHVD cows until 5 d postpartum. DHVD cows excreted more urinary Ca (CON = 0.6 vs. DHVD = 1.7 g/d; P < 0.01) and Mg (CON = 3.6 vs. DHVD = 5.5 g/d; P = 0.02) in the first 5 and 1 d postpartum, respectively. Concentrations of glucose, NEFA, BHBA, 5-HT, and CTX-1 in plasma did not differ between treatments. DHVD improved neutrophil function compared with CON. Relative to a reference cow, the percentage of neutrophils with oxidative burst activity (CON = 80.0 vs. DHVD = 101.0%; P = 0.03), the mean fluorescence intensity (MFI) for oxidative burst (CON = 96.0 vs. DHVD = 105.0%; P = 0.09), and the MFI for phagocytosis (CON = 94.0 vs. DHVD = 110.0%; P = 0.03) were all greater for DHVD than CON cows. Intake of DM and yields of milk and milk components did not differ between treatments. Administration of 300 µg of calcitriol at calving was safe and effective in increasing plasma concentrations of calcitriol, iCa, tCa, and P for the first few days after treatment and improved measures of innate immune function in early lactation Holstein cows.

Key Words: calcitriol, hypocalcemia, transition period

0725 Effect of 2,4-thiazolidinedione treatment in the inflammatory response to induced subclinical mastitis in dairy goats receiving adequate vitamin supplementation. F. Rosa*[1], M. Moridi[2], J. S. Osorio[1], J. Lohakare[1], S. Filley[1], J. L. Belveal[1], J. J. Bruton[1], E. Trevisi[3], C. Estill[1], and M. Bionaz[1], *[1]Department of Animal and Rangeland Sciences, Oregon State University, Corvallis, [2]University of Guilan, Rasht, Iran (Islamic Republic of), [3]Università Cattolica del Sacro Cuore, Piacenza, Italy*.

Mastitis is one of the most costly diseases for the dairy industry. A prior experiment in our laboratory indicated a positive role of 2,4-thiazolidinedione (TZD), a peroxisome proliferator-activated receptor γ (PPARγ) agonist, on the inflammatory response after induced subclinical mastitis in dairy goats fed hay without supplements. Despite this, lack of effect on expression of targets genes in adipose tissue and mammary cells and in vitro data suggested the possibility that TZD did not activate PPARg due to an insufficient activation of its obligate heterodimer nuclear receptor RXR by 9-*cis*-retinoic, a metabolite of vitamin A. This study investigated the hypothesis that continuous activation of PPARγ by TZD in goats supplemented with adequate amount of vitamin A can improve inflammatory response to subclinical mastitis in lactating dairy goats. To test this, 12 Saanen multiparous goats in mid lactation received a diet that met NRC requirements, including vitamin A. Does received a daily intrajugular injection of either TZD (n = 6) or saline (CTRL; n = 6). Following 14 d of treatments, all goats received an intramammary infusion (IMI) of *Streptococcus uberis* to induce subclinical mastitis in the right half with the left half used as control. Metabolic, inflammation, and oxidative-status profiling in blood including 19 parameters was performed. Milk yield and SCC and rectal temperature were assessed. Data were analyzed by GLIMMIX of SAS with treatment (TRT) and time and TRT × time interaction as main effects and goat as random effect. For milk and SCC, mammary half was also included in the main effect (including interactions). Significance was declared at Tukey's corrected $P < 0.05$. Milk yield and SCC were not affected by TZD administration. However, the udder receiving IMI had greater SCC. In blood within 2 d from IMI, ceruloplasmin, haptoglobin, and glucose were increased whereas Zn was decreased. At 3 d after IMI, AST/GOT, gGT, and bilirubin decreased, whereas by 6 to 11 d after IMI, urea, protein, albumin, globulin, NEFA, and creatinine increased. All these data confirmed successful induction of subclinical mastitis. There was a tendency for TZD to have a higher globulin and lower BHBA compared with CTRL and a tendency for a higher increase in haptoglobin after IMI (TRT × time, $P = 0.06$) with a quick recovery, indicating a stronger response of the liver to inflammation. No other parameters measured were affected by TZD treatment. Our findings indicate that addition of TZD has mild effect on inflammatory response in animals receiving adequate amount of vitamin A.

Key Words: immune response, mastitis, 2,4-thiazolidinedione

0726 Effect of increasing milk feeding frequency of an elevated plane of nutrition on glucose and insulin kinetics in male Holstein calves both before and after weaning. J. A. R. MacPherson*[1], J. Haisan[1], S. J. Meale[2], S. I. Pletts[1], and M. Steele[1], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]UMR Herbivores, INRA, Vetagro Sup, Saint-Genès-Champanelle, France*.

The objective of this study was to investigate how feeding elevated levels of milk replacer before weaning, at different feeding frequencies, could influence glucose and insulin kinetics both before and after weaning. Ten male Holstein calves (42.2 kg ± 1.8 birth weight) were randomly assigned to 2 treatments whereby calves were offered 8 L of milk replacer (150 g/L; 26% CP and 18% CF) per day in two (2x) or four feedings (4x) via an automated feeding system. Calves were gradually stepped down by 1 L/d from wk 7 until weaning on wk 8 (0 L). Postprandial blood samples were collected on wk 4 and 7 via jugular catheters during the 1000-h meal every 30 min up to 240 min after feeding. A glucose tolerance test was conducted on wk 4, 7, and 10 via the jugular catheter the day following the postprandial measurements, with 540 mg glucose/kg $BW^{0.75}$ infused after a 12-h feed restriction. Statistics were determined using SAS PROC MIXED and any data not normally distributed was logarithmically transformed. Postprandial glucose area under the curve over 240 min (AUC_{240}) tended ($P = 0.06$) to differ between treatments overall (2x: 383.51 ± 60.08 mmol/L; 4x: 246.68 ± 64.2 mmol/L) but both treatments were able to adequately control glycemia. Postprandial insulin AUC_{240} differed ($P = 0.01$) by treatment with 2x calves (13,808 ± 3,136 μU/mL) having higher insulin concentrations compared with 4x calves (4,716 ± 3,250 μU/mL), and both treatments demonstrated a decrease in insulin AUC_{240} ($P < 0.01$) with increasing age (wk 4: 14,287 ± 2,818 μU/mL; wk 7: 4,237 ± 2,686 μU/mL), which can most likely be attributed to meal size relative to calf BW. Additionally, there was no effect observed for any of the measurements (time to maximum concentration, maximum concentration, AUC_{240}, basal concentration, or change in concentration) for the glucose tolerance test between treatments or across ages, suggesting that feeding frequency in this study had no effect on insulin sensitivity. These findings suggest that feeding 8 L/d at a frequency of 2x or 4x are both viable feeding methods that do not compromise insulin sensitivity.

Key Words: calf, feeding frequency, insulin sensitivity

0727 Repeatability of residual feed intake across dietary forage concentration. M. J. Carrasquillo-Mangual*, E. Liu, and M. J. VandeHaar, *Michigan State University, East Lansing*.

Residual feed intake (RFI) has received considerable attention as a possible breeding goal in the near future. For RFI to be useful as a breeding goal, it should be repeatable for cows under different types of diets. Our objective for this study was to determine the repeatability of RFI across two levels of dietary forage NDF. Holstein cows in mid lactation were studied in winter (n = 32) and summer (n = 32). The study followed a crossover design with 2 treatment periods of 31 (winter) and 28 d (summer). Cows were milked twice daily and fed treatment diets once daily. Treatments were a high-forage–low-starch diet (HF; 36% NDF and 19% starch) and a low-forage–high-starch diet (LF; 26% NDF and 32% starch). Forage composed 70% of the DM in the HF and 47% in the LF. Dry matter intake and milk yield were recorded daily. Body weight was measured 3x weekly and milk composition was measured for 4 consecutive milkings each week. Body condition score was measured at the beginning and end of each experimental period. Statistical analysis was performed using the GLM procedure (SAS 9.4). An RFI value was obtained for each cow under each treatment; cows were ranked using SD of the RFI value as HRFI (greater than +0.5 SD), MRFI (±0.5 SD) or LRFI (less than −0.5 SD). A group rank was established for all cows under each treatment diet. The HF decreased DMI by 2.5 kg/d and milk yield by 3 kg/d when compared with the LF. Body weight changed by 0.4 kg/d on the LF but 0.2 kg/d on the HF. Fat yield, BW, and BCS were not altered by treatments. The decrease in DMI as well as the difference in energetic density of the diet could explain the differences observed in production performance as there was no significant difference in energy partitioned toward milk production. The RFI ranking was relatively repeatable (r = 0.44). Of all animals, 48% maintained their group ranking across treatments whereas 47% changed ranking by 1 group. Only 5% moved in the ranking from the HRFI to the LRFI group or vice versa. In conclusion, although intake, production, and energy partitioning were significantly altered by dietary treatments, RFI was relatively repeatable across these diets. Therefore, genomic breeding values of RFI estimated from cows fed a high-starch diet should still be useful when animals are fed more forage and less starch.

Key Words: dairy cow, residual feed intake

ADSA PRODUCTION DIVISION GRADUATE STUDENT ORAL COMPETITION: PHD

0728 Effects of supplementing rumen-protected methionine on lactational performance of Holstein dairy cows during early and mid lactation. M. A. Fagundes*[1], S. A. Blaser[2], S. Y. Yang[2], J. S. Eun[1,2], and J. O. Moon[3], *[1]School of Veterinary Medicine, Utah State University, Logan, [2]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [3]CJ CheilJedang Research Institute of Biotechnology, Suwon, the Republic of Korea*.

