Teat dips are used to reduce the incidence of new intramammary infection (IMI) on dairies. Although it is widely acknowledged that many factors affect teat dip efficacy and that all teat dips should be confirmed efficacious before commercial circulation, the studies evaluating teat dip efficacy differ in experimental design, pathogen profiles at the herd level, and teat dips tested, among other factors. The objective of the present study was to conduct a meta-analysis of data from peer-reviewed teat dip efficacy trials that used a natural exposure study design to identify factors influencing the new IMI rate. A data set of 16 studies (256 observations) was created, and the new IMI rate, based on percentage of new quarter infections per month (PNQI/mo), was calculated for each observation in the data set. The new IMI rate (PNQI/mo) was used as the dependent variable for model derivation. A linear, mixed-effects model with a random study effect, weighted for the SE of the measurement, was derived in a stepwise manner where parameters were sequentially eliminated for nonsignificance. The final mixed model included the terms of study design ($n = 2$, $P = 0.03$), mastitis pathogen group ($n = 6$, $P < 0.01$), postmilking treatment ($n = 6$, $P = 0.06$), and the two-way interaction between mastitis pathogen group and postmilking treatment ($P < 0.01$). Overall, *Corynebacterium* spp. had the highest new IMI rate, 0.0139 ± 0.0018 PNQI/mo, which was greater than that of the environmental streptococci and Gram-negative species, 0.0023 ± 0.0022 PNQI/mo, both having the lowest new IMI rate ($P < 0.05$). The new IMI rates for *Staphylococcus aureus*, *Streptococcus agalactiae*, and the coagulase negative staphylococci were 0.0046 ± 0.0017, 0.0054 ± 0.0043, and 0.0094 ± 0.0017 PNQI/mo, respectively. The new IMI rate of mastitis pathogen groups was influenced by different postmilking treatments ($P < 0.01$). Studies using a split herd study design had a greater new IMI rate, 0.0089 ± 0.0017 PNQI/mo, than studies using a split udder study design, 0.0046 ± 0.0017 PNQI/mo ($P = 0.03$). The results of this study indicate that mastitis pathogens vary in sensitivity to different postmilking teat dips and suggest that changing the postmilking teat dip used at the farm to a teat dip containing a different active ingredient may increase efficacy against specific pathogens.

Key Words: teat disinfectant, study design, mastitis

0755 Diet starch content and fermentability affects feed intake and milk yield of cows in the postpartum period. R. I. Albornoz* and M. S. Allen, *Michigan State University, East Lansing*.

The objective of this study was to evaluate the effects of diet starch content and fermentability fed during the postpartum (PP) period on DMI, yields of milk (MY) and milk components, and body reserves. Fifty-two multiparous Holstein cows were used in a randomized block design with a 2 × 2 factorial arrangement of treatments. Diets were formulated to 22 (LS) or 28% (HS) starch with dry ground corn (DGC) or high-moisture corn (HMC) as the primary starch source. Treatments were fed from 1 to 23 d PP and then switched to a common diet until 72 d PP to measure carryover (CO) effects. Treatment period (TP) diets were formulated for 22% forage NDF and 17% CP, and starch concentration was adjusted by substitution of corn grain for soyhulls. The diet for the CO period was formulated to 20% forage NDF, 17% CP, and 30% starch. Throughout the experiment, both DMI and MY were measured daily, and milk components, BCS, and back fat thickness (BFT) were measured weekly. During TP, DGC increased DMI by 2.2 kg/d compared with HMC ($P < 0.01$) but tended to increase DMI more with HS (3.4 kg/d) than with LS (1 kg/d; interaction, $P = 0.12$). Treatments also interacted over time; DGC increased DMI throughout the TP for HS but only after the first week for LS compared with the HMC treatments ($P < 0.01$). There was no main effect of starch content on DMI. The effect of corn source diminished over time during the CO period ($P = 0.03$) with no main effects of treatment on DMI. Dry ground corn increased yields of milk by 2.6 kg/d ($P = 0.12$), 3.5% fat-corrected milk (FCM) by 4.3 kg/d ($P = 0.02$), fat by 165 g/d ($P = 0.03$), and protein by 165 g/d ($P = 0.01$) compared with HMC with no effect of starch content throughout the TP. Starch source and content interacted ($P < 0.05$) to affect yields of fat and FCM during the CO period, which were greater for DGC-HS and HMC-LS (1.78 and 52.1 kg/d, respectively) than for DGC-LS and HMC-HS (1.62 and 48.6 kg/d, respectively). Dry ground corn tended to decrease BCS loss until the third week of TP ($P < 0.15$) compared with HMC but had no effect overall. No effects of treatment were detected for BFT during TP but HMC increased BFT 0.1 mm ($P = 0.04$) during the CO period. Ruminal fermentability of starch is an important consideration for diets of cows in the PP period.

Key Words: high-moisture corn, dry corn, fresh cows

0756 Meta-analysis of postruminal microbial nitrogen flows in dairy cattle. Y. Roman-Garcia*[1], R. R. White[2], and J. L. Firkins[1], *[1]The Ohio State University, Columbus, [2]Virginia Polytechnic Institute and State University, Blacksburg*.

The objective of this study was to summarize the literature and derive equations that relate the chemical composition of

diet and rumen characteristics to the intestinal supply of microbial nitrogen (MicN; g/d), efficiency of microbial protein synthesis (EMPS; g MicN/kg OM truly degraded in the rumen), and flow of nonammonia nonmicrobial N (NANMN; g/d). In this study, 619 weighted treatment means were screened from 183 studies using dairy cattle that were sampled from the duodenum or omasum (sample location [SMPLoc]). Backward elimination multiple regression was used to derive equations to estimate flow of nitrogenous components over a large range of dietary nutrients (% of DM) or ruminal pH, NH_3–N (mg/dL), or individual branched-chain VFA (BCVFA; mol/100 mol). An intercept shift indicated greater MicN flow for omasal sampling relative to duodenal sampling in all MicN models, but sample location did not interact with any other variables tested. Microbial nitrogen was associated with DMI and dietary starch percentage: MicN = −18.4 g/d + 109 g/d more (if SMPLoc = omasal) + 10.8(DMI) + 5.31(starch) − 0.0839(starch × starch). Ruminal pH and NH_3–N were negatively related to MicN flow, with a positive association with ruminal isovalerate. The EMPS = 4.71(isovalerate) + 0.260(NH_3–N) − 0.257(NH_3–N × isovalerate). A similar equation with a parallel role for isobutyrate confirms the importance of BCVFA to increase growth rate and, therefore, assimilation of NH_3–N into microbial protein. The flow of NANMN = −37.5 (if SMPLoc = omasal) + 8.70(DMI) + 9.98(NDF) −1.42(NDF×NDF) + 6.08(CP). Because NANMN is calculated by subtracting MicN, omasal sampling underestimated NANMN relative to duodenal sampling. This equation is probably associated with neutral detergent isoluble N contamination of NDF in certain rumen-undegradable protein sources. As in the MicN equation, sampling location did not interact with any other variables tested for NANMN. Equations derived from dietary nutrient composition are robust across dietary conditions and could be used for prediction in protein supply-requirement models.

Key Words: nitrogen, microbial, flow

0757 Milk yield genotype affects hepatic expression of innate immune genes when challenged with lipopolysaccharide.

G. T. Cousillas*[1], W. J. Weber[1], B. Walcheck[1], R. Chebel[1], D. E. Kerr[2], T. H. Elsasser[3], and B. A. Crooker[1], *[1]University of Minnesota, Saint Paul, [2]University of Vermont, Burlington, [3]USDA, ARS, Beltsville, MD*.

Objectives were to determine effects of milk yield genotype on hepatic expression of genes related to innate immune response during a lipopolysaccharide (LPS) challenge. Multiparous cows (n = 12/genotype) from unselected (stable milk yield since 1964; UH) and contemporary (CH) Holsteins that differed by more than 4,500 kg milk/305 d were housed together and fed the same diet ad lib for more than 4 mo before being blocked (2/genotype) by DIM and randomly assigned within genotype to receive saline or 0.25 μg/kg BW of LPS (*Escherichia coli* 055:B5). Cows were synchronized to be at Day 8 of their estrous cycle for the first challenge (C1) at 70 to 84 DIM. Liver biopsies were collected at 0, 4, and 24 h relative to treatment. Acute innate immune responses were assessed in C1. A second identical challenge (C2) and sampling was conducted 4 d later to assess the impact of a repeated challenge. Expression of 44 genes associated with immunity was determined by digital multiplexed analysis (nanoString nCounter). Expression was normalized to the positive control and the geometric mean of 4 internal control genes. Data were transformed (square root) and analyzed by repeated measures using PROC MIXED (SAS) with time as the repeated effect. Means differed when $P < 0.05$. There were time × treatment interactions for 37 genes due to changes in expression after LPS. At 4 h, LPS increased expression of 15 genes and reduced expression of FASLG in UH relative to CH. The 15 genes included TLR4, CD14, ICAM-1, IRF-1, MYD88, IL-6, and TNF. During C2, expression of these genes was less than in C1 and was not affected by genotype. There was a genotype × treatment × challenge interaction for CCL20 as its expression at 4 h in C2 was greater in CH than UH. IL-10 increased at 4 h for both genotypes, but expression during C2 was less than during C1. TGFB1 increased more in UH than CH at 4 h in both challenges. During the acute phase (C1), UH cows had a more robust expression of genes related with immune cell activation, cytokine production, and chemoattractant production and activation than CH. Responses during C2 were diminished in both genotypes, which indicates that compensatory mechanisms invoked by C1 were still affecting the response to LPS. Results indicate milk yield genotype impacts the response to LPS and contributes to a less robust response in the contemporary cow.

Key Words: gene expression, immunity, bovine genotype, lipopolysaccharide

0758 Effects of feeding different forms of polyunsaturated fatty acids on performance, plasma metabolites, and milk fatty acid composition of dairy cows.

L. D. P. Sinedino*[1], R. R.C. Mello[2], C. Lopera[1], A. Vieira Neto[1], M. G. Zenobi[3], E. Block[4], C. L. Preseault[5], A. L. Lock[5], C. R. Staples[3], W. W. Thatcher[6], and J. E. P. Santos[1], *[1]University of Florida, Gainesville, [2]Federal Rural University of Rio de Janeiro, Seropedica, Brazil, [3]Dep. of Animal Sciences, University of Florida, Gainesville, [4]Arm & Hammer Animal Nutrition, Princeton, NJ, [5]Michigan State University, East Lansing, [6]Department of Animal Sciences, University of Florida, Gainesville*.

Objectives were to determine the effects of feeding different types of PUFA on performance and yield of fatty acids in Holstein cows. Eight ruminally cannulated primiparous cows were randomly assigned to a replicated 4 × 4 Latin square design

(28 d; 19 d adaptation, 7 d collection, and 2 d rumen evacuation). Diets were identical except for the type of fatty acid supplements that were incorporated at 2.1% of dietary DM. Supplements were Ca salts (CaS) of palm oil (CaSP), oil (O; a blend of 45% palm and 55% soybean oils), CaS of O in a granular form (CaSOG), and CaS of O in a pelleted form (CaSOP). Intake and yield and composition of milk were averaged from d 20 to 26. The fatty acid profile of milk fat was analyzed in samples collected from d 24 to 26. Blood was sampled at 0, 3, 6, 9, and 12 h relative to feeding on d 26 and analyzed for hormones and metabolites. Ruminal pH was measured for 72 h in each period. Data were analyzed by ANOVA with the MIXED procedure of SAS for a replicated 4 × 4 Latin square. Results of cow performance are presented in Table 1. Results in the text are presented in the following sequence: CaSP, O, CaSOG, and CaSOP. Feeding O increased ($P \leq 0.05$) rumen fluid pH compared with CaSP or CaSOG (6.22, 6.31, 6.20, and 6.26 ± 0.07). Plasma concentration of glucose increased ($P \leq 0.05$) in O compared with CaSP and CaSOG and tended ($P = 0.08$) to be greater than CaSOP (64.8, 66.3, 64.7, and 64.9 ± 0.55 mg/dL). Glucagon concentration in plasma tended ($P = 0.06$) to be greater in CaSP compared with CaSOP (156.4, 152.6, 149.4, and 144.8 ± 8.0 pg/mL). There were no treatment effects on plasma insulin, NEFA, and urea N concentrations. Milk linoleic (3.29, 3.22, 4.88, and 4.71 ± 0.16 g/100 g of fatty acid) and linolenic acids (0.43, 0.46, 0.61, and 0.53 ± 0.02) and total *n*-3 (0.46, 0.48, 0.64, and 0.56 ± 0.02) and *n*-6 fatty acid yields (3.78, 3.64, 5.37, and 5.19 ± 0.17) increased ($P < 0.01$) in cows fed CaSOG and CaSOP compared with cows fed CaSP or O. Conjugated linoleic acids *trans*-10 *cis*-12 and *trans*-9 *cis*-11 were reduced ($P < 0.01$) in cows fed CaSP compared with cows fed other treatments (0.004, 0.013, 0.019, and 0.019 ± 0.003). Source of fatty acids did not affect DMI or milk yield, but feeding O as CaS in a pelleted form improved milk fat content. Feeding CaS of O either as granular or pelleted increased content of PUFA in milk fat.

0759 Rumen-protected methyl donors during the transition period: Circulating plasma amino acids in response to supplemental rumen-protected methionine or choline. Z. Zhou*[1], M. Vailati Riboni[1], D. N. Luchini[2], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]Adisseo S.A.S., Alpharetta, GA*.

The objective of this study was to profile plasma AA and downstream products of their metabolism during the peripartal period in response to supplemental rumen-protected methionine (MET) and choline (CHO). Forty multiparous Holstein cows were used in a randomized complete block design with 2 × 2 factorial arrangement of MET and CHO level (with or without). Treatments were control (CON), no MET or CHO; CON+MET (SMA); CON+CHO (REA); and CON+MET+CHO (MIX). From −21 (close-up) to 30 d after calving, cows received the same diet (1.52 Mcal NE_L/kg DM) from close-up to calving. From calving to 30 d, cows were on the same diet (1.71 Mcal NE_L/kg DM) and continued to receive the same treatments through 30 d. MET supplementation was adjusted daily at a rate of 0.08% (DM basis) of diet and CHO was supplemented at 60 g/cow per day. Blood samples were taken at −30, −10, 4, 14, and 28 d relative to calving. Data were analyzed as a factorial design with repeated measures using PROC MIXED in SAS. Previous results from this experiment revealed that both pre- and postpartum DMI was greater with MET ($P = 0.01$) but did not change with CHO ($P > 0.05$). As expected, MET supplementation led to greater ($P < 0.01$) plasma methionine concentration compared with other treatments. Similarly, sulfur-containing AA derivatives (homocystine, cystathionine, and cystine) and taurine (an antioxidant) also were greater in MET-supplemented cows, suggesting an enriched sulfur pool. In addition to plasma methionine concentration, lysine ($P = 0.01$), arginine ($P = 0.02$), tryptophan ($P < 0.01$), and threonine ($P = 0.07$) also were greater in MET-supplemented cows, all of which contributed to the strong tendency ($P = 0.06$) for greater essential AA (EAA) in response to MET. An overall greater ($P = 0.02$) total plasma AA concentration was observed in MET cows due to greater ($P < 0.05$) proline, asparagine, alanine, and citrulline compared with other treatments. In contrast, CHO supplementation had no effect ($P > 0.05$) on overall EAA

and total AA, as only tryptophan ($P = 0.02$) and cystine ($P < 0.01$) were greater with this treatment. Plasma concentration of 3-methyl-histidine was lower ($P < 0.05$) in response to CHO, suggesting less protein mobilization in these cows. Overall, data from the present study indicate that peripartal supplementation of rumen protected methionine has positive effects on plasma AA status.

Key Words: amino acid, choline, methionine, transition cow

0760 The nutritional quality of winter crops for silage in monoculture or with legumes. A. N. Brown*[1], G. Ferreira[1], C. L. Teets[1], W. E. Thomason[2], and C. D. Teutsch[3], *[1]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, [2]Department of Crop and Soil Environmental Sciences, Virginia Polytechnic Institute and State University, Blacksburg, [3]Dep. of Crop and Soil Environmental Sciences, Virginia Polytechnic Institute and State University, Blacksburg*.

The objectives of this study were to determine the nutritional quality of different winter crops for silage within various regions of Virginia and to determine the impact of the various winter crops on the succeeding productivity of corn and sorghum. Experimental plots were planted with 15 different winter crop treatments at 3 locations in Virginia. At each site, 4 plots of each treatment were planted in a randomized complete block design. The 15 treatments included 5 winter annual grasses (barley, wheat, rye, ryegrass, and triticale) in monoculture [NO] or with one of two winter annual legumes (crimson clover [CC] and hairy vetch [VE]). The nutritional composition (DM, ash, CP, NDF, ADF, ADL, starch, and sugars) was determined for the fresh samples. Additionally, 200

to 400 g of chopped material were placed into mini-silos and analyzed after 60 d of ensiling. The statistical model included the effects of grass, legume, the 2-way interaction, and the random effect of site. Sorghum and corn were planted after harvesting the winter crops in split plots. For the split-plot design, the statistical model included the effects of treatment, the random effect of site, treatment × site, summer crop, summer crop × site, and summer crop × treatment. There were no grass × legume interactions except for fresh ADF and silage NDF. Crimson clover tended to increase forage DM yield. Adding legumes increased CP and decreased NDF of both fresh and silage samples. However, addition of legumes increased ADL in contrast to NO. Legumes did not affect ADF concentrations of fresh samples, but for silage, VE increased ADF compared with CC and NO. In contrast to VE, inclusion of CC increased sugar content for both fresh and silage samples. Corn yields were greatest succeeding barley compared with the other grasses (15,800 vs. 14,700 kg/ha). Addition of legumes did not affect DM yield of corn (14,900 kg/ha) or sorghum (15,300 kg/ha). We conclude that although inclusion of legumes did not have a residual effect on summer annual yields, including CC could increase yield of winter crops. Addition of legumes increases CP, decreases NDF, and, for VE, decreases the sugar content of the silage.

Key Words: winter crops, cover crops, nutritional quality

0761 Housing and demographic effects on somatic cell score in southeast United States dairies. A. Stone*[1], C. Blakely[2], K. Bochantin[1], P. D. Krawczel[2], M. Myers[1], D. T. Nolan[1], C. S. Petersson-Wolfe[3], G. M. Pighetti[2], S. Ward[4], and J. M. Bewley[1], *[1]University of Kentucky, Lexington, [2]University of Tennessee, Knoxville, [3]Virginia Tech University, Blacksburg, [4]Mississippi State University, Mississippi State*.

The objective of this study, as part of the Southeast Quality Milk Initiative, was to evaluate the effects of housing systems and farm demographics on SCS. From June 22, 2014, to June 21, 2015, dairy producers in Kentucky (n = 96), Tennessee (n = 83), Virginia (n = 96), and Mississippi (n = 7) participated in an on-farm survey. Each survey variable's effect on SCS was evaluated using the GLM procedure in SAS with no covariates. Significant farm demographic variables were then included as covariates in a GLM alongside herd size, state, and all two-way interactions. The same process occurred for significant housing variables with confinement type also included (total confinement, <4 h outside access, ≥4 h outside access, or exclusively pasture). Backward stepwise elimination was used to eliminate nonsignificant interactions ($P > 0.05$). In the housing model, state ($P < 0.01$) and confinement type ($P < 0.04$) were significantly associated with SCS. Herds in Kentucky (4.33) and Virginia (4.43) had a lower SCS than Mississippi (4.84) and Tennessee (4.70; $P < 0.02$) herds. Total confinement herds had a lower SCS than herds with outside access (4.23, 4.67, 4.51, and 4.71 for total confinement, <4 h outside, ≥4 h outside, and exclusively pastured herds, respectively; $P < 0.03$). Nonsignificant variables included herd size, alley scraping frequency, fan availability, sprinkler availability, year of last housing renovation, and all interactions. In the farm demographic model, state ($P < 0.01$), age ($P < 0.01$), and plans to be in business in 5 yr ($P = 0.02$) were significantly associated with SCS. Producers ≥66 yr old managed herds with higher SCS compared with all other age groups (4.43, 4.38, 4.56, 4.45, 4.58, and 5.06 for <26, 26 to 35, 36 to 45, 46 to 55, 56 to 65, and ≥66 yr old, respectively; $P < 0.01$). Producers responding that they were "almost certainly" going to be in business in 5 yr had lower SCS than producers responding they were "very likely" to be in business in the same time frame (4.38 and 4.72, respectively; $P < 0.01$). Nonsignificant variables included herd size, regularly scheduled veterinarian visits, producer education level, plans to be in business in 10 yr, and all interactions. These results suggest both housing and demographics are associated with SCS in the southeastern United States.

Key Words: management, mastitis, Southeast Quality Milk Initiative

0762 Feeding low crude protein diets in lactating dairy cows during summer months: 1. Improvements in milk production and nitrogen utilization. J. Kaufman*, K. Kassube, and A. G. Rius, *The University of Tennessee, Knoxville*.

Heat stress increases protein catabolism and urinary nitrogen excretion resulting in reduced nitrogen-use efficiency (NUE) in livestock. Feeding low CP diets may improve performance of lactating dairy cows during summer. A study was conducted to evaluate the effect of feeding low RDP and RUP levels in cows during summer. Forty-eight midlactation Holstein cows were assigned to treatments using a complete randomized block design in a 2 × 2 factorial arrangement of treatments (n = 12/treatment). Treatments included two levels of RDP (10 and 8%) and two levels of RUP (8 and 6%). A common diet (10% RDP and 8% RUP) was fed from d 1 to 21 followed by the respective treatment diets from d 22 to 42. Milk samples were collected from d 36 to 42. Cows were housed in a freestall barn and exposed to the prevailing temperature and humidity of July and August with no supplemental cooling. Main effects and their interaction were tested using the Mixed procedure of SAS and reported as least squares means ± SEM. Rectal temperatures and respiration rates were recorded before noon and after noon during the treatments. Compare with before noon, after noon increased temperature and respiration rates (38.9–39.7 ± 0.07°C [$P < 0.001$] and 64.0–87.1 ± 1.4 breaths/min [$P < 0.001$]). Compared with the 10% RDP, the 8% RDP treatment increased DMI and milk protein yield in the 6% RUP treatment (19.0 vs. 18.4 ± 0.32 kg/d and 1.02 vs.

0.96 ± 0.02 kg/d) but decreased DMI and milk protein yield in the 8% RUP treatment (19.4 vs. 20.1 ± 0.32 kg/d [interaction, $P < 0.01$] and 1.02 vs. 1.08 ± 0.02 kg/d [interaction, $P < 0.01$]). There was a trend ($P < 0.07$) for an interaction such that the 8% RDP treatment increased energy-corrected milk (ECM) yield compared with 10% RDP in the 6% RUP treatment (31.7 vs. 29.4 ± 0.76 kg/d) but reduced ECM yield in the 8% RUP treatment (32.5 vs. 33.0 ± 0.76 kg/d). The 10% RDP treatment increased ($P < 0.001$) milk-urea nitrogen compared with the 8% RDP treatment (10.2 vs. 6.9 ± 0.28 mg/dL). The 8% RUP treatment increased ($P < 0.001$) milk-urea nitrogen compared with the 6% RUP treatment (9.8 vs. 7.2 ± 0.28 mg/dL). The 8% RDP treatment increased ($P < 0.001$) NUE compared with 10% RDP (35.1 vs. 31.6 ± 0.76%). The 6% RUP treatment increased ($P < 0.001$) NUE compared with 8% RUP (35.1 vs. 31.6 ± 0.76%). Therefore, lower RDP diets can be fed with 6% RUP diets without compromising milk production, whereas the combination of low RDP with 8% RUP depressed productivity. Lower RDP and RUP diets increase NUE in heat-stressed cows.

Key Words: crude protein, nitrogen-use efficiency, heat stress

0763 Influence of a bovine respiratory disease complex vaccine with a modified live virus or KV infectious bovine rhinotracheitis component on estrous cycle parameters and anti-Müllerian hormone concentration in nulliparous heifers.

C. L. Widener*, D. J. Hurley, W. M. Graves, A. H. Nelson, D. A. L. Lourenco, and J. F. Bohlen, *University of Georgia, Athens*.

The objective of this study was to examine the impact of a bovine respiratory disease complex (BRDC) vaccine with a modified live virus (MLV) infectious bovine rhinotracheitis (IBR) component on estrous cycle parameters and the follicular pool. Twenty-four Holstein heifers (mean 12.4 mo [SD 0.5]) in two replicates (spring, $n = 10$, and fall, $n = 14$) were synchronized for estrus using a 7-d CIDR protocol with 2 injections of PGF_{2a}, one at CIDR removal and a follow-up injection 16 h later. Heifers were calf-hood vaccinated with an IBR MLV. Heifers were observed for one complete estrous cycle to establish normal cyclicity. At Heat 2, heifers were vaccinated with either the calf-hood MLV (MLV; $n = 12$) or a BRDC vaccine with a killed (K; $n = 12$) IBR component. Heifers were blocked into treatment groups according to prevaccination bovine viral diarrhea virus (BVDV) serum neutralizing titers. Heifers were then tracked for two complete estrous cycles. Serum samples for estradiol (E2) and progesterone (P4) and ultrasound of ovarian structures were collected to track cyclicity every other day. Serum samples for anti-Müllerian hormone (AMH) were collected at estrus and mid cycle to evaluate the follicular pool. Data was normalized with ovulation as Day 0. Data were analyzed with the PROC MIXED procedure of SAS with cycle number, season, and vaccine as fixed effects. The model for P4 analysis added day of cycle as a fixed effect. There was no difference ($P > 0.05$) in postvaccination titers. Vaccination had no impact on P4 concentrations, luteal tissue area, peak E2 production, or estrous cycle lengths ($P > 0.05$). Overall variables that affected AMH concentrations were season (spring = 138.92 ± 43.1 pg/mL; $P = 0.0043$), vaccine type (MLV = −92.4 ± 42.9 pg/mL; $P = 0.0435$), and cycle number ($P < 0.0001$). Anti-Müllerian hormone concentration decreased between cycles 1 and 2 and cycles 1 and 3 for MLV vaccinated heifers ($P < 0.0003$). Anti-Müllerian hormone concentrations of cycle 2 were numerically lower between vaccine types (K = 308.22 ± 33.3 pg/mL and MLV = 181.13 ± 32.9 pg/mL; $P = 0.0953$), although not statistically different. This may be due to low animal numbers, the variability between animals, or the differences observed in the Fall killed vaccine (−70.93 ± 21.1 pg/mL; $P = 0.0145$) from cycle 1 to 2 but not in the Spring killed vaccine (3.40 ± 45.1 pg/mL; $P = 0.9969$). Anti-Müllerian hormone was weakly correlated with small follicle count ($r^2 = 0.15$, $P < 0.0001$). Although no differences were seen in overall cycle parameters, these differences in AMH concentrations may indicate a reduction of the follicular pool as a result of vaccination with an IBR MLV.

Key Words: infectious bovine rhinotracheitis modified live virus, cyclicity, anti-Müllerian hormone

GROWTH AND DEVELOPMENT

0764 Functional characterization of porcine SCD1 in stably transduced porcine SK6 cells.

J. Hwang*, N. Singh, C. Long, and S. B. Smith, *Texas A&M University, College Station*.

Fatty acid composition is an important component of foods derived from livestock species, as it contributes to both the healthfulness and the functionality of beef, lamb, pork, and dairy products. The most highly regulated and most abundant fatty acid in animal tissues and dairy products is oleic acid (18:1*n*-9). Oleic acid is synthesized by the Δ9 desaturase, stearoyl CoA desaturase (SCD1), which also is responsible for the synthesis of the putative cytokine palmitoleic acid (16:1*n*-7) and *cis*-9, *trans*-11 CLA. Owing to the importance of SCD1 in lipid metabolism, we generated a porcine SK6 transgenic cell lines for sustained overexpression or knockdown of pSCD1 in an inducible manner by using a novel All-in-One Tet-On Lentiviral expression system. We combined the inducible transcriptional activator (tetracycline-controlled transactivator protein) vector and the vector encoding the pSCD1 gene under the influence of a tetracycline-responsive promoter element into one to generate an inducible all-in-one lentiviral vector system. The cell culture models were validated for expression and functionality of pSCD1 by documenting that

the pSCD1 transformed cells overexpressed pSCD1 protein and mRNA over 1,000-fold ($P < 0.0001$). Similarly, an SCD1 shRNA designed to inhibit SCD1 gene expression decreased pSCD1 mRNA and pSCD1 protein expression levels by over 75% ($P < 0.001$). The pSCD1-transformed cells increased the synthesis of palmitoleic acid nearly 4-fold ($P < 0.05$), which was almost completely abolished when SK6 cells were transfected with the SCD1 shRNA. These results indicate that the lentiviral constructs used in this study can be further used to document the regulation of lipid metabolism by SCD1 in pigs.

Key Words: stearoyl-CoA desaturase-1, SK6 kidney cells, transfection, palmitoleic acid

0765 Gene expression profiling and fatty acid composition in muscle during growth of Yanbian Yellow Cattle. X. Li*[1], C. Yan[1], S. Choi[2], J. Shin[3], and S. B. Smith[4], *[1]Yanbian University, Yanji, P. R. China, [2]Chungbuk National University, Chengju, the Republic of Korea, [3]Kongwon National University, Chuncheon, the Republic of Korea, [4]Texas A&M University, College Station*.

We hypothesized that gene expression and fatty acid composition would differ among different muscle depots and over time on a finishing diet. The present study was conducted with 16 Yanbian Yellow cattle steers (approximately 8 mo of age). Yanbian Yellow cattle are genetically similar to Korean Hanwoo and Japanese Wagyu cattle. Steers were fed a corn-based diet and were randomly assigned to 4 sampling groups. Five consecutive biopsy samples were taken from the chuck, loin, and round muscle at age 12, 16, 20, and 24 mo. Fat content in each muscle increased from 12 to 24 mo of age and the order of fat content in muscles was loin > round > chuck at 12, 16, 20, and 24 mo of age. There were significant differences in the concentrations of stearic acid (18:0), oleic acid (18:1*n*-9), linoleic acid (18:2*n*-6), SFA, MUFA, and the MUFA:SFA ratios with age. At the earliest sampling period, muscle lipids had low MUFA:SFA ratios (0.9 to 1.1), and the muscle lipid MUFA:SFA ratios were highest at 24 mo of age (1.29 to 1.41). There were significant depot effects for stearic acid, linoleic acid, SFA, MUFA, PUFA, and the MUFA:SFA ratio across muscles. Expression of *SREBP1*, *A-FABP*, *SCD1*, *ACC*, and *LPL* in the muscle biopsy samples increased with age, whereas the expression of *PPARγ* and *FAS* decreased with age ($P < 0.05$). The presence of adipogenic gene expression indicated that the muscle biopsy samples also contained intramuscular adipose tissue. Between 12 and 24 mo of age, stearic acid decreased from approximately 16 to 10%, whereas oleic acid increased from approximately 34 to 45% of total muscle fatty acids. Correspondingly, *SCD1* gene expression increased approximately 4-fold between 12 and 24 mo of age. There also were significant muscle main effects for gene expression. Gene expression in biopsies from the loin exhibited the highest expression of all adipogenic genes included in this study; conversely, samples from the chuck had the lowest adipogenic gene expression ($P < 0.05$ for all genes). These results were consistent with loin biopsy samples having the highest fat content. The findings of this study support our hypothesis that adipogenic gene expression varies across muscles and across time on feed and provide novel information about the development and composition of marbling in Yanbian Yellow cattle.

Key Words: Yanbian Yellow cattle, fatty acids, gene expression

0766 α-Chaconine induces myogenesis of bovine satellite cells isolated from semimembranosus and longissimus muscle tissue. K. Y. Chung*, S. C. Jang, E. M. Lee, S. H. Yang, and E. G. Kwon, *Hanwoo Research Institute, NIAS, RDA, Pyeongchang, the Republic of Korea*.

α-Chaconine is a steroidal glycoalkaloid that found in leaves, fruit, and tubers of the solanaceae family such as potato, tomato, and eggplant. Alkaloid poisoning of potato plant was reported in various animal models such as mice, rabbit, and chicken. However, it is also used as a treatment for human asthma. Some medicine used for treating human asthma has been used to induce myogenesis of bovine skeletal muscle. We hypothesized that α-chaconine may affect myogenesis of bovine satellite cells isolated from different muscle depots. Bovine satellite cells were pronase-liberated from semimembranosus (SM) and longissimus dorsi (LD) muscle tissues of three newborn Hanwoo calves. Bovine SM and LD satellite cells were incubated with Dulbecco's modified Eagle medium (DMEM) with 10% fetal bovine serum for proliferation and induced differentiation with DMEM with 3% horse serum. Bovine satellite cells were treated with various levels of α-chaconine (control and 0.001, 0.01, 0.1, 1, and 10 μ*M*). Messenger RNA abundance for myosin heavy chain 1 (MHC1), MHC2X, glucose transporter 4 (GLUT4), myogenin, G-coupled protein receptor 43 (GPR43), and β2-adrenergic receptor (β2-AR) were measured by real-time quantitative PCR. Data were analyzed as a completely randomized design using the MIXED model, with each treatment performed in triplicated. Means were considered different at $P < 0.05$. Relative MHC2X mRNA abundance was increased at dose-dependent levels in both SM and LD satellite cells with α-chaconine treatments compared with the control ($P < 0.05$). However, MHC2X and GLUT4 levels were decreased in 10 μ*M* treatments ($P < 0.05$). Relative level of MHC2X and β2-AR were greater in LD satellite cell compared with SM satellite cells ($P < 0.05$). There was no tissue × dose interaction among MHC1 mRNA concentration ($P > 0.05$). These results indicated that α-chaconine has a dose-dependent effect on MHC2X mRNA but did not affect to MHC1 mRNA in bovine satellite cells.

Key Words: α-chaconine, Hanwoo, semimembranosus, longissmus dorsi, satellite cells

0767 Vitamin C supplement increased intramuscular adipose tissues but not affect myogenic development of Hanwoo steers. S. C. Jang, K. Y. Chung*, E. M. Lee, S. H. Yang, and E. G. Kwon, *Hanwoo Research Institute, NIAS, RDA, Pyeongchang, the Republic of Korea*.

Vitamin C (VC) supplements have been used for enhancing marbling fat in high-quality beef cattle. However, mode of action of vitamin C was not clearly studied for long time. The aim of this experiment was to determine the effect of additional saturated parm-oil coated VC supplement compare to a control diet (saturated parm-oil only) on the level of adipogenic and myogenic gene expressions at liver (LV), subcutaneous adipose tissue (SC), perirenal adipose tissue (PR), and longissimus dorsi muscle (LD). A 2 × 4 factorial arrangement (control, VC, and LV, SC, PR, and LD tissues) was used to feed 10 Hanwoo steers. Two steers were fed in same pen and 5 pens were used for treatment. Tissues were collected within 10 min of harvest for analysis of PPARγ, SCD, GLUT4, MHC1, MHC2X, and GPR43 mRNA abundance. Real-time RT-PCR was used to measure the quantity of respective mRNA relative to a ribosomal protein subunit 9 (RPS9) mRNA. Data were analyzed as a completely randomized design using the MIXED model. Difference between the control and treatments were determined using the LSD procedure. Overall ADG did not differ between VC supplement and the control ($P > 0.05$). Marbling score was greater in the VC treatment than in the control ($P < 0.05$). Lipid percentage tended to greater ($P = 0.084$) in the VC treatment but share force tended to be lower in the VC treatment ($P = 0.068$). Real-time quantitative PCR revealed that the mRNA content of SCD in PR from VC supplement cattle increased ($P < 0.05$) compared with the control. There was no mRNA effect at MUS in cattle. However, mRNA level of GLUT4 and GPR43 were increased at LV tissues in VC-treated cattle ($P > 0.05$). These data indicated that VC supplement increased relative mRNA level of GLUT4 and SCD in SC and LV tissue but not affect myogenic gene expression on final fattening periods of Hanwoo steers.

Key Words: Hanwoo, adipogenic, myogenic, |gene expression

0768 Chromium propionate supplementation alters feedlot performance and GLUT4 activity in feedlot steers. J. O. Baggerman*[1], Z. K. F. Smith[1], A. J. Thompson[1], J. Kim[1], P. W. Rounds[2], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, [2]Kemin Industries, Inc., Des Moines, IA*.

The objective was to evaluate the effects of increasing concentrations of chromium propionate (CrP) on feedlot performance, blood parameters, carcass characteristics, and skeletal muscle changes over time in feedlot steers. Crossbred steers ($n = 32$, 16 pens, 2 hd/pen) were blocked by BW, and each pen was randomly assigned to one of four treatments: control, 150 ppb supplemental CrP (KemTRACE Chromium, 0.04%; Kemin Industries, Des Moines, IA), 300 ppb supplemental CrP, and 450 ppb supplemental CrP. Steers were fed 1x daily ad libitum a steam-flaked corn–based diet, and the treatment was top-dressed at the time of feeding. Body weights, blood samples, and skeletal muscle biopsies were collected before time of feeding on d 0, 28, 56, 91, 119, and 147. Blood sera were harvested for analysis of glucose, insulin, serum urea nitrogen, and NEFA concentrations. Skeletal muscle biopsy samples were used for immunohistochemical analysis. Data was analyzed using the GLIMMIX procedure of SAS 9.4, with pen as the experimental unit for live and carcass data and steer as the experimental unit with day as a repeated measure for laboratory analysis. Starting on d 56 through the end of the trial, cattle fed the 450-ppb treatment were the heaviest ($P < 0.05$). A linear effect ($P < 0.05$) of treatment on BW and ADG was observed starting on d 56 until the end of the trial. For HCW, there was also a linear effect of treatment, with the greatest HCW in the cattle fed the 450-ppb treatment ($P < 0.05$). There was no effect of treatment on any blood parameter measured ($P > 0.05$). For skeletal muscle fiber cross-sectional area, there was a treatment × day interaction ($P < 0.05$), with the greatest increase in the 450-ppb treatment group. Density of total GLUT4 decreased over time for all treatments ($P < 0.05$), with the treatments receiving CrP having less of a decrease than the control group ($P < 0.05$). Internalization of GLUT4 was increased in the 300-ppb and 450-ppb treatments ($P < 0.05$). For total nuclei density and myonuclei density, there were treatment × day interactions ($P < 0.05$), where the 450-ppb treatment exhibited a greater density of total nuclei and myonuclei on d 147. These results indicated supplementation of 450 ppb CrP increases HCW, possibly due to changes in GLUT4 activity in skeletal muscle.

Key Words: beef cattle, growth, muscle

0769 Feeding five percent grass hay or wheat straw with high-starch, textured diets to weaned dairy calves between eight and sixteen weeks of age. F. X. Suarez-Mena*, T. S. Dennis, T. M. Hill, J. D. Quigley, and R. L. Schlotterbeck, *Provimi, Brookville, OH*.

This research had the objective to determine if changing diet forage fiber concentration by feeding different forages affected BW gain and structural growth of dairy calves from 8 to 16 wk of age. Male Holstein calves (24 per treatment in 6 pens with 4 calves/pen) initially 76 ± 1.6 kg BW were fed a common, textured grain-based concentrate (95% of the total mixed ration; 37% whole corn, 25% whole oats, 35% protein supplement pellet, and 3% molasses; 22% CP, 40% starch, 9% ADF, and 16% NDF) with either 5% chopped grass hay (13% CP, 40% ADF, and 67% NDF) or 5% chopped wheat straw

(2% CP, 48% ADF, and 80% NDF). During the previous nursery phase, calves were fed 0.66 kg DM from milk replacer (25% CP and 17% fat) and weaned at 42 d. Calves were also fed a similar textured, grain-based concentrate and water ad libitum. Calves remained in the nursery after weaning for 14 d. Calves were weighed and scored for body condition, and hip widths were measured initially (8 wk) and at 12 and 16 wk (periods 1 and 2; 56-d trial). Body condition score was a 5-point system (1 being thin and 5 being obese). Treatments were analyzed as a completely randomized design with repeated measurements. Initial BW, hip width, and BCS did not differ ($P > 0.10$) among treatments. The hay diet contained 3.3% NDF from forage whereas the straw diet contained 4.0% NDF from forage. There tended ($P < 0.09$) to be an interaction of treatment with 4-wk period for DMI as a percent of BW (2.87 vs. 2.76% BW in period 1 and 2.87 vs. 2.93% BW in period 2 for hay vs. straw, respectively), but there were no interactions ($P > 0.10$) for other measurements. Overall BW gain tended ($P < 0.07$) to be greater for calves fed hay vs. straw (1.04 vs. 0.97 kg/d). Change in hip width (5.0 vs. 4.6 cm) and feed efficiency (0.350 vs. 0.334 BW gain/feed) were greater ($P < 0.05$) for calves fed hay vs. straw. Change in BCS was 0.5 points for each treatment. These results further suggest that BW and structural growth in Holstein calves less than 16 wk of age is very sensitive to forage fiber concentration.

Key Words: forage, calves, growth

0770 Effects of a milk balancer protein supplement on growth and performance of dairy calves.

P. Turiello*[1], E. Martinez[1], M. Auil[2], A. Bogni[2], and O. Queiroz[2], *[1]Facultad de Agronomia y Veterinaria, UNRC, Rio Cuarto, Argentina, [2]Dpto. Tecnico Bovinos, TEKNAL SA, Cordoba, Argentina*.

In Argentina, dairy calves are commonly fed 4 L/d of milk plus starter pelleted feed containing 20% of CP during the first 8 wk of life. The objective of the study was to evaluate the effect of a milk balancer protein supplement on growth and performance of dairy calves during the first 30 d of this period. Fourteen newborn calves were randomly assigned to one of two treatments: 1) control (fed 4 L/d of raw milk) and 2) supplement (SUP; fed 4 L/d of raw milk and 0.2 kg/d of supplement). All calves had access to water and were individually offered starter feed. Body weight and body measurements (withers and hip height, thoracic diameter, and body length) were taken weekly and every 2 wk, respectively. Intake of starter feed was calculated daily based on offered and remaining feed, and total DMI was calculated taking into account milk, supplement, and starter feed intake. Milk, starter feed, and milk balancer were sampled weekly and chemically characterized. The data was analyzed as a randomized complete block design and the statistical model included treatment, time (repeated), sex, and interactions. Body measurements and weight at calving were used as a covariate. Compared with the control, calves fed SUP had greater total DMI (0.83 vs. 0.65 kg/d; SEM = 0.04) and thoracic diameter (0.83 vs. 0.85 cm; SEM = 0.01). No effect of supplement was observed on starter intake (0.14 vs. 0.15 kg/d; SEM = 0.05), daily gain (0.51 vs. 0.44 kg/d; SEM = 0.04), feed efficiency (0.61 vs. 0.67; SEM = 0.04), withers (0.80 vs. 0.81; SEM = 0.006) and hip heights (0.83 vs. 0.84; SEM = 0.007), or body length (0.73 vs. 0.73; SEM = 0.007). In conclusion, the use of the milk balancer supplement increased intake but did not significantly improve growth during the first month of age. Considering that under normal conditions, calves lose weight during the first 2 wk, it would be important to carry out a new trial considering the total 8 wk that calves are kept in the calf unit.

Key Words: calves, growth, milk supplement

0771 Effects of *trans*-10, *cis*-12 conjugated linoleic acid on gene expression and lipid content of adipocytes derived from lactating dairy cows.

S. E. Schmidt*, K. M. Thelen, W. Raphael, G. A. Contreras, and A. L. Lock, *Michigan State University, East Lansing*.

The antilipogenic effects of *trans*-10, *cis*-12 CLA are widely reported across monogastric species. However, abomasal infusions of this CLA isomer have been shown to increase expression of lipogenic genes in the adipose of lactating dairy cows. It is not clear if this is a result of energy repartitioning due to a decrease in milk fat synthesis or a direct effect of *trans*-10, *cis*-12 CLA on adipocytes. Our objective was to examine the effects of *trans*-10, *cis*-12 CLA on cultured adipocytes derived from subcutaneous adipose of lactating dairy cows ($n = 4$). Adipose samples were digested with collagenase type II and cells from the stromal vascular fraction were cultured in DMEM/F12 supplemented with 10% fetal bovine serum. Preadipocytes were obtained from outgrowth of plastic adherent cells and seeded in assay plates. After reaching confluence, cells were induced to differentiate and maintained in the plates for 10 d. From d 2 to 10, the medium was supplemented with one of two treatments: 50 μ*M trans*-10, *cis*-12 CLA (T10C12) or 50 μ*M cis*-9, *trans*-11 CLA (C9T11). On d 10, intracellular triglyceride was quantified using an AdipoRed assay and RNA was extracted to analyze gene expression using RT-qPCR. Statistical analysis was performed using linear mixed models. Fold changes (FC) in gene expression are presented relative to the C9T11 treatment. Conjugated linoleic acid supplementation did not affect triglyceride content of the adipocytes ($P = 0.47$), but the ratio of triglyceride content of adipocytes to preadipocytes indicated differentiation occurred in both treatment groups (T10C12 = 60.0 and C9T11 = 55.0). T10C12 decreased expression of the lipogenic genes ACACA (FC = 0.75; $P = 0.01$), ELOVL6 (FC = 0.73; $P = 0.03$), and SCD1 (FC = 0.52; $P = 0.03$). Expression of C/EBPβ, FAS, GAPDH, LPL, and PPARγ were not affected by treatment ($P \geq 0.43$). In contrast to what has been observed in murine-derived 3T3-L1 cells, T10C12 increased the expression of the

fatty acid transport gene FABP4 (FC = 2.06; $P = 0.01$) and tended to increase the expression of DGAT1 (FC = 1.07; $P = 0.06$), which is associated with triglyceride synthesis. Although *trans*-10, *cis*-12 CLA decreased the expression of several lipogenic genes, it did not inhibit lipid accumulation. This suggests that cultured adipocytes derived from dairy cows respond differently to *trans*-10, *cis*-12 CLA than those derived from monogastric species.

Key Words: adipocyte, conjugated linoleic acid, lipogenesis

0772 Effects of maternal exercise on postnatal growth and carcass characteristics of swine.

B. L. Ferguson*, E. K. Harris, D. J. Newman, E. P. Berg, and K. A. Vonnahme, *North Dakota State University, Fargo*.

Our laboratory has previously reported that pregnant swine allowed to exercise during mid to late gestation have increased umbilical blood flow to the piglets. Our objective was to determine how maternal exercise would impact postnatal growth and carcass parameters of their offspring at 6 mo of age. Yorkshire gilts were paired to either remain in their individual stall from d 40 to term (CON; $n = 4$) or exercise for 30 min 3 times per week from mid to late gestation (EX; $n = 4$). Within 12 h postpartum, litter size was normalized within a pair of gilts. Pigs were weighed monthly. Upon reaching an average BW of 58.1 kg, loin muscle area (LMA) and backfat were obtained every 28 d via ultrasonography. Pigs were harvested at 118 kg with organ masses recorded and carcass composition and meat quality determined. Data were analyzed with sow as the experimental unit. Maternal treatment did not impact ADG or LMA, but there was greater ($P = 0.03$) backfat in female piglets from EX dams compared with CON and male piglets from CON dams compared with EX. Backfat in female-EX and male-CON was similar. Although there were limited organ and muscle mass differences due to maternal treatment, pigs from EX dams had an increased ($P \leq 0.05$) longissimus muscle pH at 24 h (5.36 vs. 5.27 ± 0.03), decreased drip loss (6.31 vs. 4.54 ± 0.48%), and increased L* (55.73 vs. 52.40 ± 0.74) compared with CON. Maternal activity during gestation appears to have limited impacts on gross body measurements but may be advantageous to carcass quality of their offspring. Future studies are needed to confirm that the increased meat quality relates to better pork for consumers.

Key Words: carcass, maternal activity, pigs

0773 The effect of phase feeding on feed cost, growth, and performance of calves fed milk replacer.

C. Hansen*[1], W. S. Bowen Yoho[1], T. Earleywine[2], T. E. Johnson[3], and B. L. Miller[4], *[1]Land O'Lakes, Inc., Gray Summit, MO, [2]Land O'Lakes Animal Milk Products, Shoreview, MN, [3]Land O'Lakes, Inc., Webster City, IA, [4]Purina Animal Nutrition Center LLC, Gray Summit, MO*.

Ninety-six 3- to 10-d-old Holstein bull calves with an average initial BW of 44.1 kg (SD 1.67) were shipped from Wisconsin to the Land O'Lakes Research Facility in northwest Iowa. The objective of this study was to evaluate the use of phase feeding with a milk replacer (MR) containing only milk protein in the first phase and a MR using hydrolyzed soy protein modified (HSPM) in the second phase of calf rearing. Calves were randomly assigned according to BW and blood γ globulin to one of four MR diets offered in a 15% solution: 1) 27% CP containing only milk protein, 10% fat (control); 2) phase feeding, 28% CP, 20% fat in Phase 1 and 22% CP, 15% fat with HSPM in Phase 2; 3) phase feeding, 28% CP, 20% fat in Phase 1 and 25% CP, 15% fat with HSPM in Phase 2; and 4) phase feeding, 28% CP, 20% fat in Phase 1 and 28% CP, 15% fat with HSPM in Phase 2. Calves were fed to provide 816 g DM/d during Days 1 to 6 and 1,135 g DM/d during Days 7 to 41, in 2 feedings at 0600 and 1515 h. Calves were offered 567.5 g in one feeding at 0600 h during the last week. Calf starter (22% CP, as-fed basis) was offered ad libitum throughout this 48-d trial. Data were analyzed by Mixed procedures of SAS. Total weight gain, MR consumption, feed:gain ratio, and starter intake did not differ ($P > 0.05$) among treatments. Total feed costs over the 7-wk trial were significantly lower ($P < 0.05$) for the three phase-feeding treatments. Calves on the three phase-fed diets performed equally to calves on the control-fed diets and the feed costs were significantly reduced, making this a viable option where applicable.

Key Words: calf, milk replacer, phase feeding

0774 The effect of weaning over a fourteen-day versus a twenty-one-day period on the performance of calves fed milk replacer on a controlled ad libitum curve through an automatic feeder.

W. S. Bowen Yoho*[1], C. Hansen[1], E. Stephas[2], T. Earleywine[3], T. E. Johnson[4], and B. L. Miller[5], *[1]Land O'Lakes, Inc., Gray Summit, MO, [2]Purina Animal Nutrition Center, LLC, Gray Summit, MO, [3]Land O'Lakes Animal Milk Products, Shoreview, MN, [4]Land O'Lakes, Inc., Webster City, IA, [5]Purina Animal Nutrition Center LLC, Gray Summit, MO*.

Thirty-eight 3- to 10-d-old Holstein bull calves with an average initial BW of 39.2 kg (SD 1.12) were shipped from Wisconsin to the Land O'Lakes Research Facility in northwest Iowa. The objective of this study was to better understand

the impact of weaning period on the performance of calves fed a 26% CP, 20% fat milk replacer (MR) on a controlled ad libitum curve (40FIT Technology, Foerster-Technik, Engen, Germany) through an automatic feeder. Calves were randomly assigned according to BW and blood γ globulin to either a 14-d or a 21-d weaning period. Calves were limited to meal size, but not number of meals, before the start of weaning. Weaning began at either Day 29 (21-d weaning) or Day 36 (14-d weaning), offering 1.65 kg of MR DM on Day 1 of weaning and gradually decreasing MR offering daily to 0.299 kg of MR DM on the day of weaning. Milk replacer was offered in a 13.0% solids solution throughout the 49-d milk feeding phase. All calves were followed for 5 wk after weaning to monitor starter intake and growth. Calf starter (22% CP, as-fed basis) was fed ad libitum throughout this 84-d trial. Data were analyzed by Mixed procedures of SAS. There were no statistical differences ($P > 0.05$) in total BW gain or MR consumption between treatments. Calves fed according to the 21-d weaning period schedule appeared to consume more starter over the 12 wk trial compared with the calves fed according to the 14-d weaning period schedule (140.9 vs. 129.9 kg, respectively); however, due to group feeding of starter and no individual starter intake values, no statistical analysis could be performed. Either a 14-d or 21-d weaning period could be successfully used for calves fed on a controlled ad libitum curve through an automatic feeder.

Key Words: automatic milk replacer feeder, calf, weaning

0775 Effects of maternal dietary restriction during the second trimester on offspring growth and feedlot performance. S. M. Quarnberg*, J. F. Legako, J. M. Gardner, D. R. ZoBell, C. E. Carpenter, K. A. Rood, and K. J. Thornton, *Utah State University, Logan*.

This study determined the impacts of maternal dietary insult during the second trimester on offspring growth and early feedlot performance. Angus-influenced commercial cows ($n = 34$) were naturally bred to a purebred Angus sire. During preparturition, individual cow served as the experimental unit for one-way ANOVA. During 84 d of mid gestation, cows were stratified into two groups, maintenance ($n = 16$) and restricted ($n = 18$), by initial weights ($P = 0.804$) and BCS ($P = 0.723$). Restricted cows were provided with lower forage biomass (1,662 kg/ha, DM) in comparison with maintenance (2,309 kg/ha, DM). Following the insult period, restricted cows had a mean BCS 1.55 lower ($P = 0.001$) than maintenance cows and a BW difference of 85.3 kg ($P = 0.024$). Dams were commingled and uniformly managed following mid gestation. Calves were weaned approximately 215 d of age and placed on a background diet for 7 wks before entering the feedlot phase where calves were kept in individual pens and fed a grower ration ad libitum. Calves BW were measured at birth, weaning, and every 28 d of the feedlot phase. Ultrasound was used for measurement of BF and REA during the feedlot phase. Calf temperament was evaluated at weaning and during the feedlot phase. Serum glucose, insulin, IGF-1, and cortisol were determined for calves at weaning, 1 wk before the feedlot phase, and the last day of the feeding trial. One-way ANOVA was used to determine impacts of fetal programming on calves. Individual calf served as the experimental unit. Calf BW at birth, weaning, and during feeding showed no differences ($P \geq 0.245$). No differences were determined for ADFI ($P \geq 0.428$), ADG ($P \geq 0.338$), G:F ($P \geq 0.273$), REA ($P \geq 0.285$), or BF ($P \geq 0.416$) during the feedlot stage. Concentrations of glucose ($P \geq 0.504$), insulin ($P \geq 0.224$), IGF-1 ($P \geq 0.107$), and cortisol ($P \geq 0.709$) were found to be similar at all time points. Restricted calves were found to be more excitable, with greater temperament scores at weaning ($P = 0.026$). Recent work has indicated that fetal programming alters progeny carcass characteristics. However, concerns for negative impacts on performance of progeny exist. This study determined little impact on calf performance during early feedlot stages.

Key Words: feedlot performance, fetal programming, temperament

---

0776 Neonate immunity, growth, and puberty in dairy calves: Influence of dietary conjugated linoleic acid supplementation of the dam. C. L. Cardoso*[1], D. Somwe[2], and G. Esposito[3,4], *[1]Department of Production Animal Studies, Faculty of Veterinary Science, University of Pretoria, Pretoria, South Africa, [2]Department of Animal and Wildlife Science, Faculty of Natural and Agricultural Sciences, University of Pretoria, Pretoria, South Africa, [3]Department of Production Animal Studies, Faculty of Veterinary Sciences, University of Pretoria, Pretoria, South Africa, [4]Institute of Food, Nutrition and Well-Being, University of Pretoria, Pretoria, South Africa*.

Colostrum provides the calf with maturational, immune-modulatory, and antimicrobial factors. Feeding isomers of CLA reportedly increase immunoglobulin production in rats and circulating IGF-I levels in cows. The objective of the study was to evaluate the effect of CLA dietary supplementation of the dam on colostrum quality, calves immune system, growth, and attainment of puberty. Forty Holstein cows blocked by parity, BW, and BCS were randomly assigned to two groups: control (CTL; 100 g/cow per day of Ca salts) and CLA (100 g/cow per day of CLA). Individual top-dressed supplementation started 20 ± 7 d before calving until 35 d in milk. From Day 0 to 4, each calf was fed its mother's colostrum. The latter was sampled for IgG quantification. Calves were bled every other day from 0 to 15 d for IgG and total protein (TP) levels. Weekly, from Day 0 to 35, body measurements and weight were recorded for growth rate; furthermore, calves were bled

for GH and IGF-I quantification. Attainment of puberty was monitored from the age of 180 d. Monthly, body measurements and weight were recorded. Semen collection by electroejaculation was performed in males with scrotal circumference ≥23 cm for semen parameters evaluation (volume, color, mass/individual motility, and concentration). Puberty was declared with concentration of 50 million spermatozoa/ejaculate with at least 10% progressive motility. Females were bled fortnightly for progesterone levels, whereas ovarian activity was monitored by ultrasonography. Puberty was attained with progesterone levels ≥1 ng/mL and the presence of a corpus luteum. Growth rate, blood, and colostrum parameters were analyzed by ANOVA for repeated measures using the GLM procedure. Age at puberty was compared by one-way ANOVA. No differences between groups were observed for blood and colostrum IgG levels, blood GH levels, and attainment of puberty. Treatment showed decreased levels of IGF-I ($P < 0.05$) compared with the control. A trend for higher TP levels (treatment × age, $P = 0.079$) and overall ADG ($P = 0.1$), calculated from Day 0 to 300, was observed in CLA calves. However, from Day 0 to 35, growth rate was significantly higher in CLA females (treatment × age, $P < 0.05$) and lower in CLA males (treatment, $P < 0.05$) compared with the CTL. These differences were not observed from 180 to 300 d. Colostrum from CLA supplemented dams showed a gender and time-dependant effect on calf's growth; however, it did not alter immune response and attainment of puberty. Further investigation is needed to unveil CLA's possible mechanism of action.

Key Words: conjugated linoleic acid, growth, immunoglobulin G

0777 Repeatability of residual feed intake and indices of body composition in growing Columbia ewes fed the same diet. K. A. Perz*, J. G. Berardinelli, L. N. Park, R. K. Pollard, C. M. Page, W. C. Stewart, and J. M. Thomson, *Montana State University, Bozeman*.

Residual feed intake (RFI), an efficiency measurement based on the difference in expected feed intake for a given weight and growth rate and actual feed intake, is used to improve production efficiency of domestic ruminants. The purpose of this study was to evaluate the repeatability of RFI of sheep measured for two consecutive years and to investigate the relationship between indices of body composition and RFI in yearling ewes. Two trials, using the same Columbia ewe lambs ($n = 17$ per trial), were conducted in consecutive years. Ewes were individually fed for 47 and 45 d, respectively, beginning in September of each year. The diet, an alfalfa–barley pellet, was the same composition and batch for both years. Residual feed intake was calculated for each ewe in each year. Ewe was the experimental unit. Residual feed intake and performance data were analyzed using ANOVA. Residual feed intake did not differ ($P > 0.05$) between years, indicating that on the same diet and environmental conditions, RFI does not appear to change with age. Ewes were categorized into 3 RFI classes (efficient, average, and inefficient) based on RFI values 1 SD below and above the yearly average. In 2014, initial and final liveweights, ADG, and DMI did not differ due to RFI classification ($P > 0.05$). In 2015, DMI was greater for inefficient ewes ($P < 0.05$), but there was no difference in initial and final liveweights or ADG ($P > 0.05$). Ultrasound data were analyzed using ANOVA with repeated measures. Rib eye area (REA; cm^2) and backfat thickness (BF; cm) were measured by ultrasound on Day 0, 17, and 45 in 2015. These variables were used to calculate estimates of final body composition: whole-body muscle mass, intramuscular fat, empty BW, empty BW DM, empty BW fat, empty BW protein, carcass weight, carcass weight DM, carcass weight fat, and carcass weight protein. Residual feed intake classification did not affect REA or BF ($P > 0.05$). Regression analysis indicated that both REA and BF increased ($P < 0.05$) from Day 0 to 17 and BF increased ($P < 0.05$) again from Day 17 to 45. No body composition estimates were affected by RFI classification ($P < 0.05$). Results suggest that RFI is repeatable; however, indices of body composition seem to be independent of RFI in Columbia ewes fed the same diet under similar conditions.

Key Words: residual feed intake, repeatability, body composition

0778 A new view on the growth of pigs in relation to frequent body weight monitoring. A. H. Stygar*[1], K. A. Dolecheck[2], and A. R. Kristensen[1], [1]*University of Copenhagen, Department of Large Animal Sciences, Frederiksberg, Denmark,* [2]*University of Kentucky, Lexington*.

Frequent BW monitoring of growing pigs can be useful for identifying production (e.g., feeding), health, and welfare problems. However, to construct a tool that will properly recognize abnormalities in pigs' growth, a precise description of the growth process should be used. In this study, we proposed a new model of pig growth accounting for daily fluctuations in BW. Data on BW measurements of 1,710 pigs (865 gilts and 843 barrows) originating from 5 consecutive batches from one Danish commercial farm was collected. Pigs were inserted into a large pen (maximum capacity = 400) between November 2014 and September 2015. On average, each pig was observed for 42 d and weighed 3.6 times a day when passing from the resting to the feeding area. Altogether, 243,160 BW measurements were recorded. To properly account for the diurnal pattern, the time of BW measurements was corrected for daylight saving time. A multilevel model of pig growth was constructed and fitted to available data. The BW of pigs was modeled as a quadratic function of time. A diurnal pattern was incorporated into the model by a cosine wave with known length (24 h). The model included pig effect, which was defined as a random autoregressive process

with exponential correlation. Variance of within-pigs error was assumed to increase with time. The intercept, time, square value for time, and cosine wave were significant fixed effects ($P < 0.0001$). Additionally, the interaction between these fixed effect elements and each batch was determined to be significant ($P < 0.0001$). The gender effect was not significant and was removed from the final model ($P = 0.52$). According to results, pigs were lighter in the morning and heavier in the evening (the minimum BW was obtained around 1000 h and the maximum was obtained around 2200 h). However, the exact time of obtaining maximum and minimum BW during the day differed between batches. Pigs had access to natural light, and therefore, existing differences could be explained by varying daylight level during observation periods. Because the diurnal amplitude for pig growth ranged between batches from 0.9 to 1.4 kg, BW monitoring tools based on frequent measurements should account for diurnal variation in BW of pigs. This proposed description of growth was built into a monitoring tool (a dynamic linear model) consisting of an updating, forecasting, and filtering procedure. The constructed monitoring tool will be applied to farm data in future studies.

Key Words: body weight, pigs, diurnal pattern

0779 Effect of prior fiber consumption on diet-induced obesity susceptibility and metabolic health indicators in Ossabaw pigs. V. V. Almeida[1] and K. M. Ajuwon*[2], [1]*Purdue University, West Lafayette, IN,* [2]*Department of Animal Sciences, Purdue University, West Lafayette, IN*.

Sixty-three mixed-sex pigs (28 d of age and 5.63 ± 0.20 kg BW) were used to evaluate the effects of dietary fiber source and fat level on growth performance, backfat thickness (BF), and metabolic status. Pigs were blocked by BW and allotted by sex and litter to 1 of 4 treatments with 8 pens per treatment and 2 pigs per pen. Treatments were arranged in 2 × 2 factorial with 2 fiber sources (inulin and cellulose) and 2 fat levels (5 and 15%, as-fed basis, for the low-fat diet [LF] and high-fat diet [HF], respectively). Pigs received diets containing 4% of either inulin or cellulose on an as-fed basis for the first 56 d (nursery phase) and thereafter were fed LF and HF containing no added fiber source from d 56 to 140 (growing phase). On d 140, BF was measured by ultrasound and jugular blood samples were taken for insulin, glucose, and triglyceride (TAG) analyses. Data were analyzed using the MIXED procedure of SAS. There were fiber × fat interactions for final BW ($P = 0.02$) and G:F ($P = 0.01$), as pigs receiving cellulose had greater ($P < 0.05$) final BW (63.96 and 70.31 ± 1.15 kg for LF and HF, respectively) and G:F (0.136 and 0.157 ± 0.003 for LF and HF, respectively) when fed HF diet than pigs fed LF. Feeding HF, regardless of fiber source, tended to increase ADG (0.432 and 0.464 ± 0.01 kg for LF and HF, respectively; $P = 0.07$) and reduce ADFI (3.184 and 3.013 ± 0.05 kg for LF and HF, respectively; $P = 0.07$). Moreover, HF, regardless of fiber source, resulted in higher BF (13.41 and 18.18 ± 0.12 mm for LF and HF, respectively; $P < 0.01$). There was a tendency for a fiber × fat interaction ($P = 0.07$) for serum TAG concentration, as pigs receiving cellulose had greater serum TAG (0.264 and 0.392 ± 0.02 mg/mL for LF and HF, respectively; $P < 0.05$) when fed HF than pigs fed LF. Pigs fed HF, regardless of fiber source, had greater ($P < 0.01$) insulin (0.014 and 0.016 ± 0.001 mg/L for LF and HF, respectively) and glucose (100.89 and 125.03 ± 4.39 mg/dL for LF and HF, respectively) concentrations in the serum. In summary, dietary cellulose inclusion during the early life of pigs increased susceptibility to obesity and metabolic syndrome in the future, whereas dietary inulin inclusion prevented future metabolic disorders.

Key Words: early nutrition, fiber metabolic disorders, pig model

0780 Body composition at first heat of gilts exposed to three different feeding regimens. S. Van Vliet[1], T. S. Bruun[2], J. Hales[3], C. F. Hansen[3], and P. K. Theil*[1], [1]*Aarhus University, DK-8830 Tjele, Denmark,* [2]*SEGES Pig Research Centre, 1609 Copenhagen V, Denmark,* [3]*University of Copenhagen, DK-1870 Fredriksberg C, Denmark*.

This study was conducted to evaluate the possibility of increasing body fatness of gilts by nutritional means during rearing. Forty-eight gilts (Danish Landrace × Yorkshire [LY]) with an initial BM of 62 ± 2 kg were selected from 16 litters (3 littermates from each).Gilts were fed individually with one of three diets from 62 to 105 kg LW and then transferred to diets lower in CP and Lys. Littermates stratified for BM were randomly allocated to one of three dietary regimens: low protein ad libitum (LPAD) (4.3/3.5 g SID Lys/kg feed), moderate protein restriction (MPRE) (5.4/4.3 g SID Lys/kg feed), or high protein ad libitum (HPAD) (7.0/5.4 g SID Lys/kg feed). The experiment was designed to limit growth by lysine (LPAD), energy (MPRE), or the growth potential of gilts (HPAD). Body water content was measured using the deuterium oxide dilution technique before the dietary intervention were initiated ($n = 9$) and at first heat ($n = 47$). Body contents of fat, protein, and ash were calculated using prediction equations developed for LY gilts by Rozeboom and coworkers and back fat depth was measured at the P2 site. Statistical analysis of fixed effect of treatment was performed using a mixed model to account for repeated measurements. Initially, no differences were observed in body water content or derived contents of fat, protein, or ash ($P > 0.20$). On average, gilts initially contained 61.2% water, 11.2% fat, 17.9% protein, and 3.4% ash. At first heat, the measured water content was lowest in LPAD, highest in MPRE, and intermediate in HPAD gilts ($P < 0.001$), whereas the body fat content was changed inversely, as LPAD (26.6%), MPRE (23.1%), and HPAD gilts (25.3%) had highest, lowest, and intermediate body fat contents ($P < 0.001$), respectively. The

protein and ash contents were lowest ($P < 0.001$) in LPAD fed gilts (15.5 and 2.8%, respectively), highest in MPRE fed gilts (16.1 and 3.0%, respectively), and intermediate in HPAD fed gilts (15.8 and 2.9%, respectively). The change in body fatness was supported by measurements of back fat depth, which at first heat was highest ($P < 0.001$) in LPAD gilts (15.1 mm), lowest in MPRE gilts (11.8 mm), and intermediate in HPAD sows (14.3 mm). In conclusion, body fatness of gilts can be considerably increased through dietary means even in breeds that thoroughly have been genetically selected for leanness.

Key Words: body condition, body fatness, dietary composition, gilt rearing, growth performance

0781 Preweaning diet and exogenous estrogen alter mammary epithelial cell proliferation and progesterone and estrogen receptor expression.

A. J. Geiger*[1], R. M. Akers[1], and C. L. M. Parsons[2], *[1]Virginia Tech, Blacksburg, [2]Virginia Polytechnic Institute and State University, Blacksburg*.

Preweaning diet and estrogen treatment alters mammary development. Our objectives were to study the effects of diet and estrogen on mammary histology, proliferation, and expression of estrogen (ESR1) and progesterone (PR) receptors. Thirty-six Holstein heifer calves were reared on 1) a control milk replacer (MR) fed at 454 g powder/d (R; 20% CP and 20% fat) or 2) an enhanced MR fed at 1,135 g powder/d (E; 28% CP and 25% fat). Milk replacer was fed for 8 wk. At weaning, a subset of calves were sacrificed ($n = 6$/diet). Remaining calves received E_2 implants and were sacrificed at wk 10. Treatments were 1) R, 2) R + E_2 (R-E2), 3) E, and 4) E + E_2 (E-E2). One day before harvest, calves were given bromodeoxyuridine (BrdU; 5 mg/kg). At sacrifice, parenchyma (PAR) was removed and fixed. Sections from lower, middle, and distal zones were stained with H and E and antibodies to measure expression of ESR1, PR, and BrdU. Comparisons with PROC GLIMMIX in SAS on a per-area and per-cell basis were similar. At wk 8, R-fed calves had more ($P < 0.01$) PR-expressing cells in distal PAR. But PR expression intensity was greater ($P < 0.01$) in E-fed calves. The proportion of cells expressing ESR1 was not affected by diet, but expression intensity was increased for E-fed calves across all zones (62 to 81%; $P < 0.01$). Percent BrdU-positive cells was 2- and 0.5-fold greater ($P < 0.01$) for E-fed calves in zone 2 and 3, respectively. At wk 10, calves treated with estrogen had 3.9-fold greater PR expression intensity. The intensity and percent of cells expressing ESR1 was lowest in estrogen-treated calves. Overall, estrogen-treated calves had the most proliferating cells ($P < 0.01$). However, in zone 3, E-E2 calves had a higher percentage of proliferating cells than calves on all other treatments ($P < 0.01$). Results indicate both diet and estrogen administration alter proliferation rates of the mammary epithelium and that changes in expression of ESR1 and PR are at least partially responsible for changes in mammary PAR development associated with enhanced preweaning feeding of dairy calves. However, furthermore, more detailed analyses are needed to fully understand mechanisms at play.

Key Words: estrogen receptor, progesterone receptor, mammary gland

0782 In vivo knockdown of FGFR2 and MET mRNA in trophectoderm of ovine conceptuses retards their development via abrogation of MAPK and MTOR pathways.

X. Wang*, K. A. Dunlap, M. C. Satterfield, G. Wu, and F. W. Bazer, *Texas A&M University, College Station*.

The paradigm of downregulation of progesterone receptor in uterine epithelia before implantation is common to sheep, cow, pigs, rhesus monkey, women, and mice. Therefore, progestamedins, which derive from PGR-positive uterine stromal cells and include hepatocyte growth factor (HGF), fibroblast growth factor 7 (FGF7) and FGF10, regulate uterine luminal (LE), superficial glandular (sGE), and glandular (GE) epithelia during the estrous cycle/early pregnancy. Previous studies with sheep demonstrated the existence of receptors for HGF (HGFR; encoded by MET) as well as FGF7 and FGF10 (FGFR2) in conceptus trophectoderm (Tr). However, the biological roles of progestamedins in conceptus development are unknown. In this study, we conducted an in vivo morpholino antisense oligonucleotide (MAO)–mediated knockdown of translation of *FGFR2* and *MET* mRNA in ovine conceptus Tr. Normality of data and homogeneity of variance were tested using the Shapiro–Wilk test and the Brown–Forsythe test, respectively, in SAS. Data were analyzed by least squares one-way ANOVA and post hoc analysis (the Fisher LSD), with each ewe/conceptus as an experimental unit. $P < 0.05$ was considered significant. Translational knockdown of MET mRNA severely retarded conceptus development whereas translational knockdown of FGFR2 mRNA resulted in small, thin, and less elongated conceptuses compared with MAO control conceptuses. Both MAO-MET and MAO-FGFR2 conceptuses were functionally abnormal based on lower ($P < 0.05$) production of interferon tau, the pregnancy recognition signal in sheep. Quantitative immunofluorescence (IF) analysis demonstrated that MAO were evenly delivered ($P > 0.05$) into Tr but not uterine LE, sGE, and GE and that the abundance of both MET and FGFR2 proteins in Tr was decreased ($P < 0.01$) by 83.3 and 93.3%, respectively. Western blot analysis using ovine Tr cells treated with respective MAO also validated knockdown efficiencies of both MAO-MET and MAO-FGFR2. Further quantitative IF revealed that compared with MAO control, active caspase-3 in Tr of MAO-MET and MAO-FGFR2 conceptuses was increased ($P < 0.01$) by 4.5- and 6.5-fold, respectively. Moreover, phosphorylation of P38 was decreased ($P < 0.01$) by 68.7 and 84.4% in MAO-MET and MAO-FGFR2, respectively, compared with MAO control, whereas phosphorylation of MTOR was decreased ($P < 0.01$) by 75.0

and 83.3% in MAO-MET and MAO-FGFR2 conceptuses, respectively. Interestingly, phosphorylation of TSC2 was decreased ($P < 0.01$) by 79.2% in Tr of MAO-MET compared with MAO control but was no different ($P > 0.05$) between MAO-FGFR2 and MAO control conceptuses. Collectively, these results demonstrate critical roles for progestamedins (i.e., HGF, FGF7, and FGF10) in ovine conceptuses that are mediated via their receptors (MET and FGFR2) and activation of MAPK and MTOR pathways and that translational knockdown of *MET* and *FGFR2* mRNA increased apoptosis and retarded conceptus development during early pregnancy.

GROWTH AND DEVELOPMENT SYMPOSIUM: NEW -OMICS TECHNOLOGIES TO UNDERSTANDING THE BIOLOGICAL PROCESSES AND NETWORK PATHWAYS ASSOCIATED WITH CATTLE GROWTH AND HEALTH

0783 Objective-oriented genomic relationship matrices.

A. Reverter*, *CSIRO Agriculture, Brisbane, Australia*.

The advent of affordable high-density SNP genotyping platforms has boosted the implementation of genomic selection program in many livestock species. However, large reference populations are required to accurately compute genomic predictions of breeding value (GEBV). Combining information from (seemingly independent) separate populations has been highlighted as a beneficial strategy and methods to adjust the realized genomic relationship matrix (GRM) to accommodate the heterogeneity in allele frequencies have been proposed. Simulation studies based on real sequence data have shown the importance of using only variants as close as possible or identical to the causative mutations. Recently, we showed that data from reference populations from two distinct breeds can be merged to generate GEBV, provided the SNP used to build the GRM are carefully selected based on their significance and direction of the effect associated to the phenotype. We show that this approach can optimize the genomic correlation for the phenotype of interest in the two populations. We further show how a "hybrid" GRM permits the linking of genotypic data of pooled DNA samples of commercial cattle pooled according to phenotype with individual DNA samples from animals available for selection. Our examples are concerned with beef cattle raised extensively in tropical and subtropical regions of Australia. We anticipate that the use of traditional "one size fits all" relationship matrices, based on pedigree information only, is coming to an end and predict the time has come for "objective-oriented" GRM purpose built for a specific breeding objective.

Key Words: genomic selection, genomic predictions, genomic relationship matrix

0784 Multi-omics data resources and use in genetic improvement of cattle growth and health.

M. G. Thomas*, S. J. Coleman, S. E. Speidel, and R. M. Enns, *Department of Animal Sciences, Colorado State University, Fort Collins*.

Interactions of growth and health influence the progression of cattle to maturity. Growth and carcass traits typically have moderate to high heritability ($h^2 = 0.2–0.5$), whereas pathogen-disease related health traits tend to have low heritability ($h^2 \leq 0.2$). Genetic improvement in beef cattle involves selection with EPD predicted from multitrait, and often multibreed, models that incorporate genomic data derived from SNP chips. Available genotyping platforms have genomewide distance gaps of 49.4 (BovineSNP50) and 3 kb (BovineSNPHD). Genetic prediction accuracy can be improved with use of genomic data; however, process varies greatly depending on trait heritability and quality–quantity of data. Because most economically relevant traits are polygenic and single SNP within a positional-candidate gene explain limited variation, there is great interest in discovery and use large numbers of causal-mutation SNP in genetic prediction. These SNP will likely be located within nodes and hubs of gene networks and can be added to the current chips to improve their effect. Various "omics" tools evaluating transcriptome, proteome, and metabolome assist with discovery of coding and tag SNP. Differentially expressed targets from the latter two tools reveal gene products closely associated with an animal's physiologic phenotype, which can correlate with gene expression levels observed in RNA. Concordant results and enrichment analyses from these tools yield confidence to analyze target sequence, either DNA or RNA, to discover functional SNP. However, transcript splicing, peptide processing, and post-translational modifications complicate comparing results from the various approaches. The animal's epigenome and microbiome also influence phenotype. To identify functional SNP, RNA must be harvested from tissues of animal models designed to be informative for a trait collected from large breeding populations. Case versus control or comparisons of cattle from the tails of the quantitative trait distribution curves have proven useful strategies in several multi-omics growth and health studies of which pulmonary arterial pressure (PAP; $h^2 = 0.2–0.4$), an indicator of hypoxia-induced pulmonary hypertension, is an example. Here, cardiopulmonary tissues were collected from high- and low-PAP Angus steers ($n = 10$/group) with sire-pedigree diversity to growing seed stock bulls. Transcript abundance was assessed and differential expression results were obtained and are being merged with QTL and whole-genome sequence information to discover SNP genotypes for incorporation into a PAP EPD, a tool for selecting cattle for high elevation tolerance. Therefore,

strategic application of multi-omic resources to discover functional SNP and obtain population-level genotype data provides opportunity to enhance EPD accuracy.

TRIENNIAL GROWTH AND DEVELOPMENT SYMPOSIUM

0785 Muscle gene expression patterns associated with differential intramuscular fat in cattle and markers for skeletal muscle growth rate and major cell types. B. P. Dalrymple*, *CSIRO Agriculture, Brisbane, Australia*.

Growth rate, intramuscular fat content (IMF%), and IMF composition influence the value of individual animals. However, for IMF, there are many different pathways to the final common process of triacylglyceride (TAG) synthesis and storage in intramuscular adipocytes. Gene expression data from a number of cattle and sheep experiments was used to identify the pathways involved in the synthesis of IMF and the genes correlated with growth rate and as markers of cell populations. The data sets were from a time course of longissimus muscle (LM) development in Piedmontese (PxH) and Wagyu cross Hereford (WxH) cattle, from the LM of a group of 48 Brahman cattle of similar age and from the LM of a group of 20 sheep of similar age. The differential expression of genes between WxH (high marbling) and PxH (high muscling) cattle and the correlation of gene expression with measured IMF in the Brahman and sheep data sets was integrated with known biochemical pathways. Expression of genes encoding proteins involved in the synthesis and deposition of TAG was most correlated with IMF%. In well-fed immature animals, TAG deposition rate (estimated by TAG gene expression) was proportional to current IMF%. By comparing TAG gene expression and IMF%, we identified a small number of animals with unexpectedly low or high rates of IMF deposition for their IMF%. The genes in the fatty acid synthesis pathway were less correlated with IMF%, presumably as IMF TAG can contain preformed fatty acids from circulation as well as those synthesized de novo by intramuscular adipocytes. By comparing changes in expression of the TAG and fatty acid genes, we estimated the relative contributions of synthesized and preformed fatty acids to IMF deposition on different diets. The expression of two groups of genes in the LM of the Brahman steers, significantly enriched for "cell cycle" and "ECM (extracellular matrix) organization" GO terms, was correlated with ADG per kilogram liveweight. However, expression of the same genes was only partly related to growth rate across the development time course in (PxH and WxH). *K*-means clustering of genes with similar expression profiles to the ECM genes was undertaken. Analysis of the clusters and published markers of different cell types in muscle suggested that the "cell cycle" and "ECM" signals were from the fibro/adipogenic lineage. The increase in ECM remodeling required for increased IMF deposition probably altered the relationship between the expression of these genes and animal growth rate.

0786 Factors influencing bovine intramuscular adipose tissue development and cellularity. E. Albrecht*[1], L. Schering[1], Y. Liu[1], K. Komolka[1], C. Kühn[2], K. Wimmers[3], and S. Maak[1], *[1]Muscle Biology and Growth, Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [2]Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [3]Genome Biology, Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany*.

Appearance, distribution and amount of intramuscular fat (IMF) or marbling are highly variable depending on nutrition, gender, and environmental and genetic factors. On the molecular level, the concerted action of several factors, including hormones, receptors, transcription factors, etc., determines where clusters of adipocytes arise. Therefore, the aim remains to identify biological markers of IMF to increase the ability to identify animals that deposit IMF early in age to ensure the competitiveness of meat products and increase efficiency of high-quality meat production. In an attempt to unravel the cellular development of marbling, we investigated on the one hand the abundance of markers for adipogenic differentiation during fattening of cattle and on the other hand the transcriptome of muscle and dissected IMF from different breeds. Markers of different stages of adipogenic differentiation are well known from cell culture experiments. However, early markers are transiently expressed and late markers may reflect the number of mature adipocytes in the sample rather than gene activity in a tissue. On the cellular level, the development of marbling requires recruitment, proliferation, and differentiation of adipogenic cells. Hypertrophy of adipocytes is limited and hyperplasia occurs to store excess energy in the form of lipids in new cells. Within muscles, hyperplasia and hypertrophy of adipocytes can be observed throughout life. In a recent study, we investigated the localization and abundance of delta-like homolog 1 (DLK1) and CCAAT/enhancer-binding protein β (CEBPB), early markers of adipogenic differentiation, in bovine muscle tissue. Cell culture models demonstrated high expression of DLK1 in preadipocytes and complete disappearance during differentiation to adipocytes. Accordingly, we could demonstrate an inverse relationship between IMF content and number of DLK1 positive cells in bovine muscle. Considering the cellular environment of differentiating adipocytes in muscle and accepting mature adipocytes and myocytes as secretory cells, it becomes obvious that cross talk between cells via adipokines and myokines may be important

for IMF development. Secreted proteins can act on other cells, inhibiting or stimulating their development via autocrine and paracrine actions. Among them, agouti signaling protein and thrombospondin 4 were further investigated. Thromospondin 4 is a potential myokine with supposed impact on IMF development, which has been identified in a cross species comparison of muscle transcriptomes and secretomes. Furthermore, results from transcriptome analysis suggest involvement of genes that are not directly related to adipogenesis and lipid metabolism providing new candidates for future research.

Key Words: intramuscular adipogenesis, adipokines, myokines

0787 Growth and growth rate influences bovine intramuscular adipose tissue gene expression in a differential manner. C. R. Krehbiel*[1], P. A. Lancaster[2], G. W. Horn[3], J. D. Starkey[4], E. D. Sharman[5], and S. L. Roberts[6], *[1]Oklahoma State University, Stillwater, [2]Missouri State University, Springfield, [3]Oklahoma Agricultural Experiment Station, Stillwater, OK, [4]Starkey Consulting Services, Gainsville, GA, [5]Johnson Research, LLC, Parma, ID, [6]Department of Agricultural Sciences, West Texas A&M University, Canyon*.

Intramuscular (IM) adipose tissue is the last adipose depot to mature in the growing bovine, and nutrition and management practices that influence growth and growth rate can influence IM adipose tissue deposition. Diet leading to changes in rumen VFA profile can influence substrates utilized for fatty acid synthesis, but diet has a greater effect on subcutaneous (SC) than IM adipose tissue. Subcutaneous adipose tissue has a greater ability to utilize glucose and lactate to produce reducing equivalents and to use lactate and acetate for lipid synthesis than IM adipose tissue regardless of diet. The greater ability of SC adipose tissue to utilize glucose to produce reducing equivalents and acetate and lactate for fatty acid synthesis indicates limited ability to manipulate site of fat deposition through changes in rumen fermentation. Our data suggest that differentiation and lipid synthesis in IM adipose tissue are primarily related to BW whereas differentiation and lipid synthesis in SC and perirenal (PR) adipose tissue are influenced by energy intake and rate of gain. It is perplexing as to why differentiation and lipid synthesis of IM adipose tissue is not affected by rate of gain as in SC and PR adipose tissue. The close proximity of IM adipose tissue to muscle tissue during development suggests that intercellular signaling between these 2 tissues might be crucial for development of IM adipose tissue. Early in the development of IM adipose tissue, changes in gene expression in muscle that effect remodeling of the extracellular matrix along with angiogenesis appear to be critical for development of IM adipose tissue. The strong correlation of angiogenic growth factors in LM with angiogenic growth factors and markers of adipocyte differentiation in immature IM adipose tissue suggest that there is a highly coordinated change that occurs between skeletal muscle and IM during the early stage of adipose development. However, the mechanisms of IM adipose tissue development are still not fully clear and more in vitro and in vivo studies are needed to further elucidate the pathways and mechanisms involved in IM adipose tissue development. Further understanding the interactions between skeletal muscle and adipose tissue during IM development could allow for development of management strategies that optimize carcass quality in bovine.

0788 Molecular mechanisms of bovine intramuscular fat deposition. M. Baik*, H. J. Kang, S. J. Park, and M. Y. Piao, *Department of Agricultural Biotechnology, College of Agriculture and Life Sciences, Seoul National University, Seoul, the Republic of Korea*.

Intramuscular fat (IMF) content in the longissimus dorsi muscle (LM), also known as marbling fat, is one of most important factors that determine beef quality in Korea and Japan as well as in the United States. Intramuscular fat deposition is influenced by both genetic (e.g., breed, genotype) and nongenetic factors (e.g., gender, castration, nutrition, stresses, age). Castration markedly increases IMF deposition, resulting in improved beef quality in Korean cattle. We present a comparative approach in gene expression between bulls and steers in bovine tissues. The marling trait has relatively higher heritability compared with other phenotypes such as feed efficiency and BW and is quantitative, being influenced by variety of genes involved in nutrient metabolism. The identification of genes associated with IMF deposition is an important area for elucidating mechanisms of IMF deposition. Intramuscular fat deposition is determined by a balance between fat deposition and fat removal in the LM. Fat deposition is determined by lipogenesis, fatty acid uptake and transport, and fatty acid esterification and fat removal is regulated by lipolysis and fatty acid oxidation. Studies on these lipid metabolic gene expression patterns provide understanding of role and relative significance of lipid metabolic genes in IMF deposition. Several peripheral tissues, including LM and adipose as well as the liver, are involved in lipid metabolism. Therefore, understanding of significance of the tissue network on lipid metabolism is important. Our studies with several peripheral tissues provide involvement of many lipid metabolic genes in the IMF deposition as well as body fat deposition in beef cattle. Application of newly developed functional genomic tools is very efficient for elucidation of molecular aspect of metabolism. We present detailed molecular events associated with IMF deposition through the application of functional genomics tools, including microarray, RNA sequencing analyses, and bioinformatics. Expression of

gene is also influenced by epigenetic factors such DNA methylation and histone modification. Possible involvement of DNA methylation levels in regulating bovine gene expression will be discussed. New information on molecular mechanisms of bovine IMF deposition could be applicable to design nutritional or genetic methods to increase IMF deposition and to modify fatty acid composition in the LM of beef cattle.

Key Words: beef quality, intramuscular fat, functional genomics

0789 Dedifferentiated fat cells: Potential involvement in intramuscular adipogenesis. M. S. Duarte*[1], R. Bueno[1], M. V. Dodson[2], and G. J. Hausman[3], *[1]Universidade Federal de Viçosa, Viçosa, Brazil, [2]Washington State University, Pullman, [3]University of Georgia, Athens*.

Intramuscular adipogenesis and the dynamics of lipid metabolism by mature adipocytes have been investigated primarily due to the importance of altering marbling to enhance meat quality. Knowledge regarding intramuscular fat development has relied on the conversion of a variety of preadipocyte-like cells (such as stromal vascular cells) and their differentiation into lipid-assimilating adipocytes, which was thought to be the end of their cell cycle. However, a great number of studies have demonstrated the ability of the mature adipocyte to dedifferentiate into a population of a proliferative-competent cells known as the dedifferentiated fat (DFAT) cells. As early as the 1970s, in vitro studies have shown that DFAT cells may be obtained by ceiling culture, which takes advantage of the buoyancy property of lipid-filled cells. It is documented that DFAT cells may acquire a phenotype similar to mesenchymal stem cells and may redifferentiate into multiple cell lineages. From an animal science/meat science perspective, the main question that arises from the current knowledge of DFAT cells is how do DFAT cells contribute to intramuscular fat accumulation? What regulation causes the intramuscular mature adipocytes to dedifferentiate or resume their capability to proliferate? Moreover, are DFAT cells controllable so that they differentiate into lipid-assimilation cells (and perhaps other cells) and thus contribute to overall increase of intramuscular fat in vivo? Considering the fact that marbling fat accumulation is the last step in meat production, a (muscle and fat cell) intercellular regulation might trigger the differentiation of intramuscular adipocytes (regardless of origin). For example, feed restriction followed by realimentation may lead to dedifferentiation of mature adipocytes followed by its redifferentiation of proliferative competent (DFAT) progeny cells (as well as other preadipocytes/adipofibroblasts) into lipid-assimilating cells on realimentation, which may be one of the causes of changing the body composition and increase of fatness. Dedifferentiated fat cells originating from different adipose depots possess different rates of redifferentiation, whereas those originated from intramuscular fat depot are more active in adipogenesis than other fat depots. In summary, although the mechanisms of dedifferentiation of mature adipocytes have not been well defined, DFAT cells may contribute to intramuscular adipogenesis. Dedifferentiated fat cells may lead to the adoption of strategies in livestock production to enhance fat deposition in specific (desired) depots.

Key Words: adipose tissue, ceiling culture, marbling

0790 Metabolic programming and intramuscular adipogenesis. G. Takafumi*, *Kyushu University, Taketa-city, Japan*.

The study was conducted to clarify how early nutrition as metabolic programming events affected intramuscular adipogenesis of Japanese Black cattle fattened with only roughage. As a control group, the roughage group (R; n = 11) was fattened on only roughage ad libitum from 4 to 31 mo of age (mo) after nursing at standard level (replacer milk intake of 0.6 kg/d) until 3 mo. As a treatment group, the high-energy group of metabolic programming events (MP; n = 12) was also fattened on only roughage ad libitum from 11 to 31 mo after intensively nursing and feeding a high-energy diet until 10 mo. The intramuscular fat content in longissimus muscle was significantly larger in MP (13.2%) than in R (9.4%) at slaughter (Soxhlet analysis). Expression of the adipogenic genes, C/EBPb, PPARγ, C/EBPa, FASN, SCD, LEP, FABP4, ADIPOQ, IGFBP4, PPARγ2, and PRMT5, was investigated at each stage by quantitative real-time PCR analysis by using longissimus muscle biopsy samples. At 3 mo, the expression levels of PPARγ, C/EBPa, PPARγ2, ADIPOQ, IGFBP4, and PRMT5 were significantly higher in the MP than in the R. At 10 mo, the expression levels of PPARγ, C/EBPa, FASN, SCD, and LEP were significantly higher in the MP. At 14 mo, only PPARγ and LEP in the MP showed significantly higher expression. PPARγ, PPARγ2, and C/EBPa and other adipogenesis markers such as LEP, ADIPOQ, FABP4, IGFBP4, and PRMT5 were expressed at higher levels in the MP compared with the R at 30 mo. This effect may involve several factors including metabolic additivity and response to nutritional stimulus and the unstable nature of expression of these genes. Conversely, at 20 and 30 mo, FASN and SCD were expressed at significantly lower levels in the MP. Nevertheless, according to investigation of fatty acid composition of intramuscular adipose tissue, early metabolic programming events positively affected the relatively higher amounts of C18:1, MUFA, and the US:S ratio in MP at slaughter compared with R. It may be concluded that metabolic programming through high nutrition at neonatal ages can positively change adipogenic gene expression at the molecular level. These effects stimulate the early development of adipocytes at an early age and these changes were maintained over the study period. These suggest that early nutrition affects final meat quality and that early metabolic programming has potential to advance the field of

meat sciences and support the meat industry.

0791 Genetics and breeding for intramuscular fat and oleic acid content in pigs. J. Estany*[1], R. Ros-Freixedes[2], M. Tor[1], and R. N. Pena[1], [1]*University of Lleida – Agrotenio Center, Lleida, Spain,* [2]*Universitat de Lleida, Lleida, Spain*.

Total fat and fatty acid content affect both food quality and human health, and therefore, they are becoming increasingly important to industry and consumers. The intramuscular fat (IMF) and oleic acid (C18:1) content have been favorably related to pork quality, particularly in dry-cured products. This has triggered the interest of including them in the breeding goal of pig lines producing for high-valued markets. It is known that IMF responds to selection, but there is little evidence on the opportunities for genetic change in fatty acid composition. Based on research conducted on a Duroc line, we showed that C18:1, like IMF, has a moderate heritability and is genetically associated with increased IMF, BW, and backfat thickness. Despite this correlation structure, we proved that there exist selection schemes leading to response scenarios where C18:1, IMF, and lean content can be simultaneously improved. A limitation for implementing direct selection for C18:1 is that phenotypes are costly to obtain and cannot be measured on selection candidates themselves. Furthermore, results may depend on the reference tissue used for genetic evaluations. Deoxyribonucleic acid markers and genomic selection provide a complementary approach to overcome this problem. A genomewide association study was performed on Duroc pigs genotyped with a 60,000-SNP chip to detect genomic variants exhibiting influence on fat content and composition. We detected strong associations with IMF and C18:1 for two chromosomal regions colocalizing with the *SCD* (SSC14) and *LEPR* (SSC6) genes, which were then validated using a set of data from around 1,000 pigs. The DNA variant at the *SCD* gene affected the oleic to stearic desaturation index (C18:1/C18:0), C18:1, and SFA and MUFA and was consistently detected in several muscles and subcutaneous fat and both in raw and dry-cured pork. The association of *LEPR* with fatty acid composition was detected in muscle and was, at least in part, a consequence of its effect on overall fatness, with increased IMF resulting in more SFA, less PUFA, and greater SFA:PUFA ratio. With the benefits of genomic selection needing further assessment, selection combining pedigree-connected phenotypic data on IMF and C18:1 and some singled-out genetic markers is presented as a suitable alternative. However, if adopted, the response on lean growth is expected to be reduced. The extent to which it is affordable relies on how much consumers are prepared to pay for high-IMF and C18:1 pork products.

0792 The genetic landscape of intramuscular fat content and composition in pigs. M. Amills*, *Center for Research in Agricultural Genomics, Bellaterra, Spain*.

Intramuscular fat content and composition are relevant selection goals in pig breeding schemes because of their significant influence on meat tenderness, juiciness, and flavor. Muscle lipid phenotypes are determined by both nutritional and genetic factors, displaying moderate heritabilities and a polygenic architecture. In this way, genome scans with microsatellites have revealed the existence of more than 200 intramuscular fat content QTL scattered throughout the pig genome. Unfortunately, experimental limitations related with population size and marker density have prevented the identification of mutations with causal effects. The comparison of QTL maps among muscles and fat depots has evidenced a modest positional concordance, suggesting that the penetrance of polymorphisms with causal effects on lipid metabolism is modulated by tissue-specific factors. This is an important consideration that should be kept in mind when implementing gene-assisted or genomic selection schemes aimed to improve intramuscular fat content and composition in swine. Gene expression studies based on microarrays have also provided valuable clues about the biology of muscle fat deposition in pigs, showing that it is modulated by a complex network of pathways related with lipid (lipogenesis, lipolysis, and PPAR signaling) and carbohydrate (insulin signaling) metabolism. However, microarrays have a limited power because they do not allow exploring transcript structure or the expression patterns of noncoding RNA. The recent advent of high-throughput genotyping and sequencing technologies has made it possible to circumvent many of these limitations. Now, genomewide association studies take advantage of the information provided by tens of thousands of SNP markers to fine map genomic regions associated with intramuscular fat content and composition in pigs. In parallel, the RNA-seq technology is expanding the analysis of differential expression to mRNA splicing variants as well as to many noncoding RNA with functions yet to be discovered. Particularly powerful are those approaches integrating genomewide polymorphism and expression data, because they can offer an unprecedented view about the molecular mechanisms that regulate lipid deposition in the porcine skeletal muscle.

0793 Statistical models and tools for integration of omics data to uncover the genetic control of pork quality and growth traits. J. P. Steibel*[1], D. Velez-Irizarry[1], S. Casiro[1], and C. W. Ernst[2], *[1]Department of Animal Science, Michigan State University, East Lansing, [2], Michigan State University, East Lansing*.

Next-generation sequencing is drastically changing the way we study the interactions between genomes, transcriptomes, and phenomes. The next generation of animal genomics data sets should be matched by the next generation of analysis models. Those models should be flexible and adaptable to complex designs pervasive in animal genomics, statistically sound to test hypotheses and estimate parameters that are important for animal genomic research, and computationally efficient and able to accommodate massive multilayer data sets that are typical of animal genome research. The goals of this presentation are to 1) propose models for genomewide association (GWA) that can be used for expression QTL (eQTL) and phenotypic QTL (pQTL) mapping and to show their properties using simulations and real data analyses. As part of the analysis, we specify significance thresholds to control type I error rate, we compute confidence intervals of QTL positions using cross-validation, and we demonstrate under simulation that intervals have the intended coverage. Finally, we derive a meta-analysis procedure to integrate results of several independent GWA. We use plasmode simulations to show that our proposed method has a series of desirable properties for implementation of high-throughput association analyses: 1) computational cost linearly scales with the number of markers allowing rapid GWA with massive data sets, 2) genetic substructure and relationships among animals are fully accounted for, and 3) type I error rates are controlled at nominal levels. Finally, we present graphical and descriptive summary tools to represent results of massively parallel GWA analyses. To illustrate the usefulness and computational efficiency of proposed models, we present results from several projects: 1) GWA analysis of over 50 pork quality, carcass composition, and growth traits for almost 1,000 Duroc × Pietrain F_2 pigs; 2) GWA of over 40,000 gene expression phenotypes from backfat and longissimus muscle tissues of 176 individuals of the same population; and 3) meta-analysis of five meat quality traits across three divergent pig populations. We show that using our proposed methods, we can map eQTL overlapping pQTL and confirm their joint association. More importantly, we demonstrate that such mapping can be performed and represented in an unsupervised way (with minimal human input) by integrating genomewide expression and genotyping as well as high-throughput phenotyping data through proper data analysis models and tools.

0794 Marbling: Management of cattle to maximize the deposition of intramuscular adipose tissue. S. B. Smith*[1] and B. J. Johnson[2], *[1]Texas A&M University, College Station, [2]Texas Tech University, Lubbock*.

Consumers in the United States, Japan, and Korea have valued highly marbled beef for nearly a century. In the United States, most consumers prefer beef that is reasonably marbled and juicy. Early studies demonstrated that the more oleic acid in beef, the greater the overall palatability of the beef. Scientists have taken a two-prong approach to understand the biology of marbling development. Biochemists, molecular biologists, and geneticists have worked to gain a better understanding of the intracellular and extracellular factors that regulate the development of marbling adipose tissue (also known as intramuscular tissue), whereas beef cattle nutritionists have worked to optimize diets and time on feed to provide high-quality beef carcasses without exacerbating carcass adiposity. Marbling adipose tissue preferentially uses glucose as the carbon source for fat synthesis, whereas subcutaneous adipose tissue preferentially uses acetate. Early weaning of beef steers promotes greater marbling development at slaughter than normal weaning of steers, and this may be caused by increased glucose availability (from the grain-based rations) at the early stages of marbling development. In addition to providing carbon for marbling adipose tissue development, grain-based diets also increase MUFA such as oleic acid in marbling by stimulating the expression of stearoyl CoA desaturase (SCD). There is a significant correlation between the concentration of MUFA and amount of intramuscular lipid in longissimus muscle in cattle with the genetic propensity to marble that are fed grain-based diets for extended periods of time. Marbling adipose tissue can be distinguished from other fat depots by its location within perimysial connective tissues alongside muscle fibers. However, in longissimus muscle from Japanese Black A5 cattle, marbling adipocytes have been observed within muscle bundles, suggesting that muscle satellite cells can be induced to differentiate into marbling adipocytes. To date, the mechanisms responsible for this *trans*-differentiation of satellite cells to adipocytes in beef cattle have not been identified, as this process is quite difficult to measure in situ. Marbling adipose tissue from Japanese Black cattle are exceptionally high in oleic acid, and recent cell culture studies have demonstrated that oleic acid promotes *trans*-differentiation of muscle cells to marbling adipocytes. The results of these studies indicate that grain-based diets are necessary to promote the development of marbling. Furthermore, grain-based diets increase the healthfulness and juiciness of beef by promoting the production of oleic acid in marbling and other fat depots.

Key Words: beef, marbling, oleic acid

0795 Linking from the farm to the table.
M. R. McMorris*, *Beef Improvement Opportunities, Guelph, ON, Canada*.

Genomics promises tremendous opportunity to the beef industry; however, that opportunity is currently stymied by the structure of the industry and the limited use of long-standing traditional genetic evaluations. Industry segmentation and poor, or in some cases lack of, market signals can be seen in the industry response of the past decade to a demand for more highly marbled beef. From 2005 to 2015, the feeding sector simply overfed animals to achieve higher marbling at the very great expense of excess fat, poor carcass yield, and poor feed efficiency. Although a logical decision in itself at the finishing level, this approach ignored the potential of "supply-chain" genetics to meet an end goal. A further persistent need that the beef supply must address is inconsistency of tenderness of beef at the consumer level. Beef is a premium protein product and, as such, must meet a higher standard for consumer satisfaction. Considering the heritability of tenderness, it would seem obvious as a supply-chain breeding goal. And yet no selection has been attempted, due in part to the nature of the trait: difficult to measure on breeding animals. This is an area of particular interest to make use of genomics. A simple DNA test can give an estimate for tenderness, which, applied to three generations of sire selection, could have a dramatic impact on consumer satisfaction. A third trait that should be of interest to every beef producer is feed efficiency. Although a great deal of focus has been placed on residual feed intake and affordable panels have been developed, little selection pressure has been brought to bear. Again, this is due, in large part, to the segmentation of the beef industry. Genetic improvement in the beef industry will only reach its potential following a fundamental shift in outlook. Current segmentation by sector and "ranch-level" genetics must be replaced with a more holistic approach in which information and market signals flow up and down the supply chain. Only then will producers and, more importantly, consumers benefit from the promise of genomics.

Key Words: beef genomics, breeding goals, industry structure

HORSE SPECIES: MANAGEMENT

0796 Stress responses in horses tied with overchecks.
K. Bennett-Wimbush*, J. K. Suagee-Bedore, and M. Amstutz, *The Ohio State University, Wooster*.

Little information is available on the welfare of horses used for transportation. It is common to observe horses wearing a complete harness, hooked to horse-drawn vehicles, tied up for extended periods of time where horse-drawn transportation is popular. An observational survey of 305 horses at 7 locations in northeast Ohio found 29.5, 51.5, and 13.8% of the horses were tied wearing harnesses with high, low, or no overchecks. Six Standardbred mares were used in a Latin square (treatment × period) designed experiment to evaluate the effects of tying horses wearing overchecks. All horses were acclimated to harness and tying before testing. Three 90-min test periods (May and June 2015) were used, and horses were randomly assigned to treatment groups: high overcheck (HC), low overcheck (LC), or no overcheck (NC). Each test period was followed by a 2-wk recovery period. Heart rate was measured before the test; during the test at 15 (T15), 45 (T45) and 90 (T90) min; and after the test at 45 (P45) and 90 (P90) min. Plasma cortisol (ELISA) was measured before the test and at T45, T90, P45, and P90. Muscle soreness and tightness at 20 sites—(right and left) rhomboideus, trapezius, deltoideus, latissimus dorsi, triceps, biceps femoris, longissimus, gluteus, hamstrings, and tensor fascia lata—were scored by a trained professional (Powel et al. 2008. J. Equine Vet. Sci., 28(1):28–33) before testing and 24 h after testing. Heart rate tended to be higher (45 ± 2.5 bpm; $P = 0.098$) at T15 in all horses compared with pretesting values (40 ± 2.5 bpm), regardless of treatment. Plasma cortisol was higher ($P < 0.001$) in HC at T45 and T90 (159.7 and 166.3 ng/mL, respectively) compared with both LC (106.4 and 105.2 ng/mL) and NC (116.1 and 93.5 ng/mL) at T45 and T90, respectively. There was no treatment effect on muscle soreness and tightness. Overall, muscles were more sore ($P < 0.05$) and more tight ($P < 0.001$) following the test compared with pretest values in all horses. The rhomboideus ($P < 0.001$), latissiumus dorsi ($P < 0.05$), and longissimus ($P < 0.05$) showed significant changes in both muscle soreness and tightness whereas the trapezius, deltoideus, and biceps femoris were only tighter ($P < 0.05$). We recommend loosening or removing overchecks while horses are tied and advocate additional studies on the common practice of tying up horses.

Key Words: horse, welfare, cortisol

0797 Effect of prerace behavior on performance in racing quarter horses.
C. E. Ferguson*, *McNeese State University, Lake Charles, LA*.

It is purported that prerace behavior of a race horse can diminish their performance, known as "washing out." This study observed prerace behaviors of 1,040 Quarter Horse (QH) race horses that competed in 137 races over a 14-night duration at Delta Downs Racetrack (Vinton, LA). A total of 46 variables were recorded by experienced horsemen. The prerace period was divided into four different subsections: before saddling (BSAD), which was the time when the horse walked across the track's infield to right before they entered the stall to be saddled; during saddling (SAD), which was the time while the horse was being saddled; after saddling (ASAD), which was the time from when the horse was finished being saddled to when the jockey mounted the horse; and after the parade (POSTP), which was the time from when the jockey mounted

to when they were finished with the postparade. During subsections, each horse assessed a behavior type of calm, ready, or nervous. Upon completion of each race the finish type (tired, pulled-up, or running) was recorded as well as finish position, which was checked the next day on the Equibase website. Categorical variables were statistically compared using a χ^2 test and quantitative variables were compared using general linear models in SAS. The average number of previous races at Delta Downs was statistically greater ($P < 0.05$) for calm horses (3.3 ± 0.2) than ready (2.2 ± 0.1) and nervous (0.9 ± 0.1) horses during all periods. The average finish position was not different for calm (5.1 ± 0.1) and ready (5.0 ± 0.1) horses but both were significantly better than nervous (5.9 ± 0.3) horses for all periods. However, horses (during POSTP period) that were ready (4%) were less likely ($P < 0.05$) to finish tired compared with calm (10%), which was also less likely ($P < 0.05$) to finish tired compared with nervous (19%). The results show that horses that appear nervous are more likely to finish behind horses that appear calm or ready to race and are three times more likely to finish the race tired compared with ready and twice as likely compared with calm. These data support that a nervous behavior can negatively impact their performance in races, even at short distances.

0798 Evaluating the effectiveness of varying doses of supplemental tryptophan as a calmative in horses. B. Davis*[1], T. Grandin[1], T. E. Engle[1], and J. Ransom[1,2], *[1]Colorado State University, Fort Collins, [2]National Park Service, Sedro-Woolley, WA*.

The objective of this study was to examine how various doses of tryptophan supplementation impacted reactive behavior and physiological stress measurements in the horse. Eleven horses (9 geldings and 2 mares) were given four treatments—a control dose, consisting of 0 mg Trp/kg BW (CON); 20 mg Trp/kg BW (LOW); 40 mg Trp/kg BW (MED); and 60 mg Trp/kg BW (HIGH)—in a randomized crossover design. Each treatment lasted 3 d. On Days 1 and 3 of each treatment, horses underwent a behavior test to measure startle response. Heart rate measurements and the speed at which the horses fled from startling stimuli were recorded. In addition, serum glucose, lactate, and cortisol levels were analyzed both immediately before the startle test and again 15 min after the test. Significant sedative effects were seen at LOW Day 1 on heart rate increase during the startle test ($P = 0.05$) and on change in serum lactate levels ($P = 0.03$). At MED Day 1, sedative effects were seen on change in serum cortisol levels ($P = 0.01$). Some excitatory effects were seen at MED Day 3 on the time for heart rate to return to baseline after the startle test ($P = 0.03$). A subset of blood samples was analyzed for serum free Trp and the ratio of Trp to other large neutral AA, which verified treatment effect.

Key Words: behavior, horse, tryptophan

0799 Effects of barefoot trimming and shoeing on the lower forelimb: Hoof morphology. D. K. Proske[1], J. L. Leatherwood*[1], M. J. Anderson[1], K. J. Stutts[1], C. J. Hammer[2], and J. Coverdale[3], *[1]Sam Houston State University, Huntsville, TX, [2]North Dakota State University, Fargo, [3]Texas A&M University, College Station*.

Limited information is available pertaining to potential benefits of barefoot trimming techniques under standard management conditions. Therefore, 12 mature Quarter horses (8–14 yr and 450–572 kg) were used in a switch back design for a 140-d trial to determine effects of barefoot trimming and shoeing on joints of the forelimb and digital cushion thickness. Before the start of the trial, all horses were adapted to a standardized exercise protocol and lameness examinations were performed by a veterinarian; hooves were allowed to grow naturally with minimal farrier interventions. This study was divided into 3 phases: d 0 to 42, horses were barefoot trimmed (BF1); d 49 to 91, horses were shod (SD) on the forehand with standard St. Croix plain lite shoes; and d 98 to 140, horses received another barefoot trim (BF2). Between phases, a 7-d transition period was given to allow for farrier practices. Horses were group exercised 3 times/wk on a 132 by 3.7 m linear dirt track to a mean HR of 80.00 ± 1.90 bpm. Measurements were obtained every 21 d immediately following exercise. Digital cushion thickness was ultrasonically measured through the superficial frog using a 5.0-MHz convex probe and stand-off pad following previously described methods. Stride lengths were also recorded following exercise at a walk and trot (EquineTec, Monroe, GA). Data were analyzed using the PROC MIXED procedure of SAS. There was no influence of day ($P = 0.25$) on mean HR; however, there was an influence of treatment. Mean HR was lower ($P < 0.01$) during the BF1 phase (75.50 ± 1.90 bpm) compared with the SD (82.08 ± 1.90 bpm) and BF2 (82.42 ± 1.90 bpm) phases. Mean stride lengths at the walk ($P < 0.05$) and trot ($P < 0.01$) were greater in SD horses compared with BF1 and BF2 horses. There was no main effect ($P \geq 0.47$) of day or treatment on digital cushion thickness. However, on d 42 of each of the 3 phases, mean digital cushion thickness was greater ($P \leq 0.01$) during the BF1 (1.41 ± 0.03 cm) and BF2 (1.43 ± 0.03 cm) phases compared with the SD phase (1.26 ± 0.03 cm). These data indicate that a shod fore digit may cause changes in hoof morphology due to alterations in lower limb movement and hoof load dispersion and, therefore, may cause an increase in the incidence of lameness over time.

Key Words: shoeing, digital cushion, stride length

0800 Effects of barefoot trimming and shoeing on the lower forelimb: Joint inflammation. D. K. Proske[1], J. L. Leatherwood*[1], K. J. Stutts[1], M. J. Anderson[1], C. J. Hammer[2], and J. Coverdale[3], *[1]Sam Houston State University, Huntsville, TX, [2]North Dakota State University, Fargo, [3]Texas A&M University, College Station*.

Limited information is available pertaining to potential benefits of barefoot trimming techniques under standard management conditions. Therefore, 12 mature Quarter horses (8–14 yr and 450–572 kg) were used in a switch back design for a 140-d trial to determine effects of barefoot trimming and shoeing on the hoof and joints of the forelimb. Before the start of the trial, horses were adapted to a standardized exercise protocol and lameness examinations were performed by a veterinarian. This study was divided into 3 phases: d 0 to 42, horses were barefoot trimmed (BF1); d 49 to 91, horses were shod (SD) on the forehand with standard St. Croix plain lite shoes; and d 98 to 140, horses received a second barefoot trim (BF2). Between phases, a 7-d transition period was given to allow for farrier practices. Horses were group exercised 3 times/wk on a 132 by 3.7 m linear dirt track to a mean HR of 80.00 ± 1.90 bpm. Measurements were obtained every 21 d immediately following exercise protocol and included thermography images (FLIR Systems, Boston, MA) of carpal and metacarpal joints, superficial horn of the frog, and medial and lateral sole of the front digits. Joint circumferences were obtained using a soft tape measure at the accessory carpal and proximal sesamoid bones, respectively. Additionally, blood samples were collected to evaluate PGE_2 concentrations after exercise. Data were analyzed using the PROC MIXED procedure of SAS. An influence of treatment ($P < 0.01$) was detected in all areas measured, with mean surface temperatures being greatest during the BF1 phase. Although no difference was detected ($P = 0.38$) in the joint circumference of the metacarpal joint, there was an influence of treatment ($P < 0.01$) at the carpal joint with the BF1 phase having the lowest mean joint circumference compared with all other phases. PGE_2 concentration decreased throughout each phase of the trial ($P < 0.01$) independent of the treatment applied. This is likely due to an increased cardiovascular stamina of the horses from repetitive exercise as the study progressed. In the BF1 phase, the lower joint circumferences and the increased surface temperatures illustrate the presence of greater blood flow and lack of joint inflammation and swelling. These data indicate that a shod fore digit may cause inflammation on the joints of the lower forelimb accompanied by a reduction in blood flow and, therefore, may cause an increase in the incidence of lameness over time.

Key Words: shoeing, thermography, joint

0801 Characterizing the physiological response of a novel vaccine in mature horses. J. L. Leatherwood*, D. L. Parker, M. J. Anderson, K. J. Stutts, M. M. Beverly, and S. F. Kelley, *Sam Houston State University, Huntsville, TX*.

The vaccination of animals has been implemented to prevent the spread of infectious diseases through the use of inactivated or modified live organisms. Vaccination serves to induce an immune response that is effective at limiting the exposure to a natural born pathogen. Criteria for successful vaccination programs is to ensure that the vaccine does not cause the disease or produce negative side effects that may overwhelm the ability of the immune system to provide a means of protection. Therefore, the objective of this study was to characterize the physiological response of mature horses to a novel vaccine through the use of thermography and assessment of vital parameters as well as to determine differences in surface temperatures at the injection sites of the vaccine and saline to better understand the localized inflammatory response to injection. Thirty horses (5–10 yr and 413–551 kg) were vaccinated against bovine respiratory syncytial virus, bovine viral diarrhea virus, and infectious bovine rhinotracheitis as a one-time vaccination with a saline contralateral injection that was completed on the opposite side of the neck. Horses were assumed to be naïve to bovine diseases. Vitals including heart rate (HR), respiration rate (RR), and rectal temperature along with thermal images (FLIR Systems, Boston, MA) of the ocular globe (OG), rectum (RM), and injection sites were recorded at 0 and 6, 12, 24, and 48 h following vaccine administration. Data were analyzed using the GLM procedure to evaluate differences over time and a paired *t* test to evaluate differences between injection sites. Vitals including HR and RR decreased ($P < 0.01$) following initial handling at 0 h and remained consistent up to 48 h following vaccine administration. Rectal temperature increased ($P < 0.01$) and peaked at 12 h ($P < 0.01$) compared with other time points measured. Similarly, thermography data of OG and RM followed a similar pattern and peaked at 12 h ($P < 0.01$). Comparison between the vaccine and saline injection sites revealed that the vaccine site had an elevated temperature ($P < 0.01$) compared with the injection site of the saline control. This illustrates the localized inflammation detected is a result of a response to the vaccine rather than the injection alone. Similarly, changes in rectal temperature along with thermography of the OG and RM are valid indicators of a response to vaccination whereas HR and RR were not altered and may not be reliable predictors.

Key Words: equine, thermography, vaccine

0802 Application of either a single or multiple doses of an intravaginal gonadotropin-releasing hormone agonist to induce ovulation in mares.

C. D. Sinclair*[1], S. K. Webel[2], T. L. Douthit[1], D. M. Grieger[1], and J. M. Kouba[1], [1]*Kansas State University, Manhattan,* [2]*JBS United, Inc., Sheridan, IN*.

Triptorelin acetate (TA) is a GnRH agonist that is used in the swine industry to induce ovulation. In a previous study, we investigated the efficacy of an intravaginal TA gel to induce ovulation in mares. Treatment with TA gel tended ($P = 0.08$) to elicit an increase in LH concentrations by 12 h after treatment but failed to shorten the interval from treatment to ovulation or cause a greater percentage of mares to ovulate within 48 h of treatment compared with placebo-treated controls. Because peak LH concentrations were observed at 12 h after treatment and declined to nearly baseline concentrations by 24 h, we postulated that LH concentrations may not have remained elevated sufficiently to induce ovulation. Therefore, the objective of this study was to investigate whether 2 doses of TA gel would result in elevated LH concentrations sustained for a sufficient period to reduce the interval from treatment to ovulation and cause ovulation to occur within 48 h of treatment. Twenty-three cyclic mares were stratified by parity and age and randomly assigned to 3 treatments: 500 μg TA (TA5); two 500-μg doses of TA, given 24 h apart (TA5x2); or 5 mL vehicle gel only (control). Ultrasonography occurred once daily until detection of a follicle ≥25 mm in diameter was detected, at which point ultrasonography and blood collection occurred every 12 h. Once a follicle ≥35 mm was detected, treatment was administered intravaginally and ultrasonography and blood collection then occurred every 6 h until 48 h after ovulation. At 6 and 12 h after treatment, LH was increased ($P < 0.05$) in both TA5 and TA5x2. In TA5x2, the second dose of TA failed ($P > 0.05$) to elicit more LH release compared with both TA5 and control. With regard to LH concentrations, the overall treatment effect was not significant ($P > 0.05$); however, a treatment × time interaction was identified ($P < 0.05$). A greater ($P < 0.05$) percentage of mares ovulated by 48 h after treatment in TA5 but not TA5x2 compared with control. Interval from treatment to ovulation was shorter ($P < 0.01$) in both TA5 and TA5x2 compared with control. We concluded that both 1 and 2 doses of 500 μg TA hastened ovulation in cyclic mares; however, 2 doses failed to cause sustained release of LH or cause a greater percentage of mares to ovulate within 48 h of treatment.

Key Words: mare, ovulation, gonadotropin-releasing hormone

Table 0802.

Table 1 – Effects of TA gel on the interval from treatment to ovulation and the percentage of mares ovulating by 48 h post-treatment

	n	Hours from TRT to ovulation Mean ± SEM	% ovulating by 48 h
Control	7	123.1 ± 21.7[a]	0.0%[a]
TA5	8	61.5 ± 8.8[b]	75.0%[b]
TA5x2	8	61.5 ± 9.6[b]	50.0%[a]

0803 Incidence of exercise induced pulmonary hemorrhage in race horses in Puerto Rico.

V. Morales[1], S. Glass[1], J. De Angel[2], B. Vallejo[2], and A. A. Rodriguez*[1], [1]*University of Puerto Rico, Mayaguez,* [2]*Equus PR, Caguas, PR*.

Exercise-induced pulmonary hemorrhage (EIPH) is a very common disease in race horses characterized by an alteration of the respiratory system. Depending on the magnitude, the EIPH causes bleeding in lung passages making breathing difficult. Exercise-induced pulmonary hemorrhage is evaluated by endoscopies on a scale from 0 to 5, with 0 corresponding to no hemorrhage and 5 to a severe condition. In Puerto Rico, the only preventive measure used is the administration of a diuretic 4 h before the race. A data set was analyzed to determine factors associated with the incidence of EIPH and the preventive effect of the diuretic. The data were supplied by Equus PR and the factors considered were month of the year, sex (male or mare), distance of the race in meters (C1, 400 to 1,200; C2, 1,300–1,400; and C3, >1,600), and the use or not of the diuretic. The randomly selected data of 2,632 endoscopies of race horses running or not represented 20% of the total endoscopies recorded in 2014. Of this number, 1,377 were from horses within 1 h after the race, representing 52% of the total. A χ^2 test analysis was performed to determine the frequency of EIPH regarding the factors, month, sex, distance of the race, and use of the diuretic. Of the 1,377 animals, 488 presented some degree of EIPH, equivalent to 35% of the total sample. The percentage of horses suffering EIPH condition from 1 to 5 was 52.8, 23.6, 13.5, 7.3, and 2.8, respectively. The frequency and severity of EIPH was similar ($P = 0.435$) during the 12 mo of the year. Males and mares also had similar ($P = 0.587$) incidence. Horses running shorter races (C1 and C2) had a higher ($P < 0.02$) incidence of EIPH than those running longer races (C3). The number of healthy horses or those suffering the condition was similar ($P = 0.375$) regardless of diuretic use. In summary, 35% of the race horses competing presented some level of EIPH; month of the year and sex did not alter the incidence. Horses running shorter distance showed more incidence of the condition and the use of the diuretic was not effective as a preventive method for EIPH.

Key Words: diuretic, race horses, exercise induced pulmonary hemorrhage

0804 Application of gait analysis to determine if the Galiceno horse breed is a gaited horse breed.
M. C. Nicodemus*[1] and J. Beranger[2], [1]*Mississippi State University, Mississippi State,* [2]*The Livestock Conservancy, Pittsboro, NC*.

The Galiceno horse breed is classified as critically endangered by The Livestock Conservancy (LC) with less than 200 pure Galicenos in the United States. The Galiceno is one of several breeds classified as a Spanish Colonial horse breed. The breed has been noted for its ground-covering movement and its capacity for performing a running walk. Although other Spanish Colonial horse breeds have been classified using gait analysis as gaited, research documenting the gait mechanics of the Galiceno breed is unavailable. The objective of the study was to evaluate symmetrical gaits at various velocities performed by the Galiceno documenting gait mechanics that would be classified as gaited. Horses (n = 12) were selected by the LC and Galiceno Horse Registry (121.9–137.2 cm height) to represent the breed. Horses were asked to move freely along an arena railing while being filmed. Frame-by-frame analysis was performed documenting hoof contact and lift-off. A full stride cycle was determined from the time the right hind hoof made ground contact to the time it returned back to the ground. Only gaits demonstrating gait symmetry were used for this study. Student's paired t tests were performed to determine gait symmetry ($P < 0.05$). Stance durations between left and right variables that were not significantly different indicated gait symmetry. A total of 30 symmetrical strides were selected for each horse. From the strides evaluated, 32% demonstrated a 4-beat rhythm with a lateral footfall sequence and no period of suspension similar to the walk. The velocity for these strides (1.36 + 0.19 m/s) fell within the range of a typical walk for the height of the horse, thus falling under the velocity of that of a running walk performed by a gaited breed. Stride duration (1,220 + 89 ms) was comparable to a slow walk. The remaining strides demonstrated a diagonal footfall sequence with 8 to 23% of the stride duration spent in a period of suspension. Only 4% of those strides had a 4-beat rhythm demonstrating diagonal couplets as the rest demonstrated a true 2-beat rhythm. The velocity for the diagonal leaping gait was 3.78 + 0.63 m/s with disassociation of diagonal pairs occurring at the upper range of the velocity. Stride duration was 690 + 72 ms. Both stride duration and velocity were comparable to the trot seen in other nongaited Spanish Colonial horse breeds. In conclusion, those strides evaluated did not suggest the Galiceno should be classified as a gaited horse breed.

Key Words: Galiceno, kinematics, gaited

0805 Effect of body condition score on fatty acid composition of equine subcutaneous adipose tissue.
R. M. Humphrey*, A. T. Sukumaran, R. L. Lemire, E. N. Ferjak, C. Cavinder, D. D. Burnett, and T. T. N. Dinh, *Mississippi State University Department of Animal and Dairy Sciences, Mississippi State*.

Body condition score serves as a proxy indicator of the health and metabolic disposition of horses; however, this subjective assessment does not take into account the fatty acid composition of adipose tissue (AT) depots. The objective of this study was to investigate the relationship between BCS and fatty acid composition of subcutaneous AT. Fourteen horses with BCS of 4 (n = 4), 5 (n = 6), and 6 (n = 4) were euthanized, and the subcutaneous fat was collected at the junction of the last rib and the vertebral column. Samples were frozen in liquid nitrogen, pulverized, and stored at −80°C. Fat samples were directly derivatized for fatty acid identification and quantification on a gas chromatography system (Agilent Technologies, Santa Clara, CA) using an internal standard for calibration. Fatty acid methyl ester concentrations were used to calculate fatty acid percentages. Statistical analysis was performed by the GLIMMIX procedure of SAS 9.4 (SAS Inst. Inc., Cary, NC), and statistical significance was determined at $P \leq 0.05$. Overall, there was no effect of BCS on fatty acid percentages composition ($P \geq 0.129$), except that capric acid was greater in horses with BCS of 4 than in those with BCS of 6 (P = 0.008). In terms of overall composition, equine subcutaneous AT was composed of approximately 35.36 to 37.77% SFA, 35.80 to 36.90% MUFA, and 25.33 to 28.84% PUFA, which were markedly distinguishable from the relative percentages reported in ruminants and other monogastric species. Palmitic, oleic, and linolenic acids were the predominant SFA, MUFA, and PUFA with respective relative percentages of approximately 24.68, 28.96, and 16.41%, respectively. Linoleic acid, the predominant PUFA found in most ruminant and monogastric species, was the second most predominant PUFA in equine, at 6.78%. Vaccenic acid, a typical *trans* fatty acid found in ruminants, was not detected in horse subcutaneous adipose tissues. These data indicate that BCS did not have a marked impact on the fatty acid composition of the subcutaneous AT depot in the equine animal for the range of BCS investigated in the current study.

Key Words: equine, adipose, body condition

0806 Feeding a small amount of hay before concentrate neutralizes the effects of high starch diets on inflammation in horses. J. K. Suagee-Bedore*[1], K. Wimbush[1], D. R. Linden[1], and R. K. Splan[2], [1]*The Ohio State University, Wooster,* [2]*Virginia Tech, Middleburg*.