Supplementing rumen-protected methionine (RPMet) has been shown to maintain milk and milk protein yields when dietary MP is decreased by 5% due to its direct impacts on milk protein synthesis in the mammary gland. The present study investigated production responses of lactating dairy cows to RPMet supplementation in suboptimal protein (SOPD; 15.5% CP) and normal protein diet (NPD; 16.5% CP). Eight lactating dairy cows (53 d in milk, on average) were blocked by parity and days in milk, and the experiment was performed in a duplicate 4 × 4 Latin square design. Within each square, cows were randomly assigned to a sequence of 4 diets during each of the four 21-d periods (14 d of treatment adaptation and 7 d of data collection and sampling). A 2 × 2 factorial arrangement was used; SOPD or NPD was combined without or with RPMet: SOPD without RPMet, SOPD with RPMet (S+Met), NPD without RPMet, and NPD with RPMet (N+Met). An experimental RPMet product from CJ CheilJedang (Suwon, the Republic of Korea) was supplemented in the S+Met and the N+Met at 30 g/cow per day. Supplementation of RPMet did not affect DMI (25.4 kg/d) and milk yield (40.6 kg/d). Supplementing RPMet resulted in a similar milk true protein concentration (2.80%) with a numerical increase in milk protein yield at 3.6%. In contrast, supplementing RPMet increased milk fat concentration (P = 0.02) and yield (P = 0.03) and 3.5% fat-corrected milk (FCM) yield (P = 0.05) and tended to increase energy-corrected milk (ECM) yield (P = 0.06) regardless of CP level. In addition, trends were observed for increased 3.5% FCM yield/DMI (P = 0.09) and ECM yield/DMI (P = 0.10), and the positive effects were greater under NPD than SOPD, resulting in trends toward interaction between CP and RPMet (P = 0.06). Overall results in the current study suggest that supplementing RPMet in SOPD and NPD improved milk fat concentration, possibly due to increases in apolipoprotein and phospholipid syntheses in the liver, leading to an increase in fatty acid supply to the mammary gland via very-low-density lipoproteins.

Key Words: feed efficiency, lactational performance, rumen-protected methionine

0729 Effect of dextrose and purified starch at two levels of rumen degradable protein on lactation performance and enteric methane emission in dairy cows. F. Sun*, M. J. Aguerre, and M. A. Wattiaux, *University of Wisconsin-Madison, Madison*.

The objective of this study was to evaluate the effect of source of nonfiber carbohydrate (NFC) at two levels of rumen degradable protein (RDP) in the diet on lactation performance and enteric methane (CH_4) emission. In addition, hourly CH_4 emission rate relative to time of feeding was studied. Eighteen Holstein cows (mean ± SD; 148 ± 10 d in milk and 644 ± 41 kg BW) housed in a tie-stall barn were used in a split plot study. Cows were randomly assigned to either (DM basis) 11 (11-RDP) or 9% RDP (9-RDP) diets as whole plot. To lower diet RDP, soybean meal was partially replaced with expeller soybean meal and blood meal. Subplot treatments, which were allocated in three 3 × 3 Latin squares (28-d period) were (DM basis) 10% dextrose (DX), 5% dextrose and 5% purified starch (DX-ST), and 10% purified starch (ST). Cows were fed a total mixed ration with 61% forage and 39% concentrate, with approximately 16.5% CP and 45.5% NFC, once daily and milked twice daily. During wk 3 of each period, enteric CH_4 emission was measured at 1, 2.5, 4, 5.5, 10, 11.5, 13, 14.5, 16, 17.5, and 22.5 h after feeding, over a 4-d interval with GreenFeed (C-lock Inc., SD). The SAS mixed procedure with Tukey option was used to analyze the data. There was no NFC × RDP interaction ($P > 0.05$), and therefore, main effects are presented in table below. Cows fed 9-RDP had greater yield of fat–protein corrected milk (FPCM), milk (37.4 vs. 34.8 kg/d), milk fat (1.57 vs. 1.44 kg/d), and lactose (1.80 vs. 1.63 kg/d) compared with cows fed 11-RDP. Cows fed ST had lower DMI, greater feed efficiency (FPCM/DMI), and lower enteric CH_4 emission than cows fed DX and DX-ST. The hourly CH_4 emission rate was lower for the 22.5-h sampling time compared with all others (15.9 ± 2.8 vs. 20.1 ± 4.9 g/h). Dietary treatments did not influence CH_4/DMI (20.0 ± 3.5 g/kg) or CH_4/FPCM (13.1 ± 2.6 g/kg). In conclusion, the level of RDP did not influence the responses to the source of NFC in the diet. Compared with dextrose as a source of NFC, starch reduced DMI, increased feed efficiency, and reduced daily CH_4 emission.

Key Words: feed efficiency, greenhouse gas, nonfiber carbohydrate

0730 Influence of mixed cropping of corn and soybean with different seeding rates on forage yield, quality, and nutrient yield grown under organic condition. I. P. Acharya*[1], X. Gu[2], and D. P. Casper[1], *[1]Dairy Science Department, South Dakota State University, Brookings, [2]Deparment of Plant Science, South Dakota State University, Brookings*.

A field plot study was laid out using a randomized complete block design with three replicates to evaluate two organic corn hybrids (MC 5300 [N] and MasterGraze [MG]) with two soybeans (Viking 2265 [R] and Vining [V]) at four seeding rates (R1 = 65:35, R2 = 55:45, R3 = 45:55, and R4 = 35:65 of corn:soybean) in terms of forage yield, nutrient yields, and quality. Forage was hand harvested 101 (MG corn with both soybeans) and 116 d (N corn with both soybeans) after planting during 2015 season, inoculated, packed into buckets, weighed, and ensiled for 90 d. Buckets were then reweighed and opened and forage samples were collected and analyzed for nutrient composition. The main effect of corn for DM yield (DMY) was greater ($P < 0.05$) for N compared with MG (27.73 and 19.90 T/ha for N and MG, respectively), whereas the main effect of soybean for DMY was similar ($P > 0.05$; 23.77 and 23.86 T/ha for R and V, respectively). Main effect of seeding rate on DMY was higher ($P < 0.05$) for R1 and R2 compared with R3 and R4 (25.38, 24.48, 21.81, and 23.59 T/ha for R1, R2, R3, and R4, respectively). Yields of digestible DM (DDM; 19.55 and 13.67 T/ha) and CP (2.40 and 2.12 T/ha) were greater ($P < 0.05$) for N corn compared with MG corn, similar ($P > 0.05$) for both soybean (DDM: 16.65 and 16.57 T/ha and CP: 2.33 and 2.19 T/ha for R and V, respectively) and higher ($P < 0.05$) DDM for R1 and R2 compared with R3 and R4 (17.70, 17.08,15.13, and 16.54 T/ha for R1, R2, R3, and R4, respectively). Yield of starch (7.78 and 2.45 T/ha for N and MG) and 30-h NDF digestibility (NDFD30; 44.47 and 52.49% for N and MG) for main effect of corn were different ($P < 0.05$), whereas they were similar ($P > 0.05$) for the main effect of soybean (starch yield: 5.25 and 4.98 T/ha and NDFD30: 48.58 and 48.38% for R and V, respectively). The combination of N corn with either R or V soybean at the ratio of R1 or R2 resulted in the greatest yield of DM, DDM, and starch. A forage blend produced through mixed cropping of corn and soybeans holds a great potential for increasing the forage and nutrient yields to meet the nutrient requirements of lactating dairy cows.

Key Words: corn, forage, soybean

0731 Association between circulating progesterone during the luteal phase and estrous activity detected by automated activity monitoring in dairy cattle. J. Denis-Robichaud*[1], S. J. LeBlanc[1], A. Jones-Bitton[1], and R. L. A. Cerri[2], *[1]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, [2]Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada*.

The objective of this study was to evaluate the association between circulating progesterone (P4) concentration during the luteal phase (LP) and estrous activity detected by automated activity monitoring. The hypothesis was that a shortened LP would decrease the intensity of estrus expression. A total of 48 cows at the UBC Dairy Center were assigned to one of two treatments: a short (n = 23) or a normal P4 (n = 25) LP. The short LP was achieved by injecting 25 mg of prostaglandin F2α at d 7 of the cycle; normal LP cows were not treated. Ultrasound of the reproductive tract was performed at Day 0, 2, 5, 7, 9, and 11 of the cycle and then daily until ovulation to identify and measure the dominant follicle. Blood samples were taken on the same days to measure serum P4. Cows were equipped with two activity monitoring devices: Heatime HR System (SCR, Israel) and SmartDairy (BouMatic, United States). The peak activity score (Heatime), peak of relative activity (%; SmartDairy) and duration of the estrus (both systems) following the LP were recorded. Linear regression models were used to calculate marginal means (least squares means ± SEM). As expected, P4 at d 14 of the cycle differed between the short and normal LP (2.9 ± 0.4 vs. 7.6 ± 0.4 ng/mL, respectively; $P < 0.01$). The number of estrus events detected was not different between treatment groups for Heatime (short: n = 15; normal: n = 20; P = 0.25) or for SmartDairy (short: n = 15; normal: n = 16; P = 0.93). Using the Heatime system, the peak activity score differed between the short and normal LP groups (73.3 ± 4.0 vs. 84.3 ± 3.5; P = 0.05) and the duration of estrus tended to differ (10.8 ± 1.0 vs. 13.1 ± 0.9 h; P = 0.09). Using the SmartDairy system, neither the peak activity (434 ± 39 vs. 465 ± 38%; P = 0.57) nor the duration of estrus (8.0 ± 1.2 vs. 10.0 ± 1.2 h; P = 0.25) differed. There was no difference in serum P4 concentration (0.89 ± 0.14 vs. 0.95 ± 0.13 ng/mL; P = 0.75) or in ovulatory follicle size (18.7 ± 1.4 vs. 18.1 ± 1.4 mm; P = 0.78) on the day of estrus. The number of cows that ovulated was not different between short and normal LP groups (short: n = 14; normal: n = 18; P = 0.41). The shortened LP moderately reduced the intensity of estrus expression but did not affect ovulatory follicle size or ovulation. Decreased LP duration or peak circulating concentration of P4 may reduce the intensity of estrus-related activity.

Key Words: automated activity monitoring system, estrus detection, luteal phase

0732 Effect of prepartum physical activity on behavior and immune competence of dairy cows. R. A. Black*, G. M. Pighetti, and P. D. Krawczel, *University of Tennessee, Knoxville*.