When fed to horses, high starch diets elevate plasma concentrations of IL-1β as soon as 1 h post eating. This increase in IL-β is possibly due to changes in intestinal pH that result from rapid bacterial fermentation of starches and sugars in the digestive tract. This altered pH may disrupt the gut microbial environment and ultimately lead to inflammation. The purpose of this research was to investigate the effect of feeding 0.9 kg of grass hay 30 min before feeding a concentrate meal (HF) on the postprandial rise in IL-1β, as compared to control horses receiving the same concentrate without hay first (HS). Six mature light-breed geldings of moderate body condition (5–6 on a scale of 1–9) were used in a switchback design. Horses were fasted overnight before being offered a concentrate feed at 0800 h that provided 1.2 g/kg bodyweight of nonstructural carbohydrates. Plasma from blood was harvested at −30 min (sample obtained before hay feeding), 1, 2, 4, 6, and 8 h post feeding. Horses were offered ad libitum grass hay following completion of their concentrate meal. Concentrations of IL-1β, D-lactate, glucose, and insulin were analyzed by repeated measures ANOVA (SAS v. 9.3). Where necessary, values were log transformed and are presented as geometric means. The HF treatment reduced ($P < 0.01$) postprandial geometric mean concentrations of IL-1β compared to the HS treated horses at post-feeding hours 2 (296 [263–330] vs. 449 [402–500] pg/mL), 4 (272 [244–303] vs. 474 [425–530] pg/mL), and 6 (257 [230–287] vs. 439 [394–490] pg/mL). The HF treatment also decreased ($P < 0.05$) mean D-lactate concentrations at post-feeding hours 2 (1188 ± 110 vs. 1509 ± 110 μmol/L) and 4 (1186 ± 110 vs. 1581 ± 110 μmol/L), as compared to HS treated horses. Plasma glucose and insulin increased postprandially for both treatments ($P < 0.001$) with no effect of HF treatment ($P > 0.5$). Given these findings, we believe that feeding a small amount of hay before feeding a meal of moderate starch and sugar content reduced the negative effects of rapid starch and sugar fermentation in the equine digestive tract, as seen through reduced postprandial D-lactate and IL-1β concentrations.

Key Words: high-starch diet, IL-1β, inflammation

0807 Feeding DigestaWell Buffer to horses neutralizes the effects of high starch diets on blood pH and inflammation. J. K. Suagee-Bedore*[1], A. L. Wagner[2], and I. D. Girard[2], [1]*The Ohio State University, Wooster,* [2]*Probiotech International Inc., St-Hyacinthe, QC, Canada*.

When fed to horses, high starch diets elevate plasma concentrations of lipopolysaccharide (LPS) at 2 h post eating and IL-1β at 1 h post eating. These changes are possibly due to rapid bacterial fermentation of starches and sugars in the digestive tract, which may alter the pH in the digestive tract and lead to inflammation. The purpose of this research was to investigate the efficacy of a dietary supplement containing bicarbonate, DigestaWell Buffer (DB), to mitigate these postprandial changes, as compared to control horses receiving the same concentrate but without the supplement (HS). Six mature light-breed geldings were used in a switchback design. Horses were fasted overnight before being offered a concentrate feed at 0800 h that provided 1.2 g/kg bodyweight of nonstructural carbohydrates. The DB treatment supplied 150 g of top dressed DB supplement. Plasma from blood was harvested at −30 min, 1, 2, 4, 6, and 8 h post feeding. Whole blood was analyzed for pH and TCO2. Horses were offered ad libitum grass hay following completion of their concentrate meal. Concentrations of IL-1β, LPS, D-lactate, glucose, and insulin, and pH and TCO2 values were analyzed by repeated measures ANOVA (SAS v. 9.3). Where necessary, values were log transformed and are presented as geometric means. Supplementation with DB reduced ($P < 0.01$) postprandial geometric mean concentrations of IL-1β at post-feeding hours 4 (284 [253–321] vs. 474 [421–534] pg/mL), and 6 (261 [232–294] vs. 439 [390–494] pg/mL), tended to decrease geometric mean D-lactate ($P = 0.060$) concentrations at 8 h post feeding (1215 [1120–1318] vs. 1457 [1344–1581] μmol/L), and decreased mean LPS concentrations across all time points ($P < 0.001$). Meal consumption reduced blood pH in both treatments; however, pH was higher in DB than HS (7.414 ± 0.003 vs. 7.398 ± 0.003) treated horses ($P < 0.05$). Plasma glucose and insulin increased postprandially for both treatments ($P < 0.001$) with no effect of DB treatment ($P > 0.1$). Blood TCO2 levels were below the upper limit of 37mmol/L but tended to be higher in DB treated horses (31.4 ± 0.3 vs. 30.6 ± 0.3 mmol/L, $P = 0.068$). Given these findings, we believe that DB mitigates the negative effects of rapid starch and sugar fermentation in the equine digestive tract, as seen through reduced postprandial inflammation.

Key Words: DigestaWell, IL-1β, lipopolysaccharide

0808 Efficacy of a brewer's yeast supplement with or without fat added to an energy restricted diet for performance horses. L. B. Hodge[*1], A. Boyer[2], and B. J. Rude[1], *[1]Mississippi State University, Mississippi State, [2]FL Emmert, Cincinnati, OH.*

Objectives of the current trial were to evaluate effects of additional fat to a brewer's yeast supplement on hoof, coat, mane, and body condition of performance horses fed an energy deficient diet. Twelve performance geldings were randomly allotted to one of 3 dietary treatments: 1) a commercially available horse feed (10% CP, 4.5% fat) at 0.35% BW/d; 2) diet 1 plus a brewer's yeast supplement at 226 g/d; 3) diet 2 plus corn oil at 10% of the diet. Diet 1 was fed to be deficient in energy to evaluate additional energy supplied by fat. Geldings were fed half of their diet treatment twice per d for 84 d. Geldings had ad libitum access to bermudagrass pasture, hay, and water. Body weight (BW) measurements and body evaluations were collected at initiation of the trial and every 28 d until 84 d. Body evaluations included coat and mane condition, body condition score (BCS), and hoof condition. Coat, mane and hoof condition were evaluated on a scale from 1 to 5 (1 reflecting poor or damaged and 5 reflecting glossy and smooth) accounting for condition, texture and appearance. Body condition was based on the standard BCS scale of 1 to 9 (Henneke et al., 1983). Data were analyzed through ANOVA using the GLM procedures of SAS. No effect of diet was found for hoof (3.5, 3.3, and 3.6; $P = 0.7973$), coat (3.2, 3.6, and 3.7; $P = 0.2724$), mane (3.5, 3.5, 3.4; $P = 0.9885$) or BCS (5.1, 5.5, and 5.2; $P = 0.9982$) for diets 1, 2, and 3, respectively. Body weights were not different (505.6, 516.7, and 505.5 kg; $P = 1.000$) among diets 1, 2, and 3, respectively. Addition of fat to brewer's yeast supplement did not enhance body scores or body weight. In a previous trial (Seidle et al., 2014), concentrate was fed at 0.9% BW/d and fat was supplemented at 5% of diet. It was concluded that feeding concentrate at this amount may have masked the effects of increased energy from fat. In the current trial, diet 1 (basal diet fed to all treatments) was fed to be energy deficient in an attempt to evaluate if additional fat (10% of diet) added to brewer's yeast supplement had an effect on body weights and condition. Results may have been influenced by forage quality, which was not measured. Research should be conducted to evaluate brewer's yeast supplement and fat while feeding a larger amount of Brewer's yeast.

Key Words: equine, brewer's yeast, fat supplementation

0809 Modeling ammonia emission rate from horses fed different concentrations of dietary crude protein. J. Weir[*1], H. Li[2], L. K. Warren[1], E. Macon[3], and C. Wickens[1], *[1]University of Florida, Gainesville, [2]University of Delaware, Newark, [3]Middle Tennessee State University, Murfreesboro.*

Evaluating the impact of animal agriculture on air quality has been the focus of recent research. Ammonia (NH_3) volatilization occurs when excess crude protein is fed and excreted as urinary nitrogen. Information regarding NH_3 emission from equine facilities is limited, and the effects of dietary CP intake on NH_3 emission have not been investigated. Nine mature (mean ± SE, 562 ± 13.1 kg) geldings were used in a 3 × 3 replicated Latin square design study to determine the effects of dietary CP concentration on potential NH_3 losses from urine of horses fed an all forage diet. We hypothesized that increasing dietary CP concentration would increase NH_3 emission rate. Three diets were formulated using bahiagrass and bermudagrass hays fed at 3 different crude protein concentrations: LOW-CP, MED-CP, and HIGH-CP (10.6, 11.5, and 12%, respectively). Horses consumed a commercial ration balancer to meet micronutrient requirements. Each study period consisted of an 11-d diet adaptation phase, followed by a 3-d total collection of urine. Samples were pooled within a period by diet ($n = 3$) and mixed with either wheat straw or wood shavings. Ammonia emission of these samples were measured using a 12-vessel emission system with a constant airflow rate (2.5 L/min) at 20°C over a 7-d period. Concentration of NH_3 in each vessel was measured using a photoacoustic multi-gas analyzer. Temperature, airflow rate and NH_3 concentration in each vessel were used to calculate NH_3 emission rate (ER). Data were analyzed as a Latin square using the Mixed Model procedure with repeated measures (JMP Pro v. 11). Concentration and ER data were log transformed. Crude protein intake differed ($P < 0.05$) from LOW-CP to MED-CP and HIGH-CP, as designed. Vessel NH_3 concentrations were different across diets ($P < 0.05$), ranging from 51.8 ppm (LOW-CP) to 87 ppm (HIGH-CP), and bedding types ($P < 0.01$) with straw being higher than shavings (97 vs. 73.5 ppm, respectively). Cumulative urinary NH_3 ER also differed across diets ($P < 0.01$) ranging from 4.9 g/m^2 to 8.2 g/m^2 and bedding types ($P < 0.01$), with straw being higher than shavings (11.1 vs. 6.9 g/m^2, respectively). This study confirms that high crude protein intake and wheat straw bedding increases NH_3 ER from equine urine.

Key Words: ammonia emission, equine, dietary protein

0810 Dietary supplementation of DigestaWell NRG to unconditioned Warmblood mares may reduce lactate rise following exercise. A. L. Wagner*[1], R. K. Splan[2], J. K. Suagee-Bedore[3], and I. D. Girard[1], *[1]Probiotech International Inc., St-Hyacinthe, QC, Canada, [2]Virginia Tech, Middleburg, [3]The Ohio State University, Wooster*.

Lactate rise during strenuous exercise and prolonged recovery to pre-exercise levels may partially contribute to elevated muscle soreness in humans and horses. Many equine disciplines require consecutive days of competition, and thus, horses may be challenged with soreness during successive days of work or competition. Additionally, during training, muscle soreness may affect or impair progress while trying to increase fitness in horses. There are a number of commercially available dietary supplements containing spices that are marketed to improve performance or exercise recovery; however, research on their efficacy is limited. Therefore, the objective of this research was a preliminary evaluation of a novel proprietary blend of spices in the supplement, DigestaWell NRG (NRG) on lactate rise and post-exercise lactate recovery in unconditioned horses. Nine mature warmblood mares were used in a crossover design with a 7-d washout period. Mares were fed twice daily with 1 kg concentrate supplemented with or without 100 g of NRG for 7 d. On Day 7 horses performed a standardized exercise test during which venipuncture blood samples were collected pre- and 10 and 30 min post-exercise. Plasma lactate was determined using a YSI 2300 STAT Plus glucose and lactate analyzer, and changes in lactate concentration were determined using repeated measures analysis of variance in the PROC MIXED procedure of SAS 9.3. The rise in lactate concentration (change from pre-exercise to 10 min post-exercise) as a result of exercise tended to be lower ($P = 0.10$) in NRG (52 ± 15%) compared to control horses (101 ± 15%). Additionally, the return post-exercise determined by the change in lactate concentration from 10 to 30 min post-exercise tended to be higher ($P = 0.10$) in NRG (28 ± 3%) compared to control horses (20 ± 3%). The results of this preliminary trial show the promise of NRG to reduce lactate rise and improve lactate recovery in unconditioned horses in response to exercise after consuming NRG after 7 d. This may indicate the potential for NRG to reduce muscle soreness following exercise; however, additional research is warranted with a longer supplementation period to determine the effects of NRG on lactate, inflammation, and muscle soreness following exercise.

Key Words: horse, exercise, lactate

0811 Maturity of bermudagrass hay affects digestibility by horses. T. L. Hansen*, E. C. Lee, O. K. Zugay, and L. K. Warren, *University of Florida, Gainesville*.

Bermudagrass (*Cynodon dactylon*) hay is one of the most common preserved forages fed to horses in the southeastern United States. Bermudagrass, a C4 plant, typically has greater fiber concentrations than C3 plants. The objective of this study was to evaluate equine digestibility of Coastal bermudagrass hays differing in maturity. We hypothesized DM digestibility (DMD) would be reduced in bermudagrass diets, but NDF and ADF digestibility (NDFD and ADFD) would be greater in the bermudagrass diets compared to C3 legume and grass hays due to greater fiber intake. Five dietary treatments (alfalfa hay, *Medicago sativa*, ALF; orchardgrass hay, *Dactylis glomerata* L., ORCH; early maturity bermudagrass hay 4 wk regrowth, EARLY-BG; mid-maturity bermudagrass hay 5–6 wk regrowth, MID-BG; late maturity bermudagrass hay 8 wk regrowth, LATE-BG) were evaluated in this 5 × 5 Latin square design experiment with 5 mature geldings ($n = 5$, BW = 552 ± 14 kg, mean ± SEM). Hay was fed at 1.62 ± 0.02% BW (DM basis), and horses were fed a commercial ration balancer to meet micronutrient requirements. A 7-d dietary adaptation was imposed followed by a 3-d total fecal collection. A 2% subsample of daily fecal excretion was saved for DM, NDF, and ADF analyses. Fiber concentrations were determined using an ANKOM 200 Fiber Analyzer. Digestibility was calculated by difference between intake and excretion. Data were analyzed as Latin square design using a generalized linear model (SAS, v. 9.3). Statistically different means were separated by Sheffe's method. Diets differed in DMD (Table 1, $P < 0.001$). Dry matter digestibility was greatest for ALF and least for MID-BG and LATE-BG diets ($P < 0.05$). Fiber digestibility differed by diet ($P < 0.001$) with NDFD and ADFD greater ($P < 0.05$) for ALF, ORCH, and EARLY-BG diets compared to MID-BG and LATE-BG diets. Despite similar fiber concentrations among the bermudagrass hays, digestibility of EARLY-BG was comparable to other forage types with lower fiber concentrations. These findings indicate fiber structure in bermudagrass changes with maturity, reducing forage digestibility.

Key Words: equine, fiber, warm-season grass

0812 Investigation of equine hindgut microbiota development in young horses. B. St-Pierre*, M. E. Graf, B. M. Schlaikjer, and R. C. Bott, *South Dakota State University, Brooking*.

The gastrointestinal microbiota is an important contributor to the health and nutrition of mammals. Since the gut of young mammals is devoid of microorganisms at birth, its colonization by symbiotic microbes and their arrangement into complex communities is a critical aspect of a young host's post-natal development. Compared to most other experimental animal models or livestock, the gut microbiome of the horse remains largely unexplored, particularly in young foals. To gain further insight on development of the equine hindgut bacterial microbiota, fresh fecal samples were collected from 2 foals over their first 4 mo of life. Fecal samples from their respective dams were also collected as representative of mature hindgut microbial communities. Microbial DNA was extracted from the samples and used as template to generate PCR amplicons of the bacterial 16S rRNA gene (V1-V3 region), which were sequenced using the Illumina MiSeq 2×300 platform. A combined total of 333,300 high quality sequence reads corresponding to the expected full length PCR amplicons were used to determine the hindgut bacterial composition of the sampled animals. The number of sequence reads per sample ranged between 17,613 and 59,964. At the youngest age sampled (3.7 wks), the bacterial profile consisted predominantly of Verrucomicrobia (50.9%) and Bacteroidetes (22.9%) related sequences, with the most abundant species-level OTU (operational taxonomic unit) for each phylum found at 44.9% (OTU SDEc-1) and 10.7% (OTU SDEc-2), respectively. At later time points (5.86–18.57 wks), Verrucomicrobia representation was reduced dramatically (0.7– 2.1%), while Bacteroidetes appeared to be maintained within a similar range (20.3– 37.7%). However, population shifts were detected within Bacteroidetes. For instance, OTU SDEc-2 abundance was greatly reduced during this period (< 0.05%), and OTU SDEc-3 was transitionally higher (range of 5.1–7.2%) between 5.6 wks to 9.57 wks. We also observed an overall increase from 13.1% to 65.0% in Firmicutes representation among foal samples during the sample period. In comparison with the fecal bacterial composition of their dams (2.2–15.5% Bacteroidetes; 71.6–83.3% Firmicutes), our results suggest that hindgut bacterial populations in horses younger than 4 mo have not yet developed a mature microbiota.

Key Words: gut microbiota, microbial ecology, 16S rRNA, bacteria

0813 Evaluation of chromic oxide and titanium dioxide as external markers for estimating digestibility in horses. A. Fowler*[1], M. B. Pyles[1], B. Harlow[1,2], S. H. Hayes[1], A. Crum[1], and L. M. Lawrence[1], *[1]University of Kentucky, Lexington, [2]USDA-ARS Forage Animal Production Research Unit, Lexington, KY*.

Total fecal collections are frequently used when performing digestibility studies in horses, however collection of all fecal output (FO) is labor intensive. The use of indigestible markers to determine digestibility indirectly will simplify digestibility studies. The objective of this study was to evaluate the accuracy of chromic oxide (Cr_2O_3) and titanium dioxide (TiO_2) in predicting daily FO. Eight Thoroughbred mares were used in this study: four mares were fed Cr_2O_3 and four mares were fed TiO_2. The daily ration was split into two equal feedings per day and consisted of timothy hay cubes, a pelleted concentrate, and soybean oil. External markers were top-dressed on the timothy cubes and complete consumption was ensured. Diets and markers were fed for 10 d before and during the 4-d total fecal collections. Fecal samples (250 g) were obtained every 4 h for external marker analysis; the remaining feces were composited by horse per day. Actual total FO was measured using daily composites and compared to FO calculated from marker concentrations in the 4-h fecal samples using a paired *t* test. For horses fed Cr_2O_3, mean actual FO was 2.62 ± 0.16 kg DM/d and mean calculated FO was 2.64 ± 0.07 kg DM/d ($P > 0.1$). For horses fed TiO_2, mean actual FO was 2.57 ± 0.12 kg DM/d and mean calculated FO was 2.79 ± 0.12 kg DM/d ($P > 0.1$). The absolute difference between actual FO and calculated FO was determined for each horse. The absolute difference was different from 0 for all horses consuming either TiO_2 or Cr_2O_3 ($P < 0.001$) probably because some horses did not achieve constant marker excretion during the collection period. Constant marker excretion is necessary if fecal grab samples are to be used to calculate digestibility. Increasing the frequency of marker dosing may result in a more stable marker excretion. With more validation, Cr_2O_3 and TiO_2 as external markers may be useful for estimating mean daily FO.

Key Words: digestibility, equine, external marker

0814 Effect of starch source in pelleted concentrates on fecal bacterial communities in thoroughbred mares. M. B. Pyles*[1], A. L. Fowler[1], V. Bill[1], B. E. Harlow[1,2], A. Crum[1], S. H. Hayes[1], M. D. Flythe[1,2], and L. M. Lawrence[1], *[1]University of Kentucky, Lexington, KY, [2]United States Department of Agriculture, Agricultural Research Service, Forage-Animal Production Research Unit, Lexington*.

Dietary starch source has been shown to affect fecal bacterial communities of horses fed cereal grains with little to no processing. Others suggest that grain processing, such as

pelleting, increases foregut starch digestibility, possibly mitigating effects of starch source on bacterial communities. The aims were to (i) determine the effect of starch source in pelleted concentrates on *Lactobacillus* spp., total starch utilizing bacteria (TSU), and cellulolytic bacteria in mares, and (ii) evaluate pre- and postpartum changes in fecal bacterial communities from 324 d of gestation to 28 d postpartum. Nineteen Thoroughbred mares were paired by last breeding date then randomly assigned to either an oat-based (OB) or a corn and wheat middlings–based (CWB) pelleted concentrate in addition to forage. Beginning at 310 d of gestation, mares were fed 3.2 kg/d (DM) of assigned concentrate (OB or CWB). After parturition, concentrate intake gradually increased to 4.8 kg/d (DM). The concentrates contained 38.0%, 36.2% starch, 6.6%, 8.8% WSC, and 5.4%, 7.5% ESC for OB and CWB, respectively. Fecal samples were collected at 324 d of gestation, before parturition, 24 h, 14 d, and 28 d postpartum. Fecal samples were collected immediately after defecation by catch or from the center of the pile into single use plastic bags and transported to the lab in an insulated cooler (37°C) under CO_2. Samples were serially diluted 10-fold with phosphate buffered saline and the dilutions were used to inoculate selective media. Selective media were used for enumeration of *Lactobacillus* spp., TSU, and cellulolytic bacteria. Data were log transformed then analyzed with PROC MIXED (SAS 9.3) to test the main effects of treatment (OB or CWB), time of sample, and treatment by time interaction. Results were considered significant when $P < 0.05$. There was no effect of starch source on enumerated bacterial communities ($P > 0.05$), in contrast to previous work. These results suggest that pelleting concentrates may alter some of the effects of starch sources. There was no effect of time on TSU ($P > 0.05$), however *Lactobacillus* spp. and cellulolytic bacteria decreased 24 h postpartum ($P < 0.05$). Therefore, major physiological events, such as parturition, appear to alter the hindgut microbiota.

Key Words: bacteria, concentrate, horse

HORSE SPECIES SYMPOSIUM: NUTRITION AND IMMUNOLOGY

0815 Nutritional immunology for the geriatric horse.

A. A. Adams*, *The Gluck Equine Research Center, University of Kentucky, Lexington*.

Over the past century, improvements in health care and advancements in science and medicine have extended the average lifespan of humans and companion animals, including horses. We are now facing new challenges with the paradox of an older horse population with increased longevity and the potential of increased age-associated diseases. One of the most recognized consequences of aging is a decline in function of the immune system. Two main terms that characterize a declining immune system of the old horse are immunosenescence and inflamm-aging. Immunosenescence in the aged individual is characterized by changes in various aspects of cellular and humoral immunity, in particular a decline in lymphoid cell numbers and function. It has been well documented that the aged, including horses, have increased susceptibility to and prolonged recovery from infectious disease, poor vaccine responses, and increased incidence of cancers. Somewhat paradoxically, advanced age is also associated with increased production of pro-inflammatory cytokines and other inflammatory mediators, a phenomenon termed inflamm-aging. Inflamm-aging predicts both increased morbidity and mortality for a variety of chronic diseases. Together, immunosenescence and inflamm-aging may increase susceptibility to infection and contribute to aged-related health conditions such as arthritis, equine Cushing's disease, and laminitis. Nutritional immunology is a new field of study, in which nutrition is used as a modifiable factor in impacting immune function in particular to delay/reverse immunosenescence and to improve the aged resistance to infection. Further, nutritional interventions are practical, cost-effective approaches to mitigating this age-related breakdown in immune function. Natural dietary compounds found in a variety of plants, roots, fruits, vegetables, nuts, and seeds are promising candidates in helping to combat the effects of an aging immune system. Several natural dietary compounds (carotenoids, flavonoids, isothiocyanates, terpenoids, proanthocyanidins, omega fatty acids, and polyphenolic compounds) have been shown to possess broad biological activities of anti-oxidation, anti-inflammation, detoxification, regulation of signaling pathways, modulation of enzyme activities, and improvement of immune responses to vaccination. Unfortunately, few studies have been conducted to better understand what effect nutrition may have on modulating or improving immune responses of the aged horse. Previous and current nutritional studies to improve immune function in old horses by supplementation with vitamin E, n-3 polyunsaturated fatty acids (DHA), prebiotics, and polyphenols will be reviewed here. More research is needed to identify effective and optimal conditions for various nutritional intervention regimens to improve the function of the aged immune system of the horse.

Key Words: horse, aging, immune

0816 Nutrition and immunity: General principles.

K. C. Klasing*, *University of California, Davis*.

The development, maintenance, and response of the immune system are influenced by nutrition. For most nutrients the most important nutritional strategy for optimizing immunity is meeting the established requirements for maximizing growth, reproduction, and feed efficiency and avoidance of traditional signs of deficiency. Severe deficiencies of required nutrients typically impair host immunity and resistance to disease, but such deficiencies should be rare in modern animal production.

More relevant are marginally deficient and surfeit levels of nutrients. In the case of several essential nutrients, leukocytes, especially T lymphocytes, are very sensitive to marginal deficiencies, while for many other nutrients the immune system is largely unaffected by marginal deficiencies. This difference in sensitivity is due the types and amounts of nutrient transporters expressed on each cell type. Nutrients also support the anabolic processes of pathogens and increase their pathogenicity, though this troublesome effect is likely limited to a small subset of nutrients. Iron in particularly can increase the pathogenicity of some pathogens when provided in excess. Several essential and nonessential nutrients have regulatory effects on leukocytes. Required nutrients with indisputable immunoregulatory actions in rodents and livestock include the long-chain polyunsaturated fatty acids (PUFA) and vitamins A, D, and E. Many nutrients that are not normally considered as being dietary essential also modulate immunity, including carotenoids, vitamin C, and phytonutrients (e.g., capsicum, genistein, curcumin, essential oils, conjugated linoleic acids). In general those nutrients that are not structural components or cofactors for enzymes are most likely to be immunomodulatory. Unlike increases in nutrients from deficient to sufficient levels, where many indices of immunocompetence go from impairment to normal function, supplementation of immunomodulatory nutrients causes some components of immunity to be elevated and others to be diminished; in other words, the type and intensities of responses have been changed (i.e., immunomodulated). In situations where a single infectious disease dominates the production losses and where it is clearly known what type of immune response optimally protects against that disease, supplementation of a nutrient that modulates the immune system toward that optimal response is indicated. Thus, the value of an immunomodulatory nutrient to "improved" immunity is context dependent and depends on the types of disease challenges in a herd. In summary, nutritional impacts on immunity are complex and their understanding and applications requires a "first principles" approach.

Key Words: disease, immunity, deficiency

0817 Optimizing nutrition to improve immune function in horses. L. K. Warren*, *University of Florida, Gainesville*.

Nutrition plays a supportive role in immunity; thus, a balanced diet is critical to mount an appropriate immune response to infection or trauma. Many nutrients have widely recognized roles in host defense; however, nutrient requirements for horses who are stressed or immunocompromised are not fully known. Owners and farm managers are increasingly interested in holistic approaches to maintaining the health of horses in their care, which has encouraged research on the impact of various nutrients and dietary supplements on immune function. Investigations have typically targeted three populations: performance horses, foals, and horses with compromised or inappropriate immune responses (e.g., senior horses, horses with recurrent airway obstruction). Sport horses face many immunosuppressive stressors, including strenuous exercise training, frequent competition, and transport over long distances, including international shipping. This group also has increased exposure to pathogens via contact with outside horses at competition venues. Foals present a different set of challenges, which center on delayed onset of adaptive immune responses. Protection against pathogens are provided to the foal through the ingestion of immunoglobulins in colostrum soon after birth; thus, investigations often focus on the diet of the mare as a means to improve colostrum quality. Immuno-nutrition research in horses has typically been inspired by positive outcomes observed in other species. Although a comparatively small body of research has been conducted in horses, several nutrients have been explored, including vitamins (E, C), trace minerals (Zn, Se), amino acids (arginine), and fatty acids (omega-3, omega-6, conjugated linoleic acid). Additionally, prebiotic fibers (mannan-oligosaccharides, β-glucans), probiotics (lactic acid bacteria, live yeast cultures), and nonnutritive dietary supplements (resveratrol, superoxide dismutase) have received some attention in equine research. Collectively, the impact of these nutrients and supplements on the status and functional capacity of the immune system have been variable. Differences in study outcomes may be due to high variability in responses among horses, health status, dosage, length and timing of supplementation, basal diet composition, type of immune system challenge evaluated, and immunological variables measured. The latter is often more limited in scope in equine compared to other livestock research, where tissues can be harvested postmortem for more detailed evaluation of response to diet. Ultimately, the study of nutrition's impact on immunity in horses is in its infancy, with many other nutrients to explore and much to learn. Pairing equine nutritionists with immunologists could hasten research progress and improve study effectiveness.

Key Words: equine, immuno-nutrition, diet

0818 Effect of selenium and vitamin E supplementation on blood glutathione peroxidase activity and selenium in moderately exercised horses. E. Velázquez Cantón*, A. H. Ramírez Pérez, L. A. Zarco Quintero, R. Rosiles Martínez, and J. C. Ángeles Hernández, *FMVZ-UNAM, Mexico*.

The objective was to evaluate the effect of selenium (Se, Se-yeast) and vitamin E (E, α-tocopheryl acetate) supplementation on red cell glutathione peroxidase activity (GPx) and Se blood concentrations in moderately exercised horses. The Institutional Animal Care and Use Committee of the School of Veterinary Medicine, National University of Mexico, approved the experimental procedures. Twenty-four clinically healthy horses (5–15 yr, 450 kg BW) from the Mexico City Police, without physical activity the month before this trial,

Table 0818.

Blood glutathione peroxidase activity (GPx, U/L) and selenium (Se, ng/mL) in supplemented moderately exercised horses

[1]SEM: GPx, 98.9; Se, 7.0.
d0, baseline concentrations
[2]LSe, 0.1; HSe, 0.3 mg Se/kg DM; LE, 1.6; HE, 2.0 IU/kg BW
*Groups LSeHE and HSeHE are different (P<0.05) within the same column
[3]Mean values within a line with different letters are different (P<0.05)

were used. They were individually stabled and randomly allocated in a factorial experiment (2 Se × 2 E levels) with repeated measures. The groups, with 6 experimental units in each one, were: LSeLE, HSeLE, LSeHE, and HSeHE (LSe, 0.1; HSe, 0.3 mg Se/kg DM and LE, 1.6; HE, 2 IU vitamin E/kg BW; NRC, 2007). Se and E were given to supplement the deficient daily ration (Se, < 2μg; E, 14.4IU by kg DM, respectively). The study lasted 77 d distributed in 3 periods: adaptation (d 0 to d 32); moderate exercise (d 33 to d 56) and readaptation (d 57 to d 77). Exercise period consisted of 30 min (5:20:5 min. warm up: gallop: cool down) in 3 consecutive days and 4 d without exercise. At d 64, supplementation was stopped. Once a week, jugular blood samples were taken; during the exercise period it was taken 10 min after activity of the third day. Day zero corresponded to baseline measurement of studied variables. GPx was quantified by spectrophotometry (Randox Daytona) while Se was quantified by hydride generation atomic absorption spectrometry. Data were analyzed by a mixed model (PROC MIXED, SAS 9.1.3) with the design described above. Day, Se, E, and their interactions were the fixed effects, while horse nested in treatment was the random effect. Statistical significance was set at $P < 0.05$. Tukey-Kramer's test was used to compare LSM. The interaction: day × Se × E affected ($P < 0.05$) blood GPx; differences were observed at d 35–49 between HSeHE and LSeHE groups (1915.0 ± 65.9 U/L; 1510.1 ± 54.1 ng/mL, respectively). Day and Se affected blood Se ($P < 0.05$). Values from d 0 to d 14 were not different ($P > 0.05$) from d 63 to 77 (61.4 ± 2.1 ng/mL). Blood Se increased at d 28 (210.8 ± 7.0 ng/L) and decreased again at d 35 (118.38 ± 7.0 ng/L). In general, Se was higher in HSe (97.5 ± 3.8 ng/mL) than in LSe horses (82.01 ± 3.8 ng/mL). Conclusion: supplementation levels of both Se and E affect blood GPx and Se and are closely related to physical activity.

Key Words: selenium, α-tocopheryl, glutathione peroxidase

0819 Age-related changes in select fecal bacteria in foals. M. B. Pyles*[1], A. L. Fowler[1], V. Bill[1], B. E. Harlow[1,2], A. Crum[1], S. H. Hayes[1], M. D. Flythe[1,2], and L. M. Lawrence[1], *[1]University of Kentucky, Lexington, [2]United States Department of Agriculture, Agricultural Research Service, Forage-Animal Production Research Unit, Lexington, KY.*

Adult horses depend on the microbial community in the hindgut to digest fiber and produce VFAs that are utilized for energy. Microbial colonization in the gastrointestinal tract of foals is essential to develop a healthy symbiotic relationship and prevent proliferation of pathogenic bacteria. However, colonization is not well understood. The objectives were to evaluate the age-related changes and effects of maternal diet on select fecal bacterial groups in foals from 1 d to 28 d of age. Thoroughbred foals ($n = 19$) were from dams fed one of two concentrates: an oat-based (OB) or corn and wheat middlings–based (CWB) pelleted concentrate. The mares began the experimental diet at 310 d of gestation and remained on the assigned diets until 28 d postpartum. The foals had access to assigned concentrates, and a mixed grass and alfalfa hay and cool-season grass pasture were available ad libitum. Fecal samples were collected from foals at 1 d (14–36 h), 4 d, 14 d, and 28 d. Foals were continuously monitored on sample days to collect fecal samples immediately after defecation by catch into sterile specimen cups or from the center of the pile using sterile gloves. Fecal samples were transported to the laboratory in an insulated cooler (37°C) under CO_2. Samples were serially diluted 10-fold before inoculation of selective media. Enumerations were performed for *Lactobacillus* spp., total starch utilizing bacteria (TSU), and cellulolytic bacteria (CB). Enumeration data were log transformed then analyzed with PROC MIXED (SAS 9.3) to test the main effects of maternal diet (OB or CWB), time of sample, and interaction between maternal diet and time. Results were considered significant when $P < 0.05$. There was no effect of maternal diet on bacterial enumerations ($P > 0.05$). There was an interaction between maternal

diet and time in *Lactobacillus* spp. with CWB foals having more lactobacilli than OB at 1 d and 4 d ($P < 0.05$); however, there were no differences observed at 14 d ($P > 0.05$). These results indicate that maternal diet may influence some bacteria in foals. Fecal lactobacilli, TSU, and CB increased with age in foals ($P < 0.05$) with CB first appearing between 4 d and 14 d. It is evident that colonization of the hindgut is a sequential process beginning early in the foal's life.

Key Words: bacteria, maternal diet, foal

0820 Changes in equine hindgut fermentation and carbohydrate digestion in response to varying sources of nitrogen. M. O. Lass*, J. S. Drouillard, J. M. Kouba, C. I. Vahl, Y. Wei, and T. L. Douthit, *Kansas State University, Manhattan*.

Casein or urea were administered as dietary N sources in a replicated 3 × 3 Latin square experiment to evaluate impact on hindgut fermentation and carbohydrate digestion in the horse. A basal diet consisting of native prairie hay (5.9% CP; 72.7% NDF) was fed to 9 cecally cannulated horses (469 ± 109 kg BW) at 0.6% of BW DM basis every 8 h for 6 wk. Periods consisted of a 7-d acclimation to the basal diet and a 7-d dosing phase. Horses were dosed via the cecal cannula 3×/d at the time of feeding for 7 d with 200 mL of water (W), or with 200 mL of water containing casein (C) or urea (U) to provide 1.12% N in the diet. During the final 4 d of each dosing phase, total fecal output was collected, and cecal digesta was collected 4 h after each feeding. Cecal digesta and feces were analyzed for pH and concentrations of ADF, NDF, ADIA, total VFA, and ammonia. Dosing with U resulted in greater concentrations of cecal ammonia (3.00 mM, $P < 0.05$) compared to horses dosed with W (1.69 mM), or C (2.01 mM). Cecal pH increased ($P < 0.01$) in horses dosed with C (7.72) or U (7.85) compared to W (7.45), but fecal pH was not different between treatments ($P > 0.05$). Total VFA concentrations in cecal digesta were greater ($P < 0.01$) for horses dosed with U (50.27 mM) compared to those dosed with W (32.17 mM) or C (32.17 mM). Fecal NDF and ADF were decreased ($P < 0.05$) in horses dosed with U (63.07% NDF, 52.78% ADF) or C (59.68% NDF, 49.98% ADF) compared to those treated with W (66.50% NDF, 54.49% ADF), but ADIA content was not different ($P > 0.05$). Taken together, differences in cecal ammonia, pH, and total VFA, along with changes in fecal NDF and ADF as a result of treatment, indicate that protein and non-protein N sources introduced directly into the cecum lead to changes in microbial fermentation in the hindgut that increase fiber digestion in the horse.

Key Words: equine, fiber digestion, nitrogen

0821 Effects of meal size and frequency on the equine cecal microbiota. E. B. Venable*[1], S. S. Bland[1], H. Holscher[2], T. W. Liu[2], and K. S. Swanson[2], [1]*Southern Illinois University, Carbondale,* [2]*University of Illinois, Urbana*.

The effects of meal size and frequency on the equine cecal microbiota are not well documented. We hypothesized that meal size will alter the profile of the microbiota present in the equine cecum. Southern Illinois University Institutional Animal Care and Use approval (#13–070) was obtained before the initiation of this research. Cecally cannulated horses ($n = 6$) with a BCS of 5 (± 0.5) were utilized in this replicated Latin Square (3 × 3) design. All horses received group pasture turnout daily for approximately 6 h and were stalled overnight in identical box stalls (3 × 4 m). Treatment diets of Strategy® pelleted grain-based concentrate were as follows: A = one meal, 2.72 kg, 0600 h; B = two meals, 1.36 kg, 0600 and 1600 h; C = three meals, 0.91 kg, 0600, 1200, and 1600 h. Each treatment period consisted of 8 d of acclimation followed by 3 d of collection. All horses received ad libitum access to water, a white salt block, and 3 kg of mixed alfalfa/grass hay offered overnight. Body weight was recorded weekly and data were analyzed using a Latin square design with the proc MIXED procedure of SAS and was not affected by treatment ($P > 0.05$) Cecal samples (216 total) were collected four times daily over a three-day collection within each period. Cecal bacterial DNA was extracted, and 16S rRNA amplicon sequencing using Illumina technology was followed by analysis using QIIME 1.8.0 and proc MIXED. Significance was set at ($P \leq 0.05$). Weighted principal coordinates analysis (PCoA) of UniFrac distances between samples based on their 97% OTU composition indicated that Treatment A was different than Treatment C ($P = 0.028$). In addition, PCoA also revealed a significant difference associated with breed ($P < 0.05$) for both weighted (abundance) and unweighted (community composition) measures. Alpha diversity measures indicated that bacterial diversity is higher in geldings as compared to mares ($P < 0.01$). Predominant bacterial phyla included Firmicutes (58.8–63.2%); Bacteroidetes (28.78–34.2%); Proteobacteria (2.2–2.8%); and Spirochaetes (2.5–2.7%) for all treatments. Furthermore, when treatment effects were examined at the genus level, six different genera were significantly affected by treatment (*Prevotella*, *YRC22*, *Lactobacillus*, *Streptococcus*, *Coprococcus*, and *Phascolarctobacterium*). These data demonstrate that size and frequency of pelleted concentrate meals affect both the abundance and the composition of the bacteria present in the equine cecum.

Key Words: horse, microbiota, meal size

HORSE SPECIES SYMPOSIUM: URBAN STUDENTS IN ANIMAL SCIENCE AND THE IMPACT OF EQUINE PROGRAMS

0822 Making animal sciences relevant to the urban student: Connecting to the real world.
J. J. Parrish*, *University of Wisconsin, Madison*.

The current Animal Science student is not from an agricultural background and is female. Learning requires information be assimilated onto a conceptual framework. Coming from nonagricultural backgrounds makes it more difficult for students to create the conceptual framework around animals and livestock on their own without help from the instructor. Both experiential and active learning approaches are needed to create context. For example, we can use laboratories, simulations/case studies, writing exercises and international activities in or outside of the classroom. Laboratories in Animal Sciences have the opportunity to utilize animals, tissues, or forages to demonstrate how lecture connects to the real world. For students who do not have a connection with livestock, the chance to interact with cattle, sheep, pigs, or horses may be their first experience with a large animal. Any exposure to or contact with animals in the context of learning is experiential and a profound life-changing event for most students. Laboratories also ensure students learn how to interact as a team to achieve some outcome. The interplay between students in these teams allows the construction of new contextual information so critical in long-lasting learning. Simulations and case studies provide an increase in student motivation to learn by creating a "need to know" situation. While expensive initially, simulations and cases can be used in subsequent years without the initial investment or need to maintain animals. Writing exercises as a required skill in any occupation can also provide a means for students to think more deeply on a subject and create their own connections to the real world. International agriculture increasingly is becoming the focus of not only commodity sales but also direct competition for the US agriculture economy. The classical method of travel to an international destination is out of the economic reach of many Animal Science students. Case studies can have students solve problems in a foreign culture/environment and so gain novel solutions but also international competency. A key impediment to learning is not seeing anyone who connects with them as a role model or presents a point of reference for them to aspire to or that is even relevant. Female students may not see themselves as animal scientists as they only see and hear male instructors. Animal Science must remain sensitive to the needs of society and Animal Science students if it is to retain relevance in the future.

Key Words: experiential, active, learning

0823 Creating hands on learning opportunities for inexperienced equine students.
K. L. Vernon*, *Clemson University, Clemson, SC*.

Universities across the country offer equine-related classes to a diverse population of students. National trends indicate that 80–85% of these enrolled students are female, and more than 50% are from suburban or urban backgrounds. Career goals for most of these students require firsthand experiences with animal care, behavior, and management. Students interested in marketing and sales of animal health-care products or retail merchandise also require knowledge of animal husbandry. Approximately 65% of students in Animal Science programs, particularly those of urban backgrounds, have little to no experience with horses and thus require experiential learning opportunities.

The Animal and Veterinary Sciences Department at Clemson University offers Pre-Veterinary Sciences (60%), Animal Agribusiness (20%), and Equine Business (EQUI; 20%) concentrations. The latter two require a minor in Business Administration, therefore combining a foundation in animal science with business courses. EQUI is aimed at students who wish to enter any facet of the horse industry that typically does not require an advanced degree. Most students enter the work force directly onto a horse farm or indirectly in allied animal health industries, marketing positions for manufacturing, feed mills, or pharmaceutical companies or through supporting careers such as lawyers, horse associations or councils, public and higher education, and more. Students enrolled in EQUI have a diverse background; some have substantial horse experience and others have none. Therefore, it is important for faculty to provide the much-needed experiences required for successful job placement.

Courses required to meet these needs should be founded in experiential learning, utilizing live animals to provide these hands-on experiences. Formal courses and laboratories, volunteering, interning or working at a horse farm, being a working student, or enrolling in a farm immersion practicum are options. Faculty must learn their students' strengths and weaknesses to offer suggestions on the types of experiences that are required to strengthen their resumes and gain more horse experience. From basic horse handling and health care skills to working with a wide variety of production phases, creating unique individualized experiences is a must. To be successful in doing this, faculty need an organized system of integrating students from a varied background and have a diverse teaching style to cater to all students. Faculty are encouraged to develop efficient and achievable goals for students who have very little experience to provide relevant and less overwhelming experiences that align with their goals.

Key Words: horses, experiential learning

0824 Retaining urban students in animal science: The role of equine programs. J. A. Sterle* and H. D. Tyler, *Iowa State University, Ames*.

The influx of non-traditional, urban students into Animal Science programs in recent years is well documented. While there are slight differences in the percentages of urban students between programs, the trend has been steadily increasing and is often the cause of increased enrollment in Animal Science programs across the country. Many of these students also indicate a primary interest in veterinary medicine. Sometimes, once exposed to the realm of Animal Science, these students are lost to other majors. Many leave because they do not find a "home" in Animal Science; for others, it may be too much emphasis on the traditional livestock species for their liking. However, for those who remain, opportunities abound. Current placement rates of Animal Science graduates at ISU are 98% within 6 mo of graduation. So, the question is: How can we convince urban students, many of whom are high achieving, driven, and intelligent, to remain in Animal Science and one day contribute to the Animal Science industry (even in other species)? The most obvious answer is to make Animal Science more relatable to their interests early in their academic career, and one bridge for that may be equine courses and activities. Freshmen entering Iowa State University's Animal Science program in the fall of 2015 ranked horses second out of all species, with 30% (of 315 responding) citing equine as the primary or secondary interest. The species with the most initial interest from this group was companion animals/household pets (54% ranked companion animals first or second). Anecdotally, it is the urban students who list companion animals first and often list equine second and vice-versa. The current Animal Science curriculum at ISU requires sophomore students to choose three courses from a directed list representing each species (Beef Cattle Science, Swine Science, Equine Science, Sheep Science, Poultry Science, Dairy Cattle Science, Companion Animal Science, or Foods of Animal Origin; with Lab Animal Science to be added in fall 2016). Requiring the third three-credit course on another species often sparks interest in the additional area. Offering these type of courses early in the curriculum allows students to further define their interests while exposing them to a potential new area early enough to explore it further. Allowing students to take in-depth courses on their species of interest early in their academic career keeps them interested in their major and increases retention.

Key Words: equine, undergraduates, urban

0825 Prolonged head elevation causes mucosal IgA fluctuation in horses. J. M. Bobel*, M. R. Di-Lernia, J. R. Abbott, M. T. Long, and L. K. Warren, *University of Florida, Gainesville*.

Stress has a pronounced effect on immune cells and their ability to mount an effective defense against pathogens. Prolonged head elevation is thought to be a major contributor to the increased risk of respiratory disease associated with transportation in horses. Elevated cortisol and changes in leukocyte populations in response to transportation stress are well documented in horses. Few studies have investigated other aspects of immune function that may predispose horses to respiratory disease following head elevation. The objective of this study was to determine if prolonged head elevation affects mucosal IgA secretions and to evaluate the potential use of mucosal IgA as indicators of stress. Twelve horses (mean ± SEM, 552 ± 10 kg; 11.5 ± 1.4 y) were tethered for 12 h with their heads elevated at a height of 1.5 m to induce physiological stress. While tied, horses had unlimited access to bermudagrass hay and were offered water every 2 h. Each horse underwent head elevation on 4 occasions, each separated by 30 d. When not tied, horses were maintained on pasture forage. Nasopharyngeal flush (NPF), whole blood, saliva, and fecal samples were obtained before head elevation (Pre), immediately after (0 h), and 12, 24, and 72 h post head elevation. Cortisol concentration was measured in serum and saliva and IgA concentration was measured in NPF, saliva, and fecal water. Data were compared using mixed model ANOVA with repeated measures. Both serum and saliva cortisol were elevated after head elevation ($P < 0.0001$) and returned to baseline by 12 h post. Salivary ($P = 0.0005$) and fecal water ($P = 0.01$) IgA were elevated above Pre at 0 h post. At 12 h post, salivary ($P < 0.0001$) and NPF ($P < 0.0001$) IgA were lower than Pre. Fecal water IgA remained elevated above Pre at 12 h post ($P = 0.04$) but dropped below Pre at 24 h post ($P = 0.005$). Salivary IgA remained lower through 72 h post ($P = 0.006$), whereas NPF and fecal water IgA returned to normal by 24 and 72 h post, respectively. Prolonged head elevation induced physiological stress and alterations in protective mucosal secretions. Instability in IgA secretions may partially explain the heightened risk for respiratory disease following transportation. Persistent fluctuations in mucosal IgA suggests the time course of physiological stress may exceed that represented by the transient elevation of cortisol. Mucosal IgA secretions may be good indicators of both acute and chronic stress in horses.

Key Words: stress, immunosuppression, respiratory

0826 Effect of a square-toe or perimeter-fit horseshoe on quality of movement and gait kinematics of the western pleasure horse. P. Q. Underwood[1], L. M. White*[1], K. W. Walter[2], D. Hogue[1], and L. K. Hirtz[2], [1]*New Mexico State University, Las Cruces,* [2]*Truman State University, Kirksville, MO*.

Hoof-care professionals often manipulate the thoracic hooves of the western pleasure horse by squaring the toe and moving the horseshoe caudally on the hoof capsule, which is thought to shorten the point of breakover, allowing for a flatter knee and more extension out of the shoulder during the swing phase. Manipulating the shape of the shoe in this way may compromise hoof capsule integrity and could contribute to chronic lameness. Our objective was to evaluate gait quality and kinematics of the western pleasure horse shod with a square-toe aluminum shoe (ST) in comparison to a perimeter-fit aluminum shoe (PF) on the thoracic digit. Quarter horses (n = 9; 5 geldings, 4 mares; 8.4 ± 1.9 yr; 545.9 ± 34.8 kg) trained in western pleasure were utilized in an 85-d repeated measures study and randomly selected on Day 1 to be shod with either an ST or PF shoe for 6 wk, then reshod with the opposing treatment on Day 43. Horses were videoed being ridden at the walk, jog, extended jog, and lope for 3 repetitions over 50 m on Days 15 and 57 wearing each treatment. EquineTec® software was used to evaluate humeroradial extension measured as the minimal elbow angle (extension out of the shoulder) at the end of the swing phase, metacarpal flexion measured as the minimal carpal angle (knee action), and metacarpalphalangeal flexion measured as the minimal fetlock angle (lower leg action), both at the beginning of the swing phase. Equine judges (n = 11) assessed quality of movement by scoring each gait from −1.5 (extremely poor) to 1.5 (excellent), where 0 was considered average. The PF treatment improved quality of movement for some parameters, including humeroradial extension for all gaits ($P < 0.034$) and metacarpal flexion for all gaits ($P < 0.0132$) except the jog ($P = 0.079$). Metacarpalphalangeal flexion and judge evaluations were not different between treatments ($P > 0.3$). Kinematic evaluation revealed quality-of-movement advantages when the PF treatment was applied by allowing for more ideal western pleasure movement seen as decreased knee action and increased extension out of the shoulder, although professional judges did not score treatments differently. The PF treatment achieves equal or superior quality of movement compared to the ST, thus providing a more appropriate shoe for the western pleasure industry that may amplify the longevity of the western pleasure horse.

Key Words: horse, square-toe horseshoe, perimeter-fit horseshoe, western pleasure

INTERNATIONAL ANIMAL AGRICULTURE

0827 Carcass quality of guinea pigs: Age effects on weights, yields, and linear carcass measurements. R. Remache[1], J. Palmay[2], C. Hernández[1], I. Barba[1], V. Inca Guerrero[1], E. Ureña[2], D. Yumisaca[3], A. J. Morales-delaNuez[4], and D. Sánchez Macías*[2], [1]*Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Ecuador,* [2]*Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Ecuador,* [3]*Facultad de Ciencias Pecuarias, Escuela Superior Politécnica de Chimborazo, Riobamba, Ecuador,* [4]*Facultad de Ciencias Pecuarias, Escuela Superior Politecnica de Chimborazo, Riobamba, Ecuador*.

Guinea pigs are used for meat production in South America, Africa, and Asia. The increased interest in this product is due to the low production price, their relatively rapid reproduction, and the large litter size. The objective of the present study was to evaluate the effect of age on weight, yield, and drip loss in guinea pig carcasses. Fattening guinea pigs reared to different ages were used: 3 months (3M, n = 48), 4 months (4M, n = 37), and 6 months (6M, n = 41). The animals were fasted for 14 h before slaughter. Live weight at slaughter (LWS), empty body weight (EBW), and hot and cold carcass weights (HCW and CCW) were recorded. The following measurements were also recorded: carcass length (L), loin length (Lo), hind limb length (F), width of the buttocks (G), lumbar circumference (LC), thorax circumference (ThC), and thorax width (ThW). Furthermore, carcass compactness (CarC) was calculated. Hot carcass yield (HCY), cold carcass yield (CCY), yields and drip loss were calculated. LWS values increased as animals got older (888 g, 1060 g, and 1168 g, for 3M, 4M, and 6M, respectively. The gastrointestinal content for the three guinea pig groups was similar, around 90 g. The lowest values of hot or cold carcass yields were observed in 3M guinea pigs (52% and 49%, respectively), and no differences were found between the 4M and 6M groups (55–56% for HCY and 53 to 54% for CCY). With respect to drip losses, expressed as percentages, the 3M guinea pig group had the highest loss (5.8%), while the 4M and 6M groups had the lowest losses (3.7 and 3.8%, respectively). L, Lo, F, LC, ThW, and G increased as guinea pigs were reared for longer times. ThC values were similar (19 cm) in all studied animals. When CarC was analyzed, it was possible to see evidence for an age effect: the 4M and 6M groups, without significant differences between them, showed approximately 30 g cm^{-1} of carcass weight vs. 24 g cm^{-1} in 3M guinea pigs. In conclusion, rearing guinea pigs from 3 to 4 months of age increases not only the LWS but also the carcass yields and compactness. However, rearing the guinea pigs from 4 to 6 months of age does not

improve the productivity of the system.

Key Words: guinea pig, carcass yield, linear carcass measurement

0828 Effect of age on the regional composition of fattening guinea pig carcasses. R. Remache[1], V. Inca Guerrero[1], I. Barba[1], C. Hernández[1], J. Palmay[2], M. Tenelema[3], J. Espinoza[2], A. J. Morales-delaNuez[4], and D. Sánchez Macías[*2], *[1]Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Ecuador, [2]Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Ecuador, [3]Facultad de Ciencias Pecuarias, Escuela Superior Politécnica de Chimborazo, Riobamba, Ecuador,[4]Facultad de Ciencias Pecuarias, Escuela Superior Politecnica de Chimborazo, Riobamba, Ecuador*

Logically, increasing LWS could increase a farmer's profit margin by maximizing meat production. Quantification of the growth of the carcass parts is essential prerequisites of Integrated Management Systems. Guinea pigs are used for meat production in South America, Africa, and Asia, but little information is available in the literature. The objective of this work was to determine the effect of guinea pig age on the regional composition of the carcasses. Fattening guinea pigs reared to different ages were used: 3 months (3M, n = 48), 4 months (4M, n = 37), and 6 months (6M, n = 41). The animals were fasted for 14 h before slaughter. Live weight at slaughter and cold carcass weights (CCW) were recorded. Each carcass was divided into two half carcasses; the left half carcass was jointed in four cuts following anatomical points (neck, shoulder, hind leg, and ribs). Data were recorded in grams and in percent with respect to the left half carcass. ANOVA procedure was used with the statistical program SAS (v. 11). In terms of weights, neck cuts ranged from 18 to 31 g, shoulder cuts ranged from 35 to 49 g, long leg cuts ranged from 78 to 117 g, and ribs ranged from 82 to 117 g. In all cuts, the 3M animal group had the lowest weights and the 6M group the highest. When means are shown as percentages for neck and long leg cuts, the 3M guinea pig group had the lowest values (neck 8.4%), and the 4M and 6M groups the highest without significant differences (9.5–9.9%). For the shoulder, the 3M group had a higher percentage (16.3%) than the 4M and 6M groups (15.2% and 15.5%, respectively). For long leg cuts, the 3M and 4M animal groups did not differ (35.9% and 35.7%), but the results were significantly lower than obtained for the 6M guinea pig group (36.8%). And for ribs, in the 3M and 6M groups the percentages were 37.4% and 36.8%, respectively, without significant differences; these means were lower than the percentage for rib cuts in the 4M group. In conclusion, when animals are older, the cut weights are higher; however, when the results are presented as percentages, there is no linear allometric growth of the different parts of the guinea pig in carcasses.

Key Words: guinea pig, carcass, regional composition

0829 Inulin and flavomicine as growth promoters in rabbit diets: Effects on animal performance, cecum crypt depth, and serum-bone macrominerals (Ca, P, Mg). M. E. Juárez Silva, M. Cuchillo Hilario*, I. Torres Acosta, E. L. Villarreal Delgado, and R. M. Castillo Domínguez, *National Institute of Medical Science and Nutrition Salvador Zubiran, Mexico City, Mexico*.

Concern about the utilization of antibiotics in animal feeding is rising because overuse may cause bacterial and microorganism resistance. Also, the use of probiotics and antibiotics to increase animal productivity and the effects on the cecum crypt depth, mucus layer thickness, and bone macromineral metabolism are still not clear. Therefore, sixty New Zealand rabbits (female = 30/male = 30) of 40 d age (790 ± 150 g) were randomly arranged into four treatments of 15 animals each. All groups were fed with the same protein, energy, crude fiber, and ether extract content (16.9%, 13.80 KJ/g, 12.5%, and 3.9%, respectively). The study lasted 57 d, the first 15 d of which were for adaptation. Weekly weights were registered during the experiment. Basal diet consisted of alfalfa hay (43.8%), wheat bran (25.1%), soybean meal (12.9%), corn (11.6%), soybean oil (3.1), carboxymethyl cellulose (2%), calcium phosphate (1.0), sodium chloride (0.5%), and vitamins and minerals (0.1%). The control group (CG) did not receive either antibiotic (Flaveco40 ECO-Animal Health) or inulin (IPS Raftifeed, Megafarma-Orafti) supplementation. The second group (I+) was supplemented with 2.5 g of inulin/kg of feed. The third group (F+) received 0.1 g of flavomicine/kg of feed. To evaluate possible interactions, the fourth group (IF) received both inulin and flavomicine doses as discussed previously. One-way analysis of variance (ANOVA) and the Tukey test ($P < 0.05$) were employed using SPSS (15.0). Kruskal–Wallis and Mann–Whitney tests were used when the samples showed no normal distribution. Rabbit final weight was greater in CG ($P < 0.05$) than I+, F+, and IF (2269 g, 1938 g, 2036 g, and 2170 g, respectively). The cecum crypt depth and mucus layer thickness were significantly larger in rabbits with I+ ($P < 0.001$). Rabbits supplemented with inulin showed the least triglyceride level in comparison to CG and F+ ($P < 0.05$). In the same line, blood glucose in I+ was less than F+ ($P < 0.05$). In contrast, serum concentrations of calcium and magnesium were greater in I+ ($P < 0.05$). Additionally, calcium, phosphorus, and magnesium values in femur bone from I+ were greater than CG ($P < 0.05$), whereas only phosphorus and magnesium values from I+ were greater than F+ ($P < 0.05$). Nevertheless, the magnesium concentration in bone from IF was greater than CG ($P < 0.05$). Despite the slightly lesser final weight of rabbits with I+, the inclusion of inulin

has positive effects; e.g., cecum crypt depth and mucus layer thickness increased. Likewise, inulin supplementation augmented calcium, phosphorus, and magnesium in serum and in femur bone. Furthermore, inulin is capable of depressing serum triglycerides and glucose, while increasing bones mass.

Key Words: probiotics, crypt depth, bone mineralization

0830 Increased body condition during lactation increases milk production and pre-weaning growth of Bali cattle. D. Dahlanuddin*[1], M. Supriyadi[1], T. S. Panjaitan[2], D. P. Poppi[3], and S. P. Quigley[3], *[1]Faculty of Animal Science, University of Mataram, Mataram, NTB, Indonesia, [2]Assessment Institute for Agricultural Technology, Narmada, NTB, Indonesia, [3]School of Agriculture and Food Sciences, The University of Queensland, Gatton, Qld, Australia*.

Bali cattle (*Bos javanicus*), the main cattle species in eastern Indonesia, have high rates of calf mortality (up to 48%, Talib et al., 2003) and low average daily gain (ADG) (< 0.2 kg, Dahlanuddin et al., 2012). The objective of this experiment was to determine the effect of body condition score (BCS) of heifers throughout pregnancy and lactation on milk production and ADG of calves up to 6 mo of age. Non-pregnant Bali heifers [n = 24, 3.2 ± 0.1 BCS (1 to 5 scale), mean ± s.e.m.] were ranked on body weight (BW; 217 ± 6 kg) and allocated to treatments that would result in high (4.0) and low (2.5) BCS at parturition and throughout lactation. Heifers were maintained in individual pens and fed a mixture of tree legumes (*Leucaena leucocephala* and *Sesbania grandiflora*) ad libitum and 10 g maize grain DM/kg LW.day (HighBCS, 164 g CP and 8.9 MJ ME/kg DM) or King grass (*Pennisetum purpureum*; LowBCS, 75 g CP and 7.8 MJ ME/kg DM) ad libitum throughout pregnancy and lactation. Heifers observed to be in oestrus were mated with a single bull. Heifer BW was measured every week, BCS was measured every month, milk production was estimated by the weigh-suckle-weigh technique, calf BW was measured at birth and every week until weaning at approximately 6 mo of age. At parturition HighBCS heifers were heavier (292 ± 15 vs. 226 ± 10 kg) and in a higher BCS (4.2 ± 0.1 vs. 2.8 ± 0.1) than LowBCS heifers (P < 0.01). At weaning HighBCS heifers were heavier (276 ± 3 vs. 181 ± 12 kg) and in a higher BCS (4.2 ± 0.1 vs. 2.3 ± 0.1) than LowBCS heifers (P < 0.001). Calf birth weight (13.5 ± 0.2 kg) was unaffected by maternal BCS (P > 0.1). HighBCS heifers produced more milk than LowBCS heifers at each measurement during lactation and overall (2.1 ± 0.1 vs. 1.0 ± 0.1 kg/day, P < 0.001). ADG of calves between birth and 6 mo for age was higher for calves born to HighBCS heifers than those born to LowBCS heifers (0.37 ± 0.02 vs. 0.16 ± 0.02 kg, P < 0.001). In conclusion, milk production of Bali cows and pre-weaning ADG of Bali calves are influenced by BCS during lactation. Strategies to increase BCS during lactation will increase calf growth and potentially reduce calf mortality.

Key Words: Bali cattle, calf growth, milk production

0831 Alpaca and llama fiber quality comparison in Ecuadorian Andes. L. Cordova, A. J. Morales-delaNuez, M. Vaca-Cardenas, and N. F. Rodriguez Gonzalez*, *Facultad de Ciencias Pecuarias, Escuela Superior Politecnica de Chimborazo, Riobamba, Ecuador*.

The fiber quality from ten body regions (dorsal neck, RC1; wither, RC2; middle loin, RC3; rump, RC4; ventral neck, RC5; ribs, RC6; flank, RC7; caudal thigh, RC8; forearm, RC9; and dorsal to hock, RC10) of 35 alpacas (*Vicugna pacos*) and 45 llamas (*Lama glama*) were evaluated. Samples were collected from the left side of the animals before shearing. Animals belonged to the Tourism Project of Palacio Real Community (Chimborazo province, Ecuador). Length (L), number of crimps (NR), diameter (D), and medullation rate (M) were measured in ten randomly selected fibers from each body region. Repeated measures ANOVA was performed to evaluate the effects of body region, as repeat measure, and sex and species, as independent factor. Additionally, Pearson's coefficient was used to calculate correlations between parameters. No differences in NR, D, and M due to species or sex in any of the studied body regions were observed. Differences in LA from RC4 between females were observed, where alpacas had longer LA than llamas. In RC5 llama males showed longer LA than llama females, while both sexes of alpacas presented intermediate values. RC6 (ribs) was the body region with better fiber quality, while RC10 (dorsal to hock) showed the worse quality fiber. A significant high correlation (0.64) was found between M and D. In conclusion, the best quality fiber was found in RC6 for both species, whereas the worst was found in RC10. Finally, D and M were highly correlated.

Key Words: *Lama glama*, *Vicugna pacos*, Ecuador

0832 Alpaca fiber quality in Ecuadorian Andes. J. C. Simbaina-Solano, B. Aucancela, A. J. Morales-delaNuez, M. Vaca-Cardenas, and N. F. Rodriguez Gonzalez*, *Facultad de Ciencias Pecuarias, Escuela Superior Politecnica de Chimborazo, Riobamba, Ecuador*.

Nowadays, the importance of fiber from alpaca is increasing worldwide. Therefore, studies about the fiber quality from those animals is requested. To analyze the alpaca fiber quality in Ecuador, 143 alpacas from 3 rural communities from Chimborazo province and 223 alpacas from 7 rural communities from Cañar province were sampling on the middle rib area. Samples were evaluated with a wool-meter and calibrated ruler. Fiber quality was established based on four variables: diameter (D), number of crimps (NR), length (L),

and medullation rate (M). These characteristics were analyzed according to sex and age. Multifactorial ANOVA method was applied with Tukey-Kramer adjustment. Values were considered significant when $P < 0.05$. Furthermore, to establish correlations between parameters, the Pearson correlation coefficient was utilized. In Chimborazo provinces, the following averages were obtained: D: 21.75 μm, NR: 2.12 crimps/cm, L: 11.97 cm, and M of 35.3%. For D, young animals presented finer fiber than old animals. Similarly, males showed finer fiber than females. For NR, older females showed fewer crimps per cm than other groups. Older males presented the longest fiber (L). No effect of sex or age was found in M. In Cañar province, the following averages were obtained: D 21.72 μm, NR: 2.78 crimps/cm, L: 15.16 cm, and M of 53.9%. For D, young animals presented finer fiber than old animals, and sex had no effect on this variable. For NR, older animals showed fewer crimps per cm than young animals, while males had fewer crimps than females. Older animals presented longer fiber than young animals, while males showed shorter fiber than females. No effect of sex or age was found in M. Furthermore, in both provinces the diameter and medullation were strongly correlated. In conclusion, the alpacas raised in the Ecuadorian Andes have a good fiber quality, but it is necessary to improve it to increase the fabric craft quality. Sex and age must be considered for fiber quality.

Key Words: *Vicugna pacos*, South American camelids, Ecuador

0833 Guinea pig carcass quality: Traditional diet vs. high quality diet.

M. C. Tenelema[1], D. Sánchez-Macías[2], D. D. Yumisaca-Guevara[1], R. Remache[2], V. Inca Guerrero[2], I. Barba[2], C. Hernández[2], J. Palmay[2], and A. J. Morales-delaNuez[*1], *[1]Facultad de Ciencias Pecuarias, Escuela Superior Politecnica de Chimborazo, Riobamba, Ecuador, [2]Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Ecuador*.

Guinea pig meat production provides a good and low-cost source of proteins. In Africa, Asia, and South America meat production from this species is common and ensure the food security in many rural communities. Traditionally, in Andean areas, guinea pigs are raised with low quality grass and kitchen waste. Few data is available about the carcass quality in guinea pigs fed in this way. The aim of this study was to evaluate the carcass quality of guinea pigs fed with high quality and low quality feed. In this study, 60 improved guinea pigs (30 males and 30 females) were divided into 3 groups (10 males and 10 females per group). One group was fed with fresh lucerne and concentrate (ASI). Another group of animals was fed with agriculture waste and concentrate (DSI). Finally, the last group was only fed with agriculture waste (DNO). All animals were slaughtered with 120 d, after a fast of 12 h. Weight before slaughter, different carcass weights, non-carcass components, and carcass measurements were recorded and different carcass yields were calculated. Results showed that guinea pigs fed with agriculture waste (DNO) had decreased carcass quality compared to animals fed with concentrate feed. Few differences were found when animals fed with Lucerne (ASI) were compared to those fed with agriculture waste and concentrate (DSI). In conclusion, guinea pigs fed with agriculture waste and concentrate had similar carcass quality as those fed with high quality forage, so guinea pigs are able to use a low quality forage.

Key Words: *Cavia porcellus*, meat quality, nutrition

0834 Do buffaloes have better milk fat profile than cows? Where does the evidence stand in 2016?

G. Bilal* and M. Moaeen-ud-Din, *PMAS-Arid Agriculture University, Rawalpindi, Pakistan*.

The objective of the present study was to document a comprehensive comparison between the milk fat profiles of buffalo and cattle. Data on milk fat profiles of buffalo were retrieved from nine published studies on different breeds of buffalo (Nili-Ravi, Kundi, Murrah, Egyptian, Italian, Romanian), and values/proportions of individual/groups of fatty acids (FA) were averaged across breeds. Data on milk fat composition of cow milk was obtained from a recent study on Canadian Holstein cows using large gas chromatography data. Milk fat profiles (means of 29 variables each) of the buffalo and the cow were compared using Student's *t*-test. Overall, Holstein cows had approximately 3–4 times higher daily milk yield than buffalo. Buffalo milk had greater total solids (17.76% vs. 13.94%) and a higher fat percentage (7.02% vs. 3.86%) than cow milk, indicating more value for buffalo milk. Buffalo milk fat had slightly higher proportions of total saturated, total trans, and total mono-unsaturated FA but similar proportions of total polyunsaturated FA than that of cow; although differences in these groups of FA were statistically nonsignificant. Buffalo milk fat had higher proportions of human-health-related beneficial fatty acids (comparing one fatty acid at a time) such as oleic acid, CLA, cis-9 trans-11, and two omega-3 FA (C18:3 cis-9, 12, 15 and C20:5n3). Additionally, buffalo milk had relatively lower proportions of potentially undesirable (from human health standpoint) saturated FA (C12:0, C14:0, and C16:0) than cow's milk. Although the present study did not correct the data for various background effects involved in each of the reported studies, it provides a comprehensive comparison between buffalo and cow milk fat and is likely to have useful implications for the promotion of buffalo as a dairy animal from the human health point of view.

Key Words: buffalo, cattle, milk fat profiles

INTERNATIONAL ANIMAL AGRICULTURE SYMPOSIUM: THE FUTURE OF PASTORAL PRODUCTION SYSTEMS

0835 Contribution of pastoral systems to global food security and potential for sustainable intensification. A. Mottet*, F. Teillard, G. Cinardi, and G. Velasco Gil, *Food and Agriculture Organization of the United Nations, Rome, Italy*.

Pastoralists produce food in the world's harshest environments, converting scarce resources from nonarable land into edible products. Pastoral production supports the livelihoods of rural populations on almost half of the world's land and is making a growing contribution to feeding also urban populations. Though many pastoralists can be found in Africa, pastoralism is also practiced in dry and sub-humid lands in the Middle East, South and East Asia, South America, and Europe. While the global livestock sector is expected to grow by 70% between 2005 and 2050 to feed a growing population, urbanized and with higher incomes, pastoral systems are also following this trend but are submitted simultaneously to a number of major socioeconomic, agro-ecological and institutional changes such as climate change, market globalization, population migrations, changes in animal products due to urban demand, and political instability. These changes can result in higher competition between extending croplands and increasing herds for access to natural resources, a decline in cropland fertility and a degradation of pastoral resources. In addition, extensive ruminant systems are often pointed out for having high greenhouse gas emission per unit of product because of their low levels of productivity. Detailed and reliable information is essential to monitor these trends in pastoral areas and provide adequate support to the public policy planning process and to the development of strategies designed to meet the specific needs of pastoral communities and stakeholders. This communication reviews the information and knowledge available about pastoralist systems and their actual contribution to food security and livelihoods, through the production of a range of direct goods and services, such as meat, milk, fibers, hides, income generation, transport, savings and insurance, but also indirect ones, such as ecosystem services. It also explores their vulnerability and adaptive capacity to climate change and discusses possible ways for future development of the sector through sustainable intensification, including increased productivity, better resilience to climate shocks and mitigation of greenhouse gas emissions.

Key Words: pastoralist systems, food security, demand for livestock products, sustainable intensification, climate change, ecosystem services

0836 Opportunities for international research and development through the Feed the Future Innovation Lab for Livestock Systems. A. T. Adesogan*, *Dep. of Animal Sciences, IFAS, University of Florida, Gainesville*.

The U.S. Agency for International Development (USAID) awarded the University of Florida (UF) Institute of Food and Agricultural Sciences (IFAS) a $49 million, 5-yr cooperative agreement to establish the Feed the Future Innovation Lab for Livestock Systems. The grant supports USAID's agricultural research and capacity building work under Feed the Future, the U.S. Government's global hunger and food security initiative. The Livestock Systems Innovation Lab is led by UF/IFAS in partnership with the International Livestock Research Institute (ILRI). The objective of the Livestock Systems Innovation Lab is to achieve sustainable improvements in livestock productivity and marketing to increase the incomes, nutrition, and health of vulnerable livestock holders. The Livestock Systems Innovation Lab will design, lead, and implement a program of livestock research for development and capacity building aimed at addressing key opportunities in the livestock sector, including those created from the increasing demand for animal-source foods due to population growth, urbanization, and rising incomes. The primary focus of the Livestock Systems Innovation Lab will be in in East Africa, West Africa, and South Asia. The four Areas of Inquiry (AOI) of the Livestock Systems Innovation Lab are as follows: Future Livestock Systems; Animal-Source Foods (ASF) Production and Marketing, Livestock Disease Management and Food Safety, and Enabling Policies for Livestock. Across these AOI, the Livestock Systems Innovation Lab will integrate the following cross-cutting themes: The Role of Gender in Livestock Systems Research, Human Health and Nutrition, and Human and Institutional Capacity Development. The Livestock Systems Innovation Lab is led by a Management Entity at UF/IFAS, with Regional Coordinators at ILRI centers in each of the target regions. The research will be mainly conducted through competitive sub-awards. The Management Entity engaged stakeholders in the livestock and public health industries in Nepal, Ethiopia, Tanzania, and Rwanda in a participatory research for development prioritization exercise in Spring 2016 and released a Request for Applications in April 2016. Another Request for Applications will be tentatively released in September 2016 seeking proposals for research for development projects in Mali, Burkina Faso, and Cambodia, subject to USAID approval. These competitions are open to any qualified research, educational, governmental, private sector, or nonprofit institution. The projects selected for funding will fall within the objectives of the Livestock Systems Innovation Lab and contribute to the overall Feed the Future goals of reducing global hunger and improving food security.

Key Words: livestock, research, animal-source foods

0837 Community-based breeding programs: A sustainable solution for livestock keepers?

M. Wurzinger*[1], A. Haile[2], B. Rischkowsky[3], C. P. VanTassell[4], T. S. Sonstegard[5], O. Mwai[6], and J. Sölkner[7], *[1]University of Natural Resources and Life Sciences (BOKU), Vienna, Austria, [2]International Centre for Agricultural Research in the Dry Areas, Addis Ababa, Ethiopia, [3]International Center for Agricultural Research in the Dry Areas, Addis Ababa, Ethiopia, [4]Animal Genomics and Improvement Laboratory, ARS, USDA, Beltsville, MD, [5]USDA, ARS, BFGL, Beltsville, MD, [6]International Livestock Research Institute, Nairobi, Kenya, [7]University of Natural Resources and Life Sciences, Vienna, Austria*.

In recent years community-based livestock breeding programs (CBBPs) have received some attention and have been considered as a new and more sustainable option to improve livestock production under smallholder conditions and in low-input systems. Most CBBPs are found with livestock keepers owning local breeds of small ruminants. The idea of CBBPs is that livestock keepers with a common interest in improving their genetic resources work together and jointly develop breeding strategies, which are based on their local rules and institutional settings. This bottom-up process ensures that the decision-making power remains with the livestock keepers. However, scientists play an important role as facilitators, moderators, and technical experts and can provide guidance and bring their know-how to the various steps in the design and implementation of a breeding program. Beside the numerous technical challenges, there are also various socio-cultural aspects that have to be addressed and discussed with the participants of the breeding program. Enough room for reflection and discussion on traditional norms and values and possible changes has to be provided. In some cases changes can maybe more easily proposed and initiated by scientists as they are outsiders of the communities. The important role of women in the different aspects of livestock management is indisputable, but their participation in decision-making processes not only in households but also at a breeders' association or at the community level is often neglected. Therefore, new forms of cooperation and modification of traditional roles of disadvantaged groups should be considered. Exclusion of women impoverishes the knowledge base, so that future adaption options might be overlooked. In addition, excluding women undermines the legitimacy of the institutions, thus threatening the whole management system. Inclusion of different viewpoints of concerned actors leads to more sustainable solutions and makes a production system more resilient.

Key Words: community-based breeding programs, gender, resilience

0838 Innovative dissemination of small ruminant genetic improvement by a non-government institute in India.

C. Nimbkar* and P. Ghalsasi, *Nimbkar Agricultural Research Institute, Phaltan, Dist. Satara, Maharashtra, India*.

This report describes the dissemination methods of superior genetic material from sheep and goat breeding programs established by the Nimbkar Agricultural Research Institute (NARI) in Maharashtra State of India. The *FecB* gene carrier, moderately prolific NARI Suwarna breed of sheep developed by NARI has been disseminated since 2014 in village flocks in 7 districts of Karnataka State by the State Government. The first 20 sheep owners who received breeding rams were trained at NARI in the management of multiple-born lambs and their dams. Out of a total of 425 rams and 620 ewes sold for breeding so far, 167 rams and 128 ewes have been distributed in Karnataka. Seventy-three lambs born in these flocks were genotyped at the *FecB*locus at NARI and 19 good quality homozygous ram lambs were purchased by the State Government for dissemination to more flocks. The average litter size of NARI Suwarna ewes in these flocks is 1.8 with around 15% mortality in multiple-born lambs, leading to about 1.5 lambs weaned per ewe per lambing. Local ewes usually wean less than one lamb per ewe on average. The revenue generated by the sale of breeding animals has made the nucleus flock at NARI self-sustaining. NARI selects buck kids of the Osmanabadi goat breed from villages in four districts of Maharashtra State where performance recording is performed under the All India Coordinated Research Project on Goat Improvement of the Indian Council of Agricultural Research. NARI purchases from goat keepers 6-month-old, twin-born male kids with high growth rates, born to dams with a high milk yield. They are reared on NARI's farm and their semen is frozen after they attain sexual maturity. Each dose contains 100 million spermatozoa and the post-thaw progressive motility is more than 60%. Private Artificial Insemination (AI) technicians purchase buck semen straws (3800 so far) and provide cervical insemination to does in natural oestrus in the villages they visit. Village women trained by NARI under a collaborating NGO program have been found to be honest, hard-working, sincere, and skillful in goat AI. The same AI gun used with cows can be used with goats. Since 2009, NARI has made available frozen semen of Boer (10,000 straws) and Damascus (2000 straws) breed bucks from its nucleus flocks. Conception rates have been found to be about 50%. Dissemination methods that fit into the existing ethos and circumstances are likely to be more successful.

Key Words: dissemination methods, goats, sheep

0839 Pastoral systems in the developing world: Trends, needs, and future scenarios.

D. L. Coppock*[1], M. Fernandez-Gimenez[2], P. Hiernaux[3], E. Huber-Sannwald[4], C. Schloeder[5], C. Valdivia[6], J. T. Arredondo[4], M. Jacobs[5], C. Turin[7], and M. Turner[8], [1]*Utah State University, Logan,* [2]*Colorado State University, Fort Collins,* [3]*Centre National de la Recherche Scientifique, Geosciences Environment Toulouse, Toulouse, France,* [4]*Instituto Potosino de Investigacion Cientifica y Tecnologica, San Luis Potosi, Mexico,* [5]*Oikos Services LLC, Fortine, MT,* [6]*University of Missouri, Columbia,* [7]*International Potato Center, Lima, Peru,* [8]*University of Wisconsin, Madison*.

Developing-country rangelands are vast and diverse. They are home to millions who are often poor, politically marginalized, and dependent on livestock for survival. Here we summarize experiences from six case-study sites across sub-Saharan Africa, central Asia, and Latin America generally covering the past 25 yr. We examine issues pertaining to population, natural resource management, climate, land use, livestock marketing, social conflict, and pastoral livelihoods. The six study sites differ with respect to human and livestock population dynamics and the resulting pressures on natural resources. Landscape degradation, however, has been commonly observed. Climate change is also having diverse systemic effects often related to increasing aridity. As rangelands become more economically developed pastoral livelihoods may diversify, food security can improve, commercial livestock production expands, but wealth stratification widens. Some significant upgrades in rural infrastructure and public service delivery have occurred; telecommunications are markedly improved due to widespread adoption of mobile phones. Pressures from grazing, farming, mining, and other land uses—combined with drought—can ignite local conflicts over resources, although the intensity and scope of conflict markedly varies across case-study sites. Pastoralists and their herds have become more sedentary overall due to a wide variety of factors, and this can undermine traditional risk-management tactics based on mobility. Remote rangelands still offer safe havens for insurgents, warlords, and criminals, especially in countries where policing remains weak; the resulting civil strife can undermine commerce and public safety. There has been tremendous growth in knowledge concerning developing-country rangelands since 1990, but this has not often translated into improved environmental stewardship or an enhanced well-being for rangeland dwellers. Some examples of demonstrable impact are described, and these typically have involved longer-term investments in capacity building for pastoralists, local professionals, and other stakeholders. Research is shifting from ecologically centered to more human-centered issues; traditional academic approaches are often being augmented with participatory, community-based engagement. Building human or social capital in ways that are integrated with improved natural-resource stewardship offers the greatest returns on research investment. Our future research and outreach priorities include work that fortifies pastoral governance, enhances livelihoods for a diverse array of rangeland residents, and improves land and livestock management in a comprehensive social-ecological systems approach.

LACTATION BIOLOGY

0840 Duration of lactation in first-parity sows: Does it affect piglet growth in second parity?

C. Farmer*[1], M. Amezcua[2], R. M. Bruckmaier[3], O. Wellnitz[3], and R. Friendship[2], [1]*Agriculture and Agri-Food Canada, Sherbrooke R & D Centre, Sherbrooke, QC, Canada,* [2]*Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada,* [3]*Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland*.

It was recently shown that a teat which is not used in first lactation will have reduced development and milk yield in second lactation. This leads to the question of the minimum duration of suckling required in first parity for milk yield not to be hindered in second parity. The goal of the present study was to determine the impacts of a 2 d, 7 d or 21 d suckling period in first lactation on piglet growth, milk composition, and endocrine status of sows in second lactation. Pregnant Yorkshire gilts were divided into 3 groups according to lactation length: 1) 2 d (2D, $n = 20$), 2) 7 d (7D, $n = 20$); and 3) 21 d (21D, $n = 21$). After weaning, sows were bred and kept for a second parity. In both lactations, litters were standardized to 12 piglets with 12 functional teats and surplus teats were sealed with tape. During the second lactation, piglets were weighed on d 2, 7, 14, 21(weaning), 31, and 56 postpartum, and sow feed intake was recorded. Milk samples and jugular blood samples were obtained from sows on d 21 of the second lactation. Concentrations of prolactin, IGF-1, glucose, and urea were measured in blood. The MIXED procedure of SAS using a univariate model (3 levels) was used for statistical analyses and means were compared using Tukey's test. There was a tendency for 21D sows to consume more feed than 2D or 7D sows during the first week of lactation ($P < 0.10$). There was no treatment effect on BW of piglets at any time until d 56 ($P > 0.10$). Concentrations of prolactin, IGF-1, urea and glucose in sows on d 21 of lactation were not affected by treatment ($P > 0.10$). Furthermore, dry matter, fat, protein, and lactose contents in milk were not affected by treatment ($P > 0.10$). Results indicate that increasing the duration of lactation from

2 d to 7 d, or to 21 d in first-parity sows, does not improve growth rate of their piglets in the subsequent lactation. This suggests that suckling of a teat for 2 d during the first lactation is sufficient to ensure optimal mammary development.

Key Words: lactation length, parity, piglet growth

0841 Effects of glucose and amino acids on casein synthesis via JAK2/STAT5 signaling pathway in bovine mammary epithelial cells.

M. Zhang[1,2,3], S. Zhao[1,2,4], H. Gao[1,2,3,5], C. Luo[1,2,3], S. Wang[1,2,3], N. Zheng[1,2,4], and J. Wang[*2,4,6], *[1]Ministry of Agriculture-Milk Risk Assessment Laboratory, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]Ministry of Agriculture-Milk and Dairy Product Inspection Center, Beijing, China, [4]Ministry of Agriculture-Milk and Dairy Product Inspection Center (Beijing), Beijing, China, [5]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China, [6]Ministry of Agriculture Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China*.

Studies confirmed that glucose and amino acids (AAs) could be used as signaling factors to regulate milk protein gene transcription and translation through signaling cascade pathways in the mammary gland that affect milk protein synthesis. Some signaling pathways, like Janus kinase-signal transducer and activator of transcription (JAK-STAT), may play a role in the process of milk protein gene transcription. This study employed bovine mammary epithelial cells (BMEC) as a model to investigate the effects of glucose and AAs on β-casein and κ-casein gene transcription, and to determine if effects are mediated through the JAK-STAT signaling pathway. BMEC cells were cultured in specific medium (without D-glucose and AAs), starved overnight, and then subjected to 3 levels of D-Glu (0, 2.5, or 17.5 mmol/L) and 3 levels of AAs (0, 1, or 7.2 mmol/L) in a 3 × 3 factorial arrangement of treatments. After 6 h of culture, the mRNA abundance of *CSN2, CSN3, JAK2,* and *STAT5* genes were measured by qRT-PCR. Statistical analysis of data was performed using SAS 9.2 statistical software package. Differences between experimental groups were considered significant at $P < 0.05$. The results showed that, at the same level of D-Glu or AAs, increasing the concentration of the other to the medium level or higher, substantially increased the mRNA abundance of *CSN2, CSN3, JAK2,* and *STAT5* genes. These results demonstrated that D-Glu or AA supplements could promote transcription of casein genes (β-casein, κ-casein), and that process might be related to JAK-STAT signaling in the bovine mammary epithelial cell. In conclusion, our results provide basic information for the further study of the mechanisms by which glucose or AAs affect casein expression in the bovine mammary epithelial cell.

Key Words: amino acids, glucose, JAK2/STAT5

0842 Repeated mammary tissue collections during lactation have no impact on cow performance.

X. Weng[*1], A. P. A. Monteiro[1], J. Guo[1], B. M. S. Ahmed[2], J. K. Bernard[1], J. DeFrain[3], G. E. Dahl[4], and S. Tao[1], *[1]University of Georgia, Tifton, [2]University of Florida, Gainesville, [3]Zinpro Corporation, Eden Prairie, MN, [4]Department of Animal Sciences, University of Florida, Gainesville*.

Mammary biopsy (MB) collection is a necessary and valuable approach for studies in mammary gland biology, but it is not known if repeated MB impair performance of the lactating cow. Our objective was to examine the effect of multiple MB during lactation on udder health, DMI, and milk yield of dairy cattle. Sixty-four multiparous, mid-lactation Holstein cows were enrolled in a trial and 32 cows were randomly selected for repeated MB. The MB and non-MB cows had similar parity (2.6 ± 0.9, $P = 0.13$) and DIM (96.5 ± 56.3 d, $P = 0.13$) at enrollment. All animals were housed in the same barn and fed the same diet. Cows were milked three times a day and milk yield was recorded at each milking. Milk composition was measured weekly and DMI was recorded daily. Three MB were performed per cow: at enrollment and at 3 and 5 mo post-enrollment. The first and third MB were taken from the left rear quarter whereas the second MB was from the right rear quarter. The experimental procedures were approved by the Institutional Animal Care and Use Committee of the University of Georgia. Before MB, cows were mildly sedated through i.v. injection of xylazine HCL (20 μg/kg of BW). Briefly, the MB was performed using a rotating stainless steel cannula with a retractable blade at the cutting edge connected with a cordless drill. After sanitation with iodine and ethanol, an incision was made through the skin and connective tissue in the middle of the quarter and a core of mammary tissue (0.75 to 1 g) was extracted. The incision was closed using stainless wound clips and sprayed with an antiseptic dressing to avoid infection. After MB, udder health, wound healing of incisions, and appearance of blood in milk were visually examined at each milking. All bloody milk was discarded and blood was cleared from milk 3.86 ± 2.0 d after MB. During the experiment, four MB quarters and 14 non-MB quarters were diagnosed and treated for clinical mastitis. Compared with non-MB cows, MB cows had similar ($P > 0.1$) DMI, milk yield and percentage of fat, lactose, protein, solids-not-fat, and somatic cell score. In conclusion, mid- to late-lactation cows recover rapidly from MB and repeated MB have no impact on DMI, milk yield and composition, and udder health

of lactating dairy cows.

Key Words: lactating cow, lactation performance, mammary biopsy, udder health

---

0843 Lack of glucose and amino acids suppresses protein synthesis of bovine mammary epithelial cells by activating AMPK and inhibiting mTORC1 signaling pathways. S. Wang[1,2,3,4], S. Zhao[1,2,5], H. Gao[1,2,3,6], M. Zhang[1,2,3], N. Zheng[1,2,5], Y. Zhang[1,2,5], S. Yan[4], and J. Wang[*2,3,5], *[1]Ministry of Agriculture-Milk Risk Assessment Laboratory, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]Ministry of Agriculture-Milk and Dairy Product Inspection Center, Beijing, China, [4]College of Animal Science, Inner Mongolia Agricultural University, Hohhot, China, [5]Ministry of Agriculture-Milk and Dairy Product Inspection Center (Beijing), Beijing, China, [6]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China*.

Glucose and amino acids (AA) regulate milk protein synthesis via signaling pathways involving AMP-activated protein kinase (AMPK) and mammalian target of rapamycin (mTOR) in current nutrient requirement models. The objective of this study was to investigate the effects of nutritional stress due to lack of glucose and/or AAs and determine the sensitivity of bovine mammary epithelial cells to each stress by measuring cell proliferation and expression of β-casein and signaling proteins. Bovine mammary epithelial cells were cultured in specific medium (without glucose and AAs) and starved overnight, then three levels of glucose (0, 2.5, or 17.5 mmol/L) and AAs (0, 1.03, or 7.2 mmol/L) in a 3 × 3 factorial design were added to the medium. The proliferation of bovine mammary epithelial cells was detected by the thiazolyl blue (MTT) method, and the expression of β-casein and phosphorylation of signaling proteins were detected by Western blot. The results showed that proliferation of bovine mammary epithelial cells and their expression of β-casein was decreased under stress due to lack of glucose and/or AAs. When the concentration of AAs was 7.20 mmol/L and the glucose levels 17.5 and 2.5 mmol/L, cell proliferation and β-casein expression were downregulated 9.44% and 37.53%. When the concentration of glucose was 17.5 mmol/L and the AA levels 7.2 and 1.03 mmol/L, cell proliferation was downregulated 6.67% and 21.98%. Further experiments validated that the phosphorylation of AMP-activated protein kinase (AMPK, $Thr^{183/172}$) was upregulated under glucose and/or AA stress. When the AA level was 7.2 mmol/L and glucose levels were 17.5 and 2.50 mmol/L, the expression of P-AMPK($Thr^{183/172}$) was upregulated 210%. When the concentration of glucose was 17.5 mmol/L and AAs 7.20 and 1.03 mmol/L, the expression of P-AMPK($Thr^{183/172}$) had no effect. In contrast, the phosphorylation of the mammalian target of rapamycin (mTOR, Ser^{2481}), the regulatory associated protein of mTOR (Raptor, Ser^{792}), the ribosome protein subunit 6 kinase 1(S6K1, Thr^{389}), the 4E binding protein 1 (4EBP1, Thr^{37}), and the content of ATP were downregulated under glucose and/or AAs stress, and we also find that these phosphorylation proteins and ATP content are more sensitive to glucose than AAs. Results from this study suggest that stress due to lack of glucose and/or AAs can influence the energy and protein supplies in mammary epithelial cells, causing downregulation of proliferation, activating the fuel sensor AMPK, and suppressing the mTOR signaling pathway, which may lead to decreased β-casein expression. Bovine mammary epithelial cells are more sensitive to glucose stress than to AAs.

Key Words: amino acids, β-casein, glucose

0844 Genome-wide association analysis and pathways enrichment for lactation persistency in Canadian Holstein cattle. D. N. Do[*1,2], N. Bissonnette[1], P. Lacasse[1], M. Sargolzaei[3,4], F. Miglior[4,5], X. Zhao[2], and É. M. Ibeagha-Awemu[1], *[1]Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada, [2]Department of Animal Science, McGill University, Montreal, QC, Canada, [3]Semex Alliance, Guelph, ON, Canada, [4]Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, [5]Canadian Dairy Network, Guelph, ON, Canada*.

Lactation persistency (LP), generally defined as the rate of declining milk yield after milk peak, is an economically important trait for dairy cattle. Enhancing LP through genetic improvement is an interesting avenue for increasing overall milk production because it does not cause negative energy balance and related health issues for cows. We performed a genome-wide association study (GWAS) and pathway enrichment to explore the genetic mechanisms underlying LP. A GWAS based on generalized quasi-likelihood score method was performed on LP data of 866 cows and 44,023 single nucleotide polymorphisms (SNPs) with inclusion of a polygenic effect explained by genomic relationship matrix. A total of 29 and 88 SNPs were significantly associated with LP at the adjusted Bonferroni ($P < 2.15 \times 10^{-5}$) and at false discovery rate of 5%, respectively. Important genomic regions that harbored several significant SNPs for LP were: 68.2–71.2 mega base pairs (Mb) on bovine chromosome (BTA) 16, 14–16 Mb on BTA 3, 107–109 Mb on BTA 5, and 133–137 Mb on BTA 1. The most significantly associated SNP (rs41818282) is located in an intronic region of hemicentin 1 gene. Functional annotation of 599 genes in the flanking regions (0.5 Mb) of significant SNPs showed that natural killer cell-mediated cytotoxicity and TGF-β signaling pathways were important for LP. In addition, 8 among 11 gene

ontologies enriched for LP were involved in the immune process. These results suggest that biological processes involving cell death, cell proliferation, and immune response are important in the regulation of LP. However, it is necessary to further characterize the detected regions and enriched pathways for confirmation and validation. In conclusion, this study detected several genomic regions for fine mapping to identify potential markers for LP improvement.

Key Words: cows, genomics, GWAS, lactation persistency, pathways

---

0845 Effect of 17β-estradiol on milk production, hormone secretion, and mammary gland gene expression of dairy cows. J. J. Tong[1], I. M. Thompson[2], and P. Lacasse*[3], [1]*Department of Clinical Veterinary Medicine, College of Veterinary Medicine, Northeast Agricultural University, Harbin, China,* [2]*AAFC-Sherbrooke R&D Centre, Sherbrooke, QC, Canada,* [3]*Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada*.

Estradiol inhibits milk production in dairy cows. The present study evaluated the impact of estradiol injections on prolactin (PRL) secretion and mammary gland responsiveness to PRL. Eight mid-lactation cows received either 17β-estradiol (2.5 mg; E2; $n = 4$) or soy oil (2.5 mL; CTL; $n = 4$) injections during 7 d (period 1). After a resting period of 3 wk, a second treatment period was performed where the cows were switched from treatments. For each period, blood and milk samples were collected from d −4 to 14 (relative to the first injection). In addition, blood samples were collected during the a.m. milking on d −4, 2, and 7 to determine the milking-induced PRL release. Mammary gland biopsies were harvested on the last injection day of both periods. Milk fat samples were collected on d 1, 4, 7, and 14. The mRNA levels of genes encoding proteins related to mammary activity (α-lactalbumin, β-casein, and acetyl-CoA carboxylase), apoptosis (Bax, Bcl2, and caspase-3), PRL receptors (PRLR, long and short forms), LIF, and suppressors of cytokine (SOCS1, 2, and 3) were measured by real-time RT-PCR using RNA extracted from milk fat and mammary gland. Injections of E2 decreased moderately milk production during the treatment period (36.70 ± 0.45 kg/d and 39.74 ± 0.45 kg/d, respectively; $P = 0.01$). The E2 treatment tended to increase fat ($P = 0.08$), increased lactose ($P = 0.04$), and increased protein ($P = 0.03$) content of milk. Serum PRL concentration was increased by E2 injections during the treatment ($P = 0.04$) and the post-treatment ($P = 0.01$) periods. Accordingly, milk PRL concentration tended to be increased by E2 ($P = 0.09$). Milking-induced PRL release was also increased by E2 injections ($P = 0.03$). Injections of E2 increased plasma concentrations of IGF-1 ($P < 0.01$) and estradiol ($P < 0.01$) during the treatment period. Milk BSA was not affected by treatments, suggesting that mammary tight junctions were not impaired by E2. In mammary tissue, the LIF mRNA level tended to be lower during the E2 treatment ($P = 0.09$). In milk fat, PRLRL mRNA level tended to be decreased ($P = 0.07$), and PRLRS mRNA level was decreased ($P = 0.04$) by E2 injections. No difference in expression was observed for the other genes in mammary tissue and milk fat. These results suggest that a decrease of mammary gland responsiveness to PRL may be involved in the estradiol-induced inhibition of milk production.

Key Words: estradiol, gene expression, prolactin

0846 Estimation of quarter vs. composite colostrum composition via Brix refractometry, specific gravity, and visual color appearance in dairy cows. J. J. Gross*, E. C. Kessler, and R. M. Bruckmaier, *Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland*.

The control of colostrum quality is essential for successful calf rearing. Instruments for on-farm colostrum quality determination are widely used in dairy practice. However, composite colostrum samples have predominantly been considered so far, thereby not taking potential variation between quarters into account. In cases of low quality of composite colostrum, feeding a better quality colostrum from individual quarters might be beneficial. The objective of the present study was to identify relationships between colostrum color, quality (assessed by a colostrometer and a Brix refractometer), and composition (measured by different laboratory methods) of colostrum at a quarter level, for two types of colostrum sampling. Quarter and composite colostrum samples from 17 primiparous and 11 multiparous Holstein cows were analyzed for total IgG, fat, protein and lactose contents, and color was measured by a spectrophotometer. In the present study, an IgG concentration below 50 g/L, as determined by ELISA, was found in 14.3% of the analyzed quarter samples. Concentration and total mass of IgG in composite colostrum samples were greater in multiparous compared with primiparous cows ($P < 0.05$). Specific gravity (SG) of colostrum from individual and composite samples was lower in primiparous than in multiparous cows ($P < 0.05$). Milk fat content was greater in quarter and composite colostrum samples of primiparous compared with multiparous dairy cows ($P < 0.05$). Neither in primiparous nor in multiparous dairy cows were there clear relationships between IgG content and SG, Brix, and the color space coordinates L^*, a^*, and b^*. Interestingly, results indicate that despite a similar range of the variables investigated, correlations between those variables can differ between the quarter and the composite samples. Correlation coefficients with IgG concentration of the respective samples were greater using a composite compared with an individual quarter sample. This was true for SG and Brix determination, and also for the color space coordinates measured. Due to the variation in milk composition between individual quarters of a cow, correlation coefficients between colostral IgG concentration, SG, Brix-values, and colostrum

color were poorer in quarter compared with composite samples. In conclusion, both accuracy and limitations of on-farm instruments estimating colostrum quality apply for quarter colostrum samples as well as composite samples.

Key Words: colostrometer, immunoglobulin G, refractometer

0847 Effects of increasing residual milk on milk yield and composition. L. L. Hernandez[1], V. J. McKeon[*2], E. L. Endres[2], A. de Bruijn[2], A. Kleinhans[2], and D. J. Reinemann[2], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]University of Wisconsin, Madison.*

The future profitability of the dairy industry depends, in part, on faster milking time and increased milk yield. Currently, milking machines detach from the udder when milk flow decreases to a specified amount. Due to variability in quarter-level milk yield, conventional practice may result in over-milking of up to three quarters and a variable amount of over-milking of the fourth quarter. The objective of this research was to evaluate the effect of residual milk on milk yield and composition. Twelve multiparous (avg. lactation 2.83 ± 0.99) Holstein cows were milked twice daily with a quarter milking machine for 42 d beginning 5 d post calving. Twice-daily quarter milk weights were recorded. Cows were assigned alternating control and treatment half udders depending on calving order, resulting in 12 control (CON; 0% residual milk) and 12 treatment (RES; 30% residual milk) quarters. Milk removed from RES quarters was recalculated weekly to account for an increase in milk production. Milk yield was affected by treatment ($P < 0.001$; 87.64 ± 5.20 kg for CON vs. 63.25 ± 5.20 kg for RES), quarter ($P < 0.001$; 67.10 ± 4.68 kg for front vs. 83.79 ± 4.68 kg for rear), and the treatment by week interaction ($P < 0.01$). Milk samples were collected weekly starting on d 5 and ending on d 47. Milk samples were analyzed for SCC, SNF, protein, MUN, and lactose. There was a week effect for SNF, butterfat, protein, MUN, and lactose ($P < 0.001$). There was a treatment by week by quarter effect on SNF ($P < 0.05$). Milk lactose concentrations were decreased by treatment ($P < 0.05$; 4.86 ± 0.07 kg for CON vs. 4.66 ± 0.07 kg for RES), differed among quarters ($P < 0.05$; 4.81 ± 0.07 kg for front vs. 4.71 ± 0.07 kg for rear), and there was a treatment by quarter interaction ($P < 0.05$; 4.96 ± 0.08 kg for CON front, 4.76 ± 0.08 kg for CON rear, 4.67 ± 0.08 kg for RES front, and 4.66 ± 0.08 kg for RES rear). Treatment increased SCC ($P < 0.05$; 42.78 ± 14.75 kg for CON vs. 89.60 ± 14.75 kg for RES). A treatment by quarter interaction was present for SCC ($P < 0.05$; 40.75 ± 16.58 kg for CON front, 44.82 ± 16.58 kg for CON rear, 111.26 ± 16.58 kg for RES front, and 67.94 ± 16.58 kg for RES rear). Results suggest that leaving 30% residual milk in the udder suppresses milk yield, increases SCC, and decreases milk lactose content. Future research should explore optimal take-off settings of milking machines at the quarter level.

Key Words: quarter variability, residual milk

0848 Nutrient composition of milk from great apes throughout lactation. M. Garcia[*1], M. Power[2], and K. M. Moyes[1], *[1]Department of Animal and Avian Sciences, University of Maryland, College Park, [2]Smithsonian Conservation Biology Institute, Washington, DC.*

For great ape infants, milk is the primary, if not sole, food providing the only supply of water, organic nutrients, and minerals during the first 12 to 18 mo of life. Moreover, when mother's milk is not available to a great ape infant (e.g., maternal death or infant rejection), zoo nutritionists/veterinarians formulate a milk replacer to maximize the chances of neonate survival. However, very limited information on milk composition from non-human apes is currently available. This study aimed to identify the nutrient composition of milk from gorillas and orangutans throughout lactation. Fifty three milk samples from 4 gorillas and 3 orangutans were collected throughout 48 and 22 mo in milk (MIM), respectively. Samples were grouped into 5 stages of lactation (i.e., 0 < MIM = 6, 6 < MIM = 12, 12 < MIM = 18, 18 < MIM = 36, and 36 < MIM = 48). Data were analyzed as a complete randomized design. The analysis to compare gorilla with orangutan included only 4 stages of lactation. Across MIM, protein was greater in gorilla than in orangutan milk (1.27 vs. 0.85%, respectively; $P < 0.01$). Protein, fat, lactose, and gross energy were affected by the interaction of species by MIM ($P < 0.05$). For gorilla milk, all components changed with MIM, whereby protein content was greatest by 48 MIM (1.91%, $P < 0.01$) and lactose was lower by 6 MIM, reaching a nadir by 48 MIM (4.95%, $P < 0.01$). Moreover, fat and gross energy contents followed a similar pattern to that of DM, with the highest content by 36 MIM ($P \leq 0.01$). For orangutan milk, protein, DM, and fat were unaffected by MIM. However, gross energy and lactose contents were steady during the first 18 MIM (7.51% and 0.36 Kcal/g, for lactose and gross energy, respectively) and decreased (lactose, 6.67%, $P < 0.05$) or tended to decrease (gross energy, 0.39 Kcal/g, $P < 0.10$) by 36 MIM. Major macronutrients in milk were similar between orangutan and gorilla, except for a lower protein content in orangutan milk. There was some change in milk composition over lactation. Mean values for mature milk between 6 and 18 MIM are the best values to consider when formulating milk replacers (protein 1.05%, fat 2.12%, and lactose 7.21%). Coupled with immune parameters, these results provide useful information to assist professionals caring for non-human great apes under captivity.

Key Words: gorilla, milk components, orangutan

0849 Milk fat globules as a source of mammary microRNA. D. Lago-Novais[1,2], K. Pawlowski[1], J. A. A. Pires[*1], L. Mobuchon[1,3], S. Bes[1], P. Martin[3], and C. Leroux[1], *[1]UMR1213 Herbivores, INRA, VetAgroSup, Saint-Genes-Champanelle, France, [2]Universidade Federal da Bahia, CEP, Salvador-BA, Brazil, [3]UMR1313 Gabi, INRA, AgroParisTech, Université Paris-Saclay, Jouy-en-Josas, France*.

Tissue for research on mammary gland (MG) gene expression is obtained via invasive and expensive methods (biopsy or post-mortem) that limit high throughput analyses. Milk fat globules (MFG) have been used to assess the mRNA content of the mammary epithelial cells in the bovine and goat (Brenaut et al., 2012; Canovas et al., 2014) for gene expression studies. MFG is therefore a satisfactory alternative source of mammary mRNA. MicroRNAs (miRNA) are small stable noncoding RNAs involved in multiple aspects of mammary gland physiology. Whereas the use of MFG was reported in humans (Munch et al., 2013), until now MFG as the source of miRNA has not been studied in the bovine. The objective of this study was to assess MFG as a source of miRNA, and whether the latter are representative of MG miRNA expression, by comparing targeted miRNA in MFG and MG sampled from mid-lactation Holstein cows. Total RNAs were extracted from MFG (n = 6) and MG (n = 6) using TRIzol (ThermoFisher, Inc, USA). Nine miRNA (*miR-29a*, *miR-125*, *miR-126*, *miR-141*, *miR-148a*, *miR-204*, *miR-223*, *miR-320*, and *miR-494*) were studied by RT-qPCR. The results are expressed as fold change of MFG data relative to MG data using the 2-ΔΔCt method and *U6* as internal reference. Statistical analyses were performed using a t test (DataAssist™ software) and $P < 0.05$ considered as significant. Among the nine miRNA chosen on the basis of the expression in MG, two were not detected in MFG whereas they were highly abundant in MG (*miR-126* and *miR-204*), and three were significantly more abundant in MG than in MFG (*miR-29a*, *miR-125b*, and *miR-148a*, presenting a fold change value of 23.2, 13.9, and 8.7, respectively). Four miRNA were detected at the same level in both MFG and MG. Our results suggest that there are different mechanisms of miRNA transfer to milk. Nevertheless, it is possible that miRNA not present in MFG are not expressed in epithelial cells, but are present in other MG cell-types, and therefore not transferred to milk. In conclusion, MFG can be used as a non-invasive source of microRNA but do not reflect exactly the MG miRNome. Further research is warranted on the composition of MFG miRNome and modulation of their secretion in milk.

Key Words: bovine, microRNA, milk fat globule

0850 Consumption of endophyte-infected fescue seed during the dry period and lactation affects mammary gland gene expression in dairy cows. R. L. Baldwin[*1], C. Li[1], D. M. Bickhart[1], C. M. Evock-Clover[1], P. Grossi[2], R. K. Choudhary[3], T. H. Elsasser[4], G. Bertoni[5], E. Trevisi[6], G. E. Aiken[7], K. R. McLeod[8], and A. Capuco[1], *[1]Animal Genomics and Improvement Laboratory, USDA-ARS, Beltsville, MD, [2]Università Cattolica del Sacro Cuore, Piacenza, Italy, [3]School of Animal Biotechnology, GADVASU, Ludhiana, Punjab, India, [4]USDA-ARS, Animal Biosciences and Biotechnology Laboratory, Beltsville, MD, [5]Istituto di Zootecnica, Università Cattolica del Sacro Cuore, Piacenza, Italy, [6]Università Cattolica del Sacro Cuore, Piacenza, Italy, [7]USDA-ARS, Lexington, KY, [8]University of Kentucky, Lexington*.

Ergot alkaloids in endophyte-infected grasses inhibit prolactin secretion and reduce milk production when fed to lactating cows. However, we have shown this effect is temporal in that prepartum consumption of infected seed throughout the dry period does not inhibit subsequent milk production and, in fact, prior exposure to bromocriptine (ergot peptide) actually increases production. To identify changes in the transcriptome and pathways mediating the mammary gland's response to ergot alkaloids in the diet, RNA sequencing (RNA-Seq) was performed on mammary tissue obtained from 24 multiparous Holstein cows exposed to 1 of 3 treatments. Starting at 90 ± 4 d prepartum, cows were fed endophyte-free fescue seed (control, C), endophyte-free fescue seed plus 3×/wk subcutaneous injections of bromocriptine (0.1 mg/kg BW, B), or endophyte-infected fescue seed (I), as 10% of the diet on an as-fed basis. Mammary biopsies from 4 or 5 cows/treatment at each of 3 distinct phases were obtained: 7 d before dry off during the initial lactation (L1), mid-dry period (D), and 10 d postpartum (L2). Biopsy samples from each treatment group and phase of lactation were used to generate individual RNA-Seq libraries. Normalized reads of the RNA-Seq data were organized into technical and biological replicates before processing with the RSEM software package. Each lactation phase was processed separately with the "rsem-run-ebseq" pipeline, and genes that differed between any of three treatments were identified from program output. A large proportion of genes considered to be differentially expressed in at least one treatment with a posterior probability of differential expression greater than 90% (n = 866) were found to be similarly expressed in B and I treatments, but differentially expressed from C (n = 575, total for all three phases). When phases were compared, 104 genes that were differentially expressed compared to C were found to be common to the L1 and L2 phases. Consistent with the production findings, networks most affected by treatments in L1 and L2 include lipid metabolism, small molecule biochemistry, and molecular transport, while in D networks relate more to

developmental and cellular functions and maintenance. The strong similarity in pattern of expression in B and I treatments during both late and early lactation suggests, at least in part, the involvement of similar cell signaling pathways or mechanisms of action for both B and I and the importance of prolactin messaging pathways.

Key Words: ergot alkaloids, prolactin, RNA sequencing

0851 Intravenous infusion of 5 hydroxy-L-tryptophan, a serotonin precursor, to transition dairy cows pre-calving affects GH-IGF axis gene expression in the mammary gland and liver post-calving.

S. R. Weaver*[1], L. L. Hernandez[1], S. Tao[2], and J. Laporta[3], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]University of Georgia, Tifton, [3]Department of Animal Sciences, University of Florida, Gainesville*.

The role of the monoamine serotonin in the regulation of growth hormone (GH) and insulin-like growth factor-1 (IGF1) is controversial. Most studies have focused on serotonin produced in the brain. Given that the majority of total-body serotonin is produced outside of the central nervous system, we set out to determine whether infusing a serotonin precursor, 5 hydroxy-L-tryptophan (5-HTP) intravenously would impact the somatotropic axis in transition dairy cows. Multiparous Holstein cows were intravenously infused once daily for approximately 6 d pre-calving (−6 to −1), with either 1 L of saline ($n = 6$) or 1.0 mg/kg BW of 5-HTP ($n = 6$). Blood was collected before and after infusion, and at 2, 4, and 8 h post-infusion, at calving, and on d 3, 5, 7, and 14 post-calving to measure serotonin and IGF1 concentrations in serum. Mammary gland and liver biopsies were collected on d 1 and 7 post-calving to assess gene expression of the somatotropic axis. Gene expression data was analyzed using the DDCt method, using d 1 saline-infused cows as the control. Blood variables were analyzed with a two-way ANOVA (pre- and post-calving separately). Overall, 5-HTP-infused cows had greater serotonin and lower IGF1 concentrations than controls. Specifically, 5-HTP-infused cows had greater serotonin concentrations pre-calving (all days except d −2), at calving (d 0), and post-calving only on d 1 of lactation ($P < 0.05$). Infusion of 5-HTP decreased IGF1 concentrations pre-calving, particularly on d −6 and d −5, and only during the first and second hour post-infusion ($P < 0.05$). No differences in IGF1 were detected on d −4 to d −1 of infusion pre-calving. Post-calving, IGF1 concentrations markedly decreased, compared with pre-calving levels, but there were no differences between treatments on d 3, 5, or 7. On d 14, IGF-I concentrations increased to pre-calving levels only for the saline-infused cows and remained low in the 5-HTP-infused cows ($P < 0.05$). In the liver, 5-HTP treatment upregulated the mRNA expression of IGF1, IGF1-receptor and GH-receptor and IGF1-binding protein 3 on d 1 post-calving ($P < 0.01$), and no differences in gene expression were observed on d 7. In the mammary gland, 5-HTP treatment upregulated the mRNA expression of IGF1 and IGF1-binding protein 2 on both d 1 and 7 post-calving ($P < 0.05$). Regardless of the relative steadiness of circulating IGF1 concentrations post-calving, these data imply a potential benefit of 5-HTP administration pre-calving to improve the expression of genes related to the somatotropic axis in the liver and mammary tissue at the onset of lactation in dairy cows.

Key Words: lactation, serotonin, somatotropic axis

0852 Effect of cortisol on mammary epithelial cell Bax and Bcl-2 gene expression at lactation peak of goats.

G. F. Bomfim*, *State University "Julio de Mesquita Filho," UNESP, Jaboticabal/Sao Paulo, Brazil; Faculty of Animal Science and Food Engineering–FZEA/USP, Pirassununga/Sao Paulo, Brazil*.

Cortisol is one of the main hormones that characterize stress, and chronically elevated cortisol can induce apoptosis, as well as expression of Bax (pro-apoptotic), which, in high levels, signals to cellular mitochondria causing cell apoptosis. In contrast, Bcl-2 (anti-apoptotic) acts as a "protector" of cells. Thus, the aim of this study was to analyze the effects of different levels of cortisol on Bax and Bcl-2 expression in mammary epithelial cells. Twenty-four Saanen goats were distributed in two groups: ACTH administration (cortisol group) or placebo (control group), during the lactation peak, i.e., 60 d of lactation. Four goats from each group were submitted to a biopsy of mammary gland after 1 h of treatment administration. Epithelial cells were isolated and four different concentrations of cortisol were added to this culture: 0.0 (control), 10, 100, or 1000 ng/mL. After 5 d, mRNA was extracted and Bax and Bcl-2 gene expression was measured by RT-PCR. Statistical analysis was performed using ANOVA, and significance was declared at $P \leq 0.05$. In the cortisol group, there was no effect of pre-treatment on expression of Bax and Bcl-2 in cell culture. However, in the placebo group, there was a significant difference ($P < 0.05$) in Bax expression, such that at higher levels of cortisol in the culture, Bax expression was lower (2.28 ± 0.58 and 2.01 ± 0.4, respectively, for 100 and 1000 ng/mL), compared to the control (4.38 ± 1.1, 0.0 ng/mL). For Bcl-2 there was no significant difference ($P > 0.05$). In summary, high levels of cortisol in mammary epithelial cells can interfere with Bax gene expression.

Key Words: apoptosis, cortisol, mammary gland, stress

0853 Interactions among serotonin and circadian systems in the mammary gland. A. Suárez-Trujillo[1], J. S. Crodian[2], A. M. Shamay[3], S. J. Mabjeesh[*4], K. Plaut[5], and T. M. Casey[6], *[1]Department of Animal Science, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [2]Purdue University, West Lafeyette, [3]Agriculture Research Organization, Volcani Center, Bet Dagan, Israel, [4]Department of Animal Sciences, The Robert H. Smith Faculty of Agriculture, Food and Environment, The Hebrew University, Rehovot, Israel, [5]Department of Animal Sciences, Purdue University, West Lafayette, [6]Department of Animal Sciences, Purdue University, West Lafayette*.

The circadian and serotonin systems are reciprocally regulated in the brain and function to maintain homeostasis and respond to internal and external stimuli. Both systems play regulatory functions throughout the lactation cycle in the mammary gland. We hypothesized that the serotoninergic and circadian systems are reciprocally regulated in the mammary gland to mediate mammary homeostasis and respond to metabolic demands of milk synthesis. The objective of this study was to determine whether there is reciprocal regulation among the systems using approaches that encompassed bioinformatics analysis, mammary cell and tissue culture, and temporal expression analysis of mammary gene expression using sheep milk. Bioinformatics analysis of the 2000-bp upstream region of the *SLC6A4* (serotonin reuptake transporter, SERT) gene revealed the presence of a canonical E-box sequence (CACGTG) that circadian transcription factor CLOCK:BMAL1 binds. qPCR analysis of steady-state *SLC6A4* mRNA in samples isolated from sheep milk fat globules showed that this gene exhibits a circadian rhythm of expression. *SLC6A4* pattern of expression was similar to *PER2,* a core clock gene that is a transcriptional target of CLOCK:BMAL1. Moreover, comparison of *PER2* and *SLC6A4* temporal expression in wild-type HC11 cells also showed similar expression patterns in this mammary epithelial cell line. In HC11 cultures that carry shRNA that targeted *CLOCK, SLC6A4* expression was decreased across all time points ($P < 0.05$), supporting that the mammary clock regulates this serotonergic factor. To study the effect of serotonin (5-HT) on the mammary clock, mammary explants were prepared from lactating mice and divided into two treatments: control (lactogenic culture media–prolactin, glucocorticoids, and insulin) and 5-HT (lactogenic culture media and 200 μM of 5-HT). Samples were collected every 4 h over a 24-h period. One-way ANOVA of temporal variation within treatments found time had a significant ($P < 0.05$) impact on *BMAL1* expression in the control, but not the 5-HT treated samples, indicating that 5-HT attenuates *BMAL1* expression rhythm. *PER2* temporal variation was significant in both treatments ($P < 0.001$), but the differences were due to different time points, indicating that 5-HT shifted the phase of expression rhythm. Together, these data support that circadian and serotonergic systems interact in mammary gland. Further studies are needed to understand the significance of these interactions and how they may affect productivity.

Key Words: circadian clocks, mammary gland, serotonin

0854 Effects of stress on IGF-1 plasma concentrations and on expression of GH and IGF-1 receptors in mammary glands. G. F. Bomfim*, *Faculty of Animal Science and Food Engineering–FZEA/USP, Pirassununga/Sao Paulo, Brazil*.

Growth hormone (GH) and insulin-like growth factor-1 (IGF-1) have positive effects on lactation. The action of these hormones on mammary tissue can be regulated by their respective receptors, GHR and IGF-1R. When females undergo a situation of stress during the lactation period, its influence on the expression of these receptors, as well as on concentrations of IGF-1 in the blood, is unknown. The objective of this study was to evaluate the effects of cortisol on IGF-1 plasma concentrations and on the expression of IGF-1R and GHR at the peak and end of lactation. Thirty Saanen goats were distributed in two groups: ACTH administration to induce stress (cortisol group) or placebo (control group), at peak (60 d) and end (180 d) of lactation. Four goats from each group were submitted to a mammary biopsy after 60 min of treatment administration. Mammary tissue was collected to measure mRNA levels for IGF-1R and GHR via RT-PCR, and IGF-1 plasma concentrations were measured (EIA method) in blood samples of goats collected at the time of biopsy. Statistical analyses were performed using ANOVA. There was no treatment effect ($P > 0.10$) on GHR or IGF-1R gene expression or on IGF-1 plasma concentrations at 60 d and 180 d of lactation. These results suggest that an increase in concentrations of cortisol in the bloodstream does not influence GHR and IGF-1R expression in the mammary gland. In addition, IGF-1 plasma concentrations remained constant in both groups during lactation.

Key Words: ACTH, hormones, lactation

0855 Extracellular matrix molecule d*Eco*RIn signaling pathway gene expression in two bovine mammary cell lines. H. L. M. Tucker*, C. L. M. Parsons, and K. M. Daniels, *Virginia Polytechnic Institute and State University, Blacksburg.*

Previously we showed that d*Eco*RIn, an extracellular matrix (ECM) proteoglycan, is primarily located in mammary stroma and localization depends on physiological stage. Because the mammary gland is a heterogeneous tissue, the primary d*Eco*RIn producing cell populations and primary d*Eco*RIn responsive cell populations have not been identified; knowing this will advance our understanding of mammary ECM remodeling during mammary growth and involution. Our

objective was to characterize known d*Eco*RIn pathway genes in two immortalized bovine cell lines. These were bovine mammary epithelial cells (BME) and mammary fibroblasts (MF-T2). BME and MF-T2 were each grown on 6-well plastic dishes with Dulbecco's Modified Eagle Medium (DMEM) plus 10% fetal bovine serum. Initial densities were 5×10^5 cells/well for BME and 1×10^6 cells/well for MF-T2. After 16 h, media was changed to 100% DMEM. Cell lysates were collected after 16 h of DMEM incubation; total RNA and DNA were quantified. Total RNA was converted into cDNA and used in real-time quantitative PCR (qPCR). Genes of interest were: d*Eco*RIn, transforming growth factor β 1, transforming growth factor receptor 1, insulin-like growth factor 1, insulin-like growth factor receptor 1, epidermal growth factor, epidermal growth factor receptor, hepatocyte growth factor, hepatocyte growth factor receptor, and insulin receptor. Before data analyses, genes of interest were normalized to the average of three internal control genes and the final DNA content of each cell culture well. Triplicate cell culture wells were used and qPCR performed in duplicate. Separate immunocytochemistry experiments were conducted with the similar culture conditions to show cellular localization of the d*Eco*RIn core protein in BME and MF-T2 using a rabbit polyclonal d*Eco*RIn primary antibody (1:50; SC22753) and AlexaFluor 594 goat anti-rabbit secondary antibody (1:200; A11012). MF-T2 produced relatively more d*Eco*RIn core protein mRNA (31× more abundant) and protein than BME when both cell types were cultured under basal conditions. All other genes of interest were detected in both cell types, with transforming growth factor β 1 mRNA also being relatively more abundant in MF-T2 (9× more abundant). Because d*Eco*RIn has known growth regulatory properties, resultant findings will be used to design mechanistic cell culture studies. In the future, d*Eco*RIn signaling pathways may be manipulated in vivo in efforts to increase milk production efficiency via increased epithelial cell proliferation or decreased apoptosis during growth and involution.

Key Words: cell culture, ECM, gene, mammary gland

0856 Associations between quarter-level inflammation status across the dry period and health outcomes in the subsequent lactation. S. A. Metzger*[1], L. L. Hernandez[2], and P. L. Ruegg[1], [1]*Department of Dairy Science, University of Wisconsin-Madison, Madison, WI,* [2]*Department of Dairy Science, University of Wisconsin, Madison.*

The objective of this prospective cohort study was to determine associations of inflammation status of individual mammary quarters of dairy cows across the dry period with health status in the first 150 d of lactation. Milk from all mammary quarters ($n = 649$) of all lactating cows at the University of Wisconsin–Madison Emmons Blaine Dairy Cattle Research Center was sampled at dryoff before administration of dry cow antibiotic therapy and twice within the first 2 wk after the subsequent calving. Quarters with a somatic cell count (SCC) < 100,000 cells/mL and no microbiological growth at all three sampling times (low negative, LN; $n = 76$), quarters with SCC ≥ 150,000 cells/mL and no microbiological growth at the first two sample times and a variable third sample (high negative precalving, HNPre; $n = 17$), quarters with a variable first sample and SCC ≥ 150,000 cells/mL and no microbiological growth at the second and third sample times (high negative postcalving, HNPost; $n = 6$), and quarters with SCC ≥ 150,000 and positive microbiological growth at all three samples (high positive, HPos; $n = 3$) were followed until 150 d in milk (DIM). Foremilk samples were collected weekly for SCC analysis and monthly for microbiological analysis. Log-rank tests were performed to analyze survival to clinical mastitis (CM) and growth in monthly culture and SCC was analyzed with repeated measures analysis. The SCC of LN quarters was lowest throughout the first 150 DIM ($P < 0.001$) and LN quarters were least likely to experience a case of CM ($P < 0.001$). Fifty percent of HNPost quarters experienced CM, as compared to 1 of 3 HP quarters, 3 of 17 HNPre quarters, and only 2 of 76 LN quarters. LN quarters were also least likely to have bacterial growth in monthly samples ($P < 0.001$). All HP and HNPost quarters had bacterial growth in one or more monthly milk samples, while 36% of HNPre quarters and 9.7% of LN quarters had bacterial growth in one or more monthly milk samples. The most common bacteria isolated from monthly aseptic milk samples ($n = 383$) were coagulase-negative *Staphylococcus* species ($n = 22$), followed by streptococcus-like species ($n = 12$), *Corynebacterium bovis* ($n = 4$), yeast species ($n = 3$), and *Klebsiella*species ($n = 1$). Overall, LN quarters had better health outcomes during the first 150 DIM.

Key Words: dry period, inflammation, mastitis

0857 Interaction among energy status, dietary protein, and vitamin A in periparturient dairy cows: Effects on milk fatty acid profile and gross milk yield efficiency. Y. Chen*, K. C. Ramsey, C. Y. Tsai, M. A. McGuire, and P. Rezamand, *University of Idaho, Moscow*.

Diet affects the fatty acid (FA) composition of milk. The objective of this study was to determine the interaction of various rates of dietary protein (11 or 13%), vitamin A (0 or 110 IU/kg BW), and monensin (0 or 400 mg/d per head) fed during the dry period (4 wk before expected calving until calving) on milk FA profiles and feed efficiency of early postpartum dairy cows. Multiparous Holstein dairy cows ($n = 80$ total) were blocked by expected calving date and previous milk yield and randomly assigned to one of eight treatments in a 2 × 2 × 2 factorial arrangement of treatments. Milk yield and composition and feed intake were determined daily from calving (d 0) to 21 d postpartum. Results were analyzed using mixed model repeated measures ANOVA. Significance was declared at $P \leq$

0.05 while $0.05 < P \leq 0.1$ was considered a trend. Dietary vitamin A × monensin affected yield of several FA in milk; cows receiving both vitamin A and monensin during the dry period produced more C18:3 n3 as well as C22:6 compared with other treatment groups ($P = 0.004$ and 0.009, respectively). The interaction of dietary vitamin A × monensin also affected yield of C18:3 n6, sum of saturated FA, sum of unsaturated FA, sum of n3, sum of n6 FA, sum of MUFA, sum of PUFA, and sum of preformed FA. Dietary protein × monensin × vitamin A affected yields of C16:0 + C16:1, C20:4, C20:5, and C22:6 ($P < 0.03$ for all). Furthermore, greater dietary protein reduced the yield of C18:3 n3 and sum of *de novo* FA. Dietary protein × monensin × vitamin A tended to affect yields of C18:1 *cis*, C18:2 *cis*, C18:3 n3, C18:3 n6, sum of n3, sum of n6 FA, and n6:n3. Both energy corrected (ECM) and 3.5% fat corrected milk were interactively affected by dietary protein, monensin, and vitamin A ($P < 0.03$). Gross milk yield efficiency (ECM/DMI) was changed over time but no dietary effect was detected. Overall, diet composition altered the profile and yields of milk FA as well as ECM of early lactating Holstein cows.

Key Words: dairy cow, fatty acids, feed efficiency

0858 Effect of intrammamary infusion of chitosan hydrogels on bovine mammary gland involution after drying-off.

0859 Differences in body condition of gilts that are maintained from mating to the end of gestation affect their mammary development.

C. Farmer*[1], M. Comi[2], M. Vignola[3], P. Charagu[4], C. R. A. Duarte[5], and M. F. Palin[1], *[1]Agriculture and Agri-Food Canada, Sherbrooke R & D Centre, Sherbrooke, QC, Canada, [2]Dipartimento VESPA, Universitá Studi Milano, Milan, Italy, [3]Trouw Nutrition, St-Elzéar, QC, Canada, [4]Hypor Inc., Regina, SK, Canada, [5]Departamento de Zootecnia, Universidade Estadual de Maringá, Maringá, Brazil*.

The goal of this project was to determine if different body conditions in late gestation that are due to varying body conditions at mating affect mammary development of gilts. Gilts that were fed ad libitum in the growing period were selected based on their backfat thickness (BF) to form three groups at mating, namely, low (LBF; 12–15 mm, $n = 14$), medium (MBF; 17–19 mm, $n = 15$), and high (HBF; 22–26 mm, $n = 15$) BF. During gestation, LBF, MBF, and HBF gilts were fed approximately 1.25, 1.43, and 1.63 of maintenance requirements to maintain their differences in body condition. Daily feed intake was increased by 1 kg in the last 10 d of gestation. All gilts had their BF measured ultrasonically at mating and every 15 to 20 d thereafter. Blood samples were obtained at mating and on d 109 of gestation to measure concentrations of IGF-1, glucose, insulin, estradiol, urea, FFA, and adiponectin. Gilts were slaughtered on d 110 of gestation to collect mammary glands for compositional analyses and measures of mRNA abundance for selected genes. The MIXED procedure of SAS using a univariate model (3 levels) was used for statistical analyses and means were compared using the Tukey test. Mammary extraparenchymal tissue weight was less in LBF and MBF than in HBF gilts (1259.3, 1402.7, and 1951.5 ± 70.4 g, respectively, $P < 0.01$). Weight of parenchymal tissue was not altered by treatment ($P > 0.10$), but its composition was affected. Concentrations of DNA and RNA decreased as BF increased ($P < 0.01$), whereas percent fat and dry matter increased ($P < 0.01$). Mammary expression of *CSN2* (β-casein) in parenchymal tissue was also lower in HBF than LBF gilts ($P < 0.05$). On d 109 of gestation, concentrations of insulin, IGF-1, and adiponectin were greater ($P < 0.05$) in HBF than in LBF or MBF gilts, whereas those of urea were lower ($P < 0.01$). Maintaining differences in body condition from mating to the end of gestation therefore had an impact on mammary development of gilts. Extraparenchymal tissue mass was affected and, more importantly, composition of parenchymal tissue.