The objective was to determine the effect of prepartum exercise, pasture turnout, or total confinement on activity and immune competence of dairy cows. Sixty pregnant, nonlactating cows were assigned to control (19 Holstein and 1 Jersey × Holstein), exercise (19 Holstein and 1 Jersey × Holstein), or pasture (20 Holstein) treatments using rolling enrollment from Jan. to Nov. 2015 at dry-off. Cows were balanced by parity (1.8 ± 0.9), projected ME fat-corrected milk yield (13,831 ± 2,028 kg/lactation), and projected due date. Cows were housed in a naturally ventilated, 4-row deep-bedded sand freestall barn at the University of Tennessee's Research Unit (Walland, TN). Cows were moved to a maternity pen with a rubber mattress to calve. Fitted 3 d before dry-off, accelerometers determined lying time (h/d), lying bouts (number/d), lying bout duration (min/bout), and steps (number/d) at 1-min intervals. Data were averaged by four periods relative to actual calving date: −58 to −15 d (FO), −14 to −1 d (CU), d 0 (CA), and 1 to 14 d (PP). Exercise was done on five consecutive days per week for 1.4 ± 0.1 h/d (targeted 1.5 h/d), at a pace of 1.88 ± 0.58 km/h. Pasture turnout occurred on a grassy paddock five consecutive days per week for 1.8 ± 0.3 h/d (targeted 1.5 h/d). Control cows remained in the home pen throughout the dry period. Blood was sampled on d −3 and 42, relative to dry-off, to assess immune competence via ROS generation using PMA. A mixed model determined the effects of treatment, period, and treatment × period on daily lying behavior and steps and the effect of treatment, day, PMA level, and their interactions on ROS generation. Cow within treatment was the random variable. Exercise cows lay down less frequently at CA (11.6 ± 1.0 bouts/d) compared with control cows (14.6 ± 0.9 bouts/d; P = 0.03). However, lying bout duration and lying time did not differ among treatments at CA ($P > 0.31$). Exercise cows were more active at FO, CU, and CA (2,895.4 ± 107.6, 2,614 ± 125.2, and 2,824.6 ± 224.4 steps/d, respectively) than control (1,788.8 ± 103.9, 1,840.8 ± 120.7, and 1,969.3 ± 216.2 steps/d) and pasture (2,132.0 ± 103.6, 1,951.6 ± 120.9, and 2.234.9 ± 216.3 steps/d; $P < 0.01$). ROS production was not affected (P = 0.63). Exercised cows took more steps but had fewer lying bouts around calving, suggesting more comfort during calving. Furthermore, physical activity did not alter immune competence. Prepartum exercise may be a viable management strategy to improve calving performance.

Key Words: dairy cow, immune competence, physical activity

0733 Associations between preventive hoof trimming, activity, and resting behaviors. G. Stoddard*[1] and G. Cramer[2], *[1]University of Minnesota Twin-Cities, Saint Paul, [2]Department of Veterinary Population Medicine, College of Veterinary Medicine, University of Minnesota, St. Paul*.

Hoof trimming is a commonly recommend practice to prevent lameness, one of the dairy industry's biggest animal well-being and economic issues. Unfortunately, limited scientific data exists to support our current hoof trimming (HT) practices and what affects HT has on cow behavior. The objective of this research is to determine the association between HT of non-lame cows and activity and resting behaviors. A convenience sample of farms from the United Kingdom and Canada were recruited to participate. Selection criteria required that farms used free-stall housing, have a regular hoof trimming schedule, and use either Afi PedoPlus or AfiACT2 (Afimilk, Ltd.) pedometers. Activity, milk yield, resting time, and resting bout information was collected daily at the time of milking. Hoof trimming data was collected from on farm records. The association between activity, resting behaviors, and HT was evaluated by comparing the averages of the behavior parameter at different time points before and after HT. Time periods evaluated included 1 to 10 d before HT; day of HT; and 2 to 3, 4 to 7, and 8 to 10 d after HT. Models were created using linear regression with behavior as the outcome variable and including the fixed effects of farm, lactation number, milk yield, and days in milk. Time period was forced into each model and a robust SE was used to account for repeated measures. A total of 1,393 cows were used in the analysis with average days in milk, lactation, and milk yield being 182, 1.9, and 33.6 kg/d, respectively. Activity and resting bouts were associated with every time period except for on the day after HT. Resting time was positively associated with all time periods after HT. Resting time increased from 21 to 27 min/d between 1 and 10 d after HT. Activity between 2 and 10 d after HT decreased by a minimum of 20 steps/h and reached a maximum decrease of 27 steps/h. Resting bouts increased from 0.2 to 0.4 bouts between 2 and 10 d after HT. These results show that the HT process is associated with changes in activity, resting time, and resting bouts of the cow during the 10 d following HT. This indicates that there is an adjustment phase either due to the actual HT or due to the disruption of the cow's daily routine during the HT process.

Key Words: activity, hoof trimming, rest

0734 Enhanced preweaning nutrition increases mammary gland development without negatively affecting tissue composition in Holstein heifer calves. A. J. Geiger*[1], R. M. Akers[1], and C. L. M. Parsons[2], *[1]Virginia Tech, Blacksburg, [2]Virginia Polytechnic Institute and State University, Blacksburg*.

We have reported that enhanced feeding of prepubertal Holstein heifer calves increased mass of mammary parenchyma (PAR; 7.9x) and mammary fat pad (MFP; 5.3x). Our objective was to measure fat, protein, and DNA content of PAR and MFP in restricted- and enhanced-fed calves with or without estrogen. For 8 wk, 36 Holstein heifer calves received 1) a control milk replacer (MR) fed at 454 g powder/d (R; 20% CP and 20% fat) or 2) an enhanced MR fed at 1,135 g powder/d (E; 28% CP and 25% fat). At weaning a subset of calves were sacrificed (n = 6/diet). Remaining calves received E_2 implants and were sacrificed at wk 10. Treatments were 1) R, 2) R + E_2 (R-E2), 3) E, and 4) E + E_2 (E-E2). At sacrifice, udder haves were removed and snap frozen. Dissected MFP and PAR were analyzed for fat, protein, and DNA (Daniels et al., 2009). At weaning, E-fed calves had greater MFP protein (2.11 vs. 0.46 g; $P < 0.01$), DNA (22.1 vs. 4.5 mg; $P < 0.01$) and fat (116 vs. 3.3 g; $P < 0.01$). R-fed calves had increased MFP protein concentration (15.6 vs. 12.2 mg/g; $P < 0.01$), but MFP DNA concentration was not different. E-fed calves had increased PAR total protein (1.36 vs. 0.20 mg; $P < 0.01$) and DNA (20.4 vs. 2.7 mg; $P < 0.01$). After estrogen administration, E-E2 calves had more MFP total protein ($P < 0.01$) and fat ($P < 0.01$) and greater fat concentration ($P < 0.01$) than all other treatments. Calves fed E-E2 had greater MFP total DNA than R and R-E2 calves ($P < 0.01$) but not E-fed calves. In addition, E-E2 calves had greater PAR total protein ($P < 0.01$) and DNA ($P < 0.01$) compared with all other treatments. Even further, E-E2 calves had increased total PAR fat compared with R-E2 calves ($P < 0.02$) and R-fed calves had decreased PAR fat content compared with all other treatments ($P < 0.01$). Results reinforce that composition of MFP is nutrient responsive. Moreover, data indicate that the impact of an enhanced diet on PAR tissue composition is likely positive, but more research is needed to determine if observed results would correlate to altered future milk yield.

Key Words: mammary gland, milk replacer, parenchyma

0735 Effects of fuels derived from starch digestion on feeding behavior of cows in the postpartum period. L. B. Gualdron-Duarte* and M. S. Allen, *Michigan State University, East Lansing*.

Absorbed fuels from the digestion of starch include propionic acid (P) produced by ruminal fermentation and glucose (G) from intestinal digestion that is partially metabolized to lactic

acid (L). Our objective was to evaluate effects of these fuels on DMI and feeding behavior of cows in the postpartum period. We hypothesized that effects of these fuels on DMI and ME intake (MEI) are consistent with their ability to stimulate hepatic oxidation. Little or no G is extracted from blood by the liver. Although both L and P are anapleurotic and can stimulate oxidation of acetyl CoA, hepatic extraction of P is greater than L, which depends on cytosolic redox state. Continuous isoenergetic (150 kcal/h) infusions of P, L, or G were abomasally administered to eight rumen-cannulated multiparous Holstein cows (12.4 ± 6.2 DIM) in a duplicate 4 × 4 Latin square design experiment balanced for carryover effects. Treatment sequences were randomly assigned to cows. Treatments were control (C; no infusion) and P (99.5%; 0.41 mol/h), L (88.0%; 0.46 mol/h), and G (99.9%; 0.22 mol/h) infused at 500 mL/h for 22 h/d and providing 3.3 Mcal/d. Feeding behavior was recorded by a computerized data acquisition system. Gross energy digestibility of the diet was determined for each cow and used to calculate MEI from the diet. Total MEI was calculated as the sum of MEI from the diet plus energy from infusions. Data were analyzed by ANOVA; the model included random effects of block, cow within block, and period within block and fixed effects of treatment. Treatments were compared with C by preplanned contrasts. Propionic acid decreased DMI by 24.3% (14.3 vs. 18.9 kg/d; $P < 0.001$) and MEI 13.4% (34.8 vs. 40.2 Mcal/d; $P < 0.04$) compared with C by tending to decrease meal frequency ($P = 0.087$). Lactic acid decreased DMI by 13.8% (16.3 vs. 18.9 kg/d; $P < 0.05$) compared with C by decreasing meal size 19.8% ($P < 0.05$) but did not affect MEI. Glucose infusion did not affect DMI or MEI. Treatment effects on DMI and MEI were consistent with their expected effects on hepatic oxidation. Propionic acid production from highly fermentable diets might reduce energy intake of cows in the PP period.