Key Words: body condition, gilt, mammary development

0860 Stem cells and cell hierarchy in the bovine mammary gland.

I. Barash*[1] and G. Rauner[1,2], *[1]Volcani Center, Bet-Dagan, Israel, [2]Hebrew University of Jerusalem, Jerusalem, Israel*.

Elucidating cell hierarchy and lineage commitment in the mammary gland is fundamental for understanding its development and for establishing methodologies aimed at increased production via stem-cell manipulation. Here, we demonstrate the existence of bovine mammary stem cells and describe enrichment and transplantation methodologies and attempts made to manipulate this population. Lin^- bovine mammary epithelial cells (bMECs) from Holstein heifers were sorted according to CD24 and CD49f expression into four populations. The $CD24^{med}CD49f^{pos}$–enriched population maintained high expression of basal markers. In culture, it generated luminal and basal clones and had high floating-sphere formation and growth rate. Upon transplantation into cleared mouse mammary fat pad, it gave rise to multilayered outgrowths with self-renewing properties. This population was positioned at the top of the cell hierarchy and referred to as the stem cell population. A more committed, bipotent basal population generated both luminal and basal clones in vitro but was almost completely restricted to generating unilayered basal outgrowths. Together with the luminally restricted progenitor population, it may serve as a reservoir for the highly differentiated luminal cells. Two markers, E-cadherin and miR-200c, whose expression levels correlate with differentiation, assisted in more comprehensive delineation of the bovine mammary cell hierarchy. Xanthosine administration did not affect the proportion of stem cells in bovine implants

transplanted into the cleared mouse fat pad. However, it had a latent negative effect on cell proliferation and may, therefore, interfere with mammary gland development and also limit tumor growth. To analyze the development of bovine mammary morphology in the mouse mammary stroma, bMECs were transplanted into the cleared mammary fat pad of immunodeficient mice. Multilayered hollow spheres developed within fibrotic areas. They shared morphological and immunohistochemical characteristics with the heifer gland but did not extend via ductal morphology. Nevertheless, a single case of terminal ductal lobuloalveolar unit (TDLU) development was recorded in mice treated with estrogen and progesterone, implying the feasibility of this representative bovine morphology's development. *In vitro,* paracrine inhibition of bovine epithelial mammosphere development by adipocytes was recorded, and it was antagonized by FGF administration. This indicates an active equilibrium between inhibitory and promotive effects exerted by the adipose and fibrotic regions of the stroma, respectively. Together, these findings imply that unique bovine mammary cell properties are integrated within a conserved mammary cell hierarchy paradigm delineated in their mouse and human counterparts.

Key Words: bovine, cell hierarchy, mammary gland, stem cells

0861 Optimal combination of histidine, lysine, methionine, and leucine affect β-casein synthesis via mTOR signaling pathway in bovine mammary epithelial cells.

H. Gao[1,2,3,4], N. Zheng[1,2,5], S. Zhao[1,2,4], Y. Zhang[1,2,5], S. Wang[1,2,4], X. Q. Zhou[1,2,4], and J. Wang[*2,3,4,5], *[1]Ministry of Agriculture-Milk Risk Assessment Laboratory, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China, [4]Ministry of Agriculture-Milk and Dairy Product Inspection Center, Beijing, China, [5]Ministry of Agriculture- Milk and Dairy Product Inspection Center (Beijing), Beijing, China*

Assessing the regulatory effect of the optimal ratio of the essential amino acids (EAAs) on milk protein synthesis is vital to AA requirement models for lactation. The study employed response surface methodology (RSM) to determine the optimal ratio of histidine, lysine, methionine, and leucine on β-casein expression level in vitro and to clarify the effect of four EAAs on β-casein through mechanistic targeting of the rapamycin (mTOR) signaling pathway. A central composite design containing 5 axial points per EAA, and 28 combinations of the four EAAs was performed for our study. The efficiency of RSM and the changes of the mTOR-related signaling proteins were further verified by western blot. The protein band values from the AA-supplemented cells were related to their AA-deprived controls. The β-casein data from the RSM experimental design were analyzed using a regression model by Design–Expert 8.0.6. The other experimental data were analyzed using Tukey's test for post-hoc multiple comparisons of treatment means by SAS. Differences between experimental groups were considered significant at $P < 0.05$. The results showed that β-casein level was significantly affected by all four EAAs ($P < 0.01$, $R^2 = 0.71$). The optimal conditions for β-casein expression were as follows: His:Lys:Met:Leu = 5:6:1:7. Only a significant interaction of Leu and Met was observed as to β-casein expression ($P < 0.01$). Further experiments validated that under the optimal mixture of four EAAs, the expression of β-casein was 98% as high as the positive control (i.e., media with all AAs). The phosphorylation of mTOR, Raptor, GβL, S6K1, Rps6, and eEF2 was increased with supplementation of either single EAAs or the optimal combination of EAAs. Finding the best combination of these four EAAs promoted β-casein expression, and this appeared to be mediated through activation of the mTORC1 signaling pathway.

Key Words: bovine mammary epithelial cells, optimal ratio of EAAs, mTOR, β-casein

0862 The goat (*Capra hircus*) mammary gland secretory tissue proteome as influenced by weight loss: A study using label-free proteomics.

A. M. Almeida[*1,2], L. E. Hernandez-Castellano[3], A. M. Ferreira[2], P. Nanni[4], J. Grossmann[4], A. Argüello[5], J. Capote[6], G. Cai[7], J. D. Lippolis[7], and N. Castro[8], *[1]Ross University School of Veterinary Medicine, Basseterre, Saint Kitts and Nevis, [2]Instituto de Biologia Experimental e Tecnologica, Oeiras, Portugal, [3]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [4]Functional Genomics Center Zurich (FGCZ), University of Zurich, Zurich, Switzerland, [5]Department of Animal Science, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [6]Canarian Agronomic Science Institute, La Laguna, Tenerife, Spain, [7]USDA, ARS, National Animal Disease Center, Ames, IA, [8]Dep. Animal Science, University of Las Palmas de Gran Canaria, Arucas, Spain*.

The objective of this work was to study the effect of seasonal weight loss (SWL) on the mammary gland secretory tissue proteome in two goat breeds from the Canary Islands. Two lactating dairy goat breeds from the Canary Islands with different levels of tolerance to SWL were used: Majorera (tolerant) and Palmera (susceptible). Within each breed, goats with the same age and stage of lactation were divided into two groups: control (constant weight) and restricted (15% liveweight reduction). Four groups were established: Palmera control (PC, $n = 6$), Majorera control (MC, $n = 4$), Palmera restricted (PR, $n = 4$), and Majorera restricted (MR, $n = 5$).

Animals on the restricted groups were fed on standard wheat straw, and animals in the control groups were fed on alfalfa hay supplemented with maize, soy, and dehydrated beetroot. At Day 22 of the trial, mammary gland biopsy samples were obtained. Samples (30 mg) were ground in liquid nitrogen with mortar and pestle, added to 500 μL of ammonium bicarbonate 50 mM, urea 8M, and thiourea 2M buffer, homogenized, and centrifuged, and the supernatant recovered. Per sample, 15 μg of proteins were trypsin digested (FASP protocol) and desalted. Peptides were loaded onto reverse-phase C18 columns and analyzed on an LTQ-Orbitrap Velos mass spectrometer. Protein identification and label-free quantification were performed using Mascot (Matrixscience) and Progenesis software (Nonlinear Dynamics). A total of 1010 proteins were identified, from which 96 proteins were considered statistically different among groups (fold change > 1.98 and $P < 0.05$). After SWL, there was an increase of proteins related to apoptosis and stress processes in both breeds. Moreover, both breeds showed a decrease in the number of proteins related to protein, carbohydrate, and fat biosynthesis. When both breeds were compared after SWL, the Majorera breed showed higher expression of immune system related proteins compared to the Palmera breed. In contrast, the Palmera breed showed higher expression of proteins related to apoptosis, ketone body formation (fatty liver), and protein metabolic processes compared to the Majorera breed. In conclusion, the two goat breeds have different metabolic reactions to SWL, highlighting differences particularly related to the immune system (higher expression in the tolerant breed) and apoptosis (higher expression in the susceptible breed).

Key Words: goat, label-free proteomics, mammary gland, seasonal weight loss

0863 Pre-calving and early lactation factors that predict milk casein and fertility in the transition dairy cow. R. M. Rodney*[1,2], J. K. Hall[3], C. T. Westwood[4], P. Celi[5], and I. J. Lean[1,2], *[1]Scibus, Camden, Australia, [2]University of Sydney, Camden, Australia, [3]Halltech Services, Orange, Australia, [4]Kimihia Research Centre, PGG Wrightson Seeds Limited, Lincoln, Canterbury, New Zealand, [5]Faculty of Veterinary and Agricultural Sciences, University of Melbourne, Parkville, Australia*.

Multiparous Holstein cows ($n = 82$) of either high or low genetic merit (GM) (for milk fat + protein yield) were allocated to one of two diets in a 2 × 2 factorial design. Diets differed in the ratio of rumen-undegradable protein (RUP) to rumen-degradable protein (37% RUP vs. 15% RUP) and were fed from 21 d pre-calving to 150 DIM. This study evaluated the effects of these diets and GM on concentrations of milk casein (CN) variants and aimed to identify pre-calving and early lactation variables that predict milk, CN and protein yield and composition, and fertility of dairy cows. It explored the hypothesis that low milk protein content is associated with lower fertility, extending this to also evaluate the contribution of CN contents. Yields (kg/d) for CN variants were 0.49 and 0.45 of α CN, 0.38 and 0.34 of β CN, 0.07 and 0.06 of κ CN, and 0.10 and 0.09 of γ CN for high and low RUP diets, respectively. Increased RUP increased milk, CN and milk protein yields. Increased GM increased milk and γ CN yields and tended to increase milk protein yield. The effects of indicator variables on CN variant yields and concentrations were largely consistent, with higher body weight and α amino nitrogen resulting in higher yields, but lower concentrations. An increase in cholesterol was associated with decreased CN variant concentrations, while disease lowered CN variant yield. A diet high in RUP increased the proportion of first services that resulted in pregnancy from 41 to 58%. Increased pre-calving metabolizable protein (MP) balance decreased the proportion of first services that resulted in pregnancy when evaluated in a model containing CN %, milk protein yield, diet, and GM. This indicates that the positive effects of a diet high in RUP on fertility may be curvilinear as cows with a very positive MP balance before calving were less fertile than those with a lower, but positive, MP balance. Prepartum MP balance was important to production and reproduction outcomes, while surprisingly, metabolizable energy balance was not. Cows producing the lowest quartile of milk protein percentage were 28% less likely to become pregnant during the first 150 DIM. Milk CN % was similarly positively associated with improved pregnancy at first service. This study demonstrates the importance of protein metabolism to reproductive performance of the dairy cow.

Key Words: casein, fertility, protein degradability

0864 Increasing blood 5-hydroxy-L-tryptophan concentration for prevention of periparturient hypocalcemia in dairy cows. L. E. Hernandez-Castellano*[1], S. R. Weaver[2], L. L. Hernandez[2], and R. M. Bruckmaier[1], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [2]Department of Dairy Science, University of Wisconsin, Madison*.

Hypocalcemia in dairy cows is caused by the sudden increase in demand for Ca^{2+} by the mammary gland for milk production after partum and simultaneously the limited ability of Ca^{2+} to be mobilized from bone in a timely manner. Serotonin (5-HT) is a key factor which mediates Ca^{2+} mobilization from bones. Therefore, we hypothesized that administration of 5-hydroxy-L-tryptophan (5-HTP), a 5-HT precursor, would increase 5-HT concentration in blood, and in turn induce Ca^{2+} mobilization from bone. In this study, 20 Holstein dairy cows were randomly assigned to two experimental groups. Ten animals received a daily i.v. infusion of 1 L of 0.9% NaCl (control; C). The other 10 animals received 1 L of 0.9% NaCl containing 1 mg of 5-HTP/kg BW daily (5-HTP group). Infusions were performed beginning on Day 10 before estimated

parturition. Infusions were conducted until the day of parturition, resulting in at least 4 d of infusion. Until parturition, blood samples were collected every morning before the infusions, and after parturition daily until Day 7, and on Day 30. Milk yield was recorded during this period. No differences between groups were observed for blood glucose, Mg^{2+}, β-hydroxybutyrate, and non-esterified fatty acid concentrations. Serum 5-HT concentration was increased until Day 5 after partum in the 5-HTP group compared to the C group. Colostrum 5-HT concentrations were higher in the 5-HTP group than in the controls (37.10 ± 3.12 vs. 25.02 ± 2.75 nM; $P < 0.05$), but differences were undetectable in milk 7 d after partum (13.43 ± 1.12 *vs.* 14.63 ± 1.13 nM; $P > 0.05$). Serum total Ca^{2+} concentrations decreased in both groups around parturition ($P < 0.05$), however, 5-HTP group had higher blood Ca^{2+} concentrations than the controls on Day 1 (1.93 ± 0.06 vs. 1.62 ± 0.09 mM) and Day 2 (2.07 ± 0.04 vs. 1.83 ± 0.07 mM), respectively ($P < 0.05$). Additionally, colostrum yield (first milking) was lower in the 5-HTP group compared to the C group (5.63 ± 0.34 *vs.* 8.56 ± 0.47 kg; $P < 0.05$), but no differences in colostrum IgG concentration were detected (68.41 ± 5.20 vs. 60.70 ± 10.27 mg/mL; $P > 0.05$). Milk yield did not differ between groups during the rest of the experiment. In conclusion, 5-HTP infusions increased blood 5-HT concentration. Moreover, 5-HTP can reduce the decline in blood Ca^{2+} concentration around parturition and hence may influence the occurrence of clinical or subclinical hypocalcemia. Finally, 5-HTP reduced colostrum production without affecting IgG concentrations, suggesting the mass of IgG available from colostrum may be sufficient to fulfill the needs of the offspring.

Key Words: dairy, hypocalcemia, serotonin

0865 Beta-hydroxybutyrate infusion affects glucose metabolism before and after parturition in dairy cows. M. Zarrin[1,2], L. Grossen-Rösti[1], R. M. Bruckmaier[1], and J. J. Gross[*1], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [2]Department of Animal Science, Yasouj University, Yasouj, Iran*.

Recent studies in mid- and late-lactating dairy cows showed that β-hydroxybutyrate (BHBA) infusion had considerable impact on glucose metabolism and immune response during intramammary lipopolysaccharide challenge. The objective of the present study was to infuse BHBA during the dry period and after parturition to investigate the effects of elevated plasma BHBA concentrations on metabolism and endocrine changes in transition dairy cows. Eight multiparous Holstein cows in wk −2 (a.p.) and wk +2 (p.p.) relative to calving were infused (from 0800 AM to 1200 AM, 4 h) with a BHBA solution to increase plasma BHBA concentrations to 1.5 to 2.0 mmol/L (HyperB). The same period on the next day (without any infusion) was assigned as the control (Control). Blood samples were taken before the start of infusion as reference samples, and every 30 min during the following 6 h (4 h infusion and 2 h after the stop of infusion) in HyperB and on the control day, and were analyzed for glucose, BHBA, insulin, and glucagon. Plasma BHBA concentrations reached 1.7 ± 0.1 mmol/L (a.p.), and 1.6 ± 0.2 mmol/L (p.p.) in HyperB compared with 0.6 ± 0.1 mmol/L, and 0.6 ± 0.0 mmol/L in Control, respectively. The 4-h average BHBA infusion rate was 12.4 ± 1.0 and 13.3 ± 0.9 μmol/kg BW/min in wk −2 and +2, respectively ($P = 0.13$). BHBA infusion caused a decrease of plasma glucose concentrations, compared with pre-infusion levels, both before and after parturition ($P < 0.05$). The glucose response did not differ between a.p. and p.p. infusion even though basal glucose concentrations were different before and after calving (3.7 ± 0.1 vs. 3.2 ± 0.2 mmol/L, $P < 0.05$). BHBA infusion increased plasma insulin a.p. but not p.p. ($P < 0.05$) despite greater basal insulin concentrations before compared with after parturition (29.0 ± 8.4 vs. 5.8 ± 0.8 μU/mL, $P < 0.05$). Though basal glucagon concentrations were not different between wk −2 and +2 ($P = 0.30$), BHBA infusion decreased plasma glucagon only p.p. ($P < 0.05$). These findings show that effects of hyperketonemia on plasma glucose concentrations are independent of lactational stage, but endocrine adaptation to hyperketonemia differs before and after parturition. It can be assumed that BHBA has a glucose sparing effect and is a metabolic key regulator in early lactating dairy cows.

Key Words: β-hydroxybutyrate, glucagon, transition period

0866 Impact of increasing dietary crude protein content on urinary nitrogen excretion and milk nitrogen secretion of lactating sows. T. F. Pedersen[*1], C. Y. Chang[1], T. S. Bruun[2], and P. K. Theil[1], *[1]Aarhus University, Tjele, Denmark, [2]SEGES Pig Research Centre, Copenhagen, Denmark*.

The objective of the current study was to evaluate the effect of increased dietary crude protein (CP) content on urinary nitrogen (N) excretion and milk N secretion during lactation. In total, 36 sows from first to fifth parity were included in the experiment from parturition until weaning at d 28. Sows were allotted to 6 different treatments, with dietary CP contents of 149, 164, 174, 183, 193, and 208 g/kg DM, while dietary contents of SID lysine, methionine, threonine, and tryptophan were kept constant by including crystalline amino acids (AA). Sows were fed individually according to Danish recommendations, except for the recommended content of dietary CP. On d 2 postpartum, litters were equalized to 14 piglets and weighed on d 2, 10, and 17 to calculate milk production. Sows were fitted with urinary catheters on d 3, 10, and 17, and urine was collected three times during a 6-h period each week to estimate the daily urine production and N excretion. Additionally, milk samples were collected on d 3, 10, and 17 to estimate the daily secretion of N in milk. Fixed effects of week, treatment, and interaction were tested using a mixed

model. Overall, there was no effect of treatment on N content in urine ($P > 0.10$) or the amount of urine ($P > 0.10$). However, excretion of urinary N tended ($P < 0.10$) to be lowest for sows fed 164 g CP/kg DM (20.5 g N) and highest (1.5- to 1.8-fold higher) for sows fed 193 and 208 g CP/kg DM, respectively. The urinary N excretion averaged 28 g/d and did not change as lactation progressed ($P > 0.10$). Milk protein content increased with increasing dietary CP content, from 4.8 to 5.4% ($P < 0.05$). Milk production was comparable among treatments ($P = 0.09$) and ranged from 10.7 to 12.7 kg/d. The milk N secretion increased from 76 g/d on d 3 to 109 g/d on d 17, but it was not affected by dietary treatment ($P > 0.10$). In conclusion, the highest milk protein content was observed at 208 g CP/kg DM, whereas the lowest urinary N excretion was observed at 164 g CP/kg DM.

Key Words: milk protein, nitrogen loss, nutrition.

0867 Intramammary prednisolone affects the permeability of the blood-milk barrier during LPS and LTA induced mastitis in dairy cows.

S. K. Wall, L. E. Hernandez-Castellano, R. M. Bruckmaier, and O. Wellnitz*, *Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland*.

Mastitis can induce pathogen dependent changes in the permeability of the blood-milk barrier and therefore the paracellular transfer of blood and milk components. Glucocorticoids are known to increase the integrity of this barrier. The objective of this study was to examine the effect of intramammary prednisolone (PRED) on the blood-milk barrier in cows during mastitis induced by lipopolysaccharide (LPS) from *Escherichia coli* or by lipoteichoic acid (LTA) from *Staphylococcus aureus*. Thirty-one dairy cows, divided into 6 groups, were intramammarily challenged in one quarter with LPS, LTA, LPS and PRED, LTA and PRED, saline (control), or PRED. Quarters had a somatic cell count (SCC) of 60 ± 10 × 10^3 cells/mL before the experiment. The chosen doses of LPS and LTA induced a similar increase of SCC to 1420 ± 360 × 10^3 cells/mL at 4 h after challenge. Milk and blood samples were collected hourly from 0 to 8 h after challenge. Milk was analyzed for SCC, immunoglobulin (Ig) G, serum albumin (SA), and lactate dehydrogenase (LDH). Plasma was tested for the milk protein α-lactalbumin (ALA). Differences between treatments were tested by analysis of variance using a MIXED procedure and were considered significant if $P < 0.05$. The SCC in milk of control quarters and quarters treated only with PRED did not change throughout the experiment. In LTA challenged quarters with additional PRED administration, there was a reduction in SCC to control quarter level, whereas in LPS treated quarters, additional PRED administration had no effect on SCC. LDH activity did not significantly increase in LTA treated quarters, but increased in LPS quarters from 27 ± 7 U/L before challenge to 404 ± 115 U/L at 6 h after challenge, and decreased to control quarter levels with additional PRED administration. For SA and IgG, only LPS quarters showed an elevation from 0.25 ± 0.07 and 0.32 ± 0.04 mg/mL to 1.34 ± 0.57 and 1.16 ± 0.52 mg/mL, respectively, at 4 h after challenge. The PRED treatment reduced both concentrations to control quarter levels. There were no differences in plasma ALA concentrations in PRED-treated cows compared to cows that received only LPS or LTA. In conclusion, the pathogen specific appearance of blood constituents in milk during mastitis demonstrates a differential activation of the blood-milk barrier. These differential effects can be influenced by intramammary administration of glucocorticoids in a pathogen specific manner.

Key Words: blood-milk barrier, endotoxin, glucocorticoid, mastitis

0868 Regulation of sterol regulatory element binding protein-1 in bovine mammary epithelial cells.

L. Chen* and B. A. Corl, *Virginia Tech, Blacksburg*.

The objective of this study was to investigate the molecular mechanisms by which nutrients regulate sterol regulatory element binding protein-1 (SREBP1) in bovine mammary epithelial cells (Mac-T). Three models were tested. First, the relationship between SREBP1 and the mechanistic target of rapamycin (mTOR) signaling was tested through mTOR activation/inhibition as well as SREBP1 knockdown by siRNA. Second, the relationship between AMPK and SREBP1 was tested in t10,c12-CLA-treated Mac-T cells. Third, the activation of SREBP1 was tested by glucose supplementation. Results showed that mTOR activation increased SREBP1 protein as well as the lipogenic gene expression by over 50%. While inhibition on mTOR failed to increase SREBP1, siRNA-directed SREBP1 knockdown confirmed that insulin enhanced lipogenic gene transcription through SREBP1. Further examination found that mTOR signaling regulates SREBP1 by preventing its proteosomal degradation. t10,c12-CLA decreased SREBP1 protein and lipogenic gene expression through phosphorylation of AMPK, while inhibition of AMPK phosphorylation partially rescued the SREBP1 reduction. Lastly, low glucose (1 mmol/L) was able to increase mature SREBP1 level by 2.2-fold. Increasing glucose concentration increased SREBP-cleavage activating protein, a key regulator of SREBP1 activation, in a dosage- and time-dependent manner. In conclusion, these results showed that major cellular metabolic regulators play roles in SREBP1 activation and degradation thus regulating lipogenesis in response to the nutrients provided.

0869 Efficacy of dual X-ray absorptiometry as a means to measure mammary gland development in dairy heifer calves. A. J. Geiger*, C. L. M. Parsons, and R. M. Akers, *Virginia Tech, Blacksburg.*

A non-invasive means to assess mammary gland growth in dairy heifers is highly desirable from a research and animal welfare standpoint. We evaluated dual X-ray absorptiometry (DXA) as such a tool. Thirty-six Holstein heifer calves were reared on: 1) a control milk replacer (MR) fed at 454 g powder/d (CTL; 20% crude protein [CP], 20% fat), or 2) an enhanced MR fed at 1135 g powder/d (E; 28% CP, 25% fat). The MR was fed for 8 full weeks with weaning (half milk intake) occurring during the last week. Starter feed was offered after week 4 but was balanced between treatments. At weaning, a subset of calves were sacrificed ($n = 6$/diet). Remaining calves received estradiol (E_2) implants and were sacrificed at week 10. The 4 treatments were: 1) CTL, 2) CTL + E_2 (CTL-E2), 3) E, and 4) E + E_2(E-E2). After sacrifice, udders were removed and half-udders were snap-frozen. Frozen mammary glands were scanned and lipid and lean tissue contents were determined with and without the skin intact. Correlations were calculated between mammary gland lipid content via DXA, and biochemical extraction using PROC CORR function in SAS. Correlations were also calculated between mammary gland DXA lean tissue values and mammary parenchyma weight and DNA content. Correlations with skin removed were slightly higher. Overall, lipid content of the mammary gland as determined by DXA was highly correlated with lipid content determined biochemically, regardless of skin presence ($r = 0.92$; $P < 0.01$ for skin intact; $r = 0.94$; $P < 0.01$ for skin removed). With one exception, correlations were similar within treatments ($r = 0.59$, 0.91, 0.94, 0.91, and 0.96, 0.93, 0.97, 0.92 for treatments CTL, CTL-E2, E, and E-E2 with and without skin, respectively; $P < 0.01$ for all except for CTL with skin intact [$P = 0.16$]). Correlations between mammary gland lean tissue content determined by DXA and dissected parenchyma weight ($r = -0.01$; $P = 0.94$) or parenchyma DNA content ($r = 0.22$; $P = 0.21$) were low and nonsignificant. Results indicate that DXA analysis can be used to evaluate fat content of the mammary gland in young heifers but not the mass of mammary parenchymal tissue. It remains to be determined if this technology can be used in intact animals.

Key Words: calf, dual X-ray absorptiometry, mammary gland

0870 Percentages of milk fat, lactose, and protein are affected by diurnal variations in dairy goats. F. Rosa*[1], J. S. Osorio[1], J. Lohakare[1], M. Moridi[2], A. Ferrari[3], E. Trevisi[3], and M. Bionaz[1], *[1]Department of Animal and Rangeland Sciences, Oregon State University, Corvallis, [2]University of Guilan, Rasht, Islamic Republic of Iran, [3]Universita Cattolica del Sacro Cuore, Piacenza, Italy*.

Diurnal variations in milk synthesis in dairy goats are not known but can have important implications for nutrigenomic interventions to improve milk synthesis. The diurnal variation in milk synthesis was evaluated in 12 *Saanen* multiparous goats in early to mid-lactation. Six goats were treated with an intrajugular injection of 2,4-thiazolidinedione (TZD) at 1000 h, and 6 control goats received saline. Goats received an NRC-compliant diet at 0800 h. All goats received an intramammary infusion with *Streptococcus uberis* 10 d before the onset of treatment to induce sub-clinical mastitis in the right half of the udder, the left half being used as control. Goats were milked every 2 h from 0700 h to 1900 h. Besides milk yield, milk samples were collected for components analysis, and jugular blood samples were collected for analysis of NEFA, triacylglycerol (TAG), urea (BUN), and glucose. Data were analyzed using a GLIMMIX procedure of SAS with time, treatment, and treatment × time as fixed effects for blood variables, with the addition of udder halves and relative interactions as fixed effects for milk variables. Goat was used as random effect. Mean separation was done using Tukey's test. The TZD injection did not affect any of the measured milk variables. SCC was not affected by time but was greater in the right vs. left udder half in both treatment groups ($P < 0.05$). Percent milk fat peaked at 0900 h (4.9%) and decreased afterward. The percentages of milk protein and milk urea (MUN) peaked at 1100 h (2.6% and 28.2 mg/dL, respectively) and the percentages of lactose (4.4%) and solid nonfat (SNF; 7.8%) peaked between 1300 h and 1500 h. None of the single blood metabolites were affected by treatment or treatment × time interaction but all were greatly affected by time ($P < 0.05$). Glucose consistently increased until 1300 h, urea reached a peak at 1100 h, NEFA decreased until 1300 h and increased afterward, and TAG consistently decreased throughout the day. The sum of TAG and NEFA, an index of available fatty acids, was affected by treatment ($P < 0.05$), with values being greater in TZD compared with the control. Significant ($P < 0.01$) positive correlations were observed between blood glucose and percent milk lactose, NEFA and SNF, TAG and SCC, and between BUN and milk fat and MUN. Negative correlations ($P < 0.05$) were observed between glucose and percent milk fat, and between TAG and SNF. This data highlights the diurnal variations occurring in milk synthesis in goats, suggesting that synthesis of milk fat is not exclusively driven by the availability of fatty acids.

Key Words: diurnal variations, goat, milk synthesis

0871 Comparative effect of two commercial preparations of bovine somatotropin on milk yield and overall performance in Chilean dairy cows. M. A. Barrios[1], P. Melendez[*2], and M. Duchens[1], [1]*University of Chile, Santiago, Chile,* [2]*University of Missouri, Columbia*.

To compare the effect of two commercial preparations of bSTr available in Chile on milk production and overall performance of dairy cattle, 348 confined Holstein cows from a high-producing farm located in Casablanca, Valparaíso Region (33.31 S, 71.40 W) were used. Cows were randomly assigned from 70–76 DIM to one of two treatment groups. Group 1 (n = 161) was Boostin® (LG LifeSciences, South Korea) and Group 2 (n = 187) was Lactotropin® (Elanco, USA). In both groups, the hormone was administered every 14 d to about 30 d before dry off. Information was obtained from computerized systems and collected until the end of the eighth cycle of treatment (approximately 180 DIM). Milk data was processed through a repeated measures ANOVA. Fertility was analyzed by logistic regression to evaluate the risk of pregnancy at first insemination. Days open were analyzed with Kaplan-Meier survival analysis to compare days at pregnancy. Frequencies of clinical mastitis were analyzed by logistic regression. Monthly SCC linear scores were analyzed using repeated measures ANOVA. Finally, culling rate was assessed by a Kaplan-Meier survival analysis. No significant differences in the interaction of time by treatment were observed for milk yield (P = 0.07), averaging 42.3 L/d for Lactotropin®, and 42.8 L/day for Boostin®. No significant differences on calving-to-conception interval were recorded during the first 180 d of lactation (P = 0.19), showing a median of 101 d in Lactotropin® group and 90 d in cows treated with Boostin®. Conception rate at first insemination was 40% in cows treated with Boostin® and 32.8% in cows treated with Lactotropin® (P = 0.16). Cows treated with Lactotropin® have a higher incidence of clinical mastitis (33.5%) compared to Boostin® cows (21.1%) (P < 0.01). However, no significant differences were observed in SCC between groups. Finally, treatment has no effect on culling rate (P = 0.78). In conclusion, there are no substantial differences between hormone preparations regarding milk production, udder health, and fertility in high-producing Holstein cows.

Key Words: bST, fertility, mastitis, milk yield

LIVESTOCK WATER SYMPOSIUM

0872 Understanding blue and green water for feed production in animal agriculture. J. G. Warren*, *Oklahoma State University, Stillwater*.

Increasing demand for animal protein combined with concern about water scarcity demands thoughtful considerations of the water footprint of animal agriculture. This water footprint can be discussed in the context of green water, which is rainfall that does not become runoff, and blue water, which is surface or groundwater that is consumed as a result of the animal production system. Much of the green and blue water utilized by animal agriculture provides for the production of grain and forages. As such, the type of feed utilized by specific animal production systems can dramatically influence the water footprint of the system. Grazing systems will generally result in larger water footprints than grain-based production systems because the higher quality grain-based systems provide for more gain per unit of water used. However, this reduced water footprint comes with increased environmental impacts such as erosion and offsite nutrient losses from the grain production systems. Furthermore, pasture-based systems overwhelmingly utilize green water, which would likely be consumed at similar rates if the pasture was used for meat production or wildlife habitat. Lastly, regional differences in soil type, rainfall distribution, and atmospheric water demand (evapotranspiration) also influence the water footprint of animal agriculture by impacting crop water use efficiency.

Key Words: life cycle analysis, groundwater, feed production

0873 Mineral balances including TMR, drinking water and assay minerals in the milk. A. R. Castillo*, *UC Cooperative Extension, Merced, CA*.

Drinking water for dairy animals or manure for soil applications can be both a source of mineral nutrients and toxic substances. Commercial dairy production systems (grazing or indoors) are evolving to a larger scale, with more cows per farm and milk production per cow. Including assayed concentrations of minerals in the diet, drinking water and milk could improve the accuracy of calculations of herd or pen mineral balances. The aim of this presentation is to discuss mineral contents in TMR, water, and milk on mineral balances and excretion in lactating dairy cows. A mineral balance study in California on 40 dairies with low total salts (TS) drinking water for lactating dairy animals (0.2 to 1.5 g TS/L) was performed to compare TMR mineral content with the NRC requirement, with and without including minerals in drinking water, and the average NRC values for milk mineral concentrations to assayed minerals in the bulk tank milk. Most TMR minerals were in excess of NRC requirements. When including minerals in drinking water, Mg, Na, Cl, S, and Cu increased TMR median mineral contents by about 5% (ranging from 3.6% for S to 7% for Na). The assayed values of minerals in milk were lower than NRC averages (i.e., Mg, 49%; Na, 58%; Cu, 295%; and Fe, 525%). Estimated excretions of minerals via manure varied substantially across farms. Farms in the 10th percentile had estimated mineral excretions via manure 2 to 3 times less than those in the 90th. For example, daily K median excretion was 321 g/cow, from 240 (10th) to 425 g/cow (90th

percentile), daily Na excretion varied from 69 (10th) to 168 g/cow (90th percentile) with a median of almost 100 g. Median Cu and Zn excretions were 417 and 1700 mg/cow per day, but Cu excretion increased more than 3 times and Zn more than 2.5 times from the 10th to 90th percentiles. Estimates of dairy farm mineral balances should be based on assayed mineral concentrations in dietary ingredients, drinking water, and milk. Accurate estimates of mineral balance can then be used to manage excess minerals (diet and manure) and improve animal mineral nutrition, nutrient management plans, and soil mineral nutrition.

Key Words: dairy sustainability, dairy cows, drinking water, mineral balances

0874 Water: The frequently neglected nutrient in growing and finishing diets. J. J. Wagner* and T. E. Engle, *Colorado State University, Fort Collins*.

The objective of this presentation is to describe water requirements of feedlot cattle and to discuss the effects of water sulfate concentration on water intake (WI). The Recommended Nutrient Allowances for Beef Cattle report was published by the National Research Council (NRC) in 1945 and was revised in 1950, 1958, 1963, 1976, 1984, and 1996 (update 2000). Water requirements were first described in the 1976 NRC and warranted a separate chapter in 1984. However, in the much aligned 1996 (update 2000) NRC report, the discussion of water was relegated to a section in the vitamin chapter. The findings of Winchester and Morris (1956), describing WI as a function of BW, DMI, and ambient temperature, were used as the basis of the water discussion in the 1976, 1984, and 1996 (update 2000) NRC publications. Also included in the 1996 (update 2000) revision was discussion of an equation predicting WI by feedlot cattle based on maximum daily temperature (Tmax), DMI, precipitation, and dietary salt concentration (Hicks et al., 1988). Arias and Mader (2011) developed models predicting WI from several environmental measurements. Solar radiation (SR, W/m^2) and thermal heat index (THI; Thom, 1959; NOAA, 1976) were the most important factors predicting WI during summer; however, Tmax and THI were the best predictors of WI during winter. Sexson et al. (2012), using a univariate analysis, found that WI from April through October was positively related to all measures of temperature, negatively related to all measures of relative humidity, positively related to wind velocity, negatively related to sea level barometric pressure, positively related to DMI, and negatively related to BW. A multivariate model predicting WI accounted for 32% of the variation in WI. Loneragan et al. (2001) and Sexson et al. (2010) demonstrated reduced WI for steers consuming water with >1000 mg/L sulfate as compared to steers consuming water with <1000 mg/L sulfate. The observed reduction in WI associated with increased sulfate concentration was greater during summer months as compared with spring or fall. Water is described in a separate chapter in the recently released Nutrient Requirements of Beef Cattle, Eighth Revised Edition (National Academies of Sciences, Engineering, and Medicine, 2016). Equations predicting WI in the eighth revised edition were developed using surface regression of the tabular values published by Winchester and Morris (1956) and include current effective temperature index, as computed from temperature, relative humidity, wind speed, and hours of daylight.

Key Words: water intake, water sulfate concentration, feedlot cattle

0875 Simultaneous monitoring of water consumption in eight double pens as a tool for improving welfare and predicting diseases and unwanted behavioral changes in finisher pigs. K. N. Dominiak*[1], L. J. Pedersen[2], and A. R. Kristensen[1], [1]*University of Copenhagen, Department of Large Animal Sciences, Frederiksberg, Denmark,* [2]*Aarhus University, Department of Animal Science Behavior and Stress Biology, Aarhus, Denmark*.

Increasing animal welfare and heightening the level of management by sensor-based monitoring of water consumption in finisher pigs are the overall objectives of this study. It has previously been shown that water monitoring can be used to predict outbreaks of diarrhea in weaner pigs at the section level, and diarrhea or unwanted behavioral changes in finisher pigs at the double-pen level. A double pen is defined as two neighboring pens getting their water supply from the same pipe on which the sensor is placed. In this study the hourly water consumption was measured in a commercial farm by water flow sensors in eight double pens each containing 36 finisher pigs and distributed with two in each of four sections. The eight individual time series are modeled simultaneously in one dynamic linear model (DLM), and variance components are estimated by an EM-algorithm. Insertion dates are not synchronized but follow the production cycle, demanding the DLM to handle a varying number of time series at any given time. The diurnal drinking pattern is described by a combination of three harmonic waves (24 h, 12 h, and 8 h wavelength) as well as underlying levels and trends for herd, sections, and double pens. Preliminary results indicate a strong correlation between double pens in the same section as well as some pen-specific effects. In this study simultaneous monitoring is used to detect diseases (diarrhea, influenza, and respiratory diseases), as well as the unwanted behavioral changes preceding outbreaks of tail bite and fouling. Early warnings can be generated either independently at the double-pen level or merged at the section level or herd level. This quality can be used as a prioritizing tool minimizing the occurrence of false positive alarms if the warning pattern is highly different from what can be expected based on knowledge of the specific disease or behavioral change. This study is a part of an ongoing project aiming to improve the welfare and productivity of

growing pigs using advanced ICT methods.

Key Words: sensor-based, early warning, dynamic linear model

0876 Growth and health performance of dairy calves drinking reverse osmosis water compared to municipal water. N. D. Senevirathne*, J. L. Anderson, and M. Rovai, *Dairy Science Department, South Dakota State University, Brookings*.

Our objective was to determine effects of drinking reverse osmosis (RO) water versus municipal city (MC) water on growth and health performance of calves. Twenty-four Holstein calves (12 females, 12 males; 2 d old, 44.6 ± 6.10 kg BW), housed in individual hutches, were used in a 10-wk randomized complete block design study. Calves were blocked by birthdate and sex. Treatments were RO water (Culligan Water Filtration System, Brookings, SD) versus MC water (Brookings Municipal Utilities, Brookings, SD) which contained 13 and 387 mg/L total dissolved solids, respectively. Milk replacer (28% CP; 18% Fat) was fed twice daily during wk 1 through 5 and then once daily during wk 6. At each feeding, 0.45 kg of dry milk replacer was mixed with 2.8 L of respective water type, according to treatment. Calves were fed water and starter pellets ad libitum throughout the study. All intakes were recorded daily. Daily total respiratory scores (healthy ≤ 3, sick ≥ 5) were calculated from the sum of scores for rectal temperature, cough, ocular, and nasal discharge. Fecal consistency scores (0 = firm, 3 = watery) were also recorded daily. Body weights (BW) and frame growth were measured 2 d every 2 wk and jugular blood samples were collected 1 d every 2 wk at 3 h after morning feeding. Fecal grab samples were collected 5×/d for 3 d during wk 10 for analysis of total tract digestibility (TTD) of nutrients. Results were analyzed using MIXED procedures with repeated measures and Tukey's test for means comparison in SAS 9.4. Significant differences were declared at $P < 0.05$ and tendencies were declared at $0.05 \leq P < 0.10$. Total DMI and G:F increased more over time for RO than MC. Water intake was less in RO than MC, indicating more efficient water use by calves. Frame growth, BW, ADG, serum glucose, plasma urea nitrogen (PUN), β-hydroxyl butyrate (βHB), TTD of DM and CP were similar. Fecal scores tended to be less (firmer) in calves on RO, with an interaction by time. Respiratory scores had a tendency to decrease more over time when calves drank RO. Results demonstrated calves drinking RO had similar growth with improved G:F and health scores over time compared to MC.

Key Words: reverse osmosis water, growth performance, dairy calf

0877 Effect of protein supplementation on low-quality forage utilization and nitrogen balance by lambs drinking saline water. J. I. Arroquy*[1], A. Lopez[2], and A. Juarez Sequeira[3], *[1]INTACONICET–UNSE, Santiago del Estero, Argentina, [2]INTA EEA Santiago del Estero, Santiago del Estero, Argentina, [3]CONICET-FAyA UNSE, Santiago del Estero, Argentina.*

The aim of this study was to access the effect of protein supplementation on intake, digestion, and N utilization in lambs fed a low-quality hay (*Panicum maximum;* 6.4% CP, 79.5% NDF, 54.3% ADF) and drinking high-salt water. Twenty Hampshire lambs ($n = 4$; 31 ± 4 kg BW) allocated to in individual cages in a ten treatments by two period (10 × 2) trial. Treatments consisted (2 × 5 factorial) of two water qualities (WQ; low salt, LS; 442 mg/L of total dissolved solids (TDS) and 108 mg/L sulfate; and high salt, HS; 8358 mg/L TDS and 6363 mg/L sulfate) and five soybean meal levels (SBM; 0, 0.25, 0.50, 0.75, and 1.00% BW/d). Supplemental SBM × WQ interactions were significant for forage OM intake (FOMI; $P = 0.04$), total OM intake (TOMI; $P = 0.04$), whereas there was only a tendency for total tract digestibility OM intake (TTDOMI; $P = 0.07$). On average, HS had lower FOMI ($P < 0.01$; 33.0 vs. 26.1 g/kg $BW^{0.75}$), TOMI ($P < 0.01$; 42.2 vs. 35.3 g/kg $BW^{0.75}$), and TTDOMI ($P = 0.01$; 23.6 vs. 21.3 g/kg $BW^{0.75}$) than LS, while SBM levels did not significantly affect FOMI ($P = 0.86$) and TOMI ($P = 0.25$). In contrast, TTDOMI linearly increased in response to SBM ($P < 0.01$). There was no SBM × WQ interaction for water intake ($P = 0.60$), which tended to respond to SBM levels ($P = 0.07$) in linear fashion

($P < 0.01$), but was not affected by WQ ($P = 0.39$). There was no SBM × WQ interaction for total tract OM digestibility (TTOMD; $P = 0.69$). SBM linearly increased TTOMD ($P < 0.01$), and LS had lower TTOMD than HS ($P < 0.01$; 55.4 vs. 59.3% for LS and HS, respectively). Nitrogen balance was not affected by SBM × WQ interaction ($P > 0.12$), but N utilization (N-retained/N-intake ratio; $P < 0.01$) was. Regardless of WQ, we observed that SBM exerted a quadratic and linear response for N utilization ($P = 0.01$) and balance ($P < 0.01$). In LS, N balance and N utilization became positive at 0.25% of SBM, but in HS were positive only at the two greatest level of SBM (0.75 and 1.00%). In conclusion, according to our results lambs fed low-quality forage require greater levels of protein supplementation to maximize total digestible OM intake, N balance, and N utilization when they drink high-salt water compared to those drinking low-salt water.

Key Words: nitrogen balance, supplementation, saline water

MEAT SCIENCE AND MUSCLE BIOLOGY

0878 Chemical composition and expression of genes involved in lipid metabolism in the muscle of Nellore and Angus young bulls fed whole shelled corn diet.

M. M. Ladeira*[1], P. D. Teixeira[1], M. P. Gionbelli[1], M. L. Chizzotti[2], J. R. R. Carvalho[1], D. M. Oliveira[1], and T. C. Coelho[1], [1]*Universidade Federal de Lavras, Lavras, Brazil,* [2]*Universidade Federal de Viçosa, Viçosa, Brazil*.

The objective was to evaluate expression of genes involved in lipid metabolism and chemical composition of *longissimus dorsi* (LD) muscle of Nellore and Angus bulls fed whole shelled corn (WSC) or a ground corn (GC) diet. Twenty-eight bulls with average initial body weight of 378 ± 8.7 kg were used in a completely randomized design and arranged as a 2 × 2 factorial (2 breeds and 2 diets). The GC diet had 30% corn silage and 70% of a concentrate based on corn and soybean meal. The WSC diet had 85% whole shelled corn and 15% of a pellet based on soybean meal and minerals. After being harvested, samples were taken from the LD muscle between the 12th and 13th ribs for centesimal composition analyses and gene expression, which was analyzed by RT-qPCR. The model included the fixed effects of breed, diet, and their interaction. Expression of *PPARA* was greater in the LD of Nellore bulls (Table 1; $P < 0.01$) and also when bulls were fed the WSC diet ($P = 0.04$). Opposite results were found for *SREBF1* expression, which was less when bulls were fed the WSC diet ($P < 0.01$) and less in Nellore bulls ($P = 0.03$). *PPARG* and carnitine palmitoyl transferase 2 (*CPT2*) expression was downregulated in the LD muscle of Nellore bulls fed WSC and upregulated in the LD of Angus fed the same diet. Expression of lipoprotein lipase (*LPL*), fatty acid binding protein 4 (*FABP4*), acetyl CoA carboxylase (*ACACA*), and stearoyl-CoA desaturase (*SCD1*) was greater ($P < 0.05$) in the LD of Nellore bulls fed the GC diet. However, diets did not affect the expression of these genes in the LD muscle of Angus bulls. Fatty acid synthase (*FASN*) expression was greater in the LD of Nellore bulls ($P < 0.01$) and when animals were fed WSC ($P < 0.01$). Expression of acyl-coenzyme A oxidase 1 (*ACOX*) was greater for Angus fed WSC ($P = 0.04$). Meat from Angus bulls had greater intramuscular fat than meat from Nellore bulls (4.95 and 4.30; $P = 0.05$). However, there was no effect ($P > 0.05$) of diet on intramuscular fat. Moisture and protein were not affected ($P > 0.05$) by diet and breed. In conclusion, expression of *PPARA* and *SREBF1* have opposite regulation mechanisms in bovine muscle, regardless of the subspecies. Diets affected the expression of some genes involved in lipid metabolism differently in Nellore and Angus bulls.

Key Words: lipogenesis, marbling, *PPAR*, *SREBF1*, transcription factor

0879 Effects of arachidonic acid and prostaglandins on proliferation, differentiation, and fusion of bovine myoblasts. X. Leng* and H. Jiang, *Department of Animal and Poultry Sciences, Virginia Tech, Blacksburg*.

Arachidonic acid (AA) is a major lipid component of the plasma membrane and the precursor of prostaglandins (PG) in skeletal muscle. The objective of this study was to determine the effects of AA and its major PG derivatives PGE_2, $PGF_{2\alpha}$, and PGI_2 on the proliferation, differentiation, and fusion of bovine myoblasts. Satellite cells were isolated from 6 Angus or Angus crossbred steers (experimental unit) and were expanded as myoblasts in growth medium for a week before being used in the following tests. In the proliferation test, myoblasts were cultured in growth medium with 10 μM AA, 1 μM PGE_2, 1 μM $PGF_{2\alpha}$, 1 μM PGI_2, or vehicle control for 24 h. Proliferating cells were identified by EdU labeling. This test revealed that AA, PGE_2, $PGF_{2\alpha}$, and PGI_2 each increased the number of proliferating myoblasts by 13%, 24%, 16%, and 16%, respectively, compared to the control ($P < 0.05$). In the differentiation and fusion test, myoblasts were induced to differentiate and fuse into myotubes in the presence of the aforementioned treatments or control, for 24, 48, and 72 h. The differentiation status of myoblasts was assessed by reverse transcription-quantitative PCR of myogenin (*MYOG*), myosin heavy chain 3 (*MYH3*), and muscle creatine kinase (*CKM*) mRNAs, which are markers of differentiated myoblasts. The fusion level of myoblasts was estimated by calculating the percentage of nuclei located in myotubes, i.e., fusion index. Compared to the control, AA increased *MYOG* mRNA expression at 24 and 48 h, *MYH3* mRNA expression at 24 and 48 h, and *CKM* mRNA expression at 24, 48, and 72 h of differentiation ($P < 0.05$); PGE_2 increased *MYOG* mRNA expression at 24 and 72 h, and *MYH3* mRNA expression at 72 h of differentiation ($P < 0.05$); $PGF_{2\alpha}$ increased *CKM* mRNA expression at 72 h of differentiation ($P < 0.05$); and PGI_2 had no effect on mRNA expression of any of the three markers at any of the three times of differentiation. Compared to the control, PGE_2 increased the fusion index by 14% ($P < 0.05$) but the remaining treatments had no effect on this index. In conclusion, this study demonstrates that AA, PGE_2, $PGF_{2\alpha}$, and PGI_2 stimulate the proliferation, that AA and PGE_2 stimulate the differentiation, and that PGE_2 stimulates the fusion of bovine myoblasts in vitro.

Key Words: cattle, myoblasts, prostaglandins

0880 Influence of zinc amino acid complex and ractopamine hydrochloride supplementation on the sarcoplasmic protein profile of finishing steers. O. N. Genther-Schroeder*[1], E. Huff-Lonergan[1], M. E. Branine[2], and S. L. Hansen[1], [1]*Iowa State University, Ames,* [2]*Zinpro Corporation, Eden Prairie, MN*.

The objective of this study was to determine if Zn amino acid complex (ZnAA) and ractopamine hydrochloride (RH) supplementation affect the protein profile of the *longissimus dorsi* muscle of finishing steers. Twenty-four steers (477 ± 5.3 kg; SD) were fed a corn-based finishing diet in pens equipped with GrowSafe bunks to measure individual intake, as a part of a 2 × 2 factorial of ZnAA and RAC supplementation. All steers were supplemented with 60 mg Zn/kg diet DM as $ZnSO_4$ and were assigned to receive either 0 (CON) or 60 mg supplemental Zn/kg DM from ZnAA (ZN; $n = 12$ steers per treatment) for 56 d. On d 56 steers were equally assigned within treatments to receive RH at 300 mg·steer^{-1}·d^{-1} for 0 (NoRAC) or 28 d (RAC) before harvest ($n = 6$ steers per treatment). Muscle biopsies were collected from steers after 14 d of RAC supplementation. Four steers per treatment were selected to have sarcoplasmic extracts from muscle biopsy samples analyzed using 2D Difference-in-Gel Electrophoresis (2D-DIGE). Separate 2D-DIGE experiments were performed for the individual comparisons of CON+NoRAC vs. ZN+RAC (Exp. 1; $n = 4$ per treatment) to evaluate the effect of both RAC and ZnAA supplementation and CON+RAC vs. ZN+RAC (Exp. 2; $n = 4$ per treatment) to evaluate the effect of ZnAA supplementation within RH-fed steers. Proteins were selected based on relative abundance and were identified using mass spectrometry. In Exp. 1, abundance of isoforms of pyruvate kinase was decreased 20–25% ($P \leq 0.04$) in ZN+RAC, relative to CON+NoRAC steers. Phosphoglucomutase-1 abundance was decreased by 63% ($P < 0.0001$), phosphoglycerate mutase-2 was decreased by 21% ($P = 0.02$), and glyceraldehyde 3-phosphate dehydrogenase tended to be increased by 71% ($P = 0.06$) in ZN+RAC steers, relative to CON+NoRAC. In Exp. 2, phosphoglucomutase-1 abundance tended to be decreased by 60% ($P = 0.09$) and phosphoglycerate mutase-2 tended to be decreased 21% ($P = 0.06$) in ZN+RAC steers relative to CON+RAC steers. Decreases in phosphoglucomutase-1 and phosphoglycerate mutase-2 abundance in both experiments suggest these may be effects elicited by ZnAA supplementation. Changes in abundance of pyruvate kinase and glyceraldehyde 3-phosphate dehydrogenase were found only in the CON+NoRAC vs. ZN+RAC comparison and might be elicited by RH supplementation. These differences indicate that ZnAA and RH supplementation alter the protein abundance of enzymes involved in carbohydrate metabolism in skeletal muscle.

Key Words: ractopamine hydrochloride, zinc, 2D-DIGE

0881 Survey of attitudes for millennials who do not consume lamb. K. R. Wall[*1] and C. R. Kerth[2], *[1]Texas A&M University, College Station, [2]Texas A&M University Animal Science Department, College Station.*

Lamb consumption consists of the smallest percentage of red meat consumption in America. Our objective was to estimate how many Americans do not consume lamb and describe attitudes as to why not. The online survey consisted of demographic information and lamb consumption patterns and experiences. Participants were invited to complete the survey if they were within the millennial population (ages 18–34) and residing in the U.S. Participants (n = 2473) were 34.5% male, 65.5% female; 15.9% were ages 18–24, 83.2% were 25–34, and 0.9% were 35; 85.0% were Caucasian (non -Hispanic), 8.8% Latino or Hispanic, 3.0% Asian or Pacific Islander, 1.3% African American, and 1.8% other. Household income was 7.4% $24,999 or less, 17.9% $25,000–49,999, 20.8% $50,000–74,999, 19.5% $75,000–99,999, and 36.4% made $100,000 or more; 10.3% were not employed, 9.6% were employed part-time, and 80.0% were full-time. Participants reported consumption of the following protein sources either away from or at home: 92.3% chicken, 88.8% beef, 79.0% pork, 79.8% fish, 11% lamb, 92.6% eggs, and 25.8% soy-based products. 70.8% of the participants claimed to have eaten lamb before, and of these participants (n = 1719), 70.8% selected having a positive eating experience with lamb. Although 47.2% of the participants were uncertain how the lamb was prepared, braising (19.1%), grilling outside (12.5%), and panfrying (8.6%) were the most common methods of preparation. 65.1% of the participants would be willing to try lamb again, 23.2% selected maybe, and 11.6% would not be willing to try lamb again. Of the participants who had not tried lamb before (n = 716), 60.8% would be willing to try lamb. If lamb flavor were to be improved, 22.4% of the participants would definitely and 47.1% might consume more lamb. If lamb tenderness were to be improved, 23.7% of the participants would definitely and 44.8% might consume more lamb. If the eating quality of lamb were to be more consistent, 24.8% of the participants would definitely and 43.8% might consume more lamb. If lamb were to be implemented into the fast-food industry, 22.1% of the participants would definitely and only 22.8% might consume more lamb. While 72.8% of the participants selected they had never looked to buy lamb at their local grocery store, 14.4% selected lamb is hard to find and 5.1% selected finding lamb was hit or miss. Opportunities exist to increase the consumption of lamb by converting the millennial non-consumers of lamb.

Key Words: lamb, millennial, consumer

0882 Survey of attitudes for millennial lamb consumers. K. R. Wall[*1] and C. R. Kerth[2], *[1]Texas A&M University, College Station, [2]Texas A&M University Animal Science Department, College Station*.

As the interest in experiencing different foods increases among the millennial population, lamb consumption may be becoming more prominent. Our objective was to determine the attitudes of millennial consumers of lamb products by conducting an online survey. Participants were selected within the millennial population (ages 18–34) and residing in the U.S. Participants (n = 3292) reported consumption of the following protein sources either away from or at home: 99.4% chicken, 97.3% beef, 90.9% pork, 93.0% fish, 77.9% lamb, 96.9% eggs, and 35.5% soy-based products. 15.0% of participants eat lamb frequently (at least once every 2 wk), 24.1% eat lamb once a year, 30.0% eat lamb once every 6 mo, 31.0% eat lamb once every 3 mo. Participants reported eating lamb most frequently in the winter (December–February) at 35.0%, and 22.0% consume the most lamb in the month of December. When asked where consumers consume the most lamb, 66.0% responded away from home, and 23.0% responded at home. On a 5-point scale, 90.0% selected their experience consuming lamb has been "excellent" or "good," and 92.0% answered being satisfied with the eating quality of lamb at least 3 out 5 times. Only 34.0% of the consumers reported growing up eating lamb, and 94.0% selected having a positive first experience consuming lamb. Consumers declared choosing lamb over other protein sources 63.0% of the time due to flavor. When asked what origin of lamb consumers preferred, 78.0% selected no preference and only 11.0% selected American lamb. Consumers were prompted to distinguish between lamb and mutton, and 56.0% were "uncertain, they never tried both," whereas 33.0% selected that there are distinct differences. If lamb flavor were to be improved, 34.0% of the participants would definitely and 48.0% might consume more lamb. If lamb tenderness were to be improved, 35.0% of the participants would definitely and 46.0% might consume more lamb. If the eating quality of lamb were to be more consistent, 39.0% of the participants would definitely and 42.0% might consume more lamb. If lamb were to be implemented into the fast-food industry, 36.0% of the participants would definitely and 32.0% might consume more lamb. While 56.0% of the participants selected they had never looked to buy lamb at their local grocery store, 44.0% selected lamb is hard to find or that it was hit or miss. These data can be used to increase consumption among the millennial population.

Key Words: lamb

0883 A histologic and ultrastructural study of Wooden Breast Disease in modern broiler chickens.

M. P. Babak, E. M. Brannick, C. J. Schmidt, and B. Abasht*, *Department of Animal and Food Sciences, University of Delaware, Newark.*

Wooden Breast Disease (WBD) is a novel muscle disorder in the poultry industry observed to frequently affect the breast muscles of high-yielding modern broilers. Characterized by extreme stiffening of the breast muscles on palpation of the pectoral region, WBD is known to result in significant economic loss in the poultry industry and may potentially cause behavioral alterations and reduced welfare in birds. To examine tissue changes associated with onset and pathogenesis of this disorder, a time-series experiment was conducted using chickens from a high-breast-muscle-yield, purebred commercial broiler line. Birds were raised for a period of 6 wk, and breast muscles sampled on a weekly basis from selected birds and processed for light and transmission electron microscopy. Histologic presentation indicated presence of focal single-myofiber degeneration and hyalinization in the second week, preceding inflammatory reaction that started in the third week. Lesions in the fourth week were generally characterized by multifocal to diffuse muscle fiber degeneration and necrosis accompanied by increased inflammatory cell infiltration. Lesions in the fifth and sixth week were characterized by diffuse muscle fiber damage, fibrosis, fatty infiltration including granulomatous tissue encompassing lipid droplets, and irregular myofiber regeneration. Ultrastructural examination showed fibrosis with dense regular collagen fibers, irregular Z-discs, myofibril splitting, displacement, and degeneration, including mitochondrial degeneration. This study therefore demonstrates that WBD exhibits an early onset in modern broilers and appears to assume a progressive course with acute inflammatory phase occurring in the earlier stages and chronic inflammation and fibrosis in the later stages of the disease course.

Key Words: broiler chickens, Wooden Breast Disease, transmission electron microscopy

0884 High-energy forage and feedlot finishing impact on beef consumer acceptability and sensory characteristics in the upper Midwest.

R. M. Martin*[1], J. E. Rowntree[1], J. P. Schweihofer[2], J. B. Harte[1], and A. M. Merwin[1], *[1]Michigan State University, East Lansing, [2]Michigan State University Extension, Bad Axe*.

The objective of this study was to determine consumer acceptability and sensory attributes of beef longissimus thoracis steaks from finishing steers grazing high-energy forages vs. fed a conventional feedlot diet. Steaks were from 32 steers fed 1 of 4 treatment diets including: mixed pasture (MIX); simple cereal grain/brassica mixture (SIMP); complex cereal grain/brassica mixture; and conventional feedlot ration (FLOT). All steers grazed a perennial mixed pasture diet before being assigned a treatment. Steers (n = 8) were fed FLOT diet for 92 d. Steers in the MIX (n = 8), SIMP (n = 8), and COMP (n = 8) grazed respective pastures for 76 d. Steers from all treatments were slaughtered on the same day. Carcasses were aged 7 d before fabricating 2.54-cm thick steaks. Vacuum packaged steaks were aged for an additional 7 d and frozen (−20°C) until evaluation for marbling score, instrumental color, pH, and Warner Bratzler shear force. Consumer panelists (n = 106) evaluated fresh steaks aged 15 d for flavor, texture and firmness, juiciness, and overall acceptability using a 9 point hedonic scale (1 = dislike extremely, 9 = like extremely). Data were analyzed with Proc Mixed and Proc ANOVA (SAS 9.4) for sensory characteristics and consumer acceptability, respectively. Marbling scores of steaks from FLOT steers (524.58) were greater ($P < 0.01$) compared to MIX (447.50), SIMP (437.50), and COMP (427.50) steers. There were no treatment differences ($P > 0.05$) for instrumental color, pH, and Warner Bratzler shear force. There were no correlations ($P > 0.05$) between marbling and Warner Bratzler shear force. Consumer panel results indicated that steaks from steers fed the FLOT diet had more preferable ($P < 0.05$) texture and firmness as well as overall acceptability (7.00 and 6.61) when compared to MIX (6.30 and 6.08) but were not different from COMP (6.63 and 6.21) and SIMP (6.69 and 6.51). Panelists detected no treatment differences ($P > 0.05$) in the hedonic ratings of flavor or juiciness. Results indicate that steaks from steers finished on high-energy forages are comparable to those finished on a conventional feedlot diet. Additionally, the brassica-rich forage diets did not impart any noticeable off-flavors in the steaks when compared to steaks from diets without brassicas.

Key Words: sensory, forage-finished, consumer panel

0885 Effect of growth-promoting technologies on the proteome of bovine *Longissimus lumborum*.

C. A. Hayes*[1,2], W. L. Keller[1], J. K. Grubbs[3], S. M. Lonergan[3], S. M. Ebarb[4], K. J. Phelps[4], J. S. Drouillard[4], J. M. Gonzalez[4], and K. R. Maddock-Carlin[1], *[1]North Dakota State University, Fargo, [2]Purina Animal Nutrition LLC, Gray Summit, MO, [3]Iowa State University, Ames, [4]Kansas State University, Manhattan*.