Key Words: anapleurosis, fresh cows, hepatic oxidation

0736 Fetuin-A: A novel biomarker for lipolysis-induced metabolic stress in transition dairy cows.

C. Strieder-Barboza*[1], W. Raphael[2], S. E. Schmidt[2], A. L. Lock[2], L. M. Sordillo[2], and G. A. Contreras[2], *[1]Department of Large Animal Clinical Sciences, Michigan State University, East Lansing, [2]Michigan State University, East Lansing*.

Periparturient cows that experience severe adipose tissue lipolysis are at a higher risk for inflammatory and metabolic diseases. Fetuin-A (FetA) is a glycoprotein that inhibits insulin signaling and enhances inflammatory responses in adipose tissues, which are known to exacerbate lipolytic responses in humans and rodents. However, little is known about its role during lipolysis and its use as a biomarker for metabolic stress and lactation performance in dairy cows. Our objective was to determine the dynamics of serum and adipose FetA concentrations and its association with metabolic markers during negative energy balance (NEB)–induced lipolysis at different stages of lactation. In Experiment 1, 26 multiparous cows were followed through the transition period. Blood samples and subcutaneous adipose tissue were collected at dry-off (DO; −51 ± 3 d), close-up (CU; −14 ± 2 d), and early lactation (EL; 7 ± 0.5 d). In Experiment 2, FetA response to lipolysis was evaluated independently of parturition-associated metabolic challenges using midlactation cows (119–210 DIM) assigned to one of two feeding protocols: ad libitum (AL; $n = 3$; +EB = 3.2 ± 0.66 Mcal/d) or feed restricted (FR; $n = 3$; EB = −13.3 ± 0.5 Mcal/d). Blood and subcutaneous adipose tissue were collected after a 4-d period of feed restriction. FetA was determined by ELISA and western blot. Data were analyzed using a repeated measures mixed model. Serum and adipose FetA concentrations were affected by lactation stage. In Experiment 1, serum FetA concentrations were lower at EL (DO: 1.31 ± 0.06 mg/mL; CU: 1.27 ± 0.09 mg/mL; and EL: 1.14 ± 0.06 mg/mL; $P < 0.05$) when NEFA concentration was greatest (DO: 0.34 ± 0.02 mEq/L; CU: 0.63 ± 0.2 mEq/L; and EL: 1.19 ± 0.14 mEq/L; $P < 0.05$). Unlike in serum, adipose FetA expression decreased at CU (relative band density; DO: 1.5 ± 0.4; CU: 0.2 ± 0.02; EL: and 1.6 ± 0.6; $P < 0.05$). Circulating FetA concentration was higher in overconditioned dry cows (BCS ≥ 3.75; $P < 0.05$) and was positively associated with BCS ($R^2 = 0.24$, $P < 0.0001$) and BCS loss ($R^2 = 0.43$, $P = 0.0005$) during the transition period. Cows with high BCS and increased serum FetA concentrations at DO had lower serum glucose concentrations at EL ($P < 0.05$). In Experiment 2, despite the feed restriction-induced lipolysis (NEFA; FR = 0.47 ± 0.05 mEq/L and AL = 0.09 ± 0.08 mEq/L), neither serum nor adipose FetA concentrations were affected in midlactation cows ($P > 0.05$). These results demonstrate that serum and adipose FetA concentrations during lipolytic states are determined by lactation stage and BCS around parturition. Fetuin-A is a potential novel biomarker for metabolic stress induced by lipolysis during the transition period. Future work will determine the mechanisms by which FetA affects lipolytic and inflammatory responses in adipose tissues of transition dairy cows.

Key Words: adipose, biomarker, lipolysis

0737 The effect of trace mineral source and fiber source on total-tract nutrient digestion.

M. J. Faulkner*[1], K. R. Perryman[2], and W. P. Weiss[1], *[1]Department of Animal Sciences, OARDC, The Ohio State University, Wooster, [2]Micronutrients Inc., Indianapolis, IN*.

Excess rumen soluble Cu and Zn can reduce fiber digestion and alter rumen microbial populations. Substitution of forage with nonforage fiber sources (NFFS) can be economically beneficial, but the reduction in particle size can decrease rumen pH, increase fiber passage rates, and decrease fiber digestion. Eighteen multiparous cows were used in a split-plot replicated Latin square with two 28-d periods to evaluate the effects of Cu, Zn, and Mn source (sulfates or hydroxy;

Micronutrients Inc., Indianapolis, IN) and dietary NDF source (forage diet = 26% NDF vs. NFFS = 36%) on total-tract nutrient digestibility. We hypothesized that hydroxy trace minerals, which are soluble at a lower pH compared with sulfates, would increase digestibility regardless of fiber source. During the entire experiment (56 d), cows remained on the same fiber treatment but the source of supplemental trace mineral was different for each 28-d period so all cows were exposed to both mineral treatments. During each of the two 28-d periods, cows were fed no supplemental Cu, Zn, or Mn for 16 d followed by 12 d of feeding supplemental Cu, Zn, and Mn from either sulfates or hydroxy sources. Basal Cu, Zn, and Mn concentrations for the forage diet were 9, 30, and 38 mg/kg, respectively, whereas basal concentrations were 11, 50, and 47 mg/kg, respectively, for the NFFS diet. Supplemental concentrations of Cu, Zn, and Mn fed were approximately 9, 30, and 30 mg/kg, respectively. No mineral source × fiber interactions were observed for production measures or digestibility. Treatment had no effect ($P \geq 0.38$) on DMI (24.2 kg) or milk production (34.9 kg). Mineral source had no effect on macronutrient intakes ($P \geq 0.63$), but feeding hydroxy Cu, Zn, and Mn increased NDF digestibility (48.5 vs. 46.4%). Cows fed NFFS had decreased DM digestibility (65.9 vs. 70.2%), OM digestibility (67.4 vs. 71.7%), CP digestibility (58.8 vs. 62.1%), and starch intake (4.3 vs. 8.8 kg) and increased starch digestibility (97.5 vs. 96.3%), NDF intake (8.6 vs. 6.0 kg), and NDF digestibility (50.5 vs. 44.4%) compared with cows fed the forage treatment. Digestible OM (DOM) was reduced (62.0 vs. 66.8%) for cows fed NFFS compared with those fed forage, indicating a reduced concentration of DE. Mineral source did not affect DOM ($P = 0.32$). Replacing dietary forage with NFFS reduced dietary energy and although hydroxy minerals increased NDF digestibility, the effect was not great enough to influence DOM.

Key Words: fiber, total-tract nutrient digestion, trace minerals

---

0738 Economic value of cooling dry cows across the United States. F. C. Ferreira*[1,2], A. De Vries[2], G. E. Dahl[2], and R. Gennari[2], [1]*Embrapa Gado de Leite, Juiz de Fora, Brazil,* [2]*Department of Animal Sciences, University of Florida, Gainesville*.

Heat stress during the dry period reduces milk yield in the next lactation. Our objectives were to quantify the economic losses due to heat stress of dry cows and to evaluate investment in cooling of dry cows. We used weather data from The National Oceanic and Atmospheric Administration to quantify the average amount of heat stress for the 48 contiguous U.S. states. A heat stress day was declared when the average daily temperature–humidity index was ≥68. A spreadsheet was developed for economic analyses. Assumptions were that 15% of the cows were dry at any time, the dry period length was 46 d, and only cows in parities ≥2 increased milk yield if cooled in the dry period. Milk yield decreased by 0.11 kg/d in the next lactation (305 d) per heat stress day in the dry period based on a review of the literature. Marginal decrease in DMI was 0.4 kg per 1 kg less milk. Marginal value of milk minus feed cost was $0.33/kg. Economic analysis included investment in fans and soakers and use of water and electricity. Building investment was considered separately at a price of $2,500 per stall. On average, a U.S. dairy cow is under heat stress 96 d during the year and loses 271 kg of milk in the subsequent lactation if not cooled when dry. Weighted by the number of cows in each state, annual losses would be $820 million if dry cows were not cooled ($89/cow per year). For the top 3 milk-producing states (California, Wisconsin, and New York) and Florida, the average milk loss in the next lactation was 316, 212, 234, and 726 kg and profit loss/cow per year were $104, $70, $77, and $238, respectively. The average benefit:cost ratio of cooling dry cows in the United States is 2.46 (dry cow building already present) and 1.59 (including building a dry cow barn) in the baseline scenario. For positive net present values, 18 and 27 d are necessary when a building is not built (considering marginal milk prices of $0.33 and $0.22, respectively). If a barn is built, minimum days of heat stress would be 47 and 69, respectively. Other benefits of dry cow cooling, such as increased health and more productive offspring, were not considered. In conclusion, cooling of dry cows was profitable in all 48 states and very profitable in most states.

Key Words: dry cows, economics, heat stress, temperature–humidity index

0739 Palmitic acid feeding increases hepatic ceramide accumulation and modulates expression of genes responsible for ceramide synthesis in midlactation dairy cows. J. E. Rico*, A. T. Mathews, and J. W. McFadden, *West Virginia University, Morgantown*.

Circulating sphingolipid ceramides are associated with elevated NEFA availability and reduced insulin sensitivity in dairy cows transitioning from gestation to lactation. In monogastrics, palmitic acid (C16:0) can increase hepatic synthesis and lipoprotein secretion of ceramides, lipid mediators that inhibit insulin action in skeletal muscle. Increasing ceramide synthesis by feeding C16:0 may be a means to restore insulin resistance and enhance milk yield during midlactation. Therefore, our objective was to determine whether dietary C16:0 can augment liver and skeletal muscle ceramide concentrations in midlactation dairy cows. Twenty multiparous Holstein cows were enrolled in a study consisting of a 5-d covariate and a 49-d treatment period. Cows were randomly assigned to a sorghum silage–based diet containing no supplemental fat (control; $n = 10$; 138 ± 45 DIM) or C16:0 at 4% of ration DM (PALM; 98% C16:0; $n = 10$; 136 ± 44 DIM). Blood was routinely collected, and liver and skeletal muscle tissue was biopsied at d 47 of treatment. Intravenous glucose

tolerance tests (GTT) were performed at d −1, 21, and 49 relative to start of treatment. Tissue concentrations of sphingolipids were determined using liquid chromatography tandem mass spectrometry. Expression of ceramide synthesis genes was evaluated using real-time PCR. Data were analyzed under the generalized linear model. Pearson correlations were analyzed. The most abundant liver and muscle sphingolipids detected were C24:0-ceramide, C24:0-monohexosylceramide (GlcCer), and C16:0-lactosylceramide (LacCer). Relative to control, PALM increased C24:0-ceramide and total hepatic ceramide levels by 29 and 20%, respectively, at wk 7 ($P < 0.05$); a response not observed in muscle. Similarly, PALM increased hepatic C22:0-, C22:1-, C24:1-, and C26:0-ceramide at wk 7. PALM increased C16:1- and C24:1-GlcCer in liver ($P < 0.05$). Plasma total ceramide and C24:0-ceramide were positively associated with hepatic total ceramide and C24:0-ceramide ($r = 0.63$ and $r = 0.58$, respectively, $P < 0.05$). Hepatic total ceramide and C24:0-ceramide were positively associated with plasma NEFA ($r = 0.63$ and $r = 0.57$, respectively, $P < 0.001$) and negatively associated with NEFA disappearance during GTT ($r = -0.57$ and $r = -0.65$, respectively, $P < 0.001$). Ceramide synthase-6 (CerS6) was the predominant hepatic CerS isoform followed by CerS2 and CerS5. Surprisingly, PALM decreased CerS2 and CerS5 mRNA and sphingomyelinase mRNA by 35, 36, and 62%, respectively ($P < 0.05$). We conclude that feeding midlactation dairy cows C16:0 can increase hepatic ceramide accumulation and generate hepatic ceramide profiles that are similar to circulating ceramide. Our work also demonstrates a possible relationship between hepatic ceramide supply and adipose tissue insulin sensitivity.

Key Words: ceramide, insulin resistance, lactation

0740 Assessment of performance, oxidative stress status, and plasma amino acid profiles in peripartal dairy cows supplemented with rumen-protected methionine or choline and with different liver functionality indices. Z. Zhou*[1], M. Vailati Riboni[1], E. Trevisi[2], D. N. Luchini[3], and J. J. Loor[1], *[1]University of Illinois, Urbana, IL, [2]UniversitaÂ Cattolica del Sacro Cuore, Piacenza, Italy, [3]Adisseo S.A.S., Alpharetta, GA*.

Objectives were to evaluate performance, oxidative stress status, and plasma AA profiles of peripartal dairy cows with different liver functionality indices (LFI). Forty multiparous Holstein cows were randomly assigned to control (CON), no methionine (MET) or choline (CHO), CON+MET, CON+CHO, and CON+MET+CHO treatments. Cows received the same diet (1.52 Mcal/kg DM) from −21 d (close-up) to calving. Cows were on the same diet (1.71 Mcal/kg DM) after calving and continued to receive the same treatments through 30 d. Blood samples were taken at −30, −10, 4, 14, and 28 d relative to calving. Liver samples were harvested at −10, 7, 20, and 30 d relative to calving. Methionine supplementation was adjusted daily at a rate of 0.08% (DM basis) of diet and CHO was supplemented at 60 g/cow per day. Main effect of LFI was analyzed using PROC MIXED in SAS. The LFI is an index assessing transition cow metabolic health by measuring changes in plasma albumin, cholesterol, and bilirubin. A high LFI (better liver function) is characterized by lower bilirubin and higher cholesterol and albumin, and the opposite is true for low LFI. Cows were ranked retrospectively and assigned to low (L; LFI < 0), medium-low (ML; 0 < LFI < 1.5), medium-high (MH; 1.5 < LFI < 3), and high (H; LFI > 3) groups according to LFI regardless of MET or CHO supplementation. Most (13/20) of the MET cows fell into the MH and H groups, whereas CHO cows were evenly distributed across the 4 LFI groups. Close-up and lactation DMI, milk yield, and protein yield increased ($P < 0.01$) with higher LFI. Compared with L and ML, cows in MH tended ($P = 0.08$) to have greater total and reduced hepatic glutathione concentration. Similarly, compared with L, plasma paraoxonase was greater ($P = 0.04$) in MH and H, suggesting better oxidative stress status in cows with higher LFI. A main effect of LFI was detected for essential AA ($P < 0.01$) and branched-chain AA ($P = 0.04$) concentration due to increased ($P < 0.05$) concentration of methionine, lysine, histidine, arginine, tryptophan, valine, leucine, and isoleucine with higher LFI. Concentrations of serine, asparagine, proline, alanine, tyrosine, citrulline, and ornithine also increased ($P < 0.05$) with higher LFI and contributed to greater ($P < 0.05$) total AA concentration. Overall, results indicate that cows with higher LFI had improved production performance, a reduction in oxidative stress, and a better plasma AA profile.

Key Words: amino acid, liver functionality index, transition cow

ADSA PRODUCTION DIVISION GRADUATE STUDENT POSTER COMPETITION: MS

0741 Effect of intrammamary infusion of chitosan hydrogels on bovine mammary gland involution after drying-off. S. Lanctot*[1], X. Zhao[1], P. Fustier[2], A. Taherian[2], B. Bisakowski[2], and P. Lacasse[3], *[1]Department of Animal Science, McGill University, Montreal, QC, Canada, [2]Food Research and Development Centre, St-Hyacinthe, QC, Canada, [3]Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada*.

The transition from lactation to the dry period in dairy cows is a period of high risk for acquiring new intramammary infections. This risk is reduced when the involution of the mammary gland is completed. Accordingly, approaches that accelerate the involution process after drying-off could reduce

the incidence of mastitis. The current study aimed to develop a biological response modifier that could be injected into cow teats to promote immune cell migration and speed up involution. Chitosan is natural polysaccharide derived from chitin, which is able to trigger host innate immunity. We have developed two formulations, using crab or shrimp chitosan, which are liquid at room temperature but form a hydrogel at the body temperature. Each quarter of 7 Holstein cows in late lactation was randomly assigned at drying-off to an intramammary infusion of 2.5 or 5 mL of crab chitosan hydrogel (crab2.5 or crab5), 5 mL of shrimp chitosan (shp5), or 5 mL of saline (control). Milk (mammary secretion) samples of each quarter were collected on d −4, 0 (dry-off), 1, 3, 5, 7, and 10. Milk somatic cell counts (SCC) and concentrations of involution marker such as bovine serum albumin (BSA), lactate dehydrogenase (LDH), and lactoferrin gradually increased ($P < 0.01$) during the first 10 d following the last milking whereas the citrate concentration decreased ($P < 0.01$). Intramammary infusion of chitosan hydrogel (crab5, crab2.5, and shp5) hastened the increase in SCC, BSA, and LDH ($P < 0.01$). The SCC and BSA concentrations for chitosan-treated quarters were greater ($P < 0.01$) than those of milk from control quarters on Days 1, 3, and 5. The LDH concentration was greater ($P < 0.01$) in milk from chitosan-treated quarters than in that of control quarters on Days 1, 3, 5, and 7. Similarly, chitosan induced a faster rise in lactoferrin concentration, which was greater ($P < 0.01$) than that of the control quarters on Days 3 and 5. Milk citrate concentration was unaffected by treatments but the citrate:lactoferrin ratio was lower ($P < 0.05$) in chitosan treated quarters on Days 3 and 5 than that in control quarters. No major differences between source or volume of chitosan were noted for the measured parameters. These results suggest that chitosan hydrogel infusion hastened mammary gland involution, which may reduce the risk of acquiring new intramammary infection during the drying-off period.

Key Words: involution, mastitis, immunity

0742 Mitigation of variability in feeding patterns between competitively fed dairy cows through increased feed delivery frequency. R. E. Crossley*, A. Harlander, and T. J. DeVries, *Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada*.

The objective of this study was to determine if increased frequency of feed delivery can mitigate the effects of feed bunk competition. We hypothesized that at a greater frequency of feed delivery, 1) there will be improved access to feed (i.e., greater feeding time and consumption of more meals per day) and 2) there will be greater consistency in feeding and meal patterns between cows. Sixteen lactating Holstein dairy cows, with an average DIM of 72 ± 35 d and production of 42 ± 6 kg/d at the start of the trial, were categorized by parity as either young (≤second lactation) or mature (≥third lactation) and paired to maximize difference in parity. Pairs were housed 4 at a time and competitively fed at a ratio of 2 cows:1 feed bin. They were exposed, at a pair level, in a crossover design to each of 2 different treatments: 1) lower feed delivery frequency (2x/d) or 2) higher feed delivery frequency (6x/d). Treatments were applied for 10 d, with DMI and feeding behavior (feeding time, feeding rate, and meal patterns) for each cow recorded using an automated feed intake system on d 6 to 10 of each period. Data were summarized by pair and treatment period and analyzed using a general linear mixed model. Dry matter intake (27.1 kg/d), feeding time (180.2 min/d), and feeding rate (0.17 kg DM/min) were unaffected by increased feed delivery frequency ($P \geq 0.22$). There was a tendency for rumination time to increase with higher frequency of feed delivery (low = 520.5 min/d and high = 547 min/d; SE = 11.32, $P = 0.06$). No differences in meal patterns were found between feed delivery frequency treatments ($P \geq 0.20$). However, comparing the young and mature individuals within each treatment pair revealed differences in both feeding and meal patterns. Feeding rate (young = 0.16 kg DM/min and mature = 0.19 kg DM/min; SE = 0.032, $P = 0.02$) and DMI (young = 25.6 kg DM/min and mature = 28.6 kg DM/min; SE = 1.36, $P = 0.04$) were lower for the young cows on both treatments. Meal frequency was greater in young cows (young = 9 meals/d and mature = 7 meals/d; SE = 0.7, $P = 0.03$) and meal size was greater in mature cows (young = 3.2 kg DM/meal and mature = 4.2 kg DM/meal; SE = 0.35, $P < 0.001$) across treatments. These results suggest that for cows fed at a high level of competition, increasing feed delivery frequency from 2x/d to 6x/d did not improve access to feed. However, under these conditions, the relative parity of competitively fed cows had a greater impact on feeding behavior and meal patterns than the frequency of feed delivery.