The objective of this study was to identify the extent to which the protein profile of bovine *Longissimus lumborum* (LL) muscle in beef cattle is influenced by growth-promoting technologies (GP) during the finishing period. Crossbred heifers (n = 66) from two harvest groups were fed a conventional feedlot diet, blocked by BW, and randomly assigned to 1 of 3 treatments: no GP (CON, n = 22); implant, no ractopamine hydrochloride (IMP, n = 22); and implant and ractopamine hydrochloride (COMBO, n = 22). Heifers assigned to the IMP treatment were administered an implant containing 200 mg trenbolone acetate and 20 mg estradiol on d 0 of the study, and

the COMBO group received the same implant protocol as the IMP group, in addition to being fed 400 mg·d^{-1}·heifer $^{-1}$ of ractopamine hydrochloride for the final 28 d before harvest. Heifers were harvested on d 90 of feeding, and a section of the LL was removed (n = 66) 1 h post mortem, placed on dry ice, and stored at −80°C. A subset (n = 6) from each treatment from the first harvest group was randomly selected for proteome analysis by two-dimensional difference in-gel electrophoresis (2D DIGE) coupled with mass spectrometry (MS) to identify proteins of interest. Peptide identifications with > 95% probability with at least 2 identified unique peptides were accepted. Twenty-five spots selected in the sarcoplasmic fraction corresponding to 21 proteins differed in relative abundance among growth promoting programs. Nine spots from the myofibrillar fraction corresponding to 6 proteins were also identified to be different among treatment groups. Increased abundance (P < 0.05) of identified proteins in sarcoplasmic and myofibrillar fractions of the LL muscle from heifers subjected to the COMBO treatment when compared with the LL from CON included metabolic enzymes (creatine kinase M-type, triosephosphate isomerase, β-enolase), oxidative resistant proteins (peroxiredoxin-6, peroxiredoxin-2, protein deglycase DJ-1), muscle recovery proteins (myosin binding protein H, eukaryotic translation initiation factor 5A-1), and chaperone proteins (heat shock 70 kDa protein 1A). The results demonstrate that growth promoting technologies alter the protein profile of bovine muscle and suggest several metabolic pathways that are influenced by management practices that use these technologies. These pathways include metabolic processes, oxidative stress, and apoptosis cascades that can have an impact on growth efficiencies and meat quality in beef cattle.

Key Words: bovine, muscle, proteome

0886 Effects of post-weaning exposure to a high-concentrate diet vs. pasture on live performance, carcass characteristics, and meat quality of early harvested steers.

B. M. Koch*[1], L. E. Bowen[1], J. T. Milopoulos[1], G. Volpi Lagreca[2], and S. K. Duckett[1], [1]*Clemson University, Clemson, SC,* [2]*INTA, Anguil, Argentina*.

Twenty Angus steers (261 ± 21.5 kg) were used to evaluate the effect of post-weaning feeding strategy on live performance, carcass characteristics, and meat quality. Steers were randomly assigned to one of two feeding treatments: high-concentrate based diet (cracked corn, corn silage, and soybean meal [F]) or high-quality pasture (winter annuals, alfalfa, and non-toxic fescue [P]) for 127 d. At slaughter, subcutaneous adipose tissue samples were collected from each steer and flash frozen for later analysis. The 6–12 rib section of each carcass was collected for further analysis on Day 2 post-harvest. Steers consuming a high-concentrate based diet had a greater overall ADG than P ones (1.36 vs. 0.68 kg/d; P < 0.0001) resulting in heavier final BW and HCW, and greater dressing percentage (P < 0.001). Steers consuming grain had larger ribeye area (P = 0.0006) and more fat at the 12th rib (P < 0.0001) than steers on forages, whereas there were no differences for KPH and calculated yield grade (P = 0.22). The high-concentrate based diet resulted in much greater marbling scores than grazing high-quality forages (P < 0.0001; 448 vs. 240). Despite the increased marbling, there was no difference in longissimus muscle (LM) b* (P = 0.956), whereas LM from F were brighter and more red (greater a*; P < 0.003). Both subcutaneous L* and b* were not different between treatments (P = 0.20), whereas subcutaneous a* was greater for F than P (P = 0.0018). Fat cell sizes of subcutaneous tissue were larger in perimeter and area for F (P < 0.0001) whereas P had a greater fat cell number (P < 0.0001). Steers on F had greater LM total lipid (P < 0.0001), whereas P resulted in greater moisture, nitrogen, and ash (P < 0.0001). There were no differences in SFA or PUFA n-6 in LM (P = 0.49) whereas F had greater MUFA (P = 0.0037) and P had greater PUFA and PUFA n-3 percentages (P < 0.01) resulting in a more desirable PUFA n-6/PUFA n-3 ratio (P = 0.0003; 1.46 vs. 7.35 for P and F, respectively). This suggests that exposure to high-concentrate based diets early in the finishing process results in increased performance and carcass quality, along with deposition of intramuscular adipose tissue.

Key Words: grain, pasture, meat quality

0887 Effects of post-weaning exposure to a high-concentrate diet vs. pasture on carcass ultrasound, plasma insulin and glucose, and gene expression of lipogenic enzymes of early harvested steers.

B. M. Koch*, L. E. Bowen, N. M. Long, and S. K. Duckett, *Clemson University, Clemson, SC*.

Twenty Angus steers (261 ± 21.5 kg) were used to evaluate the effect of post-weaning feeding strategy on plasma insulin and glucose levels and gene expression of lipogenic genes. Steers were randomly assigned to one of two feeding treatments: high-concentrate based diet (cracked corn, corn silage, and soybean meal [F]) or high-quality pasture (winter annuals, alfalfa, and non-toxic fescue [P]) for 127 d. Blood samples were collected at 21-d intervals. At slaughter, s.c. adipose tissue samples were collected from each steer and flash frozen in optimal cutting temperature compound for later histology. Steers consuming a high-concentrate based diet had a greater overall ADG (1.36 vs. 0.68 kg/d for F and P, respectively; P < 0.0001) resulting in heavier final BW and HCW (P < 0.001). There was an interaction of treatment and time for ultrasound ribeye area (REA) and 12th-rib fat thickness (P < 0.014) as F resulted in increased REA and fat deposition over time whereas P did not differ over time. Similarly, there was a treatment by time interaction for plasma insulin with insulin levels of steers consuming a high-concentrate based diet increasing over time while steers grazing forages did not. There was no interaction of treatment and time on glucose (P

= 0.469) whereas steers on F had greater plasma glucose than those on P ($P < 0.0001$). RefFinder was used to evaluate reference gene candidates. Thy1 was selected as the most stable reference gene. There was no difference in the expression of acetyl CoA carboxylase, elongase-6, leptin, or glucose transporter type 4 ($P > 0.14$). Fatty acid synthase and stearoyl CoA desaturase-9 were upregulated by 16- and 81-fold, respectively for steers on F when compared to P ($P < 0.002$). Additionally, steers receiving a high-concentrate based diet had a 42-fold increase in mRNA of elongase-5 compared to steers grazing high-quality forages ($P = 0.0006$) and threefold more expression of lipoprotein lipase ($P = 0.011$). Early exposure of steers post-weaning to high concentrate diets increased the ratio of insulin to glucose and marbling deposition with greater expression of lipogenic genes.

Key Words: gene expression, insulin, glucose

0888 Effects of dietary coated cysteamine hydrochloride on meat quality in finishing pigs. H. Liu[*1], M. Bai[1,2], K. Xu[1], B. Zou[3], R. Yu[3], Q. Xi[2], and Y. Yin[1,2], *[1]Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, China, [2]College of Animal Science, South China Agricultural University, Guangzhou, China, [3]King Techina Group, Hangzhou, China*.

Cysteamine is used as a feed supplement in animal production to promote growth rate and improve feed efficiency. Coated cysteamine hydrochloride (CC) target releases cysteamine in small intestine and protects gastrointestinal mucosa from oxidative damage. However, little information is known regarding the effects of CC supplementation in carcass characteristics and meat quality. The aim of present study was to investigate potential effects of cysteamine supplementation on growth performance, carcass characteristics, and meat quality in finishing pigs. A total of 144 crossbred finishing pigs (87.60 ± 0.20 kg) were assigned randomly to one of the two dietary groups, with eight pens/group (nine pigs/pen). Pigs were fed with a basal diet containing 0 (control) and 70 mg/kg CC for 29 d. The CC was supplied by King Techina Group (Hangzhou, China), containing 27% cysteamine hydrochloride. One pig from each pen was selected randomly to be killed by exsanguination after electrical stunning. A longissimus dorsi sample was collected and stored at 4°C for meat quality measurement. Muscle pH was determined by the electrometric method using a Testo 205 thermometer (Testo, Germany) at 1 h, 24 h and 48 h postmortem Meanwhile, meat color (L* = lightness, a* = redness, b* = yellowness) was measured by a chromameter at 24 h and 48 h after slaughter. The meat tenderness of the longissimus dorsi was measured with a tenderometer, and longissimus dorsi heme pigment estimation (myoglobin, oxygen-myoglobin, and metmyoglobin) was conducted based on Krzywick's method (1982). MDA was determined by commercial reagents (Nanjing Jiancheng Bioengineering Institute, Nanjing, China) according to the manufacturer's instructions. We find that dietary CC has tended to increase average daily gain and decrease feed conversion rate ($0.05 < P < 0.1$). Compared with the control diet, supplementation of CC increased carcass weight, lean rate, and eye muscle area of finishing pigs by 8.9%, 15.9%, and 11.9%, respectively. Dietary CC increased the tenderness of the longissimus dorsi significantly ($P < 0.05$). There were no significant differences in the meat color lightness and yellowness, content of oxygen-myoglobin, metmyoglobin, and MDA between groups. But the redness of meat color and the relative contents of myoglobin increased with CC supplementation ($P < 0.05$). Collectively, 70 mg/kg coated cysteamine hydrochloride diet shows a positive effect on growth performance, tenderness, and meat quality in finishing pigs; in particular, coated cysteamine hydrochloride improves the meat color by regulating the content of myoglobin in the longissimus dorsi.

Key Words: cysteamine, finishing pigs, meat quality

0889 Meat quality of lambs fed diets containing different levels of residual frying oil. M. Capelari[*1], E. L. T. Peixoto[2], E. S. Moura[3], E. L. A. Ribeiro[3], and I. Y. Mizubuti[3], *[1]Michigan State University, East Lansing, [2]Universidade Federal do Sul e Sudeste do Pará, Maraba, Brazil, [3]Universidade Estadual de Londrina, Londrina, Brazil*.

The objective of this study was to evaluate the effect of feeding different levels of residual frying oil (RFO) on meat quality traits of confined lambs. Forty growing male lambs (21.0 ± 3.4 kg initial BW) were randomly allocated to 5 pens, each representing an experimental treatments (0, 20, 40, 60, and 80 g of RFO/kg of diet DM; 8 replications per treatment) in a completely randomized block design. Animals were fed ad libitum, twice daily, a 60:40 forage-to-concentrate basal diet consisting of sorghum silage, ground corn, soybean meal, and mineral and vitamin premix and formulated to be isonitrogenous and isocaloric among treatments. After 70 d, animals reached average BW of 35 kg and were transported to a slaughterhouse. Total *Longissimus dorsi* samples were taken from all animals, subdivided into 6 equal parts and transported to the meat science laboratory of Universidade Estadual de Londrina, where they were submitted to analysis of shear force, coloration and pH, marbling, water loss by pressure, sensory analysis, and lipid oxidation. Data was tested for normal distribution and submitted to analysis of variance and regression analysis with 5% significance level. There was a linear effect of RFO inclusion on shear force (2.72 vs. 3.84 kgf for 0 and 80 g RFO/kg DM, respectively; $P < 0.01$). However, even with the increase effect on shear force with higher inclusions of RFO, in the sensory test, samples were classified as high tenderness. Lipid oxidation, color parameters and pH, chemical composition, and

sensory attributes did not differ among levels of RFO inclusion in the diet. The inclusion of RFO in lamb diets up to 80 g/Kg DM did not affect meat quality.

Key Words: shear force, *Longissimus dorsi*, lipid oxidation

0890 Sensory properties of meat of Nellore cattle fed different levels of lipid-based diets.

T. N. P. Valente*[1], E. S. Lima[2], J. P. G. Morais[3], R. O. Roça[4], and D. P. B. Costa[5], *[1]IFGOIANO, POSSE, Brazil, [2]Environmental Health, FMU, São Paulo, Brazil, [3]Agricultural Sciences Center, UFSCar, Araras, Brazil, [4]São Paulo State University (FCA/UNESP), Botucatu, Brazil, [5]IFMT, Cuiabá, Brazil*.

Use of agroindustrial by-products in the feed of animals should be analyzed for better understanding of their impacts on cattle meat quality. The objective of this study was to determine the effect of the dietary inclusion of lipid-based diets on the sensory properties. The study was performed on a farm in Aguaí, SP, Brazil. A group of 39 uncastrated Nellore cattle was enclosed in individual pens. The animals were 36 mo old, and the initial mean live weight was 494.1 ± 10.1 kg. Animals were randomly assigned to one of three treatments, based on dry matter: feed with control diet 2.50% cottonseed (CD), feed with 11.50% cottonseed (CS), and feed with 3.13% cottonseed added of 1.77% protected lipid (PL). After 63 d mean final live weight was 577.01 ± 11.34 kg. Then, part of the *M. longissimus thoracis* of each animal was removed between the 12th and 13th rib of the left half carcass. The samples steaks were 2.5 cm thick and were stored frozen in a freezer at −18°C. Sensory analysis was performed after samples were thawed in the refrigerator (± 20 h at 2.5 ± 0.5°C) and heated on automatic superposed grills. At an internal temperature of 71°C, the steak was removed from the grill and heated in a microwave oven for 30 s until the temperature reached 50°C. Immediately after, they were randomly distributed to the panelists in sterile Petri dishes codified with four-digit numbers. Sensory evaluations were conducted using 11 trained panelists. Sensory tests used a 9-point scale: aroma intensity (ranging from absent to extremely intense), strange aroma (ranging from absent, 1, to extremely strong, 9), flavor (ranging from extremely bad to extremely good), strange flavor (ranging from absent, 1, to extremely intense, 9), tenderness (ranging from extremely tender, 1, to extremely hard, 9), juiciness (ranging from extremely dry, 1, to extremely juicy, 9), color (ranging from bright cherry red to dark red), and overall appearance (ranging from very bad to very good). The intensity of the aroma (mean 5.66), strange aroma (mean 2.27), flavor (mean 6.09), strange flavor (mean 1.85), juiciness (mean 5.36), color (mean 5.60), and overall appearance (mean 6.48) were similar between treatments, except for tenderness ($P <$ 0.05) while for CD and CS mean 5.16 versus 6.36 for PL. The addition of PL in the diets of finishing cattle led to less tender meat. Acknowledgments for financial support in Brazil: IFGOIANO, FAPEG, and CNPq.

0891 Genome-wide efficient mixed-model study for meat quality in Nellore cattle.

C. E. Buss[1], P. C. Tizioto[2], P. S. N. Oliveira[3], M. A. Mudadu[4], A. S. M. Cesar[5], R. V. Ventura[6], J. Afonso[1], A. O. D. Lima[1], L. L. Coutinho[5], R. R. Tullio[3], and L. C. A. Regitano*[3], *[1]Federal University of Sao Carlos, UFSCar, Sao Carlos, Brazil, [2]Embrapa Southeast Livestock, Sao Carlos, Brazil, [3]Embrapa Southeast Livestock, Sao Carlos, Brazil, [4]Embrapa Pecuária Sudeste, São Carlos, Brazil, [5]Animal Biotechnology Laboratory-ESALQ, University of São Paulo, Piracicaba, Brazil, [6]Beef Improvement Opportunities, Guelph, ON, Canada*.

The quality of meat, which includes several traits such as tenderness, juiciness, and fat thickness, is essential for the beef industry. Previous genome-wide association studies (GWAS) using Bayesian methods have shown that Brazilian Nellore cattle have enough genetic variation for improvement of these traits. Thus, the aim of this study was to further identify quantitative trait loci (QTL) associated with meat-quality-related traits in Nellore beef cattle by using the univariate linear mixed model (LMM) approach implemented in the GEMMA software and compare it with our previous GWA studies performed using Bayesian approaches. A total of 387 Nelore steers comprising 34 half-sib families were genotyped using the IlluminaBovineHDBeadChip. We analyzed the association between markers and Warner-Bratzler shear force, backfat thickness, ribeye muscle area, scanning parameters lightness (L*), redness (a*), and yellowness (b*) to ascertain color characteristics of the meat, water-holding capacity, cooking loss, muscle pH, myofibrillar fragmentation index, saturated fat sum, omega-6 fatty acids sum, omega-3 fatty acids sum, and ethereal extract. These phenotypes were measured in the Longissimus dorsi muscle between the 11th and 13th ribs collected at slaughter. We identified fifty-three genomic regions that each contained at least one single nucleotide polymorphism (SNP) that showed a significant association with meat quality traits (1-Mb SNP windows). Highlighted, we found regions associated with three genes—neuronal growth regulator 1 (NEGR1, chr03: 70884613–71949611), dynamin 3, and phosphatidylinositol glycan anchor biosynthesis class C (DNM3/PIGC, chr16: 37340706–38007593)—related to lipid metabolism and obesity. Our results provide a better understanding of QTL regions associated with meat quality unexplored in our previous Bayesian approach.

Key Words: GWAS, Nellore, meat quality

0892 Comparison of carcass and sensory traits and contents of fatty acids and volatile compounds in Longissimus dorsi of three cattle breeds.

M. Baik*, M. Y. Piao, H. J. Lee, H. J. Kim, S. J. Park, H. J. Kang, and C. Jo, *Department of Agricultural Biotechnology, College of Agriculture and Life Sciences, Seoul National University, Seoul, The Republic of Korea*.

This study was performed to compare carcass and sensory traits, physicochemical composition, fatty acid (FA) contents, and volatile compounds in Longissimus dorsi (LD) of Korean cattle, Holstein, and American Angus. A total of 36 steer LD samples were obtained from Korean cattle (n = 12), Holstein (n = 12), and American Angus (n = 12) with quality grade (QG) 1+, QG 2, and Choice grade, respectively. Korean cattle had the highest ($P < 0.05$) contents of intramuscular fat and reducing sugar but the lowest ($P < 0.05$) shear force values. Korean cattle revealed the highest ($P < 0.05$) sensory traits (flavor, tenderness, juiciness, and overall acceptance), and these traits were positively correlated with fat ($0.95 \leq r \leq 0.99$; $P < 0.001$) and reducing sugar contents ($0.55 \leq r \leq 0.63$; $P < 0.001$). Korean cattle had the highest ($P < 0.05$) contents (g/100 g LD) of most of the FAs, including palmitic acid, stearic acid, oleic acid, saturated fatty acids, monounsaturated fatty acids, and unsaturated fatty acids, and these FA contents were positively correlated ($0.65 \leq r \leq 0.78$; $P < 0.001$) with all sensory traits. Korean cattle had the highest ($P < 0.05$) concentrations of several volatile compounds, including acetaldehyde, 2-methyl butanal, 3-methyl butanal, 2,3-butanedione, and 3-hydroxy-2-butanone, and these compounds were positively correlated ($0.56 \leq r \leq 0.81$; $P < 0.001$) with all sensory traits, whereas Angus had the highest ($P < 0.05$) concentrations of pentanal, hexanal, and n-pentane. In conclusion, the LD contents of fat, reducing sugar, and FAs, the concentrations of LD volatile compounds, and sensory traits varied among breeds of cattle. Sensory traits had positive correlations with contents of fat, reducing sugars, and most of the FAs, and these showed positive or negative correlations with several volatile compounds.

Key Words: cattle breed, reducing sugar, volatile compound

0893 Label-free MS^E proteomic analysis of the bovine skeletal muscle: New approach for meat tenderness evaluation.

M. D. Poleti*[1], R. C. Simas[1,2], A. S. M. Cesar[1], S. C. S. Andrade[3], G. H. M. F. Souza[4], L. C. Cameron[5], L. C. A. Regitano[6], and L. L. Coutinho[1], *[1]Animal Biotechnology Laboratory, ESALQ, University of São Paulo, Piracicaba, Brazil, [2]Thomson Mass Spectrometry Laboratory, UNICAMP, Campinas, Brazil, [3]Genetics and Evolutionary Biology Department, IB, University of São Paulo, São Paulo, Brazil, [4]Waters Corporation, São Paulo, Brazil, [5]Laboratory of Protein Biochemistry, Federal University of State of Rio de Janeiro, Rio de Janeiro, Brazil, [6]Embrapa Southeast Livestock, São Carlos, Brazil*.

Meat tenderness is an important trait for beef consumer satisfaction and presents a large individual variation among animals. Meat from Nellore cattle is less tender, resulting in lower economic value. Although many biochemical factors associated with meat tenderness have been studied, the alterations in the muscle proteome profile that reflect the biological complexity of the tenderness process remain unclear. The aim of this study was to investigate pathways and biological mechanisms associated with meat tenderness in one Nellore steer population using label-free proteomic approach by high definition mass spectrometry with HDMS^E acquisition. We evaluated differential protein expression in the *Longissimus dorsi* muscle, collected at 20 min. postmortem, from 10 animals with lower and 10 with higher values of shear force at the seventh day postmortem. The proteome analysis was performed using the nanoACQUITY UPLC Synapt HDMS G2-S system (Waters, Manchester, UK), and the data were processed using Waters Progenesis QI for proteomics software. A Nellore transcriptome database build from RNaseq data from the *Longissimus dorsi* muscle was used to identify the proteins. A total of 5016 proteins were identified, of which 3311 were quantified and 1816 were present in at least 8 out of 10 biological replicates. Among these, 125 proteins were differentially expressed (DE, $P < 0.05$), 66 proteins presented as downregulated, and 59 as upregulated in the group of animals with lower values of shear force. Functional annotation analysis of the list of DE proteins using DAVID identified two pathways (KEGG): pyruvate metabolism and viral myocarditis; catabolic processes, such as glucose, hexose, carbohydrate, and monosaccharide; and molecular functions, such as actin binding, cytoskeletal protein binding, and calcium ion binding. These results provide a comprehensive protein profile of the skeletal muscle and indicate that changes in energy metabolism and cytoskeletal structure of muscle could influence meat tenderness.

Key Words: beef cattle, mass spectrometry, proteome

0894 Carcass grading effects on the fatty acid and amino acid composition of pork loin from Duroc pigs. J. Álvarez-Rodriguez[1], R. Ros-Freixedes[1], S. Gol[1], E. Henríquez-Rodríguez[1], R. N. Pena[1], L. Bosch[2], J. Estany[1], F. Vilaró[3], and M. Tor*[1], *[1]University of Lleida, Agrotecnio Center, Lleida, Spain, [2]Universitat de Girona, Girona, Spain, [3]University of Lleida, Lleida, Spain.*

Eighty purebred Duroc pigs slaughtered at 210 d of age were used to evaluate the effect of carcass grading according to lean content (R, 45–50%, n = 18; O, 40–45%, n = 28; P, < 40%, n = 34) on the fatty acid and amino acid composition of fresh pork loins. The crude protein content of loin was higher while the intramuscular fat content was lower in R carcasses than in the rest ($P < 0.05$). Carcass group had a major effect on fatty acid composition, with R carcasses showing lower MUFA and greater PUFA content than the rest of groups ($P < 0.05$) and with similar SFA content across groups ($P > 0.05$). Amino acid composition was not affected by carcass grading except for a tendency for isoleucine and glycine to have lower levels in P and R carcasses, respectively ($P < 0.1$). The balance of amino acids in the pork loin was compared with the recommended balance of indispensable amino acids for adults (WHO/FAO/UNU) by expressing the relevant amino acids relative to lysine and then calculating the proportion of the recommended amount of each amino acid that was provided by a sample containing the recommended amount of lysine. The balance of indispensable amino acids was less than ideal, with valine being the limiting amino acid by about 30–35%,

Table 0894.

Chemical composition of fresh loins (24 h post-mortem) from Duroc barrows according to carcass commercial grading

	R (45-50% lean)	O (40-45% lean)	P (<40% lean)	P-value

MUFA= monounsaturated fatty acids (C16:1n-7; C17:1n-7; C18:1n-9; and C20:1n-9); SFA= saturated fatty acids (C10:0; C12:0; C14:0; C16:0; C17:0; C18:0; and C20:0); PUFA=polyunsaturated fatty acids (C18:2n-6; C18:3n-3; C20:2n-6; C20:3n-6; C20:4n-6; C20:4n-6 and C22:6n-3). EAA= essential amino acids (Lysine, Methionine, Threonine, Isoleucine, Valine, Phenylalanine, Leucine and Histidine); NEAA= non-essential amino acids (Cistine, Arginine, Hydroxyproline, Tyrosine, Alanine, Glycine, Glutamic acid, Serine, Proline, and Aspartic acid). Within each row, different letter denotes statistical differences among carcass grading categories (P<0.05).

indicating that consumption of 144–151 g of pork loin would be needed to match 100 g of a sample with the recommended balance of the indispensable amino acids. The amount of Duroc pork meat that would need to be consumed to get a satisfactory balance of amino acids was highest in the P (< 40% lean) carcass grade group. In conclusion, in the Duroc swine breed, carcass adiposity modifies the fatty acid profile of meat but hardly affects the amino acid balance of raw loin.

0895 The longissimus thoracis muscle proteome in Alentejana bulls as affected by growth pattern.

A. M. Almeida*[1,2], P. Nanni[3], A. M. Ferreira[1], C. Fortes[3], J. Grossmann[3], R. J. Bessa[4], and P. Costa[4], *[1]Instituto de Biologia Experimental e Tecnologica, Oeiras, Portugal, [2]Ross University School of Veterinary Medicine, Basseterre, Saint Kitts and Nevis, [3]Functional Genomics Center Zurich (FGCZ), University of Zurich, Zurich, Switzerland, [4]CIISA, FMV-Ulisboa, Lisboa, Portugal*.

Beef production is an important economic activity worldwide. In southern Europe there are two major types of beef production systems based on the growth pattern the animals are subjected to: continuous versus discontinuous growth (CG vs. DG). The first can be characterized as more intensive with the animals being finished on concentrate and imported feedstuffs, while the second? The objective of this work is to conduct a comparison between the protein expression profiles of the longissimus thoracis (LT) muscle in CG and DG animals using label-free quantitative proteomics. Forty purebred *Alentejana* male calves (9 mo old, 239 kg live weight) were randomly allocated to two distinct feeding regimens: CG and DG. CG animals were fed ad libitum on concentrates plus grass hay throughout the trial and slaughtered at 18 mo of age. DG animals were only fed ad libitum on hay from 9 to 15 mo of age and then fed the same diet provided to the CG group (concentrates plus hay) until 24 mo of age. Animals were slaughtered and the LT muscle sampled. Samples (100 μg) were added to 500 μL of ammonium bicarbonate 50 mM, urea 8M, thiourea 2M buffer and homogenized and centrifuged and the supernatant recovered. Proteins were trypsin digested (FASP protocol) and desalted, and peptides were loaded onto reverse-phase C18 columns and analyzed on an LTQ-Orbitrap Velos mass spectrometer. Protein identification and label-free quantification were performed using Mascot (Matrixscience) and Progenesis (Nonlinear Dynamics). The study identified a total of 531 different proteins in the bovine LT muscle, with 26 showing differential expression, of which 25 were overexpressed in the CG group. Several of these proteins (e.g., myozenin-2, myosin regulatory light chain 2, glyoclythic pathway enzymes, and 14-3-3 protein zeta/delta) could be proposed as markers of a more intensive growth pattern that slaughters cattle at a younger age. The myosin binding protein H was the only protein having the higher expression in the DG group, suggesting that this protein may be putatively used as a marker of quality associated to discontinuous growth.

Key Words: growth pattern, longissimus thoracis muscle, proteome

0896 Ferulic acid in diets of heifers and its effect on the oxidative stability of meat stored in refrigeration.

E. Peña Torres*, H. Gonzalez Rios, T. Islava Lagarda, M. Valenzuela Melendres, A. Peña Ramos, L. Zamorano Garcia, A. Pinelli Saavedra, and J. L. Davila Ramirez, *Centro de Investigacion en Alimentacion y Desarrollo, Hermosillo, Mexico*.

Ferulic acid (FA) is a naturally occurring compound with important antioxidant activity. Therefore, it could be an interesting alternative to improve the shelf life of meat. The aim of this study was evaluate the oxidative stability in meat from commercial heifers supplemented with 5 or 10 ppm of FA by 30 d. Two hundred seventy heifers (480 ± 10 kg) in the finishing phase were fed with a basal diet (20:80 forage : concentrate ratio). Treatments were Control (without additive), 5 ppm of ferulic acid (FA5), and 10 ppm of FA (FA10) per kg of body weight, assigned randomized to 90 animals per treatment by 30 d. Finishing the feeding phase, animals were slaughtered and a section of the *Longissimus thoracis* muscle (LT) was collected between 4th and 12th rib (n = 9 per treatment). The LT muscle was sliced (1-inch thickness) for oxidative stability analysis for 0, 7, 10, and 14 d of storage. Objective color variables and pH were evaluated with a Minolta colormeter and Hanna pH meter, respectively; thiobarbituric acid-reactive substances (TBARS) and metmyoglobin were evaluated by spectrophotometry. A descriptive sensory test was done according to the guidelines of AMSA, and attributes, such as loss of fresh flavor, loss of fresh odor in cooked meat, and color and discoloration in raw meat, were evaluated. All data were analyzed by GLM-ANOVA with a 3 × 4 factorial arrangement considering as fixed effects the treatments and storage time using the statistical package NCSS 2007. There were no effects of FA supplementation or interaction to a*, b*, hue angle, and pH ($P > 0.05$), where the values were normal for fresh beef. L* values were higher in FA5 (40.48) and FA10 (41.03) compared with Control (38.91) ($P < 0.05$). On overall storage time, FA10 caused an increase in lipid oxidation of beef (TBARS values) compared with Control and FA5 ($P < 0.05$); while metmyoglobin values were lower in FA10 than FA5 and Control ($P < 0.05$). No differences were detected between treatments for sensory attributes ($P > 0.05$), which were qualified with high values. Results indicated that the doses of FA used in finished diets for heifers had no antioxidant effect.

Key Words: ferulic acid, shelf life, meat oxidation

0897 Label-free quantification of myosin isoforms in porcine skeletal muscles. J. Y. Jeong*[1], H. S. Yang[2], J. K. Seo[2], H. W. Yum[2], and G. D. Kim[1,3], [1]*Institute of Agriculture & Life Science, Gyeongsang National University, Jinju, The Republic of Korea,* [2]*Division of Applied Life Science (BK21 plus), Gyeongsang National University, Jinju, The Republic of Korea,* [3]*Department of Animal Sciences, University of Illinois Urbana-Champaign, Urbana*.

Myosin isoform (myosin heavy chain, MHC) in skeletal muscles has been usually qualified and quantified by electrophoresis, immunoblotting, and immunohistochemistry. However, it was difficult to clearly analyze myosin isoforms due to high homology among myosin isoforms. In the present study, label-free quantification (LFQ) was studied to both identify and quantify porcine myosin isoforms. *Longissimus thoracis* (LT), *psoas major* (PM), and *semimembranosus* (SM) muscles were taken from three pigs (180 ± 1 days old, female, 109.2 ± 2.4 kg slaughter weight) at 24 h postmortem in a slaughter house. Myofibrillar protein, which was isolated with rigor buffer (75 mM KCl, 10 mM K_2HPO_4, 2 mM $MgCl_2$, 2 mM EGTA, pH 7.0), was loaded onto sodium dodecyl sulfate-polyacrylamide gel electrophoresis. MHC bands were cut and in-gel digested with trypsin. Spectra were obtained by analysis of liquid chromatography (LC)-mass spectrometry (MS). LFQ was performed using MaxQuant software (ver. 1.5.3.30, Max-Planck Ins., Germany). Four myosin isoforms—myosin-1 (MHC 2x), myosin-2 (MHC 2a), myosin-4 (MHC 2b), and mysoin-7 (MHC I/slow)—were identified, and their matched peptides were 193.3, 154.7, 201.2, and 77.1, respectively. Unique peptides among the matched peptides were selected for quantification of each myosin isoform. The spectral count and summed MS intensity of selected peptide were evaluated. Similar patterns were found in the relative spectral count and relative peak intensity regardless of muscle types. LT and SM muscles had a higher composition of myosin-4 than PM muscle ($P < 0.05$), whereas myosin-7 was higher in PM than the others ($P < 0.05$). Myosin-1 and myosin-2 were relatively lower than myosin-4 and myosin-7 ($P < 0.05$). These LFQ results showed a similar trend to previous reports, which observed the composition of myosin isoforms or myosin heavy chain-based fiber compositions in porcine skeletal muscles. Therefore, LFQ can be a useful approach to overcome the problem of myosin quantification caused by high homology among their isoforms.

Key Words: label-free quantification, myosin, pig

0898 Identification of novel genes and mechanisms involved in bovine myogenic differentiation. H. Jiang*[1], R. Settlage[2], X. Leng[1], and Y. Hou[1], [1]*Department of Animal and Poultry Sciences, Virginia Tech, Blacksburg,* [2]*Biocomplexity Institute, Virginia Tech, Blacksburg*.

Myogenic differentiation, whereby the mononuclear myoblasts differentiate into the multinucleate myotubes, is a critical step in the formation of skeletal muscle. The objective of this study was to identify genes and pathways that regulate myogenic differentiation in cattle. Satellite cells, the myogenic progenitor cells in adult skeletal muscle, were isolated from 4 Angus crossbred steers (experimental unit). The isolated satellite cells were first propagated as myoblasts in growth medium containing 10% fetal bovine serum and then induced to differentiate into myotubes in differentiation medium containing 2% horse serum. Transcriptomes in myoblasts immediately before and 48 h after induction of myogenic differentiation were analyzed by RNA sequencing (RNA-seq). The RNA-seq analysis identified a total of 5538 transcripts that were differentially expressed (counts > 20; the false discovery rate-adjusted $P < 0.05$) between the two conditions. Of these transcripts, 2937 were upregulated and 2601 downregulated in differentiated myoblasts compared to undifferentiated myoblasts. Expression patterns for 20 of these genes were verified by reverse transcription-quantitative PCR. The list of genes upregulated in differentiated myoblasts included myogenin and myogenic factor 6, which are known to stimulate myogenic differentiation, and sex determining region Y-box 6 (SOX6) and growth hormone releasing hormone (GHRH), whose roles in myogenic differentiation are unknown. The list of genes downregulated in differentiated myoblasts included myostatin and myogenic differentiation family inhibitor (MDFI), which are known inhibitors of myogenic differentiation, and ZNF469 and SOX9, which are not known to be involved in myogenic differentiation. Functional annotation clustering analysis (DAVID 6.7) of 1107 transcripts upregulated $\geq$ twofold in differentiated myoblasts revealed enrichment (false discovery rate < 0.05) in contractile fiber, sarcoplasmic reticulum, calcium signaling, muscle contraction, cell adhesion, and steroid biosynthesis. Functional annotation clustering analysis of 817 transcripts downregulated $\geq$ twofold in differentiated myoblasts revealed enrichment (false discovery rate < 0.05) in cell cycle, microtubule cytoskeleton, growth factor binding, and ATP binding. Overall, this study not only confirms known factors and pathways that control myogenic differentiation but also suggest novel genes and mechanisms that may contribute to myogenic differentiation in cattle.

Key Words: cattle, muscle, myogenic differentiation

0899 Omega-3 and omega-7 oil supplementation on tissue fatty acid accumulation. S. K. Duckett*, I. F. Furusho-Garcia, M. F. Miller Jr., B. M. Koch, and G. Volpi Lagreca, *Clemson University, Clemson, SC*.

Eighteen Southdown ewe lambs (42 + 5.6 kg BW) were used to assess the effects of n-3 and n-7 oil supplementation on tissue accumulation of these fatty acids. Lambs were blocked by weight and randomly assigned to one of three treatments: 1) control (CON), no oil supplement, 2) flaxseed oil (FLAX; 56% C18:3 n-3) supplementation at 0.1% of BW, or 3) Provinal® oil (PO; 56% C16:1 n-7) supplementation at 0.1% of BW. All lambs were fed ad libitum the same basal diet consisting of 75% soybean hull pellets and 15% alfalfa pellets. Lambs were fed the treatment diets for 60 d individually. Overall average daily gain was reduced by PO compared to FLAX ($P < 0.05$). Hot carcass weights were also reduced by 12% for PO vs. FLAX ($P < 0.05$). Lambs in the PO treatment had a lower ($P < 0.01$) dressing percentage than CON or FLAX. Total lipid content of the LM was highest ($P < 0.05$) for FLAX and lowest ($P < 0.05$) for PO. Supplementation with PO increased palmitoleic (C16:1 n-7), cis-11 vaccenic (C18:1 cis-11), eicosapentaenoic (C20:5; EPA, n-3), and docosahexaenoic (C22:6; DHA, n-3) acids compared to CON or FLAX ($P < 0.01$). Supplementation of FLAX increased linolenic (C18:3 n-3) acid compared to CON or PO ($P < 0.1$). These changes in individual fatty acid concentrations with oil supplementation resulted in increased ($P < 0.01$) omega-3 fatty acid concentrations (+69%) and a lower (*P*..?) ratio of n-6 to n-3 compared to CON (3.13 for FLAX and PO vs. 5.02 for CON). In conclusion, supplementation with PO increased palmitoleic acid (+95%), cis-11 vaccenic acid (+77%; a known elongation product of palmitoleic acid), EPA (+104%), and DHA (+150%) compared to CON or FLAX. Flaxseed oil supplementation increased linolenic acid (+113%) but did not further convert this n-3 fatty acid into EPA, DPA, or DHA.

Key Words: lamb, n-7 fatty acids, n-3 fatty acids, oil supplementation

0900 Supplementation of glycerol or fructose via drinking water of pasture-fed lambs. G. Volpi Lagreca, I. F. Furusho-Garcia, B. M. Koch, M. F. Miller Jr., and S. K. Duckett*, *Clemson University, Clemson, SC*.

Eighteen wether lambs (40.1 ± 7.4 kg BW, 4.9 mo.) were used to assess the impact of glycerol or fructose supplementation via drinking water on animal performance and tissue glycogen content. Lambs were blocked by BW and allocated to alfalfa paddocks (2 hd/paddock, 3 paddocks/treatment). Each paddock within block was assigned randomly to drinking water treatments for 30 d: 1) control (CON), 2) 120 g fructose/L (FRU), or 3) 120 g glycerol/L (GLY). Lambs grazed alfalfa for 28 d and then were fasted in pens for 2 d before slaughter with access to water treatments only. Glycogen content was measured in the *Longissimus* muscle (LM) and *Semitendinosus* muscle (ST) at 30 min, 1, 2, 3, 4, 5, 6, 12, and 24 h postmortem. Data were analyzed using PROC MIXED of SAS. Daily water intake (3.5 L/animal/day) did not differ between treatments ($P > 0.05$). During the 28-d grazing period, ADG was greater ($P < 0.05$) for GLY (0.200 kg/an/d) compared to CON (0.116 kg/an/d) or FRU (0.078 kg/an/d). During the 2-d fasting period, BW shrink was lower ($P < 0.05$) for GLY (−0.392 kg/an/d) compared to CON (−1.680 kg/an/d) or FRU (−1.340 kg/an/d). HCW was greater ($P < 0.05$) for GLY compared to FRU (22.7 vs. 17.6 kg) and tended to be greater ($P = 0.06$) for GLY compared to CON. There was a treatment x time interaction ($P = 0.003$) in the LM; glycogen content was greater ($P < 0.05$) for GLY at 2 and 3 h and for FRU at 1 h compared to CON. Glycogen content in ST did not differ between treatments ($P > 0.05$). Liver glycogen content at 30 min postmortem was greater ($P < 0.01$) for GLY (5.61%) compared to FRU (1.45%) or CON (0.32%). Liver free glucose was greater for GLY, intermediate for FRU, and lower for CON ($P < 0.01$). Overall, GLY supplementation increased ADG during grazing period, reduced BW shrink during fasting, increased HCW, and increased glycogen in liver and muscle, and free glucose content in liver.

Key Words: lamb, liver, glycerol, fructose, glycogen

0901 Comparison of meat quality and fatty acid composition of grain-fed calves to grass-fed steers as an alternative beef production system in Chilean Patagonia. F. Sales*[1], R. Morales[2], R. Lira[1], L. Bravo[3], and Q. Sciascia[4], *[1]Instituto de Investigaciones Agropecuarias, Punta Arenas, Chile, [2]Instituto de Investigaciones Agropecuarias, Osorno, Chile, [3]Universidad del País Vasco, Bizkaia, Spain, [4]Leibniz Institute, Dummerstorf, Germany.*

Steers finishing in Chilean Patagonia are based on grazing lands with low nutritive value, which may lengthen the fattening phase of steers, so grain-fed calves appear as an option to reduce the farming period. However, the effect of grain inclusion in the diet on meat quality or fatty acid composition under those conditions is not clear. The aim of this study was to compare the effects on meat quality and the fatty acid profile of beef from grass-fed steers or grain-fed calves in Patagonia. Forty Angus cross steers were raised on pasture (2.0 Mcal/kg DM ME, and 11% CP) and slaughtered at 18–20 mo of age (448 ± 31.7 kg BW). On the other hand, ten calves were weaned at 9 mo of age (303 ± 8.0 kg BW) and started receiving 2.5 kg corn (3.4 Mcal EM, 8.5% CP) and 1.0 kg Cosetán® (2.95 Mcal EM, 15% CP) daily during 47 d. Meanwhile they were maintained on pasture (2.0 Mcal/kg DM ME, and 5% CP) until they reached slaughter weight (316 ± 13.9 kg BW). Animals were slaughtered the same day,

Table 0901.

Table 1. Meat quality analysis obtained from *longissimus lumborum* (lean muscle) of steers and calves that were slaughtered in Chilean Patagonia.

	STEER	CALVES	*P*-value
Body Weight in ranch (kg)	440 ± 33.0	316 ± 13.8	0.000
Slaughter Body Weight (kg)	417 ± 30.7	326 ± 13.9	0.000
Intramuscular fat (%)	7.95 ± 2.61	4.56 ± 1.18	0.000
Shear force (kgf)	2.22 ± 0.251	1.97 ± 0.298	0.030
Meat Color			
*L**	39.6 ± 1.76	42.4 ± 1.64	0.000
*a**	25.5 ± 1.83	23.2 ± 1.39	0.000
*b**	12.7 ± 1.17	12.7 ± 0.679	0.954
Fat color			
*L**	67.0 ± 1.86	65.9 ± 1.49	0.061
*a**	13.2 ± 2.03	12.9 ± 1.54	0.649
*b**	17.2 ± 1.47	14.1 ± 0.824	0.000
Fatty acid composition			
SFA (%)	47.6 ± 2.45	45.8 ± 3.22	0.120
MUFA (%)	39.0 ± 2.09	34.3 ± 1.79	0.000
PUFA (%)	7.60 ± 2.27	11.9 ± 2.91	0.001
P/S	0.162 ± 0. 0577	0.265 ± 0.0896	0.005
n-6	4.80 ± 1.36	7.88 ± 2.10	0.001
n-3	2.80 ± 0.927	3.99 ± 0.839	0.001
n-6/n-3	1.74 ± 0.155	1.96 ± 0.19	0.005
Rumenic acid (%)	0.268 ± 0.0407	0.425 ± 0.0526	0.000

SFA, saturated fatty acid; MUFA, monounsatured fatty acid; PUFA, polyunsatured fatty acid; P/S, PUFA/SFA; n-6/n-3, ratio between n-6 and n-3 PUFA.
Rumenic acid (9*c*,11*t*-18:2), principal conjugated linoleic acid.
P-value indicate significantly differences when $P \leq 0.05$.

and *Longissimus lumborum* muscle was obtained to perform meat quality and fatty acid profile analyses. A T-student was used to compare the two finishing methods (calves/grain vs. steers/pasture). As was expected, calves show lighter hot carcass weight than steers (173.9 ± 7.2 vs. 223.7 ± 17.5 kg, $P \leq 0.001$). Regarding meat quality characteristics, the color of calves' muscle was lighter (with higher *L** and lower *a** values, $P \leq 0.001$) and more tender ($P \leq 0.05$) than meat from steers. Calves' meat had lower intramuscular fat content (4.56 ± 1.18 vs. 7.95 ± 2.61%, $P \leq 0.001$), possibly because they were slaughtered younger than steers. In general, the fatty acid composition of steers' and calves' meat show healthy profiles, although calves' meat was healthier because of its higher content of polyunsaturated fatty acid, (PUFA, 11.9 ± 2.91 vs. 7.60 ± 2.27%, $P \leq 0.01$) and rumenic acid (0.425 ± 0.053 vs. 0.268 ± 0.041%, $P \leq 0.01$). However, calves' meat has a lower content of monounsatured fatty acids (MUFAs, 34.3 ± 1.79 vs. 39.0 ± 2.09%, $P \leq 0.001$) and higher n-6/n-3 ratio (1.96 ± 0.19 vs. 1.74 ± 0.155%, $P \leq 0.01$) than steers' meat. Results suggest that Patagonian beef meat has interesting quality characteristics and differs depending on the finishing methods and the slaughter age. Intramuscular fat content and fatty acid profile gave calves' meat (with an extra energy intake by grain) a higher nutritional and healthy quality compared to steers produced on pasture, which could be demanded by consumers.

Key Words: meat quality, calves' meat, beef

0902 Influence of tannins extract supplementation on lipid oxidation of beef kept in refrigerated storage.

B. O. Lopez*[1], R. Barajas[2], M. A. Mariezcurrena[3], M. D. Mariezcurrena[4], and Y. Libien[5], *[1]FMVZ-Universidad Autonoma de Sinaloa, Culiacan, Mexico, [2]FMVZ-Universidad Autónoma de Sinaloa, Culiacan, Mexico, [3]FMVZ-Universidad Autonoma del Estado de Mexico, Toluca, Mexico, [4]Universidad Autónoma del Estado del México, Toluca, Mexico, [5]FM-Universidad Autónoma del Estado de México, Toluca, Mexico*.

Steak samples of longissimus dorsi obtained from sixteen fattened bullocks (*Bos taurus* × *Bos indicus*) with 505 ± 22.23 kg final weight were used to evaluate the effect of tannin extract fed-supplementation on lipid oxidation of beef kept in refrigerated storage. Treatments were: 1) diet with 13.3% CP and 2.0 Mcal NE_m/kg DM (CTRL) and 2) CTRL plus 0.3% (DM basis) of tannin extract (TE). The tannin extract was offered from Bypro (Indunor S.A., Buenos Aires, Argentina), which contains 70% tannins. Treatments were fed during 70 d before harvesting. Bullocks were harvested in a processing plant, and after 24 h chilling at 4°C, a cross cut was performed in the longissimus dorsi of carcass left side, between 12th and 13th ribs. Beef samples were kept frozen (−20°C) until used for lipid oxidation analyses. Lipid oxidation was estimated as thiobarbituric acid-reactive substances (TBARS) and was determined at 0, 3, 6, 9, and 12 display d at 4°C. Because TBARS data were not normal ($P < 0.05$), before analyses, they were

transformed to $\log_{10}$ (n * 1000) to be normalized ($P = 0.68$). The results were analyzed by ANOVA for a completely randomized design, with a 2 × 5 factorial arrangement (two levels of factor TE: 0 and 0.3% diet DM; and five levels of factor d: 0, 3, 6, 9, and 12). The steak sample from each bullock was the experimental unit. A tendency ($P = 0.10$) for interaction TE × d was observed, where meat lipid oxidation from d 0 to d 9 was similar ($P > 0.10$) between treatments; but at display d 12, beef from TE supplemented bullocks exhibited a lower ($P < 0.05$) TBARS value than CTRL (0.04 vs. 0.11 mgMDA/kg meat^{-1} wet basis). The results suggest that supplementation of a 0.3% tannin extract to feedlot cattle may help to increase shelf life of beef by decreasing lipid oxidation.

Key Words: bovines, meat lipid oxidation, tannin

0903 Differentially expressed genes in genetically divergent Nellore steers for calcium content in the Longissimus dorsi muscle.

J. Afonso[1], P. C. Tizioto[2], P. S. N. Oliveira[2], W. J. S. Diniz[1], A. O. D. Lima[1], M. M. D. Souza[1], M. I. P. Rocha[1], J. V. D. Silva[1], C. E. Buss[1], C. F. Gromboni[3], G. B. Mourão[4], A. R. Nogueira[5], L. L. Coutinho[6], and L. C. A. Regitano[*5], *[1]Federal University of Sao Carlos, UFSCar, Sao Carlos, Brazil, [2]Embrapa Southeast Livestock, Sao Carlos, Brazil, [3]Federal Institute of Education, Bahia Science and Technology, Valenca, Brazil, [4]University of São Paulo, Piracicaba, Brazil, [5]Embrapa Southeast Livestock, Sao Carlos, Brazil, [6]Animal Biotechnology Laboratory, ESALQ, University of São Paulo, Piracicaba, Brazil*.

Calcium is an important mineral for mammals, because it is involved in muscle contraction and neuro impulse transmission and controls the flow of substances in the cellular environment. Calcium is the major part of the mammal skeleton; it is found in great amount in milk and can be found in beef. In addition, the calcium content in bovine muscle can influence meat quality traits, such as meat tenderness, due to its importance for calcium-dependent proteases. Although calcium functions in the organism have been extensively studied, a lack of knowledge of the mechanisms regulating calcium content is still observed. In this study, we identified differentially expressed (DE) genes in genetically divergent Nellore steers for calcium content in the *Longissimus dorsi* (LD) muscle using an RNA-seq approach. From an initial population of 120 animals presenting genomic breeding value (GEBV) estimates for calcium content, we chose 10 animals in two groups selected for their extremely low or high GEBV. The analysis of RNA-seq samples using the Tuxedo suit pipeline revealed 43 DE genes, 32 upregulated in the group with low calcium content. A functional gene enrichment analysis performed by DAVID software indicated 10 functional clusters involved in membrane and extracellular matrix proteins, cell and tissue adhesion, skeleton, neurological system and cartilage development, calcium, carbohydrate and metal binding, and sensorial and sound perception. Gene functions, such as cell and tissue adhesion, and calcium, carbohydrate, and metal binding are related to meat tenderness due to their role in the rigor mortis process and in muscle contraction through the interaction with troponin. Among the upregulated genes in the low calcium content group, we found the collagen genes *COL11A1* and *COL11A2* involved in skeletal morphogenesis and associated with several genetic syndromes related to abnormal calcium deposits in humans. *COL11A1* is downregulated in female Quinchuan cattle, which might explain part of the higher tenderness in this sex, since there is a negative correlation between this trait and collagen. In *Bos taurus coreanae* both genes are upregulated in intramuscular fat in comparison with subcutaneous fat, along with integrins, calcium dependent proteins that are related to cellular adhesion. These are intermediate results and further experiments will allow the exploration of the genetic findings influencing muscle calcium concentration in Nellore cattle. The results will provide a more comprehensive picture of gene expression associated with calcium content in bovine muscle.

Key Words: *Bos indicus*, calcium, RNA-Seq

0904 Fatty acid profile and gene expression of lipogenic transcription factors in the muscle of Nellore bulls fed processed soybean.

C. V. Oliveira[1], M. M. Ladeira[*1], O. R. Machado Neto[2], D. R. Casagrande[1], L. Ruiz[1], J. R. R. Carvalho[1], J. P. Schoonmaker[3], and A. C. Rodrigues[1], *[1]Universidade Federal de Lavras, Lavras, Brazil, [2]Universidade Estadual Paulista, Botucatu, Brazil, [3]Purdue University, West Lafayette, IN*.

The objective was to evaluate the fatty acid profile and gene expression of *PPARA*, *PPARG*, and *SREBF1* in the muscle of Nellore bulls fed ground or extruded soybean. Sixty crossbred Nellore young bulls, with initial average weight of 320 ± 8.12 kg, were distributed in a completely randomized design. The animals were placed in 12 pens, with 3 treatments, 5 animals per pen, and 4 replications, and therefore pens were the experimental units. The bulls were fed the following diets: diet without soybean inclusion (NSB), ground soybean diet (GSB), and extruded soybean diet (ESB). These diets containing corn silage as forage (40% DM), 14% CP, and 2.4, 6.1, and 6.3% of ether extract (EE), respectively. Soybean content was 20.4% in both ground and extruded soybean diets. Bulls were slaughtered at an average of 442 ± 10.4 kg. After being harvested, samples were taken from the *longissimus dorsi* (LD) muscle of 24 bulls randomly, 2 bulls from each pen, between the 12th and 13th ribs for fatty acid analyses, using gas chromatography, and gene expression, which was analyzed by RT-qPCR. The model included the fixed effect of diet and was analyzed using the GLM procedure in SAS 9.4. Muscle of bulls fed soybean diets, regardless of processing, had lower

concentrations ($P < 0.05$) of C12:0 and the CLA C18:2 c9, t11; and higher ($P < 0.05$) concentrations of C18:0. The C14:0 content was higher ($P < 0.05$) in the muscle of bulls fed NSB, compared to those receiving GSB. The concentration of C18:1 *trans* isomers were higher ($P < 0.05$) in the muscle of bulls fed GSB compared to those fed ESB and NSB. On the other hand, C18:1 c9 content in the muscle of bulls fed GSB was lower ($P < 0.05$) compared to the muscle of bulls fed the other diets. LD muscle of bulls fed soybean diets, regardless of processing, had greater concentrations of saturated fatty acids. Polyunsaturated fatty acid content was lower ($P < 0.05$) when bulls were fed ESB. Gene expression of *PPARA* and *PPARG* was not affected by diet ($P > 0.05$). However, expression of *SREBF1* was greater ($P < 0.05$) in the muscle of bulls fed ESB. In conclusion, extrusion of soybean contributes to the greater biohydrogenation of polyunsaturated fatty acids and consequently greater expression of the gene *SREBF1*. The use of ground or extruded soybean does not increase CLA C18:2 c9, t11 content in beef cattle muscle.

Key Words: CLA, extruded soybean, *PPAR*, *SREBF1*

0905 Heat shock protein expression differs in 14 d aged longissimus lumborum in agreement with Warner-Bratzler shear force values. N. E. Ineck*, R. G. Christensen, S. M. Quarnberg, J. McClellan, J. F. Legako, and K. J. Thornton, *Utah State University, Logan*.

Despite similar production practices, beef cattle exhibit undesirable variation in the rate and extent of postmortem proteolysis lending to inconsistencies in tenderness. The objective of this study was to determine whether heat shock proteins (HSP) play a role in postmortem proteolysis and thus, development of tenderness. To address this, HSP expression was determined in the longissimus lumborum after 14 d of aging. A total of 32 samples were placed into either a more tender (MT; $n = 16$) or less tender (LT; $n = 16$) group based on previous Warner-Bratzler shear force (WBSF) values. Western blot analyses were then completed to determine expression of two different HSP: HSPβ1 and HSP70. Statistics were completed using Proc MIXED in SAS to determine whether HSP expression varied between MT and LT samples; the model included tenderness as a fixed effect and gel and sample as random effects. Spearman-Pearson correlations were also completed in SAS to determine whether WBSF value and HSP expression were related. The two tenderness groups had different ($P < 0.001$) WBSF values; the MT group had an average WBSF value of 1.9 kg, while the less tender group had an average WBSF value of 5.5 kg. Less tender samples showed increases ($P = 0.03$) in HSPβ1 when compared to the MT samples. Furthermore, there was a correlation ($R = 0.5238$, $P = 0.008$) between WBSF value and HSPβ1 expression. No differences ($P = 0.49$) in HSP70 expression were observed between the MT and LT groups. There was no ($R = 0.031$, $P = 0.89$) correlation identified between WBSF values and HSP70 expression. These data demonstrate that HSPβ1 expression in meat samples from the longissimus lumborum after 14 d aging may play a role in postmortem proteolysis, and thus development of tenderness. Further research is needed to improve our understanding of how HSP are involved in the postmortem proteolysis process.

Key Words: heat shock proteins, tenderness, Warner-Bratzler shear force

MEAT SCIENCE AND MUSCLE BIOLOGY SYMPOSIUM: SCIENCE OF RED MEAT CONSUMPTION

0906 Beef's role in a healthy diet. J. N. Martin*, D. R. Woerner, R. Delmore, K. E. Belk, and J. D. Tatum, *Colorado State University, Fort Collins*.

Although red meat has long been established as a tremendous source of essential nutrients, its posed contributions to heart disease, obesity, and various cancers have resulted in growing criticism of its role in the diet. This widespread criticism and posited associations to negative health outcomes have fostered an overall decrease in the consumption of red meats in the U.S. over the past several decades. Although this decrease hasn't resulted in overt and direct improvements to human health, its absence has highlighted the vital nutritional role of lean, red meat in the diet. Concurrently, the entirety of the meat industry has steadfastly pursued investigating—and further, communicating—the nutritional profile and health value of red meats. A noteworthy example of efforts to demonstrate the nutritional advancement of red meats has been the remarkable progress on reducing the total available fat in consumed red meat products. Through targeted efforts in animal husbandry and processing innovation, the meat industry has reduced the total fat available from red meats by up to 70% in the past three decades. Furthermore, multiple industry efforts have addressed concerns regarding the fatty acid profile of red meats by demonstrating the relatively high proportion of unsaturated fatty acids and the cardiovascular neutrality of certain saturated fatty acids (i.e., stearic acid) in red meats. Likewise, although the value of red meat proteins has been long established, recent investigations of their role in weight loss and weight maintenance have highlighted their beneficial contributions to the diet and long-term health. Similarly, the exclusion of red meats in certain dietary patterns has been demonstrated to exacerbate iron deficiency and sarcopenia. Overall, the totality of data regarding the nutritional profile of red meat suggests that criticisms of its inclusion in dietary recommendations are unwarranted. Instead, the body of evidence suggests that negative health outcomes are complex, yet the inclusion of lean, red meats in a balanced diet can promote health and well-being.

Key Words: health, nutrition, red meat

0907 How certain can we be about the association of meat consumption and cancer? D. M. Klurfeld*, *USDA Agricultural Research Service, Beltsville, MD*.

The recent evaluation from the World Health Organization's International Agency for Research on Cancer (IARC) Working Group 114 concluded that processed meat consumption is a definite carcinogen in humans and red meat is probably carcinogenic. These were expert opinions of the majority of members of the group who evaluated the evidence they deemed most convincing. Most of the data that drove these two decisions were epidemiological studies, which are limited in their ability to distinguish causation from association. Animal studies do not support the conclusions and mechanistic studies are not convincing. Importantly, there are two large intervention studies in humans that were published but were not taken into consideration. These studies reduced meat intake significantly, as part of an overall dietary pattern, but that reduction had no effect at all on development of either colon polyps or cancer. Schemes for evaluating the totality of evidence to establish causality have been in the literature for 50 yr but were not used by IARC. In addition, no systematic review or meta-analysis was done, both of which have become the standard for such comparisons. Weaknesses inherent in evaluating long-term intake of any foods in observational studies should preclude using such data as the sole or primary determinant of causality in relation to health. It has been demonstrated conclusively that the food frequency questionnaire used to estimate meat intake in those studies is not able to quantify the amount of protein consumed. Statistical adjustment for confounders and covariates differed from study to study making combined analysis problematic. Finally, lack of registration of most observational studies without clear designation of the hypotheses to be studied and the numerous associations reported force the conclusion that any findings from them need to be accorded the higher statistical threshold that should be required of secondary results. A convincing argument can be easily defended that we do not have enough valid data to classify the carcinogenicity of red or processed meat for humans.

Key Words: red meat, processed meat, cancer, health, human nutrition

0908 The role of red and processed meat in colorectal cancer development: A perspective. S. De Smet*, *Ghent University, Melle, Belgium*.

Red and processed meat provide high biological value proteins and important micronutrients, but at the same time there is increasing epidemiologic evidence for an association between red and processed meat consumption and the risk to develop several chronic diseases. With respect to colorectal cancer, meta-analyses have reported a 15–20% increased risk of colorectal cancer per 100 g per day of red meat and per 50 g per day of processed meat consumption. A working group of IARC recently assessed the carcinogenicity of red and processed meat consumption through an elaborate evaluation of epidemiologic, animal, and mechanistic studies. Taking into account the amount of data, the nature and quality of the studies, and the extent to which chance, bias, and confounding from other dietary and lifestyle factors can be ruled out, it was concluded from the epidemiologic studies that there is sufficient evidence in human beings for the carcinogenicity of the consumption of processed meat, and limited evidence for red meat. Inadequate evidence was found in experimental animals, but the mechanistic evidence for carcinogenicity in the digestive tract was assessed as strong for red meat and moderate for processed meat. For genotoxicity and oxidative stress, evidence was considered moderate. Substantial supporting mechanistic evidence is available for multiple meat components (N-nitroso-compounds, haem iron, and heterocyclic aromatic amines). Taking this together, the IARC working group classified processed meat as "carcinogenic to humans" and red meat as "probably carcinogenic to humans.. This classification has unfortunately frequently been misinterpreted and has led to polarized and scientifically incorrect statements in the media. However, it should be realized that the IARC assessment was a hazard analysis according to established procedures and was not a full risk assessment, nor was it intended to make dietary recommendations. The question remains whether nutrition authorities will adapt their advice on the role of meat in a healthy diet based on this report. This is evidently a concern for the meat industry. On the other hand, insight into the mechanisms of the association between meat consumption and diseases offers opportunities for mitigation, as was already shown for the use of calcium. More research is needed on the mechanisms and on strategies to improve the composition, processing, and heating of meat, allowing for reduction of the harmful effects. Even more important, it is believed that the interaction of meat with non-meat food ingredients in dietary patterns should be investigated.

Key Words: colorectal cancer, processed meat, red meat

0909 Is there a role for meat in a plant-based diet? M. A. Binnie*, *Canadian Pork Council, London, ON, Canada*.

Many North Americans are overfed and undernourished, resulting in significant negative health consequences. Obesity is of global concern, with rates tripling in Canada in one generation. Dietary patterns have shifted away from fresh and minimally processed foods to include alarming amounts of added sugars and ultra-processed foods. In the U.S., added sugars in ultra-processed foods (21.1% of calories) was eightfold higher than in processed foods (2.4%) and fivefold higher than in unprocessed or minimally processed foods and processed culinary ingredients grouped together (3.7%). Similarly, 22% of calories in the average Canadian diet come from foods that provide little or no nutritional value. Foods not included in Canada's Food

Guide make up a greater percentage of the calories in the diet of Canadians than do foods from the Meat and Alternatives, Milk and Alternatives, or Vegetables and Fruits food groups. To counter the obesity epidemic, plant-based diets are often promoted as a solution. However, it is widely accepted that animal products supplement and complement a diet based on plant foods so that it is nutritionally adequate. Replacing some carbohydrate with high quality protein foods may have clinical benefits. The nutritional lens needs to be adjusted to focus on the dietary quality meat contributes to a plant-based diet.

Key Words: dietary patterns, dietary quality

MILK PROTEIN AND ENZYMES

0910 Intrinsic and extrinsic factors affecting milk yield and composition of camel milk in northern Eritrea. Y. N. Berhane*, *Uludag University, Bursa, Turkey.*

Although camel milk contributes rich dietary components to the people living in Eritrean lowlands, factors affecting its average daily yield and composition have not yet been studied. Hence, the objective of our study was to investigate effects of extrinsic factors (season) and intrinsic factors (stage of lactation and parity) on milk yield and its composition in camels kept under traditional management conditions in northern semiarid areas of Eritrea. We collected 300 random milk samples from January to October in 2013, 30 samples each month. The analysis of milk composition was done using the lacto scan milk analyzer, an automated milk analyzer system, and the obtained data were analyzed using the general linear model on SPSS 18 software. The average daily yield of milk and compositions of fats, protein, and lactose were 3.78 L, 2.43%, 2.71%, and 4.8%, respectively. Stage of lactation, parity, and season of the year significantly influenced ($P < 0.05$) daily milk yield and composition of fats and protein. The percentage composition of lactose remained unaffected by any variables considered. The highest average daily milk yield was recorded at the second month of lactation (4.04 ± 0.10 L), whereas the least was after 8 mo of lactation. The daily milk yield was significantly higher at the third month. The percentage composition of fat and protein were also at their peak during the first 3 mo of lactation period (3.21 ± 0.14 and 2.76 ± 0.11%, respectively). Similarly, the highest average daily milk yield and percentage composition of protein, fat, and dry matter were recorded from camels of 3rd parity (4.43 ± 0.2 L, 5.11 ± 0.51, and 3.19 ± 0.22%, respectively). This study revealed that camels are a reliable source of milk with persistent yield and composition throughout most of the period of lactation. Effective herd management, proper selection and culling, and provision of supplemental feed during the dry seasons may contribute to high quality camel milk in the region.