Key Words: dairy cow, competition, behavior, feed frequency, meal patterns

0743 Infusion of a serotonin precursor prepartum induces dynamic glucose and fat metabolism gene expression in the livers of multiparous dairy cows during peripartum. A. P. Prichard*[1], S. R. Weaver[2], E. L. Endres[1], M. S. Akins[3], R. M. Bruckmaier[4], and L. L. Hernandez[2], *[1]University of Wisconsin-Madison, Madison, [2]Department of Dairy Science, University of Wisconsin, Madison, [3]Univeristy of Wisconsin, Platteville, [4]Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland*.

Nonneuronal serotonin receptors are dynamic in the liver of transition cows and serotonin is known to affect metabolism. Yet the extent to which glucose and fat homeostasis during the transition period are transcriptionally regulated in response to serotonin is unknown. To this end, we intravenously infused multiparous Holstein ($n = 12$) and Jersey ($n = 12$) cows daily with either 1 L of saline (CON; $n = 6$ for Holstein and Jersey)

or 1 mg/kg BW of 5-hydroxytryptophan (5-HTP; n = 6 for Holstein and Jersey). Holsteins were infused for 5.67 ± 0.78 d and Jersey cows for 8.67 ± 1.53 d prepartum, until parturition. A liver biopsy was performed before treatment, on the day following parturition (d 1), and on Day 7 (d 7) of lactation. Ribonucleic acid was extracted from all samples and real-time PCR was performed. Ribonucleic acid expression was analyzed using the delta-delta CT method and statistical analysis was conducted using a two-way ANOVA for time, treatment, and the interaction on gene expression of phosphoenolpyruvate carboxykinase 1 (PCK1), fructose 1-6 bisphosphatase (FBP1), acetyl co-A carboxylase (ACACA), and carnitine palmitoyltransferase 1 (CPT1A). On d 1, PCK1 and FBP1 expression was elevated in the liver of 5-HTP Holsteins relative to CON Holsteins, but not in Jerseys (P = 0.05 for both PCK1 and FBP1 in Holsteins). In Holsteins, FBP1 expression was greatest on d 1 and returned to baseline levels on d 7 (P < 0.0001). In Jerseys, time had a dynamic effect on FBP1 expression but without the dramatic decline to baseline expression seen in Holsteins (P = 0.04). Expression of ACACA was elevated on d 1 in 5-HTP Holsteins compared with CON (P < 0.05). ACACA expression in 5-HTP Jerseys compared with CON Jerseys was highest on d 7 compared with d 1 or baseline (P = 0.03). There was a treatment (P = 0.03) and time (P = 0.009) effect on CPT1A expression in the Holsteins, with 5-HTP Holsteins having higher expression than CON on d 1 and 7 of lactation. In Jerseys, CPT1A expression was higher on d 7 than on d 1 (P < 0.0001), but there was no treatment effect. Given the roles of PCK1 and FBP1 in promoting gluconeogenesis and the dynamic fatty acid metabolism roles of ACACA and CPT1A, serotonin appears to have an effect on regulating energy and fat homeostasis in a breed- and time-dependent manner during the transition period in dairy cattle.

Key Words: serotonin, liver, gene expression

744 Sire performance and reproductive breeding values are associated with feed efficiency and growth in dairy heifers. C. E. Owens*, *Virginia Polytechnic Institute and State University, Blacksburg*.

Feed costs represent upward of 60% of total inputs in the dairy industry; moreover, poor fertility is the primary factor influencing cow productive life (PL). To improve profitability, producers must begin selecting for metabolic and reproductive efficiency. To do this, the relationship between feed efficiency and growth must be assessed for milk production and fertility measures. Therefore, the objective of this study was to determine the relationship between sire performance predicted transmitting ability (PTA) with progeny feed efficiency (G:F) and ADG. Twelve dairy heifers (1 wk age and 40.41 ± 4.34 kg BW) were randomly administered one of two diets, restricted (R; 20% CP and 20% fat) or enhanced (E; 28% CP and 25% fat), for 8 wks. Heifers were weighed weekly and daily feed intake measurements were collected to determine G:F and ADG. Sire PTA (milk, fat, protein, PL, somatic cell score, daughter pregnancy rate, and heifer conception rate [HCR]) were collected via the Council on Dairy Cattle Breeding. Using PROC CORR in SAS, phenotypic correlations were determined between sire PTA with calf G:F and ADG, regardless of diet and within diet. There was a strong positive phenotypic correlation between heifer G:F and milk PTA (r_p = 0.76, P = 0.007), and ADG tended to have a moderate positive phenotypic correlation with milk PTA (r_p = 0.57, P = 0.068). A suggestive moderate positive phenotypic correlation (r_p = 0.60, $P \leq 0.081$) was determined between G:F with HCR and PL (r_p = 0.55). Within treatment, R heifers had a strong positive phenotypic correlation between ADG with milk (r_p = 0.94, P = 0.005) and protein (r_p = 0.90, P = 0.016) PTA. There was also a strong positive phenotypic correlation between G:F with milk (r_p = 0.93, P = 0.008) and protein (r_p = 0.93, P = 0.007) PTA for R heifers. Results suggested that sires with more favorable predictors for milk and protein production compared with contemporaries produced heifers with increased feed efficiency and growth. Additionally, sires with increased HCR and PL PTA produced heifers with greater feed efficiency. Overall, favorable selection for sire PTA estimates for performance and reproduction may provide an opportunity to increase heifer feed efficiency and growth.

Key Words: feed efficiency, fertility, growth

0745 Dry matter intake, milk yield, and milk composition of dairy cows fed corn silage from corn treated with various application times of foliar fungicide. C. Kalebich*[1], M. Weatherly[1], G. M. Fellows[2], and P. Cardoso[1], *[1]University of Illinois, Urbana, [2]BASF Corporation, Research Triangle Park, NC*.

Little is known about the ideal timing of foliar fungicide application on corn and its effects on corn silage when fed to dairy cattle. The objective of this study was to determine which timing of fungicide application on corn that was further ensiled as corn silage would have the most advantageous impact on DMI and milk yield and composition in dairy cattle. Holstein cows (n = 64) with parity 2.2 ± 0.8, 626 ± 77 kg BW, and 134 ± 37 DIM were blocked and randomly assigned to 1 of 4 treatments (45% of the DM as corn silage). Treatments were as follows: corn silage with no application of foliar fungicide (CON), corn silage from corn that received one application of pyraclostrobin and fluxapyroxad (PYR+FLUX) foliar fungicide (Priaxor; BASF Corp.) at corn stage V5 (V5), corn silage from corn that received one application of PYR+FLUX at corn stage V5 plus another application of PYR+FLUX at corn stage V8 (V5/V8), and corn silage from corn that received one application of PYR+FLUX at corn stage V5 and one application of PYR+FLUX at corn stage V8 plus a third application of pyraclostrobin and metconazole (PYR+MET) foliar fungicide (Headline AMP; BASF Corp) at corn stage R1 (V5/

V8/R1). Corn was harvested at 31.2% DM and three-fourths milk line kernel development, and ensiled for more than 200 d. Treatments were fed to cows for 5 wk with the last week being used for statistical inferences. Data was analyzed using the MIXED procedure in SAS (version 9.4), with cow as the experimental unit. No differences in DMI (19.5, 19.5, 20.8, and 20.4 kg for CON, V5, V5/V8, and V5/V8/R1, respectively; $P = 0.48$) or milk yield (30.55, 31.17, 29.06, and 29.33 kg/d, respectively; $P = 0.55$) were observed. However, corn silage in V5 compared with corn silage in V5/V8 fed to cows tended to increase 3.5% fat-corrected milk (FCM) (32.42 and 28.58 kg/d, respectively; $P = 0.07$) and energy corrected milk (ECM) (31.35 and 27.76 kg/d, respectively; $P = 0.07$). Percentage of milk lactose tended to be greater for cows fed corn silage treated with foliar fungicide when compared with CON ($P = 0.09$). In conclusion, cows receiving corn silage from corn treated with fungicide at V5 tended to have greater FCM and ECM than cows treated with corn silage from corn treated with fungicide at V5/V8.

Key Words: corn silage, foliar fungicide, fat-corrected milk

0746 Identification of loci associated with fertility in United States Holstein heifers. E. Keuter*[1], C. M. Seabury[2], M. Neupane[3], J. N. Kiser[1], J. Moraes[4], G. Burns[4], T. E. Spencer[4], and H. L. Neibergs[3], *[1]Department of Animal Science, Washington State University, Pullman, [2]Texas A&M University, College Station, [3]Department of Animal Sciences, Washington State University, Pullman, [4]Division of Animal Sciences, University of Missouri, Columbia*.

Current conception rates in U.S. Holstein heifers are estimated to be between 55 and 60%. The objective here was to identify genomic loci associated with fertility in Holstein dairy heifers. Breeding and health records of Holstein heifers were analyzed from a commercial dairy heifer raising facility in southern Idaho. All heifers were bred by AI at observed estrus, and pregnancy was determined at Day 35 after AI via palpation. Records analysis identified 497 heifers that could be classified as highly fertile (HF) due to conceiving on first AI service and 429 subfertile (SF) that did not conceive until after fourth AI service or were culled due to failure to conceive. Deoxyribonucleic acid was extracted from blood samples and genotyped using the Illumina Bovine HD BeadChip. Quality control consisted of removing animals with <90% of genotypes and removing markers with <90% of genotypes or a minor allele frequency <1% or if they failed Hardy–Weinberg equilibrium testing. A total of 466 HF and 368 SF heifers and 590,904 SNP remained for the analysis. A genomewide associated analysis (GWAA) was conducted using an additive model of the efficient mixed-model association expedited statistical test with a genomic relationship matrix. Covariates used in the analysis accounted for relatedness (identity by descent ≥ 0.2) of heifers and the AI bull the heifer was bred to as conception rates differed between AI sires ($P < 6.9 \times 10^{-13}$). The GWAA identified 153 SNP representing 147 QTL ($P < 5.5 \times 10^{-5}$) that were moderately associated and 34 SNP representing 26 QTL ($P < 5.5 \times 10^{-7}$, proportion variance explained ranged from 0.032 to 0.115) that were strongly associated with heifer fertility. Pseudo-heritability was estimated to be 0.46 and l = 0.98. These results indicate that there is ample opportunity to make significant gains in fertility in Holstein heifers with genomic selection. This project was supported by Agriculture and Food Research Initiative Competitive Grant number 2013-68004-20365 from the USDA National Institute of Food and Agriculture.

Key Words: dairy, fertility, quantitative trait loci

0747 The effects of increased metabolizable protein and amino acid supplementation in fresh dairy cattle. E. G. Carder*, *The Ohio State University – OARDC, Wooster*.

The first few weeks after parturition in dairy cattle is a time marked by low but increasing feed intake and sharply increasing milk production. Because of low intake, nutrient density of the diet may need to be higher during this period to support increasing milk yields. We hypothesized that feeding higher levels of MP or feeding supplemental rumen protected methionine and lysine would increase milk yield and protein concentration. Fifty-six Holstein cows (21 primiparous and 35 multiparous), starting at 3 DIM, were used in a randomized-block design with three diets. The treatments were control (16.5% CP, 10.9% RDP, and 5.6% RUP, formulated for 25.1 kg/d MP allowable milk based on an NRC model), high protein (HP; 18.5% CP,11.6% RDP, 6.9% RUP, and 29.9 MP allowable milk), and AA treatment (AA; 17.5% CP, 10.5% RDP, 7.0% RUP, and 29.7 MP allowable milk). The AA diet included a proprietary spray-dried blood meal product (Perdue Agribusiness, Salisbury, MD) that provided 174 and 62 g/d of rumen-protected lysine and methionine, respectively, per the NRC model. The HP diet provided an estimated 156 g/d lysine and 45 g/d methionine and the control diet provided 149 g/d lysine and 41 g/d methionine. Milk production and DMI were measured daily and milk was sampled for components on Day 8, 15, and 20 after moving into tie stalls. Statistical model included parity, treatment, and week fixed effects, random effect of block, and cow as the experimental unit. Treatment and treatment by parity interaction did not affect milk yield (33.6, 34.5, and 33.1 kg for control, HP, and AA), DMI (17.8, 17.8, and 18.5 kg/d for control, HP, and AA), or milk protein yield (1.11 kg/d). Milk protein concentration was higher (3.30 vs. 3.16 and 3.17%; $P < 0.05$) for AA treatment compared with the HP and control, respectively. Energy corrected milk (ECM) was higher (35.1 and 35.1 vs. 32.0 kg; $P < 0.05$) for HP and AA than for the control, respectively. MUN

was higher (14.3 vs. 12.7 and 11.5 mg/dL; $P < 0.05$) for HP than for AA or control, respectively. Plasma BHBA and NEFA were unaffected by treatment or treatment × parity interaction but increased from Day 8 to Day 15 in both multiparous and primiparous cows. Overall, supplementing rumen-protected lysine and methionine with extra MP can increase ECM yield and milk protein concentration.

Key Words: rumen-protected lysine, rumen-protected methionine, metabolizable protein, fresh cow, dairy cow

0748 Effects of supplementing lactating dairy cow ration with sodium sesquicarbonate on reticulorumen pH, rumination, and dry matter intake. M. L. Jones*[1], J. D. Clark[1], N. A. Michael[2], and J. M. Bewley[1], *[1]University of Kentucky, Lexington, [2]Arm & Hammer Animal Nutrition, Princeton, NJ*.

The objective of this study was to assess the effects of sodium sesquicarbonate (SQ-810), a reticulorumen buffer, on rumen pH, rumination time, and DMI. Sixteen early lactation multiparous, Holstein cows were housed in a tie-stall barn and milked twice daily at the University of Kentucky Coldstream Dairy from October 31, 2015, to January 1, 2016. Cows were balanced by parity and milk production and then split into 2 treatment groups for a crossover study with a low-buffer (LB; $n = 8$) group and a high-buffer (HB; $n = 8$) group. The base total mixed ration (TMR) contained 0.16 kg/d sodium bicarbonate. The LB group did not receive SQ-810 whereas the HB group received 0.30 kg of SQ-810 as fed. Eight cows proceeded through sequence 1: three 21-d periods receiving the LB diet in period 1, the HB diet in period 2, and the LB diet in period 3. The remaining 8 cows proceeded through sequence 2: three 21-d periods receiving the HB diet in period 1, the LB diet in period 2, and the HB diet in period 3. Each group was fed ad libitum and DMI was collected. All cows were administered an iNovotec Animal Care (iNovotec Animal Care, Austria) reticulorumen pH and temperature bolus. Daily rumination time was recorded using HR tags (SCR Engineers Ltd., Netanya, Israel) and CowManager SensOor (SENRUM) tags (Agis Automatisering, Harmenlen, Netherlands). Low pH was calculated as the total time pH was <5.60. The MIXED procedure of SAS was used to evaluate the effects of cow, sequence, treatment and period on each parameter measured. Rumen pH and low pH time (pH < 5.60) were influenced by treatment ($P < 0.01$). Rumen pH was 5.82 ± 0.07 for LB cows and 5.85 ± 0.07 for HB cows. Low pH time (pH < 5.60) was greater ($P < 0.01$) for LB days (64.17 ± 11.71 min/d) than for HB days (56.31 ± 11.71 min/d). Dry matter intake was 25.68 ± 0.61 kg/d for LB cows and 26.53 ± 0.61 kg/d for HB cows. Treatment affected SCR rumination times ($P < 0.01$) for LB cows (457.84 ± 19.15 min/d) and HB cows (435.02 ± 19.15 min/d). Rumination time measured using SENRUM was not significantly different between treatments. The addition of SQ-810 to the TMR significantly increased reticulorumen pH and DMI ($P < 0.01$). This research demonstrates the positive effects of SQ-810 rumen buffer in a lactating cow diet.

Key Words: rumen pH, sodium sesquicarbonate

0749 Feeding low crude protein diets in lactating dairy cows during summer months: 2. Improvements in energy metabolism. J. Kaufman*, K. Kassube, K. G. Pohler, and A. G. Rius, *The University of Tennessee, Knoxville*.

Lactating dairy cows experience changes in nutrient partitioning and decrease production during summer months. Dietary concentrations of RDP and RUP affect nutrient partitioning and utilization. A study was conducted to evaluate the effect of feeding low RDP and RUP levels on energy metabolism in cows during peak summer months. Forty-eight primiparous and multiparous midlactation Holstein cows were assigned to treatments using a complete randomized block design in a 2 × 2 factorial arrangement of treatments ($n = 12$/treatment). Treatments included two levels of RDP (10 and 8%) and two levels of RUP (8 and 6%). A common diet (10% RDP and 8% RUP) was fed from d 1 to 21 followed by the respective treatment diets from d 22 to 42. Cows were housed in a freestall barn and exposed to the prevailing temperature and humidity of July and August with no supplemental cooling. Blood samples were collected from individual cows at d 42. Plasma was harvested for analysis of glucose, insulin, NEFA, and β-hydroxybutyrate (BHBA). Main effects and their interaction were tested using the Mixed procedure of SAS and reported as least squares means ± SEM. Rectal temperatures and respiration rates were recorded before noon and after noon during the treatment period. Compared with before noon, after noon increased temperature and respiration rates (38.9–39.7 ± 0.07°C [$P < 0.001$] and 64.0–87.1 ± 1.4 breaths/min [$P < 0.001$]). The 10% RDP treatment decreased ($P < 0.04$) glucose concentrations compared with the 8% RDP treatment (3.0 vs. 3.1 ± 0.05 mmol/L). The 10% RDP treatment increased ($P < 0.01$) insulin concentrations compared with the 8% RDP treatment (20.9 vs. 15.8 ± 1.1 μU/mL). The 8% RUP treatment tended to increase ($P < 0.08$) insulin concentrations compared with the 6% RUP treatment (19.8 vs. 16.9 ± 1.12 μU/mL). The 8% RUP treatment decreased ($P < 0.01$) NEFA concentrations compared with the 6% RUP treatment (141 vs. 173 ± 16.5 μEq/L). Compared with 10% RDP, the 8% RDP treatment decreased BHBA concentrations in the 8% RUP treatment (251 vs. 407 ± 26.5 μmol/L) but increased BHBA concentrations in the 6% RUP treatment (190 vs. 173 ± 26.5 μmol/L; interaction, $P < 0.01$). In conclusion, these results indicate that lower RUP diets promoted lower concentrations of insulin and greater concentrations of NEFA. This may allow metabolic adaptations to mobilize lipids and sustain milk production.

Key Words: crude protein, energy utilization, heat stress

ADSA PRODUCTION DIVISION GRADUATE STUDENT POSTER COMPETITION: PHD

0750 Elevation of circulating serotonin prepartum decreases β-hydroxybutyrate concentrations and improves energy status postpartum in multiparous dairy cows. S. R. Weaver*[1], A. P. Prichard[2], E. L. Endres[2], M. S. Akins[3], R. M. Bruckmaier[4], and L. L. Hernandez[1], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]University of Wisconsin-Madison, Madison, [3]Univeristy of Wisconsin, Platteville, [4]Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland*.