Key Words: camel, Eritrea, milk composition, milk yield, extrinsic and intrinsic factors

0911 Effect of lactoferrin hydrolysates on cytokine expression in Raw264.7 cells. Y. W. Park*[1], J. Y. Son[2], G. Renchinkhand[2], S. H. Paik[3], and M. S. Nam[2], *[1]Fort Valley State University, Fort Valley, GA, [2]Chungnam National University, Daejeon, The Republic of Korea, [3]Cheonan Yonam College, Cheonan, The Republic of Korea*.

Lactoferrin (LF) is an iron-binding glycoprotein which is present in colostrum, milk, and other body secretions. LF is associated with human infants' inflammatory and immune responses. The objective of this study was to determine the effects of alkaline protease generated lactoferrin hydrolysates (LH) on immunomodulatory activities of nitric oxide (NO) production and cytokines production, including anti-inflammatory cytokines [interleukin(IL)-4], pro-inflammatory cytokines (interleukin-6, tumor necrosis factor-α, interferon-γ), Th2 cytokines (interleukin-4 or interleukin-6), and Th1 cytokines [tumor necrosis factor (TNF)-α, interferon (IFN)-γ] in immune cells. The presence of LH was confirmed by SDS-PAGE and HPLC analyses. The LH above 10 kDa and below 10 kDa were isolated from the extracted LH using 10 kDa cut-off centricon. Raw264.7 cells were treated with 3 different LH concentrations (1, 50, 100 μg/ml) for three types of LH (whole, above and below 10 kDa) treatments at 37°C for 3 hr, and then the culture supernatants were quantified by TNF-α and IL-1β ELISA kit. Cytokine expression levels in Raw264.7 cells were analyzed by reverse transcription-polymerase chain reaction (RT-PCR). Results showed that 1 μg/ml of three types of LH treatments produced 1500–2,000 ng/ml TNF-α, whereas the positive LPS (lipopolysaccharide) and negative controls produced 2450 and 1000 ng/ml TNF-α, respectively. The 50 μg/ml treatments of the three types of LH produced about 20–28 ng/ml IL-1β at 3, 6, 9 h, while the negative control had 7 ng/ml. TNF-α expression was decreased dose-dependently by the 3 LH groups, while none of the LH treated groups affected IL-6. The mRNA expression of IL-13 appeared in all LH concentrations. In RAW264.7 cells treated with 1, 50, 100 μg/ml for 3 h, the mRNA expression induced a remarkable increase in nitric oxide synthesis (INOS) with dose dependent manner. NO was secreted dose-dependently from macrophages which were activated by all concentrations of the 3 LH treated groups. The results of RT-PCR revealed that LH caused INOS and inhibited the production of TNF-α in Raw264.7 cells. It was concluded that lactoferrin hydrolysates had immunomodulating effects on anti-, pro-inflammatory, and anti-allergic reactions.

Key Words: lactoferrin hydrolysates, cytokines, Raw264.7 cells

0912 Three new bovine α_s-CN phosphorylation isoforms reveal different phosphorylation pathways. Z. H. Fang[*1,2,3], M. H. P. W. Visker[3], G. Miranda[1,2], A. Delacroix-Buchet[1], H. Bovenhuis[3], and P. Martin[4], *[1]INRA, UMR1313 GABI, Jouy-en-Josas, France, [2]Agroparistech, UMR 1313, GABI, Jouy-en-Josas, France, [3]Animal Breeding and Genomics Centre, Wageningen University, Wageningen, Netherlands, [4]UMR1313 Gabi, INRA, AgroParisTech, Université Paris-Saclay, Jouy-en-Josas, France*.

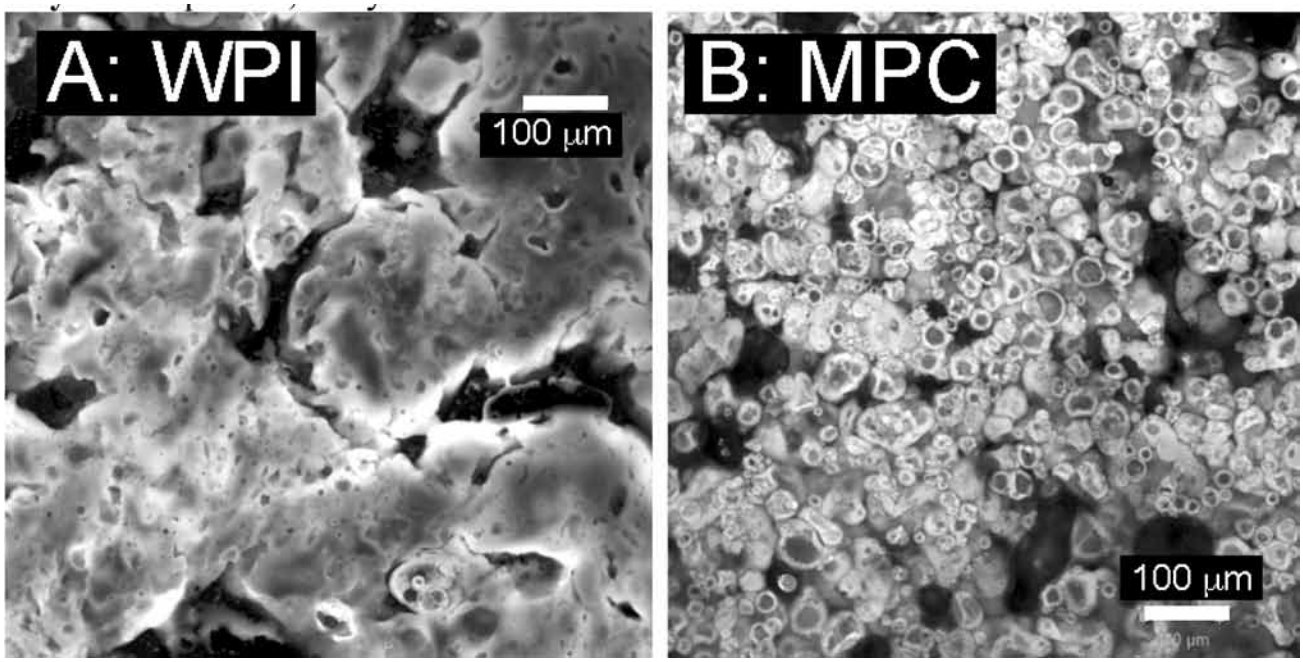
Casein (CN) phosphorylation is an important post-translational modification, and it is one of the key factors responsible for constructing and stabilizing casein micelles. Variation in phosphorylation degree of α_s-CN is of great interest because it is suggested to affect milk technological properties. Our objective was to investigate the variation in phosphorylation degree of α_s-CN among milk of individual cows and to explore relationships among different phosphorylation isoforms of α_s-CN. For this purpose, we analyzed morning milk samples from 529 French Montbéliarde cows using liquid chromatography coupled with electrospray ionization mass spectrometry (LC/ESI-MS). We detected three new phosphorylation isoforms: α_{s2}-CN-9P, -14P, and -15P in bovine milk, in addition to the known isoforms α_{s1}-CN-8P and -9P, and α_{s2}-CN-10P, -11P, -12P, and -13P. The relative concentrations of each α_s-CN phosphorylation isoform varied considerably among milk of individual cows (coefficient of variation $\geq$ 8). Furthermore, the phenotypic correlations and hierarchical clustering suggest two regulatory systems for the phosphorylation of α_s-CN: one responsible for isoforms with lower levels of phosphorylation (α_{s1}-CN-8P, α_{s2}-CN-10P and -11P), and the other responsible for isoforms with higher levels of phosphorylation (α_{s1}-CN-9P, α_{s2}-CN-12P, -13P and -14P). Identifying all phosphorylation sites of α_{s2}-CN and investigating the genetic background of different α_{s2}-CN phosphorylation isoforms may provide further insight into the phosphorylation mechanism of caseins.

Key Words: phosphorylation, casein, milk protein composition, LC/ESI-MS

0913 Hardening and microstructure of high protein nutrition bars made using whey protein isolate or milk protein concentrate. S. K. Hassan[1] and D. J. McMahon[*2], *[1]College of Education, Al-Qadisiya University, Al-Qadisiya- Diwaniya, Iraq, [2]Western Dairy Center, Utah State University, Logan*.

High-protein nutrition (HPN) bars (especially those containing > 30% protein) became hard during storage and have a limited shelf life, resulting in disappointment by consumers or loss of product as older products are discarded. The effect of different components on hardening of HPN bars was studied in bars containing 34% (wt/wt) whey protein isolate (WPI) or milk protein concentrate (MPC) powder, along with either sorbitol syrup or glycerol, and vegetable shortening or cocoa butter. The bars were stored at 20°C and 35°C and monitored for changes in hardness (measured using a penetration test), water activity, state of water and denaturation of whey proteins (measured using differential scanning calorimetry), and microstructure using confocal scanning laser microscopy. Substituting MPC for WPI made the bars brittle and crumbly. Using glycerol initially made bars softer but accelerated

Fig 0913.



hardening. Cocoa butter increased bar hardness because of its higher solid to liquid content. Most water (~99%) in HPN bars made using sorbitol syrup is present as bound water, with ~0.9% as intermediate water and ~0.1% as bulk water. During storage, bound water increased ~0.02 g/100 g of solids while intermediate water decreased, suggesting changes in state of water taking place at protein surfaces. During storage, there were changes in protein conformation indicated by an increase (~4°C) in heat denaturation temperature of β-lactoglobulin and α-lactalbumin and a 15 to 40% decrease in denaturation enthalpy. In bars made using WPI, the protein was present as a continuous network (see Figure A) while in bars made using MPC the protein remained in separate particles of protein powder dispersed throughout the sorbitol-water cosolvent mixture (see Figure B). It is proposed that hardening of HPN bars is a result of interactions between the cosolvents and the protein surface and not because of a phase separation between protein and cosolvents as was previously hypothesized.

Key Words: protein, whey microstructure

0914 Effect of casein non-phosphopeptides on the development of rat muscle analyzed using computed tomography (CT) scanning technology.

N. Zhang[*1,2], S. Ikeda[3], Y. Shi[1], and Q. Guo[4],
[1]Harbin University of Commerce, Harbin, China, [2]University of Wisconsin, Madison, [3] University of Wisconsin, Madison, [4]Northeast Forestry University, Harbin, China.

About 2% of the population of age 50 suffers from sarcopenia, and the proportion is more than 50% after the age of 80. Sarcopenia may lead to physical weakness and reduced balance and mobility, which in turn have possible metabolic effects such as diabetes, arthritis, osteoporosis, and heart diseases. The leucine-rich whey protein α-lactalbumin has been found to counteract the muscle loss caused by sarcopenia. Casein non-phosphopeptide (CNPP) is a by-product from casein phosphopeptide production and is rich in leucine. The objective of this study was to investigate the effect of CNPP on the muscle development of healthy rats. Ten 32-wk-old male rats were fed one of the four dosage levels of CNPP or α-lactalbumin (high dose, 10 g/kg/d; moderate dose, 5 g/kg/d; low dose, 2.5 g/kg/d; and blank, 0 g/kg/d) for 50 d. Each feeding group was divided into two exercise groups: resistive exercise group (REG) and no exercise group (NEG). The resistive exercise consisted of three sets of 5 min of stair climbing with 1 min intervals daily. At 0, 15, 25, 35, and 50 d of feeding, rats were anesthetized and their cross-sectional body images were obtained using a transverse spiral CT scanner. Muscle groups were identified based on anatomical features. The areas of these muscle groups in the obtained images were determined using the CT software. The blood levels of growth hormone, insulin, and testosterone were determined using assay kits. Results were analyzed statistically using SPSS software. The results showed that the cross-sectional area of the trunk, back muscle group, and left upper limb muscle roots of the REG rats fed the moderate dose CNPP for 50 d increased significantly ($P < 0.05$). The cross-sectional area of the trunk and lumbar muscle group of the REG rats fed the high dose CNPP for 50 d also increased significantly ($P < 0.05$). Furthermore, the cross-sectional area of the trunk, β scapular muscles, and left upper limb muscle roots of the NEG rats fed the moderate dose CNPP for 50 d increased significantly ($P < 0.05$). In both CNPP-fed REG and NEG groups, the blood levels of growth hormone, insulin, and testosterone increased significantly after feeding for 50 d compared to those on Day 0 ($P < 0.05$). Our studies have demonstrated that the leucine-rich CNPP stimulates the synthesis of certain rat muscles and increases the blood levels of insulin, growth hormone, and testosterone.

Key Words: casein non-phosphopeptide, sarcopenia, CT scanning

0915 Physico-chemical properties and antioxidant efficacy of whey protein isolate and casein hydrolyzate stabilized nano-vesicular vehicle systems containing curcumin. Z. Z. Haque*and S. Mukherjee, *Food Science, Nutrition and Health Promotion, Mississippi State University, Mississippi State*.

Development of stable nano-emulsion systems, designed for efficient delivery of hyper-active natural antioxidants, nutraceuticals, and other bioactive compounds is crucial for effective enhancement of dairy product shelf-life as well as to alleviate the detrimental biological consequences caused by the reactive oxygen species. This study investigated the physicochemical and antioxidant properties of a nanoemulsion system, developed as nano-vesicular vehicles (NVVs) for efficient delivery of curcumin (CU), a highly potent, generally recognized as safe (GRAS) antioxidant. Coarse emulsions were first produced by dispersing whey protein isolate (WPI) (1% w/v, primary emulsifier), tween-20 (20% w/v of WPI, secondary emulsifier), chymotryptic hydrolyzate of casein (CH) (1:50 w/w of WPI), and CU (0.22% w/v) in 200 mM phosphate buffer with a pH of 8.0 (the continuous phase) for 3 h with gentle stirring at 22°C. The NVVs were generated by subjecting the coarse emulsion to single-pass ultra-high-pressure homogenization (UHPH) at 140 and 210 MPa. Physico-chemical and antioxidative properties of the CU-loaded-NVVs containing CH (CU+CH-NVVs) were analyzed and compared to the NVVs without CH (CU-NVVs) for 16 d of storage at 4°C. Increasing the trace amount of CH resulted in a significant enhancement ($P < 0.05$) of both short- and long-term antioxidative properties [antioxidant activity (AA) and persistence (AP), respectively], in all CU+CH-NVVs throughout the study compared to CU-NVVs. The CU+CH-NVVs generated using 210 MPa showed 497 and 567% enhancement of AA and AP, respectively, relative to the CU-NVVs on the 16th day of storage. The former also showed 6222 and 11278% enhancement of AA and AP compared to the control (buffer alone). The CU+CH-NVVs generated at 210 MPa exhibited a considerable (7.4%) reduction in mean globular particle diameter as well as a substantial increase (17%) in zeta potential compared to the CU-NVVs formulated using the same UHPH at the final day of storage, indicating the efficacy of even a minute quantity of CH to remarkably enhance the stability of NVVs.

MILK SYMPOSIUM: MARKETING MILK FOR ENTREPRENEURIAL AND BIG BUSINESS VALUE

0916 Get in the driver's seat: Marketing milk and dairy products to today's and tomorrow's consumers. D. M. Berry*, *Dairy & Food Communications, Inc., Chicago, IL*.

Who buys a head of iceberg lettuce anymore when pre-washed, trimmed lettuce blends are readily available? It's the same person who buys a gallon of the white stuff and a chunk of cheddar. It's not the consumer—today's consumer–who grew up with more than 87,000 possible Starbucks combinations to create a customized drink. Millennials and their offspring are today's and tomorrow's consumers, demographics with unprecedented expectations of the food supply chain. They want customization, simplicity, and transparency but at the same time demand convenience, deliciousness, and portability. According to the International Food Information Council Foundation's 2015 Food and Health Survey, compared to the general U.S. population, Millennials have differing opinions on traditional eating habits, usage of resources and information for staying healthy, and even on the value of some nutrients. Understanding these views is paramount for dairy brands to thrive. According to the International Dairy-Deli-Bakery Association, the food retail world is changing, and the products and the players must change in tandem. Traditional food retailers are the most challenged, with data suggesting they will experience a 9% drop in market share (from 71% to 62%) over the next 10 yr as non-traditional channels like fresh formats and online retailers gain 38% of the food market. Traditional supermarkets that want to survive are responding to the changing retail channel landscape by featuring full-service restaurants, smaller formats, and Millennial-focused products and services. In 2014, e-commerce sales for consumables were $24.4 billion, an increase of 13.5% from 2013. Online purchases of foods and beverages are projected to almost quadruple between 2015 and 2020, to $49 billion, representing 4.5% of all food retail sales. When it comes to dairy, deli, and bakery, as well as prepared foods, specialty cheese, and specialty meats, the six fresh parameter departments in the traditional supermarket, consumers continue to appreciate the in-person experience. It's no wonder that the greatest percentage of increase in store count has come from channels outside of traditional food, drug, and mass-merchandising formats, including convenience stores, warehouse clubs, and dollar stores. Stores that focus on fresh foods, in particular single-serve options and convenience, invite consumers inside. And once inside, they often buy more than they really intended. Dairy foods manufacturers must make sure they are competing in this space.

Key Words: Millennials, innovation, consumer

0917 Practices and programs to ensure the safety of artisan cheese. D. J. D'Amico*, *University of Connecticut, Storrs*.

Historically, milk processing and cheesemaking were conducted on farms. In the mid-1800s the factory system for cheesemaking was introduced in the United States and quickly came to dominate the industry. By the beginning of the 20th century, farmstead cheesemaking in the U.S. had all but disappeared. More recently, small-scale and on-farm processing of dairy products is experiencing a resurgence as producers are looking to add value to milk while consumers are increasingly looking for unique and locally produced products with minimal processing. This growth is particularly apparent in the artisan cheese sector that has seen the number of U.S. producers increase from ~75 in 1990 to ~1000 today. Increasing demand provides opportunities for selling and marketing unique dairy products in local, national, and international markets. From a food safety perspective, artisan and farmstead cheese producers face common as well as unique risks and challenges including those related to on-farm processing, the production of higher-risk cheese varieties, and the renewed interest in the use of unpasteurized milk. Many small and very small establishments may also lack the resources, capital, technical expertise, or training to implement robust food safety programs and related technology. With the changing food safety and regulatory landscape and the expansion of international trade, there is a need to preserve traditional practices and products while ensuring food safety. Using examples from various countries, including efforts in the U.S., this presentation addresses these food safety risks and challenges and discusses food safety programs and best practices.

Key Words: safety, small-scale, cheese

0918 Camel milk from commodity to added value product. The science behind the development of the camel dairy industry. P. Nagy*, *Emirates Industries for Camel Milk and Products, Dubai, United Arab Emirates*.

Until recently, camels were regarded mainly as packing or racing animals by many, including the general public, scientists, funding agencies, and policymakers, but the food production potential of the species has been neglected. Camel milk had been produced exclusively by hand milking in traditional farming systems for household consumption. Such production could not provide a constant quantity and acceptable quality of raw milk for urban markets. However, during the last 10 to 15 yr, intensive camel milk production has been going through a major development. Machine milking has been introduced in several traditional camel-keeping countries, like the United Arab Emirates, Saudi Arabia, and Tunisia. Small-scale farms in Australia, Europe, and the USA have also been reported to be using milking machines for dromedaries. The world's first large-scale camel dairy farm (EICMP, Dubai, UAE) with a processing facility and distribution was established during this period. In addition, several commercial and scientific projects have been started. The demand for camel milk triggered research and development on camel lactation physiology, behavior, nutrition, reproduction, husbandry, management, etc. In addition, camel milk microbiological quality and chemical composition have been defined; studies were conducted to improve product characteristics and new products were developed, such as probiotic fermented milk, laban, labneh, cheese, milk, and whey powder. The medicinal properties of camel milk has also received increased attention, and data have been published in peer-reviewed medical journals that support field observations and anecdotes from camel-keeping countries. Despite significant progress made in intensive dairy management, machine milking, composition, and product development, the task is far from completion. More basic and applied research is required in all of the above fields for better understanding and optimized production. Important areas for research could be (1) improvement of machine milking technologies, (2) neuro-endocrine control of lactation, (3) phenotypic and genetic variation of breeds/ecotypes, (4) role and application of environmental factors (like photoperiod, nutrition), (5) variation in milk quality and composition, and (6) chemistry of camel milk proteins. The aim of this presentation is to review the recent development of the camel dairy industry, summarize our present knowledge on camel milk production and processing, and highlight areas for future research.

Key Words: camel milk, intensive management, machine milking

0919 Terroir: Science based or marketing gimmick. L. Goddik*, *Oregon State University, Corvallis*.

The concept of terroir is rapidly gaining importance in the U.S. marketplace in alignment with the growth of the local food sector. Terroir for products such as coffee and wine are well recognized, but there is little science to support terroir for dairy products. Nevertheless, it's common to see promotions for regional cheeses such as Wisconsin cheese or New York Cheddar. This presentation will evaluate factors that influence farm and regional milk sources and their impact on cheese characteristics. Our current research has focused on the simple question: If all other factors are kept constant, will milk from different farms and regions produce cheeses that are different? Initial results have demonstrated that milk from farms, selected due to similar herd management principles, produce Cheddar cheeses that are different based on sensory and flavor chemistry profiles. Non-starter lactic acid bacteria (NSLAB) profiles

are unique to individual farms. The link to the individual farms (terroir effect) is more pronounced in 5 mo aged Cheddar than in 9 mo aged Cheddar. Milk from coastal regions appears to be particularly suited for cheese production, likely due to complex NSLAB profiles and flavor development.

Key Words: milk source, cheese, flavor

NONRUMINANT NUTRITION: ENZYMES

0920 The effect of increasing *Buttiauxella* phytase dose on performance in piglets: Meta-analysis from 5 trial studies. Y. Dersjant-Li, R. M. Bold, and W. Li*, *Danisco Animal Nutrition, DuPont Industrial Biosciences, Marlborough, United Kingdom*.

The effect of *Buttiauxella* phytase on the performance of piglets was evaluated combining the datasets of five trials. A total of 234 data points (364 piglets, average initial BW 10 kg) were used in the analysis. Treatments included a nutritionally adequate positive control diet (PC), a negative control diet (NC, with an average reduction of 0.15% calcium and 0.19% phosphorus compared to the PC), and NC supplemented with *Buttiauxella* sp. phytase at 500, 1000, or 2000 phytase units (FTU)/kg feed. One FTU was defined as the amount of enzyme required to release 1 μmol of iP per minute from sodium phytate at pH 5.5 at 37°C. Piglets received the test diets (based on corn/SBM, wheat/SBM or wheat/barley and SBM) for 14 d. No grain source × phytase dose interaction was found, thus data from the 5 trials were pooled for statistical analysis (JMP 11.0, SAS). Treatment means were separated using Tukey's HSD test, trial was used as a random factor. Linear or nonlinear response was tested with increasing phytase dose from 0 (NC) to 2000 FTU/kg. Phytase dose at 1000 and 2000 FTU/kg improved ADG by 12.3 and 19.3% respectively vs. NC ($P < 0.05$), and by 3 and 9.4% vs. PC ($P > 0.05$). No significant differences were seen in feed intake. FCR was improved with phytase at 1000 and 2000 FTU/kg by 8.8 and 10.2% vs. NC ($P < 0.05$), and by 5.5 and 6.3% vs. PC ($P > 0.05$). Increasing phytase dose from 0 (NC) to 2000 FTU/kg increased ($P < 0.05$) ADG linearly and reduced FCR in a nonlinear manner. The data demonstrated that phytase at 500 FTU/kg could replace 0.19% P and 0.15% Ca. Increasing phytase dose to 1000 or 2000 FTU/kg could further improve performance of piglets fed P and Ca deficient diets, most likely due to the extra-phosphoric effects of the phytase. Cost calculation (based on feed cost and 14-d performance data) showed a net value of $0.11, 0.35, and 0.62 per pig ($11.8, 39, and 65/ton of feed) with *Buttiauxella* phytase at 500, 1000, and 2000 FTU/kg respectively compared to PC. In conclusion, increasing *Buttiauxella* phytase dose up to 2000 FTU/kg may provide production benefits in piglets.

Key Words: piglets, meta-analysis, performance

0921 Effects of dietary β-mannanase supplementation with soybean meal in the performances in weanling pigs. B. Balasubramanian*, H. M. Yun, Y. M. Kim, J. K. Kim, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, South Korea*.

Soybean meal (SBM) is by far the most popular protein source used for feeding livestock. The objective of the present study was to test the efficacy of supplementation of β-mannanase in diets containing de-hulled or conventional hulled SBM (44% and 48%) as well as to evaluate the interactive effects of SBM and enzyme on growth performance, nutrient digestibility, fecal microflora, and noxious gas emission in weanling pigs. In total, 140 pigs [(Landrace × Yorkshire) ×Duroc] with a initial BW of 5.97 ± 1.01 kg were used in a 6-wk feeding trial, randomly allotted in a 2 × 2 factorial arrangement, with feed consisting of hulled or de-hulled SBM with or without β-mannanase [T1 (SBM 44%), T2 (SBM 44% + 0.05% β-mannanase), T3 (SBM 48%), and T4 (SBM 48% + 0.05% β-mannanase)]. Pigs were allocated randomly to 4 treatment groups consisting of 7 replicate pens per treatment with 5 pigs per pen. Pen was the experimental unit. In this study, pigs fed diets containing 0.05% β-mannanase had greater BW, ADG, G:F, and ADFI than pigs fed diets without β-mannanase, but the differences were not statistically significant; however, interactions of SBM diets showed significant differences for ADFI ($P = 0.0334$) at the second week and showed significant effects on DM ($P = 0.0077$), N ($P = 0.0082$), E ($P = 0.0362$), P ($P = 0.0472$) at the sixth week. Furthermore, when compared with SBM, β-mannanase had effects on DM ($P = 0.0105$), N ($P = 0.0416$), P ($P = 0.0591$), but not E and Ca. There were no significant differences for serum BUN, WBC, Lymphocytes, however observed significance on RBC ($P = 0.0130$), when compared with SBM diets at the sixth week. Effects on diarrhea score ($P = 0.0469$) at d 3 and noxious gas emission were not significantly different ($P > 0.05$). The significant effects of β-mannanase supplementation with SBM on fecal microflora (*E. coli* and *Lactobacillus*) showed a significant difference at sixth week ($P < 0.05$). In conclusion, β-mannanase supplementation in a SBM diet showed positive effects on nutrient digestibility (DM, N, E, P), on feed efficiency, and for reducing *E.coli* population in weanling pigs.

Key Words: β-mannanase, soybean meal, weanling pigs

0922 Effect of a multi-enzyme component on growth performance, nutrient digestibility, carcass quality, and gas emission in broilers.
D. H. Nguyen*, H. S. Kim, S. Kathannan, S. Shanmugam, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, South Korea*.

A total of 480 broiler chicks (BW = 42 ± 1 g) were used in a 5-wk feeding trial in which there were two phases, starter (1 to 18 d) and finisher (19 to 35 d), to investigate the effect of dietary supplementation with multi-enzymes in broiler chickens. The chicks were randomly divided into 4 treatments with 8 replications per treatment and 15 birds per pen. Experimental diets consisted of two different levels: high-energy diet (HE) and low-energy diet (LE). The LE diet had 12.34 (starter) and 13.08 MJ ME/kg (finisher); The HE diet had 12.66 (starter) and 13.39 MJ ME/kg (finisher). Dietary treatments included 1) LCON (low-energy diet); 2) LME (LCON + 375 g multi-enzyme/ton of feed); 3) HCON (high-energy diet); and 4) HME (HCON + 375 g multi-enzyme/ton of feed). The multi-enzyme component contained protease, amylase, xylanase, glucanase, pectinase, galactosidase, debranching enzymes, and phytase. The broilers were weighed by pen and feed intake (FI), and data was recorded on d 1, 18, and 35 for calculating body weight gain (BWG) and feed conversion ratio (FCR). Fresh excreta samples were collected from each pen for the measurement of nutrient digestibility according to the procedures of AOAC (2000). All data were subjected to the GLM procedures of SAS with a 2 × 2 factorial arrangement, and probability values of $P < 0.05$ were considered to be significant. During the starter phase and overall, the effect of multi-enzymes and HE were observed to increase BWG (overall, LME and HME vs. LCON and HCON were 1,581.8 and 1,607.8 vs. 1,534.8 and 1,582.5 g/d; $P < 0.05$). In addition, the FCR improved in broilers fed with HE during d 1 to 18 and overall ($P < 0.05$). The apparent total tract digestibility (ATTD) of DM and N was improved (DM: LME and HME vs. LCON and HCON were 76.8 and 77.9 vs. 75.3 and 76.0%; N: LME and HME vs. LCON and HCON were 73.4 and 74.0 vs. 71.9 and 72.2%; $P < 0.05$) by the multi-enzymes on d 35. An increase was observed in breast muscle on carcass quality when broilers fed with HE ($P < 0.05$). Furthermore, feeding chicks with multi-enzyme supplementation reduced fecal NH_3 and H_2S concentrations ($P < 0.05$). However, no other carcass characteristics were affected by the treatments. In conclusion, dietary supplementation with a multi-enzyme component improved BWG and nutrient digestibility and reduced excreta noxious gas emission in broilers. Breast muscle was improved when broilers were fed the HE diet.

Key Words: broilers, growth performance, multi-enzymes

0923 Efficacy of dietary supplementation of protease and xylanase in plant-based diets on growth performance and health of nursery pigs at 6 to 9 wk of age.
I. Park*, H. Chen, and S. W. Kim, *North Carolina State University, Raleigh*.

This experiment was conducted to determine the supplemental effects of protease and xylanase (BRI, Durham, NC) in plant-based diets on growth performance and health of nursery pigs at 6 wk of age. One hundred and twenty pigs (60 barrows and 60 gilts at 15.5 ± 3.0 kg BW) were randomly allotted to 4 treatments with 10 pens (3 pigs per pen) per treatment, and fed the experimental diets for 3 wk in a 2 × 2 factorial arrangement. Two factors were protease (0 or 15,000 unit/kg diet) and xylanase (0 or 1400 unit/kg diet), which were supplemented to the basal diet, which included yellow dent corn (50%), soybean meal (26%), and distillers dried grains with solubles (20%) as major feedstuffs. All diets contained essential nutrients meeting the NRC requirements. Feed intake and BW were recorded weekly. At the end of the study, a pig representing median BW of each pen was selected for blood collection from jugular vein. Blood was used to obtain plasma. Plasma samples were used to measure plasma urea nitrogen (BUN), tumor necrosis factor-α (TNF-α), and immunoglobulin G (IgG). Data were analyzed using the Mixed procedure in SAS with pen as the experimental unit with treatments and sex as fixed effects and initial BW as a random effect. Statistical differences among treatment means were considered significant with $P < 0.05$. Overall, supplementation of protease did not affect growth performance of nursery pigs. Supplementation of xylanase, however, increased ($P < 0.05$) ADG (1.62 to 1.83 kg/d) without affecting ADFI and tended to increase ($P = 0.061$) G:F (0.803 to 0.860). Combinational use of protease and xylanase on growth performance did not differ among treatments. Plasma BUN and IgG were not affected by both factors, whereas plasma TNF-α was decreased ($P < 0.05$, 40.2 to 25.2 pg/mL) by supplementation of xylanase. There were no interactions of the effects of protease and xylanase in any measurements. In conclusion, dietary supplemental xylanase improved growth performance by reducing systemic inflammatory response. However, a combinational use of xylanase with protease did not enhance the effects of a single use of xylanase in nursery pigs at 6 to 9 wk of age.

Key Words: growth performance, intestinal health, nursery pigs, protease, xylanase

0924 Effects of microbial phytase on the apparent and standardized total tract digestibility of calcium in milk co-products fed to growing pigs.
Y. She[*1], D. Li[2], and H. H. Stein[1], [1]*University of Illinois Urbana-Champaign, Urbana,* [2]*CAU, Beijing, China*.

The objective of the experiment was to determine effects of microbial phytase on the apparent total tract digestibility (ATTD)

and the standardized total tract digestibility (STTD) of Ca in milk co-products fed to growing pigs. Sixty-four growing barrows (average initial BW: 15.97 ± 3.11 kg) were allotted to a randomized complete block design with 8 diets, 2 blocks, and 4 pigs per treatment in each block. A basal diet based on corn, potato protein isolate, and soybean oil was formulated. Three additional diets were formulated by adding whey powder, whey permeate, or skim milk powder to the basal diet. All diets were formulated without or with 1000 units per kilogram of microbial phytase for a total of 8 diets. All diets were formulated to contain the same concentration of Ca and total P. The basal endogenous loss of Ca was assumed to be 0.123 g/kg DMI. Feces were collected quantitatively for 5 d based on the marker-to-marker approach after a 7-d adaptation period. Results indicated that the STTD of Ca in whey powder, whey permeate, and skim milk powder were 96.18, 52.52, and 95.94% without phytase, respectively, and 94.43, 73.12, and 98.90% with phytase, respectively. Regardless of inclusion of microbial phytase, the ATTD and STTD of Ca in whey powder and skim milk powder were greater ($P < 0.05$) than in whey permeate. Inclusion of microbial phytase increased ($P < 0.05$) the ATTD and STTD of Ca in the whey permeate diet. Microbial phytase also increased ($P < 0.05$) the ATTD of P in the whey powder diet from 79.31 to 81.29%, in the whey permeate diet from 64.17 to 73.05%, and in the skim milk powder diets from 80.15 to 86.40%. Regardless of inclusion of microbial phytase, the ATTD of P was greater ($P < 0.001$) in whey powder and skim milk powder diets than in whey permeate diets. In conclusion, skim milk powder and whey powder had greater ATTD and STTD of Ca than whey permeate, but microbial phytase increase digestibility of Ca in whey permeate. The ATTD of P was also greater in skim milk powder and whey powder diets than in the whey permeate diet.

Key Words: calcium, milk co-products, pigs

0925 Effect of different levels of zinc and phytase on growth performance in weanling pigs. L. Blavi*, D. Solà-Oriol, S. M. Martín-Orúe, and J. F. Pérez, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain*.

It is common to use 2500–3000 ppm Zn as ZnO to prevent post-weaning diarrhea. However, most of the dietary Zn supply is excreted, causing environmental accumulation, and recently antimicrobial resistance concerns have also increased. Phytate supplementation in most piglet diets may create insoluble salts with several divalent cations (Ca, P, Zn) inhibiting their absorption. Therefore, the objective of the present experiment was to observe the effect of the interaction between the use of therapeutic doses of Zn and phytase supplementation on growth performance in weanling piglets (0 to 35 d post-weaning). A total of 320 pigs were used in a 2 × 2 factorial arrangement, where the main factors were Zn inclusion (125 or 2500 ppm Zn) and phytase inclusion (0 and 1000 FTU). Piglets were reared in 32 pens (10 pigs/pen; 8 replicates per treatment). The pre-starter (0–14 d) and starter (14–35 d) diets contained 2520 and 2460 Kcal NE/kg, 19.65 and 19.00% CP, 1.25 and 1.23 digestible Lys, 0.35 and 0.77% Ca, and 0.33 and 0.25% P digestible, respectively. The pre-starter diet had low Ca levels (0.33%) without $CaCO_3$. Feed intake and individual BW were registered on d 0, 14, and 35 post-weaning. Performance parameters were analyzed with ANOVA by using the Mixed procedure of the statistical package SAS. There was an effect of Zn on BW at d 14 and 35 ($P < 0.05$); where pigs with no ZnO addition presented higher weights compared to pigs with ZnO (11.12 and 21.84 vs. 10.56 and 20.76 Kg, respectively). There was no phytase effect on BW, ADG, ADFI, and FCR. However, there were significant interactions on BW at d 35, ADFI 0–14 and ADG 0–35 ($P < 0.05$), where piglets without ZnO and 1000 FTU of phytase obtained better results (higher BW, ADG, and ADFI) compared to piglets with ZnO and 1000 FTU of phytase (22.2 vs. 20.19 Kg; 327.13 vs. 261.13 g/d; and 416.76 vs. 357.34 g/d, respectively), suggesting that phytase does not have the same benefits with high levels of Zn on the diet. There was also a statistical trend for the interactions on BW14 ($P = 0.08$), ADG 0–14 ($P = 0.07$), ADG 14–35 ($P = 0.06$), and ADFI 0–35 ($P = 0.06$), following the same pattern. It can be concluded that diets without therapeutic ZnO and low levels of Ca but 1000 FTU of phytase allow better growth than diets with high Zn levels.

Key Words: phytase, pigs, zinc

0926 New bacterial 6-phytase expressed in *Pseudomonas fluorescens* improved growth performance, bone parameters, and P digestibility in growing pigs. F. N. Almeida*, M. Vázquez-Añón, and J. Escobar, *Novus International, Inc., St. Charles, MO*.

A study was conducted to determine the effects of a new bacterial 6-phytase expressed in *Pseudomonas fluorescens* (CIBENZA® PHYTAVERSE®, Novus International, Inc., St Charles, MO) on growth performance, bone parameters, and P digestibility in growing pigs fed a diet deficient in standardized total tract digestible (STTD) P. A total of 144 pigs (initial BW = 44.27 ± 0.74 kg) were randomly allotted to 1 of 4 treatments with 18 replications and 2 pigs/pen. Treatments included 1) a positive control (POS) that met the requirements (NRC, 2012) for all nutrients, 2) a negative control (NEG) deficient only in STTD P (−0.10% vs. POS), 3) NEG supplemented with 250 FTU/kg phytase (NEG+250), and 4) NEG supplemented with 500 FTU/kg phytase (NEG+500). Data were analyzed using the Mixed Procedure (SAS® Institute, Cary, NC). The ADG and G:F was less ($P < 0.01$) for pigs consuming the NEG diet compared with POS (0.964 vs. 1.093 kg and 0.356 vs. 0.387, respectively). The ADG of pigs consuming NEG+250 or NEG+500 was not different ($P > 0.05$)

from that of pigs consuming POS (1.061 or 1.066 vs. 1.093, respectively). Phytase linearly ($P < 0.01$) improved the ADG of pigs fed the NEG diet. The G:F of pigs fed NEG+250 or NEG+500 was not different from pigs fed the POS. Phytase supplementation to the NEG diet tended ($P = 0.06$) to linearly improve the G:F of pigs. Bone ash weight and bone P weight were greater for pigs fed the POS diet than for pigs fed the NEG diet (6.42 vs. 4.70 g and 1.19 vs. 0.86 g, respectively). Supplementing pigs with either 250 or 500 FTU/kg, however, linearly improved ($P < 0.01$) bone ash weight compared with pigs fed NEG (4.70 vs. 5.63 or 5.99 g, respectively). Likewise, bone P weight was linearly increased ($P < 0.01$) in pigs fed NEG+250 (1.04 g) or NEG+500 (1.11 g) compared with pigs fed NEG (0.86 g). The STTD of P was greater ($P < 0.05$) for pigs fed NEG+500 (48.71%) that all other treatments, with the NEG being the least digestible (35.03%). In conclusion, this new phytase efficiently improved the growth performance, bone parameters, and STTD of P in grower pigs.

Key Words: bone, pigs, phytase

0927 Effect of timing of post-weaning supplementation of xylanase on growth performance, nutrient digestibility and fecal microbial composition in weanling pigs.

H. Lu*[1], H. Yan[1], H. Masey O'Neill[2], C. L. Bradley[3], M. Bedford[4], P. Wilcock[3], C. Nakatsu[1], O. Adeola[1], and K. M. Ajuwon[5], *[1]Purdue University, West Lafayette, IN, [2]AB Vista Feed Ingredients, Marlborough, United Kingdom, [3]AB Vista Feed Ingredients, Marlborough, United Kingdom, [4]AB Vista Feed Ingredients, Marlborough, United Kingdom, [5]Department of Animal Sciences, Purdue University, West Lafayette, IN*.

The study was conducted to investigate the effect of timing of xylanase (Econase XT) supplementation to weanling pigs fed a corn-soybean meal based diet, and its effect on growth performance, nutrient digestibility, and gut microbial composition. A total of 128 weanling pigs ([Hampshire × Duroc] × [Yorkshire × Landrace]; barrows: gilts = 1:1; 6.2 ± 0.6 kg BW; weaning age: 21 d) were randomly assigned to 4 treatments, 8 replicate pens with 4 pigs per pen based on their BW at weaning. The 4 treatments were a combination of 2 dietary treatments (xylanase added at 0 or 16,000 BXU/kg) and 2 feeding time points [period 1 (d 0–14) and period 2 (d 14–42)]. Treatments were: xylanase-xylanase, xylanase-control, control-xylanase, and control-control. The study lasted 42 d with a 3-phase feeding program: d 0 to 14, d 14 to 28, and d 28 to 42. Chromic oxide marker was included in the diets at 0.5% from Day 28. BW and feed intake were recorded every 2 wk. On d 41, fecal samples were collected from each pig for determination of microflora diversity and apparent total tract nutrient digestibility (ATTD). Ileal digesta were also collected on d 42, for determination of apparent ileal nutrient digestibility (AID). From d 0–14, pigs had lower BW, ADG, and feed efficiency when xylanase was included in the diets. The final BW and overall ADG was higher ($P < 0.05$) when xylanase was supplied from d 14 compared with that from d 0. The AID and ATTD of DM, energy, N, and phosphorus was increased ($P < 0.05$) by xylanase and not impacted by timing of xylanase inclusion. The overall bacterial community structure was not influenced by different treatments. However, xylanase significantly decreased ($P < 0.05$) Veillonellaceae and tended to decrease ($P < 0.08$) *Megasphaera* abundance in period 2 compared to the control group. Therefore, timing of xylanase inclusion in weanling pig diets has an effect on performance in the nursery.

Key Words: weanling pigs, xylanase, digestibility, gut microbial profile

0928 Effect of xylanase and live yeast supplementation on growth performance and gut microflora diversity of growing pigs.

H. Lu*[1], H. Yan[1], H. MaseyONeill[2], C. L. Bradley[3], M. Bedford[4], P. Wilcock[3], C. Nakatsu[1], O. Adeola[1], and K. M. Ajuwon[5], *[1]Purdue University, West Lafayette, IN, [2]AB Vista Feed Ingredients, Marlborough,, United Kingdom, [3]AB Vista Feed Ingredients, Marlborough, United Kingdom, [4]AB Vista Feed Ingredients,, Marlborough, United Kingdom, [5]Department of Animal Sciences, Purdue University, West Lafayette, IN*.

The objectives of current study were to determine the effect of xylanase and live yeast (LY) supplementation, and the timing of xylanase supplementation, on future growth performance and gut microflora diversity of pigs. In the study, 180 weanling pigs (21 ± 2 d, BW: 6.2 ± 0.16 kg) were assigned to 5 treatments in a randomized complete block design (6 replicate pens, 6 pigs per pen) from weaning to market. The 5 treatments were: control-control, control-xylanase, xylanase-xylanase, LY-xylanase, and xylanase+LY-xylanase, where the first diet was fed from weaning to 2 wk and thereafter 6 additional corn/soy/corn DDG based phases were fed until d 127. Xylanase (Econase XT) was added at 16,000 BXU/kg and LY (Vistacell) at 1 kg/t. On d 15, 2 pigs per pen were euthanized to obtain jejunal mucosa samples. Fecal samples from Days 0, 14, 43, and 127 were collected for volatile fatty acids (VFA) and microbial diversity analysis. Pigs fed with LY and LY+xylanase from d 0–15 had higher BW and ADG at d 15 compared with the control ($P < 0.05$). Overall, G:F was higher in the xylanase+LY-xylanase and control-xylanase groups ($P < 0.05$) on d 127. Additionally, glucose transporter 2 (GLUT2) mRNA expression was higher in the LY and LY+xylanase groups on d 15 compared with control ($P < 0.05$). Furthermore, intestinal alkaline phosphatase (IAP) mRNA expression was highest in the xylanase-xylanase group and lowest in the LY-xylanase group ($P < 0.05$). Fecal VFA concentration significantly increased with age ($P < 0.01$). LY supplementation significantly increased propionate acid, valeric acid, and isovaleric acid

concentrations on d 127 ($P < 0.05$). Age significantly affected microbial diversity structure ($P < 0.01$). In summary, LY supplementation with or without xylanase improved growth performance of weanling pigs in the first 2 wk after weaning. Fecal VFA concentrations and microbial community structure were significantly influenced by age, with xylanase and LY supplementation having only a minor effect.

Key Words: xylanase, live yeast, weanling pigs, growth, microbial profile

0929 Effects of dietary supplementation of β-mannanase on digesta viscosity and intestinal health of nursery pigs. I. Park*, Y. I. Kim, and S. W. Kim, *North Carolina State University, Raleigh*.

This study was conducted to determine the effects of β-mannanase (CTC BIO Inc., Seoul, Korea) on digesta viscosity and intestinal health of nursey pigs. Pigs (36 barrows and 36 gilts at 15.5 ± 2.3 kg BW) at 45 d of age were housed individually and randomly allotted to 3 treatments (24 pens/treatment). Experimental diets had 3 levels of β-mannanase (0, 400, and 600 Unit/kg) and were fed to pigs for 10 d. Feed intake and BW were measured on d 7 and 10 to calculate growth performance. On d 10, all pigs were euthanized to obtain jejunal digesta to measure viscosity and mucosa from the duodenum and jejunum to measure tumor necrosis factor-α (TNF-α), immunoglobulin G (IgG), and malondialdehyde (MDA). Duodenal and jejunal tissues were used to measure morphology and proliferation of mucosa cells by Ki-67 immunohistochemistry. Tight junction proteins between jejunal mucosa cells were measured by the Western blot. Data were analyzed using polynomial contrasts in the Mixed procedure of SAS. Statistical differences among treatment means were considered significant with $P < 0.05$. Overall, viscosity of jejunal digesta was decreased ($P < 0.05$, 2.50 to 2.10 cP) as increasing β-mannanase from 0 to 600 Unit/kg diets. Increasing β-mannanase in the diets linearly decreased ($P < 0.05$) TNF-α (5.81 to 3.81 ng/g protein in the duodenum, 6.23 to 4.19 ng/g protein in the jejunum), IgG (1.44 to 1.07 mg/g protein in the duodenum, 1.20 to 0.80 mg/g protein in the jejunum), MDA (1.46 to 1.26 μmol/g protein in the duodenum, 1.06 to 0.69 μmol/g protein in the jejunum) and PC (7.11 to 4.22 μmol/g protein in the duodenum) of mucosa. Increasing β-mannanase in the diet linearly increased ($P < 0.05$) villus height (579 to 651 μm of duodenum, 426 to 516 μm of jejunum) and crypt depth (281 to 301 μm of duodenum, 175 to 246 μm of jejunum). Increasing β-mannanase in the diet linearly increased ($P < 0.05$) the number of proliferating cells (29.3 to 35.5%) and ZO-1 tight junction proteins (0.81 to 1.41) in the jejunum. Increasing β-mannanase in the diet, however, did not affect the growth performance of pigs during 45 to 55 d of age. In conclusion, dietary supplementation of β-mannanase (up to 600 Unit/kg diet) enhanced intestinal health by reducing the inflammatory response and oxidative stress which may be related to reduced viscosity of jejunal digesta. A 10-d feeding of β-mannanase, however, did not benefit the growth performance in nursery pigs.

Key Words: digesta viscosity, intestinal health, mannanase, nursery pig

---

0930 Effects of dietary supplementation with xylanase on growth performance, ileal digesta viscosity, apparent ileal digestibility, and excreta noxious gas emission of broilers fed wheat-based diets. W. C. Liu*, J. H. Park, S. I. Lee, S. D. Upadhaya, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, South Korea*.

This study was conducted to evaluate the effects of dietary xylanase supplementation in wheat-based diets on growth performance, ileal digesta viscosity, apparent ileal digestibility, and excreta noxious gas emission of broilers. A total of 600 one-d-old male Ross 308 broilers were used in this 35-d growth trial. Birds with an initial average BW of 43 ± 0.6 g were randomly allotted into 4 treatments with 10 replicate pens per treatment and 15 broilers in each pen. Dietary treatments were as follows: (1) CON, basal diet; (2) T1, basal diet + 0.0125% xylanase (the concentration guaranteed 9000 U/g); (3) T2, basal diet + 0.025% xylanase; (4) T3, basal diet + 0.0375% xylanase. Broilers were weighed and feed consumption was recorded by pen on d 0, 18, and 35 to calculated BWG, ADFI, and FCR. From d 29 to 35, Cr_2O_3 was used as an indigestible marker and supplemented in the diets at a level of 2 g/kg. On d 35, 120 chicks (3 per pen and 30 per treatment) were slaughtered, and the ileal digesta was immediately collected for determining the ileal digesta viscosity and apparent ileal digestibility (AID) of nutrients. For analysis of excreta noxious gas emission, fresh excreta samples from each pen were collected in 2.6-L plastic boxes at the end of experiment. All data were analyzed by using the GLM procedure of SAS, orthogonal polynomial contrasts were used to test the linear and quadratic effects of the increasing levels of xylanase. Statements of statistical significance were based on $P < 0.05$. Dietary addition of xylanase improved (linear, $P < 0.05$) the BWG and decreased (linear, $P < 0.05$) the FCR during d 1–18 and d 0–35. Oral administration of xylanase led to a decrease (linear, $P < 0.01$) in ileal digesta viscosity. In addition, the AID of DM, CP, energy, and most amino acids, with the exception of Ile, Phe, Asp, Glu and Pro, were improved (linear, $P < 0.05$) by xylanase supplementation. Furthermore, xylanase supplementation reduced excreta NH_3 (linear, $P < 0.05$; quadratic, $P < 0.05$) and R.SH (linear, $P < 0.01$) emission. In conclusion, dietary xylanase supplementation in broilers' wheat-based diets could mitigate the detrimental effect of NSP from wheat, reduce the viscosity of gut contents, and improve nutrient digestibility, thus improving broilers' growth performance. Moreover, inclusion of xylanase not only led to more consistent and uniform performance, but it also reduced

the release of odor emissions from broiler houses.

Key Words: growth performance, ileal digesta viscosity, xylanase

0931 Effects of corn-expressed phytase on growth performance and gut health of nursery pigs. J. K. Lee*, H. Chen, I. Park, and S. W. Kim, *North Carolina State University, Raleigh*.

This study was conducted to determine the super-dosing effects of phytase from corn-expressed phytase (CEP, Agrivida, Inc., Medford, MA) on growth performance and gut health of nursery pigs. Pigs (16 barrows and 16 gilts; 21 d of age; 6.19 ± 0.71 kg BW) were individually housed and allotted to one of 4 dietary treatments based on a randomized complete block design with the initial BW and sex as blocks. Pigs were fed a basal diet supplemented with ground CEP to provide phytase activity at 0, 500, 1500, or 3000 FTU/kg during 2 phases (Phase 1: 10 d and Phase 2: 20 d) for a total period of 30 d. Dietary Ca and P were not reduced, with 0.83% Ca and 0.44% STTD P or 0.74% Ca and 0.36% STTD P during Phases 1 and 2, respectively. Feed intake and BW were recorded every 10 d. Plasma samples were collected on d 25 postweaning to measure cytokine tumor necrosis factor-α (TNF-α) and malondialdehyde (MDA). Pigs were euthanized on d 30 to collect tissues from the duodenum and jejunum for the evaluation of morphology, TNF- α, and MDA. Digesta were collected from the proximal jejunum to measure viscosity. Data were analyzed using polynomial contrasts in the MIXED procedure of SAS version 9.3 (SAS Inc., Cary, NC, USA). Increasing the levels of phytase increased (linear, $P < 0.05$) BW on d 20 (10.2 to 12.1 kg) and on d 30 (16.1 to 18.6 kg), increased (linear, $P < 0.05$) ADG from d 10 to 20 (0.32 to 0.49 kg/d), and tended to increase (linear, $P = 0.052$) overall ADG (0.33 to 0.41 kg/d). Increasing supplemental levels of phytase increased (linear, $P < 0.05$) villus height in the duodenum (420 to 559 μm) and jejunum (426 to 491 μm), and the villus height-crypt depth ratio (1.5 to 2.1) in the duodenum. Increasing levels of phytase tended to decrease (Con vs. $T_1 + T_2 + T_3$, $P = 0.089$) TNF- α (6.53 to 5.36 pg/mg) in the duodenum and tended to decrease (linear, $P = 0.080$) MDA (0.5 to 0.34 umol/g protein) in the jejunum. Viscosity of jejunal digesta tended to decrease (quadratic, $P = 0.078$) from 2.55 to 2.15 cP (at 1500 FTU/kg). In conclusion, super-dosing corn-expressed phytase up to 3000 FTU/kg enhanced the growth performance of nursery pigs with improved villus developments and reduced inflammatory cytokine levels and oxidative stress products.

Key Words: corn-expressed phytase, growth performance, gut health, nursery pigs

0932 Effects of xylanase and protease on gut health and growth performance of newly hatched broiler chickens. M. P. Herchler*, L. Zheng, and S. W. Kim, *North Carolina State University, Raleigh*.

This study was to investigate the effects of supplemental xylanase and protease (BRI, Durham, NC) on gut health and growth performance of broiler chickens (288-d-old, male) fed experimental diets for 28 d. Treatments were based on 2 × 2 factorial arrangement with xylanase (0 and 15,000 XU/kg) and protease (0 and 300 U/g) as 2 factors with 9 cages/treatment and 8 birds/cage. Birds and feeders were weighed weekly for calculation of ADG, ADFI, and feed:gain (F:G). On d 7 and 28, 2 birds per pen were randomly chosen to collect blood and gut tissues for immunoglobulin G (IgG), malondialdehyde (MDA), protein carbonyl, and morphology measurements. Ileal digesta were collected to determine viscosity and apparent ileal digestibility (AID). Digesta viscosity tended to decrease ($P = 0.059$) and decreased ($P < 0.05$) when both enzymes were used in wk 1 and 4, respectively, whereas it was not affected by using enzymes individually. Protease increased ($P < 0.05$) villus height (611 to 689 μm) in wk 4. Xylanase decreased ($P < 0.05$) concentrations of serum IgG (2.66 to 2.06 g/L) and ileal protein carbonyl (0.41 to 0.29 μmol/g protein) in wk 1. Protease tended to decrease ($P = 0.083$) serum protein carbonyl (0.78 to 0.66 μmol/L) in wk 1. Protease decreased ($P < 0.05$) ileal protein carbonyl (0.39 to 0.31 μmol/g protein) in wk 1, which was more effective ($P < 0.05$) with xylanase together. Protease decreased ($P < 0.05$) serum MDA (0.56 to 0.30 μmol/L) and ileal MDA (0.53 to 0.35 μmol/g protein) in wk 4. Xylanase did not affect AID, whereas protease tended to increase AID of DM ($P = 0.064$; 74.7 to 76.5%), which was more effective ($P < 0.05$) with xylanase together. In wk 1, xylanase decreased ($P < 0.05$) F:G (1.213 to 1.173) and tended ($P = 0.063$) to decrease ADFI (20.1 to 19.4 g/d), whereas protease reduced ($P < 0.05$) ADG (17.2 to 16.0 g/d) and ADFI (20.1 to 19.4 g/d). Overall, protease increased ($P < 0.05$) F:G (1.504 to 1.528) whereas tended ($P = 0.089$) to reduce ADG (51.3 to 50.2 g/d), which was more effective ($P < 0.05$) with xylanase together. Mortality was not affected ($P > 0.10$) by the treatments. In conclusion, xylanase and protease benefited gut health by decreasing digesta viscosity, enhancing gut morphology, decreasing gut oxidative stress, and increasing nutrient digestibility, whereas these benefits were not related to growth performance.

Key Words: broiler chickens, protease, xylanase

0933 Effect of supplemental enzyme on growth performance, digesta viscosity, apparent total tract digestibility of nutrients in nursery pigs. U. P. Tiwari*[1], H. Chen[2], S. W. Kim[2], and R. Jha[1], [1]*University of Hawaii at Manoa, Honolulu,* [2]*North Carolina State University, Raleigh*.

Arabinoxylans and mannans are present in high concentrations in coproducts like distillers dried grain with solubles (DDGS), which are not degraded by the endogenous enzymes of swine, increase the digesta viscosity, and subsequently reduce the digestibility of nutrients. Feed enzymes can mitigate the negative effect of fiber, thereby enhancing the utilization of relatively low-cost coproducts in swine feeding. Three enzymatic treatments (xylanase, mannanase, and xylanase + mannanase) were used in a 20-d feeding trial to evaluate the effect of supplemental enzymes on fiber degradation and nutrient digestibility in nursery pigs fed corn-soybean meal based diet with 15% DDGS. A total of 32 weaner pigs (PIC 337 × Camborough 22, initial BW 6.2 kg) were used in the study. Feed intake and BW were recorded weekly. On d 14, titanium dioxide was blended into experimental diet (0.3%) as an indigestible marker for calculation of digestibility. Fecal samples were collected over 3 consecutive days, from d 17 to 19. On d 19, pigs were fasted overnight, and exactly 4 h after refeeding on d 20 in the morning, pigs were euthanized by captive bolt followed by exsanguination. There was no significant effect of enzymes on the growth performance of pigs, as the 20-d period might not have been sufficient to show the change, as well as on the pH of jejunal, ileal, and colon digesta. Addition of xylanase reduced ($P < 0.05$) the viscosity of jejunal digesta (2.1 to 1.5 centipoise) and increased ($P < 0.05$) apparent total tract digestibility (ATTD) of acid detergent fiber (18.1 to 26.9%) and neutral detergent fiber (35.1 to 41.2%). Addition of mannanase tended to increase ($P = 0.060$) ATTD of neutral detergent fiber (35.1 to 41.4%). In conclusion, use of feed enzymes targeting fiber in coproducts degrades fiber, increases fiber digestibility, and decreases the viscosity of digesta, ultimately increasing the digestion and absorption of nutrients.

Key Words: coproducts, enzymes, fiber digestibility

0934 Effects of full fat or defatted rice bran and microbial xylanase on growth performance of weanling pigs. G. A. Casas*and H. H. Stein, *University of Illinois at Urbana-Champaign*.

The objective was to determine effects of increased concentrations of full fat rice bran (FFRB) or defatted rice bran (DFRB) in diets without or with supplementation of a microbial xylanase on growth performance and concentrations of tumor necrosis factor-α (TNF-α) and IgA in plasma of weaned pigs. A total of 532 pigs (initial BW: 9.3 ± 0.5 kg) were allotted to 14 diets in a randomized complete block design using 4 blocks and 2 replicate pens per diet in each block. A diet containing corn, soybean meal, and whey powder, and 6 diets containing corn, soybean meal, whey powder, and 10, 20, or 30% of either FFRB or DFRB were used. All diets were prepared without or with 16,000 units per kg of microbial xylanase (Econase XT-25, AB Vista, Marlborough, UK). All diets also contained 1500 units per kg of microbial phytase. On the last day of the 23-d experiment, blood samples were collected from one pig per pen to determine TNF-α and IgA. Results indicated that ADFI decreased linearly ($P < 0.05$) as inclusion of FFRB increased in diets, and that there was a tendency ($P = 0.08$) for reduced ADFI as DFRB increased in the diets. Pigs fed diets containing DFRB had greater ADFI ($P < 0.05$) than pigs fed diets containing FFRB, but ADG increased and then decreased (quadratic, $P < 0.05$) with increasing concentrations of FFRB or DFRB, in the diets. The G:F ratio was not affected by inclusion of DFRB in the diets but increased linearly and quadratically ($P < 0.05$) as the inclusion of FFRB increased, and G:F was greater ($P < 0.05$) in pigs fed diets containing FFRB than in pigs fed diets containing DFRB. There was a tendency for the concentration of TNF-α to decrease linearly ($P = 0.09$) as the inclusion of FFRB increased in the diet, but that was not the case when DFRB was added to the diets. Addition of xylanase had no effect on the variables evaluated. The concentration of IgA was not affected by inclusion of FFRB or DFRB in the diets. In conclusion, both FFRB and DFRB may be included in diets fed to weanling pigs from 2 wk post-weaning by at least 20% without compromising growth performance.

Key Words: pigs, rice bran, xylanase

935 Addition of optimal non-starch polysaccharide enzymes using in vitro method to a corn-soybean meal diet and a corn-miscellaneous meal diet for growing pigs. L. Gao, L. Chen, R. Zhong, L. Zhang, and H. Zhang*, *Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, China*.

The objectives of the present study were to evaluate the effect of optimized non-starch polysaccharide (NSP) enzymes using an in vitro digestion method on the digestibility of energy and nutrients in a corn-soybean meal diet and a corn-miscellaneous meal diet (corn–soybean meal–rapeseed meal–cottonseed meal–sugar beet pulp meal diet) of pigs. In Exp. 1, the optimal NSP enzymes (cellulase, xylanase, β-glucanase, β-mannanase, α-galactosidase, and pectinase) of the two diets were screened using a quadratic regress-orthogonal rotary design. In Exp. 2, the effects of the optimal NSP enzymes on the digestibility of energy and nutrients in the 2 diets were determined. A total of 12 ileal-cannulated pigs (initial BW = 50.9 ± 4.9 kg) were allotted to 4 treatments in an incomplete block design (4´3), 4 diets (the 2 diets with or without the addition of optimum NSP enzymes) were fed to the growing pigs. The NSP enzymes had a quadratic effect on the in vitro

dry matter digestibility (IVDMD), and the optimal enzyme combination was 534 U/kg cellulase, 9984 U/kg xylanase, 1014 U/kg β-glucanase, 4081 U/kg β-mannanase, 252 U/kg α-galactosidase, and 107 U/kg pectinase in the corn-soybean meal diet (R^2 = 0.69, P = 0.04), and 960 U/kg cellulase, 17,178 U/kg xylanase, 406 U/kg β-glucanase, 19,023 U/kg β-mannanase, 307 U/kg α-galactosidase, and 97 U/kg pectinase in the corn-miscellaneous meal diet (R^2 = 0.72, P = 0.02), respectively. Pigs fed the corn-soybean meal diet with the addition of NSP enzymes had greater ($P < 0.05$) apparent ileal digestibility (AID) of DM, NDF, and insoluble NSP, and apparent total tract digestibility (ATTD) of soluble NSP and total NSP than those fed the diet without NSP enzymes. The AID of all nutrients, with the exception of the ether extract and the ATTD of GE, DM, CP, EE, and insoluble NSP, were greater in a corn-miscellaneous meal diet with the NSP enzymes than without the NSP enzymes ($P < 0.05$). The ATTD of total NSP content had a tendency (P = 0.05) to increase with the corn-miscellaneous meal diet having the addition of NSP enzymes. In conclusion, a corn-soybean meal diet and a corn-miscellaneous meal diet with the optimal NSP enzymes using in vitro digestion method can increase nutrient digestibility of diets fed to growing pigs.

Key Words: digestibility, energy, in vitro digestion method, non-starch polysaccharide enzyme, nutrient, pig

0936 Growth performance, bone measurements, and P digestibility in nursery pigs fed diets supplemented with increasing levels of a new bacterial 6-phytase expressed in *Pseudomonas fluorescens*. F. N. Almeida*, M. Vázquez-Añón, and J. Escobar, *Novus International, Inc., St. Charles, MO*.