Peripheral serotonin is known to mediate energy homeostasis in late-lactation dairy cows. However, the majority of energy-related disorders occur primarily during the transition period. To establish if serotonin mediates energy homeostasis during the transition period, we intravenously infused multiparous Holstein (n = 12) and Jersey (n = 12) cows daily with either 1 L of saline (CON; n = 6 for Holstein and Jersey) or 1 mg/kg BW of 5-hydroxytryptophan in 1 L of saline (5-HTP; n = 6 for Holstein and Jersey). Holsteins were infused for an average of 5.67 ± 0.78 d and Jersey cows for 8.67 ± 1.53 d prepartum, until parturition. On infusion days, blood was collected before, after, and at 2, 4, and 8 h after infusion. Blood was also collected for 14 d postpartum and on Day 30 postpartum and assayed for glucose, β-hydroxybutyrate (BHBA), and NEFA. Milk yield and feed intake were monitored throughout. All data were analyzed using a two-way ANOVA in SAS for treatment, breed, and day effect and the interaction. Holsteins treated with 5-HTP had elevated circulating serotonin for 6 d before parturition and on Day 0 and Day 1 of lactation (P < 0.05). The5-HTP Jerseys treated with 5-HTP had elevated serotonin concentrations 2 d prepartum and on the day of parturition (P < 0.003). Treatment did not affect milk yield (P > 0.05). There was no treatment effect on feed intake for either breed (P > 0.05). The CON Holsteins had higher circulating glucose than CON Jerseys from Day 8 to Day 15 postpartum (P < 0.05) and this effect was mediated by 5-HTP treatment. There was no treatment effect in either breed on circulating glucose levels (P > 0.05). β-Hydroxybutyrate concentrations tended to be lower on Days 7 and 10 in Holstein 5-HTP compared with Holstein CON (P = 0.09) and were significantly lower on Day 7 in Jersey 5-HTP compared with Jersey CON (P = 0.02). The CON Jerseys had the highest BHBA concentrations on Days 6 to 10 postpartum. There was no effect of BHBA prepartum in either breed. Nonesterified fatty acids were not affected either pre- or postpartum (P > 0.05), although they were elevated in both breeds within an infusion day (P < 0.05). Taken together, these data demonstrate that serotonin administration prepartum may have a positive effect on mediating energy status postpartum. Specifically, decreased BHBA concentrations on Days 6 to 10 postpartum demonstrate serotonin's potential to mediate ketosis incidence.

Key Words: energy, serotonin, transition cow

0751 Temporal effects of ruminal propionate infusion on feeding behavior of Holstein cows in the postpartum period. G. Maldini*[1,2], M. S. Allen[1], and K. M. Kennedy[1], *[1]Michigan State University, East Lansing, [2]CAPES Foundation, Brasilia, Brazil*.

Suppression of appetite during the postpartum (PP) period is likely caused by a signal related to hepatic energy status from oxidation of fuels. Propionic acid (PA) is likely the most important fuel stimulating hepatic oxidation within meals in ruminants. However, PA production rate in the rumen varies greatly among starch sources and the temporal pattern of propionate supply to the liver might affect satiety within meals. The objective of this study was to determine the temporal effect of intraruminal propionic acid infusion at initiation of meals on feeding behavior of PP cows. We hypothesized that a faster rate of PA infusion would decrease meal size by stimulating satiety sooner within a meal. Six ruminally cannulated, multiparous Holstein cows in the PP period were used in a duplicated 3 × 3 Latin square design experiment balanced for carryover effects. Cows were blocked by parturition date and randomly assigned to treatment sequence within square. Treatments included a control (no infusion) or infusion of 1.25 mol of propionic acid over 5 (FAST) or 15 min (SLOW) at each meal. Infusions were initiated at the beginning of the conditioned meal (1200 h) and were triggered at each spontaneous meal for 22 h. Feeding behavior was monitored by a computerized data acquisition system. A 24-h recovery period was included between infusion days to reduce potential carryover effects of treatment. In contrast to our hypothesis, FAST increased meal size 55% (1.30 vs. 0.84 kg DM; P < 0.02) compared with SLOW. FAST also increased intermeal interval 67% compared with SLOW (149.7 vs. 89.8 min; P < 0.05) while decreasing meal frequency 29% (8.0 vs. 11.2 meals/d; P = 0.01). Although both PA treatments decreased DMI 48% compared with the control, DMI was not affected by infusion rate. FAST PA supply to the liver at the initiation of meals might have resulted in a saturation of propionate metabolic pathways in the liver, resulting in greater bypass for FAST compared with SLOW. Increased intermeal interval and reduced meal frequency for FAST compared with SLOW might have been caused by extended anapleurosis and hepatic oxidation of acetyl CoA over a longer time after meals, delaying hunger. These results indicate that the depression in feed intake by more fermentable starch sources might be more related to the amount of PA produced rather than its rate of production within meals.

Key Words: feeding behavior, meal size, hepatic oxidation

0752 Forage yield, nutrient composition, and grain yield of corn and soybeans when intercropped at different seeding rates grown under organic conditions. I. P. Acharya*[1], X. Gu[2], S. Acharya[1], P. Poudel[1], and D. P. Casper[1], *[1]Dairy Science Department, South Dakota State University, Brookings, [2]Deparment of Plant Science, South Dakota State University, Brookings*.

Previous research has demonstrated that feeding of forage blends produced through intercropping of corn and soybean could be beneficial for livestock. A field plot study was laid out using a randomized complete block design having three replicates to evaluate an organic corn hybrid, MC 5300 (C), with an organic soybean, Viking 2265 (N) or Vining soybean (V), at five different seeding rates to create nine different treatments (100:0:0 [T1], 0:100:0 [T2], 0:0:100 [T3], 50:50:0 [T4], 67:33:0 [T5], 33:67:0 [T6], 50:0:50 [T7], 67:0:33 [T8], and 33:0:67 [T9] of C with N and V) to determine the optimal intercropping seeding rates. Forages were hand harvested 110 d after planting, inoculated, packed into buckets, weighed, and ensiled for 90 d. Buckets were then reweighed and opened, and forage samples were collected and analyzed for nutrient composition. Fresh biomass yield was higher ($P < 0.01$) for T8 compared with remaining treatments (88.37, 31.34, 17.34, 85.07, 101.49, 68.06, 85.78, 107.00, and 74.86 T/ha for T1, T2, T3, T4, T5, T6, T7, T8, and T9, respectively). Dry matter yield was higher ($P < 0.01$) for T8 compared with others (10.60, 5.93, 27.10, 24.44, 29.31, 36.55, and 25.41 T/ha for T2, T3, T4, T6, T7, T8, and T9, respectively). Nitrogen accumulation by treatments forage was lower ($P = 0.01$) in T3 (0.20 T/ha) compared with the others (0.38 T/ha). Corn grain yield was higher ($P < 0.01$) for T5 and T8 compared with T4, T6, T7, and T9 (11.84, 15.44, 8.84, 11.89, 16.66, and 9.68 T/ha for T4, T5, T6, T7, T8, and T9, respectively). Soybean grain yield was higher ($P < 0.01$) in T4 and T6 compared with T5, T7, T8, and T9 (3.06, 1.80, 3.38, 1.90, 0.53, and 2.36 T/ha for T4, T5, T6, T7, T8, and T9, respectively). Land equivalent ratio was higher ($P < 0.01$) for T4 (1.32) and T5 (1.31) compared with T7 (1.15), T8 (1.16), and T9 (1.11). Crude protein content was higher ($P < 0.01$) for T6 (9.64%) compared with T4 (8.96%), T5 (8.22%), T7 (8.20%), and T8 (7.94%). Starch content was higher for T4 (29.18%) compared with T9 (26.03%). Thirty-hour NDF digestibility was higher ($P < 0.01$) for T4 (45.81%), T6 (47.41%), and T9 (46.19%) compared with T5 (43.86%) and T8 (43.38%). The production of forage blends through intercropping of corn and soybeans has the potential to yield greater quantities of digestible nutrients.

Key Words: corn, silage soybean

0753 Refinement of the *DST* locus associated with bovine respiratory disease complex in Holstein calves. M. Neupane*[1], J. L. Hoff[2], J. F. Taylor[2], C. M. Seabury[3], J. E. Womack[3], T. Bovine Respiratory Disease Complex[3], and H. L. Neibergs[1], *[1]Department of Animal Sciences, Washington State University, Pullman, [2]University of Missouri, Columbia, [3]Texas A&M University, College Station*.

Despite best management practices including vaccination and treatment programs, bovine respiratory disease complex (BRDC) continues to be a major cause of morbidity and mortality in cattle. An additional approach to reduce BRDC is to select animals that are less susceptible to respiratory disease. A previous genomewide association analysis identified a 10-kb QTL region on chromosome 23 (BTA23) that included the dystonin (*DST*) gene that plays a major role in herpes virus infections in cattle. The objective of this study was to determine if there were additional variants on BTA23 with a greater association with BRDC that could be used in the selection of cattle with enhanced BRDC resistance. An analysis was conducted using genotypes imputed to whole genome sequence (WGS) for preweaned Holstein calves from California that consisted of 996 controls and 982 cases as defined by the McGuirk health scoring system. Illumina BovineHD genotypes on BTA23 were imputed to WGS using Run 5 data from the 1000 Bull Genomes Project and accuracy was checked by using the WGS of 30 Holstein calves included in the study. Imputation was conducted using Fimpute and errors were corrected by using Beagle 4.1 software. Single nucleotide polymorphisms were filtered for low minor allele frequency (<1%) and low call rate (<90%), resulting in 2,196 biallelic markers being used for analysis in a 1-Mb region surrounding *DST*. Analyses were performed using an allelic model and an additive model with efficient mixed model association expedited (EMMAX) that included age and sex as covariates. A 2.5-kb region including intron 57 (ENSEMBL) of *DST* contained 19 SNP that were associated with BRDC with both allelic ($P = 6.72 \times 10^{-7}$ to $P = 5.07 \times 10^{-5}$) and additive models ($P = 3.82 \times 10^{-6}$ to $P = 6.88 \times 10^{-5}$). Many of the 19 SNP were highly conserved across species, suggesting that they may have a functional or regulatory role in gene expression. These SNP will be used to confirm the BRDC association in independent cattle populations to determine their value for inclusion in a genomic PTA for BRDC. This project was supported by Agriculture and Food Research Initiative Competitive Grant number 2011-68004-30367 from the USDA National Institute of Food and Agriculture.

Key Words: bovine respiratory disease complex, dairy, calves, imputation, loci

0754 Meta-analysis of factors influencing new intramammary infection rate in natural exposure teat dip efficacy trials. B. D. Enger*[1], R. R. White[1], S. C. Nickerson[2], and L. K. Fox[3], *[1]Virginia Tech, Blacksburg, [2]University of Georgia, Athens, [3]Washington State University, Pullman*.