An experiment was conducted to determine the effects of a new bacterial 6-phytase expressed in *Pseudomonas fluorescens* (CIBENZA® PHYTAVERSE®, Novus International, Inc., St Charles, MO) on the growth performance, bone parameters, and P digestibility in nursery pigs. A total of 280 pigs (initial BW = 6.25 ± 1.03 kg) were randomly allotted to 1 of 5 treatments with 14 replications and 4 pigs/pen. Treatments included 1) a positive control (POS) that met requirements (NRC, 2012) for all nutrients, 2) a negative control (NEG) deficient only in standardized total tract digestible (STTD) P (−0.18% vs. POS), 3) NEG supplemented with 500 FTU/kg phytase (NEG+500), 4) NEG supplemented with 1000 FTU/kg phytase (NEG+1000), and 5) NEG supplemented with 2000 FTU/kg phytase (NEG+2000). Data were analyzed using the Mixed procedure (SAS® Institute, Cary, NC). Orthogonal polynomial contrasts were used to determine linear and quadratic effects of increasing levels of phytase. ADG, ADFI, and G:F were greater ($P < 0.01$) in POS fed pigs than in NEG fed pigs. The ADG was improved (linear and quadratic, $P < 0.01$) from 0.308 (NEG) to 0.475 (NEG+2000) kg as phytase supplementation level increased. Likewise, ADFI and G:F were also improved (linear and quadratic, $P < 0.01$) by increasing levels of phytase. Bone ash and bone P content were greater ($P < 0.01$) in pigs fed POS vs. pigs fed NEG (1.159 and 0.215 g vs. 0.557 and 0.101 g, respectively). As phytase supplementation increased, bone ash and P weight also increased (linear and quadratic, $P < 0.01$) compared with NEG fed pigs. Bone ash and P weight in pigs receiving NEG+2000 were not different ($P > 0.05$) from that of pigs receiving the POS diet (1.106 and 0.192 g vs. 1.159 and 0.215 g, respectively).Phytase supplementation improved (linear and quadratic, $P < 0.01$) the STTD of P from 17.31 (NEG) to 70.74% (NEG+2000). Results from this experiment demonstrate the efficacy of this new 6-bacterial phytase to improve growth performance, bone traits, and the STTD of P.

Key Words: bone, pig, phytase

937 Nutritive value of cold-pressed soybean cake with or without extrusion or supplementation of multi-carbohydrase for pigs. T. A. Woyengo*[1], R. Patterson[2], and C. L. Levesque[1], [1]*South Dakota State University, Brookings,* [2]*Canadian Biosystems, Calgary, AB, Canada*.

The objectives were to determine the standardized ileal digestibility (SID) of AA and the NE value of cold-pressed soybean cake (CP-SBC), and the effect of extrusion or adding multi-carbohydrase to CP-SBC diet for growing pigs. Eight ileal-cannulated pigs (initial BW = 80 kg) were fed 4 diets in a replicated 4 × 4 Latin square design to give 8 replicates per diet. Diets included a cornstarch-based diet with CP-SBC, extruded CP-SBC, and SBC plus multi-carbohydrase (1200 U of xylanase, 150 U of glucanase, 500 U of cellulose, 60 U of mannanase, 700 U of invertase, 5000 U of protease, and 12,000 U of amylase/kilogram of diet; Superzyme CS, 1 g/kg); and a N-free diet. The CP-SBC was the sole source of protein in the CP-SBC-containing diets. The ratio of cornstarch to sugar and soybean oil in CP-SBC-containing diets was identical to the N-free diet to allow calculation of energy digestibility of CP-SBC by the difference method. The evaluated CP-SBC had been produced by heating the soybean seed at 105°C for 60 min followed by pressing the heated soybean seeds at less than 42°C (barrel temperature). On a DM basis, CP-SBC and extruded CP-SBC contained 47.8 and 47.1% CP, 15.6 and 10.5% ADF, 7.23 and 8.85% ether extract, 3.11 and 3.08% Lys, and 2.25 and 3.70 TIU/mg, respectively. Extrusion increased ($P < 0.001$) the SID of AA for the CP-SBC by an average of 12%. Also, extrusion increased ($P < 0.001$) the NE value of the CP-SBC from 2743 to 2853 kcal/kg of DM. Supplementation of CP-SBC diet with the multi-carbohydrase increased ($P < 0.05$) the SID of Arg and Pro and tended to increase ($P < 0.1$) the SID of Ile and Trp. However, the multi-carbohydrase supplementation did not affect the NE value of CP-SBC. In conclusion, the CP-SBC evaluated in the

present study could be an alternative source of AA and energy in swine diets, and its nutritive value can be increased by extrusion after the cold-pressing. However, there was little additional benefit in nutritional value of the CP-SBC gained with multi-carbohydrase supplementation.

Key Words: cold-pressed soybean cake, nutrient digestibility, pig

0938 Influence of *Acacia tortilis* leaf meal-based diets on growth performance of pigs. M. Khanyile, S. P. Ndou, and M. Chimonyo*, *University of KwaZulu-Natal, Pietermaritzburg, South Africa*.

The objectives of the study were to assess the nutritive value of *Acacia* leaf meals and to determine the optimum inclusion level of *Acacia tortilis* leaf meal in finishing pigs. Five dominant leguminous leaf meals namely, *Acacia tortilis*, *Acacia robusta*, *Acacia nilotica*, *Acacia nigrescens* and *Acacia xanthophloea*, were individually hand-harvested and analyzed for their chemical and physical properties. Although the crude protein content of *A. xanthophloea* and *A. tortilis* were similar, the latter was incorporated into the experimental diets as it had the lowest water-holding capacity and swelling capacity and moderate levels of condensed tannins. *A. tortilis* was also the most abundant in the locality. Thirty finishing male F_1 hybrid (Landrace × Large White) pigs with an initial weight of 60.6 (s.d. = 0.94) kg were randomly allotted to six diets containing 0, 50, 100, 150, 200, 250 g/kg DM inclusion levels of *A. tortilis* leaf meal. Each diet was offered ad libitum to five pigs in individual pens for 21 d. Average daily feed intake (ADFI), average daily gain (ADG), and gain:feed (*G*:*F*) ratio were measured every week. There was an increase in both ADFI and ADG ($P < 0.001$) as *A. tortilis* leaf meal increased, before they started to decrease. An increase in *A. tortilis* leaf meal levels in the diets caused a quadratic decrease ($P < 0.01$) in the *G*:*F* ratio. The change in ADFI, ADG, and *G*:*F* ratio during each week of successive feeding decreased ($P < 0.05$) with incremental levels of *A. tortilis* in the diets. Using piecewise regression (broken-stick analyses), it was observed that *A. tortilis* leaf meal can be included up to 129 g/kg DM in finishing pig feeds without negatively affecting the *G*:*F* ratio. The ability with which pigs utilize leaf meal-based diets improves with duration of exposure to such diets.

Key Words: *Acacia tortilis*, condensed tannins, feed intake, pig performance

0939 Different responses of Ross 308 and 708 broiler strains in growth performance and related properties to diet treatment with or without tributyrate glycerides. A. Bedford[1], H. Yu[1], M. Hernandez[1], J. Squires[2], S. Leeson[3], Y. Hou[4], and J. Gong[*1], *[1]Agriculture and Agri-Food Canada, Guelph, ON, Canada, [2]Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, [3]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [4]Wuhan Polytechnic University, Wuhan, China*.

Within genetically similar broiler strains, there can be significant performance differences, making strain selection an important decision for producers to meet their requirements. This study has investigated the differences in growth performance, including body composition, between Ross 308 and Ross 708 birds, and compared how each strain responds to the supplementation of tributyrin. Tributyrin is a butyric acid glyceride that has been shown to have multiple positive effects on broiler performance and can be a potential alternative to in-feed antibiotics. Two hundred and forty-day-old Ross 308 and 240-d-old Ross 708 birds were divided into treatment groups and fed either a basal diet or diets supplemented with low or high levels of tributyrin for 35 d. Neither the strain nor tributyrin supplementation had an effect on overall average daily gain or feed:gain ratios ($P > 0.05$). Ross 708 control birds had significantly decreased relative abdominal fat weight at 5 wk of age compared to Ross 308 control birds ($P < 0.05$), and tributyrin supplementation further decreased relative abdominal fat weight in Ross 708 birds ($P < 0.05$). Ross 708 control birds had significantly higher fat deposition in the breast muscle compared to Ross 308 controls ($P < 0.05$), and the addition of tributyrin lowered this deposition in both strains ($P < 0.05$). Breast muscle lipid profiles were significantly different between strains, with Ross 308 control birds having decreased saturated and monounsaturated fatty acids and increased polyunsaturated fatty acids compared to Ross 708 control birds ($P < 0.05$). Significant differences in the hepatic expression of genes associated with lipid metabolism (SREBP-1 and ATPCL) were observed both between strains and with tributyrin supplementation ($P < 0.05$). These results support the modulation of lipid metabolism by tributyrin and show that even genetically similar strains can perform significantly differently at the metabolic level and respond differently to dietary supplementation of tributyrin.

Key Words: broiler, tributyrin, growth performance

0940 Immunomodulatory effects of whole yeast cells and capsicum in weanling pigs challenged with pathogenic *Escherichia coli*. S. Wojnicki[*1], V. G. Perez[2], and R. N. Dilger[1], [1]*University of Illinois, Urbana,* [2]*ADM Animal Nutrition, Decatur, IL*.

Global concerns over antibiotic resistance triggered the development of nutritional technologies to support animal health. In weaned pigs, enterotoxigenic *Escherichia coli* infections are common. In this study, we sought to quantify the combined dietary effects of whole yeast cells (WYC) and capsicum (CAP) on performance and immune indices in weanling pigs experiencing an *E. coli* infection. Weanling pigs (32 barrows and 32 gilts, 21 d of age, 5.90 ± 1.03 kg BW) were allotted to experimental treatments in a randomized complete block design based on genetics, sex, and initial BW. Four pigs were individually housed within each containment chamber and assigned to 1 of 4 dietary treatments (n = 13), which included a control diet without or with 0.2% WYC (CitriStim, ADM, Decatur, IL) or 10 ppm of CAP, provided either alone or in combination. After receiving diets for 13 d, pigs were orally inoculated with F18$^+$ *E. coli* and maintained on the same diets for an additional 10 d; a separate cohort of pigs (n = 12) receiving the control diet was sham-inoculated using PBS. Body and feeder weights were recorded, and fecal swabs collected, on 0, 5, and 10 d post-inoculation (DPI), with blood sampled at 7 DPI for clinical outcomes. Data were analyzed as a 2-way ANOVA (infected pigs only), with a separate comparison between unchallenged and challenged control-fed pigs. While no interactive effects were observed for growth performance, main effects revealed that WYC increased (P < 0.05), and CAP decreased (P < 0.05), ADFI 0–10 DPI; reciprocal effects were observed for G:F due to a lack of differences in ADG. The challenge *E. coli* strain was undetectable in fecal swabs on 0 and 10 DPI but differed between unchallenged and challenged control-fed pigs at 5 DPI. Total bacterial counts were lower (P = 0.02) at 5 DPI in pigs fed CAP-containing diet, and the combination of additives elicited higher total bacteria counts compared with either additive alone (interaction, P = 0.03) at 10 DPI. Blood leukocyte counts were increased in infected pigs receiving the combination of additives compared with infected pigs on other dietary treatments (interaction, P = 0.04), and addition of WYC increased lymphocyte counts (main effect; P = 0.01) at 7 DPI. Overall, these data indicate that WYC and CAP have different effects on ADFI and individually or in combination may affect the immune response in weaned pigs experiencing an enterotoxigenic *E. coli* infection.

Key Words: *Escherichia coli*, yeast, essential oils

0941 Comparing the effects of zinc oxide, milk hydrolysate, yeast β glucan, and combination of milk hydrolysate/yeast β glucan on growth, gut microbiota, and cytokine gene expression in weaning piglets. *A*. Mukhopadhya[*1], J. V. O'Doherty[2], N. Noronha[3], M. T. Ryan[1], and T. Sweeney[1], [1]*School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland,* [2]*School of Agriculture and Food Science, University College Dublin, Dublin 4, Ireland,* [3]*Food for Health Ireland, University College Dublin, Dublin, Ireland*.

Concerns over the usage of prophylactic antibiotics and pharmacological doses of zinc (ZnO) are driving the need to develop natural sustainable alternatives to support gut health in the piglet during the post weaning period. Our hypothesis was that a diet consisting of a combination of yeast β-glucan (YBG) and sodium caseinate hydrolysate (NaCASH) will improve gut health in weaning piglets and replace the requirement for ZnO in the diet. Thus, the objective of this experiment was to compare the effects of supplementing the weaning piglet diet with ZnO, NaCASH, YBG, and a combination of NaCASH + YBG on piglet body weight (BW), gut microbiota, and gut cytokine gene expression. Forty 21-d-old piglets (7.3 ± 0.2 kg) were weaned and assigned to either 1) control diet, 2) control diet supplemented with 3.1 g/kg ZnO, 3) 0.25 g/kg NaCASH, 4) 0.25 g/kg YBG, or 5) 0.25 g/kg NaCASH + 0.25 g/kg YBG (combination) for 12 d (n = 8). Fecal scores per pen were recorded daily and BW recorded on Days 0, 6, and 12. Following sacrifice on Day 12, caecal and colonic digesta and colonic tissues were collected. Digesta samples were used to enumerate a selected panel of bacterial colonies by 16s rRNA QPCR, while tissue samples were used to evaluate a selected panel of cytokine gene expression by QPCR. Lower fecal scores were recorded in piglets from d 6–12 supplemented with either ZnO (P < 0.01) or the combination (P < 0.05) compared to control group. Similarly, overall ADG, FI, and gain to feed ratio were improved in ZnO and combination (P < 0.05) groups compared to the control group. However, only ZnO supplementation improved BW (P < 0.05) compared to control group. In caecal digesta, *Bacteroidetes* abundance was increased by ZnO and NaCASH supplementation (P < 0.05) compared to control group, whereas YBG group had higher enteropathogenic AEEC compared to control group (P < 0.05). In colonic tissues, while *IL-1α, IL-1β, IL-8*, and *IL-17* expression were downregulated in ZnO group, only *IL-1α* expression was downregulated in NaCASH and combination diet groups compared to control group (P < 0.05). Therefore, NaCASH or YBG individually did not improve weaning piglet growth or health, yet in combination they improved growth parameters similar to ZnO supplementation. Hence, these results substantiate our hypothesis that a YBG-NaCASH combination could be a suitable alternative to

zinc oxide during the weaning period.

0942 Effects of a standardized blend of carvacrol, cinnamaldehyde, and capsicum oleoresin on performance of growing finishing pigs using multiple trial analysis methodology.

C. Oguey*, *Pancosma, Geneva, Switzerland*.

The optimization of performance at limited expense in growing-finishing pigs is a constant concern of producers. Many phytomolecules have been reported to influence production efficiency of monogastric animals. The objective was to assess the effect of a standardized protected blend of cinnamaldehyde, carvacrol, and capsicum oleoresin (XT, XTRACT® 6930, Pancosma, Geneva, Switzerland) on performance and carcass quality of growing-finishing pigs. The database regrouped 14 trials organized in 7 studies (500 pigs; mean initial BW of 47.0 kg, mean duration of 69.0 d, mean XT dose of 83.5 g/t). All trials reported side-by-side comparisons of an unsupplemented control diet and the inclusion of XT in pigs. Outcomes selected were DMI, ADG, FCR, carcass yield, fat thickness in G2, and meat %. Data were analyzed using a mixed model with the TRIAL variable as a random effect and the TRT variable as a fixed effect. Mean values were calculated using the LSMEANS procedure of XLstat, weighting the data for the variance among trials. Results showed that XT increased ADG by 2.6% ($P < 0.05$) and reduced FI and FCR by. respectively. 1.1% ($P < 0.05$) and 3.8% ($P < 0.01$). For these outcomes, the lower limit of the 95% confidence interval was then used to assess the effect of XT supplementation on fattening duration or pig weight at slaughter. For a fixed slaughter weight of 120 kg, the effect of XT on performance resulted in a reduction of growing and fattening by 2.2 d. After 115 d of fattening, XT increased final BW by 1.7 kg. Finally, XT did not affect carcass yield and fat thickness G2 ($P > 0.50$) but increased meat percentage by 1.2% ($P = 0.06$). These findings suggest that the dietary supplementation of XT improves performance of growing-finishing pigs.

Key Words: multiple analysis, phytomolecules, pig performance

0943 Extracts of laminarin improve growth rate and small intestinal morphology in newborn chicks but do not influence *Campylobacter* colonization.

A. Mukhopadhya*[1], S. Vigors[1], J. V. O'Doherty[2], H. Meridith[1], K. Thornton[1], and T. Sweeney[1], *[1]School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland, [2]School of Agriculture and Food Science, University College Dublin, Dublin 4, Ireland*.

Promoting growth performance while limiting the proliferation of bacteria such as *Campylobacter jejuni* is a key goal of the broiler industry. Therefore, the objective of this study was to evaluate the effects of supplementing the post-hatch diet with laminarin and fucoidan extracts on growth performance, small intestinal morphology, and *C. jejuni* colonization following an experimental challenge in 13 d old chicks. The experiment consisted of three diets: 1) basal diet, 2) basal diet + 200 ppm laminarin (LAM), and 3) basal diet + 200 ppm LAM and 160 ppm fucoidan (LAM/FUC). Day-old Ross chicks ($n = 135$) were housed in groups of three, with 15 replicates per treatment group. On Day 3, all chicks were orally gavaged with 0.1 ml × 10^6 colony forming units of *C. jejuni.* Following humane sacrifice on Day 13, caecal digesta samples were collected for enumeration of *C. jejuni* and *Lactobacillus*. Ileal tissue was also collected post-slaughter to examine small intestinal morphology. Chicks offered diets containing the seaweed extracts LAM or LAM/FUC had increased live weights (311 g, s.e. 4.14 and 302 g, s.e. 3.99, respectively, $P < 0.05$) compared to the basal diet (290 g, s.e 3.99) at the end of the experimental period (Day 13). The mean total intake for the chicks fed the LAM and LAM/FUC extracts at the end of the experiment (Day 13) were 373 g/d (s.e. 3.89), 411 g/d (s.e. 4.03), and 411 g/d (s.e 3.89), respectively, with chicks fed the basal diet having lower feed intake compared to both the LAM and LAM/FUC fed chicks ($P < 0.05$). Dietary inclusion of LAM/FUC combination increased the feed conversion ratio (FCR) (1.63 g/g vs. 1.69 g/g; s.e ± 0.02) compared to the basal diet ($P < 0.05$). Chicks offered the LAM diet had increased ileal villus height compared to chicks offered the basal diet (307 µm vs. 231 µm s.e ± 17.24, $P < 0.05$). There was no effect of LAM or LAM/FUC extracts on the proliferation of *C. jejuni* or on *Lactobacilli* numbers in the cecum. In conclusion, supplementation with LAM or LAM/FUC in the post-hatch period improved growth performance and positively modified small intestinal architecture but did not impact the extent of *C. jejuni* proliferation.

Key Words: broiler chicks, *Campylobacter jejuni*, performance, histology, seaweed

0944 Effects of defatted microalgae on nutrient digestibility and retention in broiler chicks.
T. Sun*, A. D. Magnuson, L. Tao, M. Burke, M. Barcus, and X. G. Lei, *Cornell University, Ithaca, NY*.

This experiment was to determine the impact of supplemental 10% defatted microalgae (*Nannochloropsis oceanica*, 45% CP and 3.8% ether extraction, EE) from biofuel production in a corn-soybean meal basal diet (BD) on nutrient digestibility and retention in broiler chicks. Day-old hatchling Cornish Giant cockerels were divided into two groups (5 cages/group, 4–5 chicks/cage) and fed the BD or the microalgae diet for 6 wk. Starting at wk 3, chicks were fed diets containing 0.2% chromic oxide as an indigestible marker. Total excreta of individual cages was collected daily for consecutive 5 and 3 d during wk 5 and 6, respectively. At the end of wk 6, chicks were euthanized to collect ileal digesta from 1 chick/cage. Concentration of DM, CP, EE, AA, and chromic oxide in digesta, excreta, and diets were assayed. Apparent nutrient retention was calculated based on total excreta collection and chromic oxide as an indigestible marker. The latter was also used to estimate apparent ileal digestibility of nutrients. Data were analyzed by Student *t* test. Chicks fed the two diets had similar ADFI and G:F ratio, although those fed the microalgae diet had 3–5% ($P < 0.05$) heavier BW than chicks fed the BD. Feeding the microalgae diet enhanced ($P < 0.05$) and decreased ($P < 0.05$) apparent retention and digestibility of DM by 3.3% and by 1.8%, respectively. Feeding the microalgae diet elevated (1.6 to 3.8%, $P < 0.05$) apparent retention of EE determined by the indirect method, but not by the direct method. Supplemental defatted microalgae did not affect apparent retention of CP determined by both methods at either time point except for a 17.8% decrease ($P < 0.01$) by the 5-d total collection. Feeding the microalgae diet decreased ($P < 0.05$) apparent ileal digestibilities of 8 essential AA and 6 nonessential AA, ranging from 32% for isoleucine to 7% for glutamic acid. Feeding that diet decreased ($P < 0.05$) apparent retention of 6 essential AA and 5 nonessential AA, ranging from 16% for threonine to 0.6% for leucine. In conclusion, supplementing 10% of defatted microalgae in the corn-soybean meal diet did not show consistent effect on apparent retention or ileal digestibility of DM, EE, or CP determined by the two methods at the two time-points, but the diet decreased apparent retention or ileal digestibility of a number of AA. (Supported by USDA/DOE Biomass R&D Initiative Grant and a Cornell Hatch Grant).

Key Words: algae, amino acid, broiler, digestibility, retention

0945 Defatted microalgae-mediated enrichment of n-3 polyunsaturated fatty acids in muscle of broiler chicks was not affected by supranutrition of vitamin E and(or) Se.
L. Tao, T. Sun, A. D. Magnuson, M. Burke, and X. G. Lei*, *Cornell University, Ithaca, NY*.

We previously demonstrated an enrichment of docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) in breast and thigh muscles of broiler chicks fed defatted microalgae. This study was to determine if that enrichment affected the physical quality of the meat and was enhanced by feeding less corn oil and extra vitamin E/Se. Day-old hatchling Cornish Giant cockerels (total: 216) were divided to six groups (6 replicate cages/treatment and 6 chicks/cage). The treatments included Diet 1 (control) = corn-soybean meal based diet containing 4% corn oil, 25 IU vitamin E as dl-α-tocopherol/kg, and 0.2 mg Se as sodium selenite/kg; Diet 2 = Diet 1 + 10% defatted *Nannochloropsis oceanica* (45.1% CP, 3.8% EE); Diet 3 = Diet 2 − 2% corn oil; Diet 4 = Diet 3 + 75 IU vitamin E/kg; Diet 5 = Diet 3 + 0.3 mg Se/kg; and Diet 6 = Diet 3 + 75 IU vitamin E and 0.3 mg Se/kg. The experiment lasted for 6 wk. Data were analyzed by one-way ANOVA with Bonferroni's post-hoc comparisons tests or by Student's *t* test (GraphPad Prism 6.0). Diets produced no difference in growth performance of chicks. Feeding Diet 2 enhanced ($P < 0.05$) concentrations of breast CP (14%), glycine (60%), and serine (70%) at wk 6 compared with the control. Feeding Diet 2 elevated ($P < 0.05$) DHA and EPA concentrations of both breast and thigh muscles over the control, whereas feeding Diets 3–6 did not further enhance the enrichments. Both breast and thigh muscles were cooked (175°C oven for 30 min) for texture analysis. Springiness of the thigh muscles was elevated by 23% ($P < 0.05$) in chicks fed Diet 2 than in those fed Diet 1. Chewiness of the breast muscle was elevated by 41–83% ($P < 0.05$) in chicks fed Diet 5 than in those fed the other diets. Chewiness of the thigh muscles was elevated by 79% ($P < 0.05$) in chicks fed Diet 5 than in those fed Diet 1. In conclusion, supplementation of 10% defatted microalgae in the corn-soybean meal basal diet effectively enriched DHA and EPA in breast and thigh muscles, whereas inclusions of extra vitamin E and Se or less corn oil in the diets did not enhance the enrichments. The additional Se, however, improved chewiness of the muscles. (Supported in part by a USDA/DOE Biomass R&D Initiative Grant and a Cornell Hatch Grant).

Key Words: chicken quality, DHA, EPA, microalgae, selenium, vitamin E

0946 Effect of supplementing milk during first 4 d postweaning on growth performance, energy digestibility, gut morphology, and severity of diarrhea for nursery pigs in a commercial farm.
J. Guo*[1], J. Wang[1], J. M. Purvis[1,2], and S. W. Kim[1], [1]*North Carolina State University, Raleigh,* [2]*N. G. Purvis Farm Inc., Robbins, NC*.

The experiment was conducted to evaluate the effects of supplemental milk (6.5, 8.7, 10.9, and 10.9 g DM milk/pig/d; 10% of estimated feed intake) during the first 4 d postweaning on growth performance, energy digestibility, and severity of diarrhea of nursery pigs. A total of 644 crossbred pigs, weaned at 3 wk of age (6.4 ± 1.2 kg of BW), were randomly assigned to 2 dietary treatments (12 pens/treatment, 27 pigs/pen) in a randomized complete block design with sex and initial BW as blocks. Pigs were fed pellet feed either with or without milk supplementation from d 1 to 4 postweaning (4 times daily) in a T-shaped feeder that was placed in the pens for 2 h at each feeding. All pigs had free excess to another nursery feeder with the same pellet feed during the entire nursery period in 3 phases (phase I: 10 d; phase II: 14 d; and phase III: 25 d). Fecal score was evaluated daily according to the observation of fresh feces in pens from d 1 to 4 postweaning following a scale of 1 to 3 (3 = liquid diarrheal feces). Titanium dioxide (0.3%) was added in the phase I pellet feed as an indigestible marker to measure apparent ileal digestibility (AID) of DM and GE. Jejunal tissue and ileal digesta from 1 pig/pen were collected at d 4 and 10 postweaning. Data were analyzed using the Mixed procedure of SAS. Statistical differences among treatment means were considered significant with $P < 0.05$. The results showed that milk supplementation did not affect the ADG and ADFI during the entire nursery period. However, supplementing milk tended to increase ($P = 0.073$) the G:F ratio (0.708 to 0.748) during phases I and II. The AID of DM and GE at d 10 of postweaning did not differ between treatments. Supplemental lipid milk tended to enhance ($P = 0.062$) villus height:crypt depth (2.04 to 2.15) in the jejunum at d 10 postweaning. Supplemental milk tended to reduce ($P = 0.065$) the fecal score (2.04 to 1.84) and decreased ($P < 0.05$) mortality (4.35 to 1.55%) during the entire nursery period. Collectively, supplementing milk 4 times daily for the first 4 d postweaning helped nursery pigs by enhancing feed efficiency and gut morphology with decreased severity of diarrhea and mortality during phases I and II.

Key Words: growth performance, gut health, milk, nursery pigs

0947 Effects of dietary lysophospholipid complex on apparent ileal digestibility and growth performance in nursery pigs.
L. Zheng*, A. C. Weaver, and S. W. Kim, *North Carolina State University, Raleigh*.

Two experiments were conducted to evaluate the effect of dietary lysophospholipid complex (LPC; Lipidol, Easybio System, Korea) on apparent ileal digestibility (AID) and growth performance of nursery pigs. The LPC used in this study includes lysolecithin, lysophosphatidylinositol, lysophosphatidylethanolamine, and lysophosphatidic acid (5%) with calcium silicate as a carrier (95%). In Exp. 1, 24 newly weaned pigs (12 barrows and 12 gilts at 7.2 ± 0.1 kg BW) were randomly allotted to 2 treatments in a randomized complete block design. Sex and initial BW were used as blocks. Pigs were fed a basal diet supplemented with either 0 or 0.1% LPC in 2 phases (7 and 12 d, respectively). Titanium dioxide (0.5%) was added to the diets from d 14 as an indigestible external marker. Body weight and feed consumption were recorded on d 7, 14, and 19. On d 19, jejunal digesta were collected to measure viscosity, and ileal digesta were collected to measure AID of DM, GE, lipid, and CP. In Exp. 2, 150 pigs at 6 wk of age (75 barrows and 75 gilts, 14.2 ± 0.2 kg BW) were randomly allotted to 2 treatments in a randomized complete block design. Sex and initial BW were used as blocks. Pigs were fed a basal diet supplemented with either 0 or 0.1% LPC for 3 wk. Body weight and feed consumption were recorded weekly. Blood samples were collected at the end of the study to measure the concentrations of tumor necrosis factor-α and immunoglobulin G to observe general health status of the pigs. Data were analyzed using the Mixed Model procedure of SAS. In Exp. 1, AID of lipid tended to be increased (72.7 to 84.2%, $P = 0.086$) by LPC whereas AID of DM, GE, and CP were not affected. Viscosity of jejunal digesta were not affected by LPC. Dietary LPC increased ADG (681 to 774 g/d, $P < 0.05$) and ADFI (1000 to 1089 g/d, $P < 0.05$) of nursery pigs from d 14 to 19. In Exp. 2, dietary LPC tended to increase ($P = 0.072$) ADG (664 to 708 g/d) during the 3-wk period whereas ADFI and G:F were not affected by dietary LPC. Serum concentrations of tumor necrosis factor-α and immunoglobulin G were not affected by dietary LPC. In conclusion, dietary supplementation of LPC improved the growth of nursery pigs, potentially by enhancing lipid digestibility.

Key Words: apparent ileal digestibility, growth performance, lysophospholipid, nursery pigs

0948 Effects of dietary supplementation of phytobiotics on intestinal health and growth performance of nursery pigs. I. Park*, J. K. Lee, J. Wang, and S. W. Kim, *North Carolina State University, Raleigh*.

This study was to determine the effects of dietary supplementation of phytobiotics (By-O-reg, Advanced Ag Products, Hudson, SD) on growth efficiency and intestinal development of nursery pigs. Phytobiotics included encapsulated oregano essential oil. Forty pigs (20 barrows and 20 gilts at 6.4 ± 0.3 kg BW) were randomly allotted to 4 treatments (2 × 2 factorial arrangement) with 10 pens (1 pig per pen) per treatment based on a randomized complete block design, and fed the experimental diets for 3 wk. Two factors were antibiotic growth promoter (AGP; 0 or 0.5 g/kg) and phytobiotics (0 or 0.5 g/kg diet), respectively. All diets were formulated to meet or exceed the NRC nutrient requirements. Feed intake and body weight were measured weekly. Blood samples were taken on d 20 to measure tumor necrosis factor-α (TNF-α), immunoglobulin G (IgG), IgA, and protein carbonyl (PC). On d 21, all pigs were euthanized to obtain the duodenal and jejunal mucosa and tissue. The mucosa samples were used to measure TNF-α, IgG, IgA, and PC. The tissues were used to measure morphology. Data were analyzed using the Mixed procedure in SAS with factors, interaction between factors, and sex as fixed effects and initial BW as a random effect. Interaction between factors were again analyzed using PDIFF to evaluate a different effect of each treatment. Overall, there were AGP × phytobiotics interactions ($P < 0.05$) on ADG and G:F. Among these interactions, both dietary AGP ($P = 0.071$; 627 g/d) and phytobiotics ($P = 0.057$; 624 g/d) tended to increase ADG compared with the basal diet (543 g/d) at wk 3. Dietary phytobiotics increased ($P < 0.05$) jejunal villus height (443 to 471 μm). Dietary phytobiotics decreased ($P < 0.05$) the concentrations of TNF-α (4.41 to 3.82 ng/g protein) and IgG (1.42 to 1.19 μg/mg protein) in the jejunum and PC (4.2 to 2.9 nmol/mg protein) in the plasma. Dietary AGP tended to decrease ($P = 0.063$) jejunal IgA levels (1.60 to 1.14 μg/mg protein) in the jejunum. Collectively, both dietary AGP and phytobiotics enhanced ADG only when they were used independently. A combinational use of AGP and phytobiotics had negative effects on growth performance. Dietary phytobiotics improved jejunal development by reducing inflammatory and humoral immune reaction.

Key Words: antibiotic growth promotor, growth performance, intestinal health, nursery pigs, phytobiotics

0949 Growth performance and toxic response of broilers fed diets containing unfermented or fermented cottonseed meal. J. L. Xiong[1], L. Y. Wu*[1], H. L. Zhou[2], Z. J. Wang[1], F. T. Meng[1], and L. H. Miao[1], *[1]Hubei Key Laboratory of Animal Nutrition and Feed Science, Wuhan Polytechnic University, Wuhan, China, [2]Xiangyang Engineering Research Center of Animal Medicine, Xiangyang Vocational and Technical College, Xiangyang, China.*

Cottonseed meal (CSM) is produced locally in sizeable quantities in China, but the amount of CSM used in animal diets has been limited mainly by the presence of toxic gossypol. Microbial fermentation is now known as one of the most promising detoxification techniques of CSM. Therefore, reliable evaluation of fermented cottonseed meal (FCSM) can give guidance on its appropriate dose in animal diets to ensure animal health and welfare. The objective of this study was to verify the hypothesis that the reduced free gossypol content and the improved growth performance were not the only marker factors to evaluate FCSM using in broiler diets. A total of 150 1-d-old male Cobb 400 broilers were randomly assigned to 3 dietary treatments with 5 replications of 10 birds per treatment and were fed diets with 31.0% soybean meal (SBM) (control), 15.5% SBM and 15.5% CSM, 15.5% SBM and 15.5% FCSM until 21 d of age, respectively. Birds were weighted after 12 h feed withdrawal on the end day, and then were slaughtered for measure of organ weights. Blood samples were collected through a jugular vein for analysis of serum enzyme activities on the finishing day. All data were statistically analyzed by SAS software. The level of significance was based on probability of 0.05. Fermentation decreased free gossypol from 583.40 to 191.70 mg/kg CSM, and degraded total gossypol from 5830.19 to 3882.91 mg/kg CSM. Compared with the control, the diet with 15.5% FCSM did not affect ($P > 0.05$) average daily growth and feed conversion ratio, while the diet containing 15.5% CSM decreased ($P < 0.05$) these parameters. However, the diet with 15.5% FCSM, similar with the diet containing15.5% CSM, increased ($P < 0.05$) the relative weight of liver and the activity of serum alanine aminotransferase, and decreased ($P < 0.05$) the relative weight of thymus compared with the control. In conclusion, residual gossypol or/and degradation products of gossypol in FCSM may still be hepatotoxicity and immunotoxicity, even though free gossypol and total gossypol have been markedly reduced so as not to alter adversely growth performance of broilers fed the diet with 15.5% FCSM, as half replacement of the SBM in the control.

Key Words: cottonseed meal, gossypol, fermentation, broilers

0950 Protein value of eight triticale genotypes for pigs based on standardized ileal amino acid digestibility. E. J. P. Strang[*1], M. Eklund[1], P. Rosenfelder[1], J. K. Htoo[2], and R. Mosenthin[1], *[1]University of Hohenheim, Institute of Animal Science, Stuttgart, Germany, [2]Evonik Nutrition & Care GmbH, Hanau-Wolfgang, Germany.*

The study was conducted to determine the chemical composition, physical characteristics and standardized ileal digestibility (SID) of CP and AA of 8 currently available genotypes of triticale fed to growing pigs. The experiment was conducted with 8 barrows (initial BW of 30 ± 2 kg) that were fitted with a simple T-cannula at the distal ileum. The pigs were randomly allotted to an 8 × 8 Latin square design. Diets were based on 1 of the 8 triticale genotypes each, with triticale as the sole source of CP and AA. An N-free diet was fed to determine basal ileal endogenous losses of CP and AA. Diets were supplemented with titanium dioxide as an indigestible marker, and fed at a daily intake level of 4% of pigs' average BW corresponding to about 3 times the pigs' energy requirement for maintenance (106 kcal of ME/kg of $BW^{0.75}$). Each experimental period consisted of 5 d for adaptation to the diets and 2 d for ileal digesta collection. Ileal digesta samples were collected consecutively for a total of 24 h. Data were analyzed by the Mixed Procedure of SAS with genotype and pig as fixed effects; period and period × pig were considered as random effects. The CP and non-starch polysaccharide (NSP) contents (as-fed basis) of the 8 triticale genotypes ranged from 10.5 to 11.8% and 8.5 to 10.0%, respectively. The greatest contents of NDF, ADF and ADL in the 8 genotypes amounted to 14.9, 2.9 and 0.6% (as-fed basis), respectively. Among the 8 genotypes, SID of CP, Lys, Met, Thr and Trp ranged from 81 to 85, 72 to 77, 84 to 87, 73 to 77 and 79 to 83%, respectively. The SID of CP and AA did not differ among the 8 triticale genotypes, except for SID of Arg, Glu and Gly ($P \leq 0.05$). The SID of CP and AA was not affected by NSP or NDF content due to the small variations of these fiber fractions among genotypes. Compared to SID values for triticale in current feed tables, the SID of CP, Lys, Met and Trp in the present 8 triticale genotypes was up to 4, 4, 4, and 1%-units lower, respectively, and up to 5%-units higher for Thr. These differences in SID of AA need to be accounted for in diet formulation for pigs when new genotypes of triticale are used.

Key Words: amino acid digestibility, growing pigs, triticale

0951 Effect of metabolizable energy and sulfur amino acid levels on productive performance and economic return of laying hens. C. Gallardo[*1] and E. Salvador[2], *[1]University of São Paulo, Pirassununga, Brazil, [2]National University of San Luis Gonzaga, Ica, Peru.*

One trial was conducted to evaluate the effect of metabolizable energy (ME) and sulfur amino acids (AAAS) on the productive performance and economic return of laying hens. A total of 405 ISA Brown laying hens (5 birds/pen) of 30 wk of age were distributed in a randomized experimental block design in a 3 × 3 factorial arrangement, composed of three levels of ME (2,646, 2,793 and 2,940 Mcal/Kg) and 3 levels of SAAs (0.67, 0.71 and 0.745%). Egg production, feed intake, feed conversion ratio, egg weight and egg mass, ME intake, SAAs intake, Haugh unit and feed cost (kg of egg mass), were evaluated. Significant interaction ($P < 0.05$) between ME × SAAs was observed on feed intake, feed conversion, ME intake and SAAs intake. 2,793 Mcal/kg of ME and 0.745% of SAAs propitiated higher ($P < 0.05$) feed intake, SAAs intake and better feed conversion ratio. Birds fed low-ME and SAAs diets showed low feed intake, egg production, feed conversion, egg mass, ME intake and SAAs intake. Diets providing 2,793 Mcal/kg of ME maximized ($P < 0.01$) egg production and egg mass. While Diets providing 0.745% of SAAs maximized ($P < 0.05$) egg weight and egg mass. The diet with 2,793 Mcal/kg of ME and 0.745% of SAAs had the lowest feed cost and the higher profit per kg of egg mass. Thus, the best productive performance and economic return of laying hens diet may be obtained with levels of 2,793 Mcal/kg of ME and 0.745% of SAAs.

Key Words: Egg production, intake, egg mass

0952 Intestinal microbiota, microbial metabolites and carcass traits are changed in a pig model fed a high-fat/low-fiber or a low-fat/high-fiber diet. S. N. Heinritz[*1], E. Weiss[1], M. Eklund[1], T. Aumiller[1], S. Messner[1], C. M. E. Heyer[1], S. Bischoff[2], and R. Mosenthin[1], *[1]University of Hohenheim, Institute of Animal Science, Stuttgart, Germany, [2]University of Hohenheim, Department of Nutritional Medicine, Stuttgart, Germany.*

For gastrointestinal functions and health, the intestinal microbiota and its metabolites appear to be an important factor. However, further elaboration of potential relationships between nutrition, gut microbiota, and host's health by means of a suitable animal model are required. The present study was designed to examine the impact of diets high in fat or fiber content, thus rather representing an "unhealthy" or "beneficial" diet, on gut microbiota composition, microbial activity, and carcass traits by using the pig as a model for humans. Eight pigs (initial BW 28 ± 2 kg) were allotted to 2 treatments,

either fed a low fat/high fiber (LF), or a high fat/low fiber (HF) diet for 7 wk. Then, pigs were slaughtered to determine carcass and intestinal weights, as well as backfat thickness. Digesta samples of cecum and colon were taken to measure short-chain fatty acid (SCFA) concentration and gene copy numbers of total eubacteria, *Lactobacillus* spp., *Enterobacteriaceae*, *Bifidobacterium* spp., and *Bacteroides-Prevotella-Porphyromonas* (*Bacteroides* group) by use of real-time qPCR. Body weight at slaughter was 72.5 kg for the HF treatment and 77.1 kg for the LF treatment ($P > 0.05$). Carcass weight was also similar for both treatments, whereas full stomach and colon as well as liver weights were higher for the LF when compared to the HF treatment ($P < 0.05$). Gene copy numbers of total bacteria in the cecum digesta were higher in the HF compared to the LF treatment ($P < 0.05$), yet abundance did not differ in colon digesta. *Bifidobacterium* spp. occurred in higher numbers in the LF treatment, both in cecum and colon digesta ($P < 0.05$). Higher numbers in HF than in LF pigs were found for the *Bacteroides* group ($P < 0.05$) and *Enterobacteriaceae* ($P < 0.001$) in cecum and colon digesta. Total SCFA, acetate and butyrate showed higher colonic concentrations in LF than in HF pigs ($P < 0.05$), while in cecal digesta of LF only acetate and butyrate concentrations were higher ($P < 0.05$). Results confirmed the trophic action of dietary fiber on epithelium of digestive organs and revealed that the low-fat/high-fiber diet stimulated beneficial bacteria and SCFA production, especially butyrate. On the other hand, the high-fat/low-fiber diet promoted potential pathogenic bacteria. These findings are comparable to those in humans and are in support of the potential of the pig to serve as model for assessing diet-gut-microbiota interactions.

Key Words: dietary fat/fiber content, intestinal microbiota, pig model

0953 Use of zinc oxide nanoparticles as growth promoter for weanling pigs. N. C. Milani*, N. Y. Ikeda, M. Sbardella, and V. S. Miyada, *Universidade de São Paulo, Piracicaba, Brazil.*

Pharmacological levels of zinc (as ZnO) have been used in weanling pig diets for diarrhea control and growth performance improvement. Due to its low absorption, Zn-excretion has motivated environmental concerns. Thus, ZnO nanoparticles (ZnO-N) appear to be an alternative to reduce zinc oxide (ZnO) use in diets, once this form has shown higher antimicrobial activity. The purpose of this study was to evaluate the effects of dietary ZnO-N on performance and diarrhea occurrence of weanling pigs. One hundred and ninety-two 21d-weaned pigs (5.90 ± 0.83 kg BW) were used in a randomized complete block design experiment with 6 treatments, 8 replications per treatment, and 4 animals per experimental unit (pen). The treatments were: negative control (NC): basal diet (based on corn, soybean meal, dried whey and dried plasma) with 100 mg Zn (as ZnO)/kg diet; positive control (PC): basal diet with 2400 mg Zn (as conventional ZnO, 150nm)/kg diet and basal diet with 12, 24, 48 or 96 mg Zn (as ZnO-N, 70nm)/kg diet. Pigs were fed dietary treatments from 1 to 21 d feeding period followed by a common diet (same diet for all treatments) from 22 to 35 d feeding period. ANOVA and polynomial regression analysis (for levels of Zn as ZnO-N) were performed. No effects of Zn levels (as ZnO-N) were observed on performance and diarrhea occurrence (Table 1). The PC had higher ADFI and lower diarrhea occurrence compared to NC and Zn (as ZnO-N) levels during the first 21 d post-weaning period ($P = 0.0001$), without affecting ADG, G:F and BW. No residual effects of treatments were observed during 22 to 35-d period, when all pigs were fed with same diet. Therefore, ZnO-N was not effective for post-weaning diarrhea control and growth rate improvement.

Key Words: nanoparticle, performance, pigs, zinc oxide

0954 Effect of dietary flaxseed oil on growth performance, nutrient digestibility, blood profiles, and meat quality in pigs. P. Y. Zhao*, T. S. Li, S. Shanmugam, S. Kathannan, R. X. Lan, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, South Korea.*

Alpha-linolenic acid (ALA) is the parent compound of the omega-3 fatty acids, which have several specific metabolic and structural roles within the body. However, ALA can't be synthesized by mammals. As flaxseed oil is rich of ALA, 2 experiments were conducted to investigate the effect of dietary flaxseed oil in pigs. In Exp. 1, 135 weanling pigs (5.50 ± 0.42 kg) were used in a 4-wk trial and were allotted to 3 treatments: 1) CON, basal diet, 2) FO0.5, CON + 5 g/kg flaxseed oil, 3) FX1, CON + 10 g/kg flaxseed oil. There were 9 replications with 5 pigs per pen. In Exp. 2, 40 finishing pigs (89.90 ± 0.41 kg) were used in a 4-wk trial and allotted to 2 treatments: 1) CON, basal diet, 2) FO0.5, CON + 5 g/kg flaxseed oil. There were 5 replications with 4 pigs per pen. Individual pig BW and the feed consumption of each pen were monitored to calculate the ADG, ADFI, and G:F. Chromium oxide (2 g/kg) was added to the diets to determine the ATTD of DM, N, and GE. Blood profiles were analyzed by using an automatic biochemistry blood analyzer. All data were subjected to the GLM procedures of SAS as a randomized complete block design (SAS Inst. Inc., Cary, NC). Tukey's range test was used to compare the means of the treatments. A $P < 0.05$ was considered to be statistically significant. In Exp. 1, no difference ($P > 0.05$) was observed on growth performance and nutrient digestibility in weanling pigs, but total cholesterol (65.29 vs. 54.14 mg/dL) and triglycerides concentrations (30.43 vs. 24.71 mg/dL) were decreased ($P < 0.05$) by 5 g/kg flaxseed oil supplemention. In Exp. 2, flaxseed oil did not affect ($P > 0.05$) growth performance and nutrient digestibility. Total cholesterol (120.42 vs. 104.11 mg/dL), LDL-cholesterol (73.69 vs. 52.18 mg/dL) and triglyceride concentrations (55.02 vs. 48.87 mg/dL) were decreased ($P < 0.05$) by 5 g/kg flaxseed oil, however, HDL-cholesterol concentration (44.43 vs. 49.64 mg/dL) was increased ($P < 0.05$). Higher ($P < 0.05$) meat pH (5.77 vs. 5.59) was observed in pigs fed 5 g/kg flaxseed oil diet. There was no difference ($P > 0.05$) in meat quality and back fat thickness in finishing pigs. In conclusion, the inclusion of 5 g/kg flaxseed oil decreased total cholesterol, LDL-cholesterol, and triglyceride concentrations, increased HDL-cholesterol concentration without any negative effect on growth performance, nutrient digestibility, and meat quality of pigs.

Key Words: blood profile, flaxseed oil and pigs

0955 The effect of three levels of unmilled rice on growth performance and digestive tract development in broilers and ducks. C. P. Villemarette*, E. Lyons, B. Chung, E. Ferguson, and F. M. LeMieux, *McNeese State University, Lake Charles, LA.*

Three experiments Exp. 1 = 144 broilers; Exp. 2 = 118 mallard *Anas platyrhynchos* ducklings; and Exp. 3 = 75 mature mallard *Anas platyrhynchos* ducks were conducted to determine the effects of 3 levels of unmilled hybrid rice on growth performance, linear measurements and weights of organs, and gastrointestinal tract. Each experiment had 3 dietary treatments: (1) corn-soybean meal (basal), (2) basal + 5% hybrid rice, and (3) basal + 10% hybrid rice. All diets were formulated to meet or exceed dietary requirements for ducks and broilers from 0 to 9 wk of age. Treatments were replicated 8 times with 6 birds per pen (Exp. 1), eight times with 4 or 5 birds per pen (Exp. 2), and 3 replications with 8 or 9 birds per pen (Exp. 3). At Day 11 (Exp. 1), and Day 14 and 21 (Exp. 2) 1 bird from each pen ($n = 24$) was randomly selected to determine linear measurements and weights of organs and gastrointestinal tract. At experiment termination 28 d and 35 d experiment 2 and 3 respectively all remaining birds $n = 70$ (Exp. 2) and $n = 75$ (Exp. 3) were euthanized for internal tract measurements. Average initial weight of the chicks and ducks was 34.8 g, 31.8 g, and 821 g in Exp. 1, 2, and 3, respectively. Final BW of the chicks and ducks was 362.1 g, 446.6 g, and 1202.0 g in Exp. 1, 2, and 3, respectively. Data was analyzed by ANOVA procedures using the GLM procedure of SAS. Tukey's Honestly Significant Difference test was used to find difference among treatments and significance was considered at ($P < 0.05$). In Exp. 1 and 2, birds fed 10% rice grew slower ($P < 0.05$) than birds fed the basal diet. In Exp. 3 the addition of rice did not affect growth, feed intake or feed efficiency. Rice addition did not affect organ length or weight ($P > 0.1$) in Exp. 1. However in Exp. 2 birds fed 5% rice had increased ($P < 0.05$) pancreas, ileum, and jejunum weights and in Exp. 3, the addition of 10% rice increased ($P < 0.05$) liver weight. These results suggest the addition of 10% unmilled rice to broiler and duck diets may decrease growth performance.

Key Words: broilers, ducks, rice

0956 Influence of zinc-methionine complex supplementation on reproductive performance and immunity of gestating-lactating sows under hot weather condition. J. M. Romo[1], J. A. Romo[2], R. Barajas[*2], H. R. Güémez[1], I. Enriquez[2], and G. Silva[1], *[1]FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Mexico, [2]FMVZ-Universidad Autónoma de Sinaloa, Culiacan, Mexico.*

Thirty eight pregnant sows (Yorkshire × Landrace) were used to determine the influence of zinc-methionine complex supplementation on reproductive performance and immunity of gestating-lactating sows under hot weather condition. Thirty 5 d after be pregnant, sows were randomly assigned to treatments as follows: 1) Basal corn-soybean meal gestation diet (14.17% CP; 3.27 Mcal ME/kg) and lactation diet (17.95% CP; 3.35 Mcal ME/kg) that provided 60 mg of inorganic Zn/kg from $ZnSO_4$ (Control; CTR); and 2) Control plus 100 mg Zn/kg provided from Zn methionine complex (ZnM; ZINPRO 120, Zinpro Corp., Eden Prairie, MN). Treatments were offered since d 35 of gestation period, until Day 21 of lactation when piglets were weaned. Sows were placed in individual cages and fed ad libitum. Parametric data were analyzed by ANOVA for a completely randomized design, and percentage of piglet mortality was analyzed by Chi-square test using 2 × 2 tables. Each sow was the experimental unit. Across experiment weather means values were: air temperature 31.1 ± 1.2°C; relative humidity 68.24 ± 7.26%; and THI 82.57 ± 1.30, respectively. Sow back fat thickness (BFT) at d 35 of gestation was similar between treatments ($P = 0.93$), but in d-111 of gestation BFT was increased ($P = 0.05$) by ZnM (16.6 vs. 14.9 mm).The litter size (12.6 vs. 11.6 piglets), litter weight (12.6 vs. 12.3 kg), piglets born alive (10.4 vs. 9.4 piglets), and number of piglets weaned (7.7 vs. 8.3) were not affected by treatments ($P > 0.10$). Adjusted-21 d weaned litter weight was similar ($P = 0.32$) between treatments, with mean values of 42.3 and 45.6 kg for CTR and ZnM, respectively. Zinc methionine supplementation decreased ($P < 0.01$) piglets-mortality with mean values of 26% and 11% for CTR and ZnM, respectively. IgA in colostrums (1 682 ± 500 ng/mL) was no altered by treatments ($P > 0.10$). In piglet 14 d post weaned serum concentration of IgG (178 ± 144 ng/mL) and IgM (185 ± 101 ng/mL) were similar ($P > 0.10$) between treatments. Results suggest that ZnM supplementation to gestating-lactating sows under hot weather conditions could contribute to increase sow fat reserves and decrease mortality of piglets.

Key Words: reproductive performance, sows, zinc.

0957 Japanese quail (*Coturnix japonica*) responses to low protein diets supplemented with crystalline lysine, methionine, and threonine. C. R. Herrera Cortés[1], H. Bernal Barragán[*1], F. Sánchez Dávila[1], J. E. Hernández Quiroz[1], M. A. Montemayor Abundiz[1], and M. Cervantes Ramírez[2], *[1]Universidad Autónoma de Nuevo León, San Nicolás de los Garza, Mexico, [2]ICA- Universidad Autónoma de Baja California, Mexicali, Mexico.*

This study was conducted with the aim to determine the effect of dietary levels of lysine, methionine, and threonine on growth efficiency, environmental impact, and carcass quality of growing quails (*Coturnix japonica*). A sorghum-SBM basal diet with 21.1% crude protein, 1.08% lysine, 0.32% methionine, and 0.78% threonine (Diet 1) was formulated. Four additional diets (Diet 2 to 5) were supplemented with crystalline lysine, methionine, and threonine to contain 1.19, 1.30, 1.41, and 1.53% lysine; 0.46, 0.50, 0.54 and 0.59% methionine and 0.93, 1.02, 1.11, and 1.20% threonine, respectively. All diets were isoenergetic (2,958 kcal EM/kg feed). Ninety 14-days old quails were distributed in 30 cages, and randomly assigned to the five experimental diets ($n = 6$ replicates/treatment) during 28 d. Body weight, feed intake, average daily weight gain, and feed efficiency were monitored weekly. On the fourth week, excreta were collected during 48 h. Data were statistically analyzed with ANOVA. Final body weight, and average daily gain responded in a quadratic manner ($P < 0.05$) to incremental levels of crystalline amino acids. Birds fed Diet 5 had a body weight gain 12% higher ($P < 0.005$) than those fed the basal diet (3.26 g/d). Birds fed Diets 2 and 4 had 50 to 70% heavier thighs than birds in basal diet (16.9 vs. 9.7 g; $P < 0.05$), with no other carcass differences. On the other hand, birds receiving Diet 3 with 1.30% lysine, 0.50% methionine, and 1.02% threonine, reduced 23% ($P < 0.05$) the amount (1.17 g) of N excreted per unit of body weight gain of birds fed the basal diet. It was estimated that requirements of lysine, methionine, and threonine for growth traits of quails are 1.53%, 0.59%, and 1.20%, respectively. In conclusion, supplementing crystalline lysine, methionine, and threonine, improved growth efficiency, carcass quality, and protein utilization of growing Japanese quails fed a 21.1% CP sorghum-SBM based diet.

Key Words: Japanese quail, essential amino acids, growth efficiency

0958 Bioavailability of D-methionine relative to L-methionine for nursery pigs using slope-ratio assay. C. Kong*, J. Y. Ahn, and B. G. Kim, *Konkuk University, Seoul, The Republic of Korea.*

An experiment was conducted to determine the bioavailability of D–methionine (Met) relative to L–Met for nursery pigs using the slope-ratio assay. A total of 50 crossbred barrows with an initial BW of 13.5 kg (SD = 1.0) were used in an N balance study. A Met-deficient basal diet (BD) was formulated to contain adequate amount of all AA for 10 to 20 kg pigs except for Met. Two reference diets were prepared by supplementing the BD with 0.4 or 0.8 g L–Met/kg at the expense of corn starch, and the equivalent concentrations of D–Met were added to the BD for the 2 test diets. The pigs were adapted to the experimental diets for 5 d and then total but separated collection of feces and urine was conducted for 4 d according to the marker-to-marker procedure. Nitrogen intakes were similar across the treatments. Fecal N output was not affected by Met supplementation regardless of source, and apparent N digestibility did not change. Conversely, there was a linear response ($P < 0.01$) to Met supplementation from both Met isomers in urinary N output, which resulted in increased retained N (g/4 d) and N retention (% of intake). No quadratic response was observed in any of the N balance criteria. The estimated bioavailability of D–Met relative to L–Met from urinary N output (g/4 d) and N retention (% of intake) as dependent variables using supplemental Met intake (g/4 d) as an independent variable are 87.6 and 89.6%, respectively, but approximate 95% fiducial limits for the relative bioavailability estimates included 100%. In conclusion, with the absence of statistical significance, the present study indicated that the mean relative bioequivalence of D–Met to L–Met was 87.6% based on urinary N output and 89.6% based on N retention.

Key Words: methionine isomers, nitrogen balance, relative bioavailability, swine

0959 Energy value of bakery meal and peanut flour meal for broiler chickens determined using the regression method. F. Zhang*[1] and O. Adeola[2], *[1]Purdue University, West Lafayette, IN, [2]Department of Animal Sciences, Purdue University, West Lafayette, IN.*

The energy value of bakery meal (BM) and peanut flour meal (PFM) for broiler chickens were determined in the current experiment with Ross 708 broiler chickens from d 21 to 28 post hatching. The birds were fed a standard broiler starter diet from d 0 to 21 post hatching. 320 birds were grouped by weight into 8 blocks of 5 cages with 8 birds per cage and assigned to 5 diets. Experiment used a corn-soybean meal reference diet (RD) and 4 test diets (TD) in which test ingredients partly replaced the energy sources in the RD. The TD consisted of 200 g BM, 400 g BM, 100 g PFM, or 200 g PFM/kg, respectively. The DM of BM and PFM were 878, and 964 g/kg, respectively and the respective gross energies were 4,060, and 5,783 kcal/kg DM. The result showed that an addition of either BM or PFM to the RD did not affect the growth performance of birds from d 21 to 28 post hatching. The ileal digestible energy (IDE), ME, and MEn of both ingredients were determined by the regression method. The determined IDE values were 3,412 kcal/kg DM for BM and 4,801 kcal/kg DM for PFM; ME values were 3,176 and 4,601 kcal/kg DM for BM and PFM, respectively. And the MEn values were 3,093 kcal/kg DM for BM and 4,112 kcal/kg DM for PFM. In conclusion, the current study provides energy values for BM, and PFM, and shows that adding up to 100 g BM or PFM/kg broilers diets from d 21 to 28 did not affect growth performance.

Key Words: bakery meal, metabolizable energy, peanut flour meal

0960 Kinetics of lipid peroxidation in fats and oils as affected by lipid source, heating temperature, and length of heating. S. C. Lindblom*[1], G. C. Shurson[2], J. Moser[3], and B. J. Kerr[4], *[1]Iowa State University, Ames, [2]Department of Animal Science, University of Minnesota, St. Paul, [3]USDA-ARS, Peoria, IL, [4]USDA- ARS, Ames, IA.*

Lipid peroxidation is a chain reaction of generation and degradation of peroxidation compounds including acids, aldehydes, ketones, and polymers. However, assays used in farm animal research commonly measure 1 or 2 compounds and do not assess the change in a lipid's peroxidation status over time. Consequently, a laboratory-study was conducted to evaluate the impact of heating temperature and length of heating on the generation of lipid peroxidation products in lipids varying in fatty acid composition. Six lipids were selected based on their divergent fatty acid composition and predicted peroxidizability index (Hammond, 1954). Lipids used in this study included tallow, palm oil, soybean oil, linseed oil, menhaden oil, and a manufactured oil were heated at 4 temperatures to reflect ambient, summertime feed temperature in a bulk bin, an elevated feed processing temperature, and a frying temperature (22.5°, 45°, 90°, and 180°C, respectively). Oils (2.5 L each) were placed in a 5 L round-bottom glass flask and heated with an electric heating mantle with power controller, with bubbling air at 3 L/min. Because tallow and palm oil were solids at room temperature, they were evenly spread into a 30.5 × 45.7 cm pan to allow for air reaction to the lipid. Samples were taken at equally distributed time points within a temperature (22.5°C for 0, 6, 12, 18, 24 d; 45°C for 0, 3, 6, 9, 12 d; 90°C for 0, 18, 36, 54, 72h; and 180°C for 0, 3, 6, 9, 12h). Lipid analysis for composition, quality, and peroxidation indicators were conducted. Depending on the lipid source, heating temperature, and sampling time, peroxide value increased from 11 to 1200 mEq/kg, *p*-anisidine value from 0 to 810, hexanal from 0 to 300 mg/kg, 2,4-decadienal from 0 to 690 mg/kg, polar

compounds from 5 to 60%, polymers from 0 to 30%, and OSI from 0 to 22 h at 110°C. The data show that the peroxidizability of lipids varies greatly depending on their fatty acid profile, the degree of heating and time of sampling. Because peroxidized lipids have been shown to impact animal performance, gastrointestinal integrity, gene expression, immune competence, and metabolic oxidative status, the understanding of how and when lipid peroxidation compounds are generated and degraded, and their concentration in a lipid at specific time point is important to their use in livestock feeding programs.

Key Words: kinetics, lipid peroxidation, lipid quality

0961 Effects of feeding dried cabbage leaf residues on broiler performance, ileal digestibility and total tract nutrient digestibility. A. Mustafa, V. Higginson*, and B. Baurhoo, *McGill University, Ste-Anne De Bellevue, QC, Canada.*

A study was conducted to determine the effects of feeding dried broccoli floret residues on growth performance, apparent ileal digestibility, apparent total tract nutrient digestibility and intestinal microbial populations in broiler chickens. One thousand two hundred 1-d-old male Ross 508 broilers were randomly allotted to 4 dietary treatments and were grown over a 35-d experimental period. Dietary treatments included 4 levels of dried broccoli floret residues: 0, 3, 6, and 9%. Results showed that inclusion of dried broccoli floret residues increased body weight gain (quadratic effect, $P = 0.004$) and feed conversion ratio (quadratic effect, $P = 0.002$) with no effect on feed intake. Apparent ileal crude protein (CP, quadratic effect, $P = 0.003$) and dry matter (DM, quadratic effect, $P = 0.002$) digestibility for younger birds (25 d of age) increased as the level of dried broccoli floret residues in the diet increased. However, apparent ileal CP (linear effect, $P = 0.022$), DM (linear effect, $P = < 0.001$) and gross energy (linear effect, $P = 0.001$) digestibility for older birds (35 d of age) decreased as a result of dried broccoli residue inclusion. Nitrogen correct apparent metabolizable energy decreased (linear effect, $P < 0.001$) as the level of dried broccoli floret residues in the diet increased. However, N retention was not influenced by dried broccoli floret residue inclusion. It was concluded that incorporation of dried broccoli floret residues in broiler diet at moderate levels (i.e., 3 to 6%) may improve the growth of broiler chickens with no detrimental effects on nutrient digestibility and retention. However, at high levels (i.e., 9%), dietary dried broccoli floret residues may compromise ileal and total tract nutrient digestibility.

Key Words: Broiler, dried boccoli residues, ileal digestibility, total tract digestbility

0962 Effect of type of fibrous sources in the phosphorus-free diet on the basal endogenous loss of phosphorus in growing pigs. A. R. Son[*1] and B. G. Kim[2], [1]*Konkuk University, Seoul, South Korea,* [2]*Konkuk University, Seoul, The Republic of Korea.*

The objective of this study was to investigate the influence of fiber sources in P-free diets on the basal endogenous loss (BEL) of P in growing pigs. Eight barrows with an initial BW of 37.4 ± 2.7 kg were individually housed in metabolism crates. The pigs were allotted to dietary treatments in a replicated 4 × 4 Latin square design with 4 diets, 8 pigs, and 4 periods. Four P-free diets were formulated based mainly on cornstarch, sucrose, and gelatin, and contained 10% of cellulose, pectin, silica sand, or sawdust as a fiber source in each P-free diet. Each period consisted of a 4-d adaptation period and a 4-d period of total collection of feces according to a marker-to-marker procedure. Chromic oxide was added at 0.5% to the morning meal as an indigestible marker on d 5 and 9 in each period. The feed intake of pigs fed the sawdust diet was less ($P < 0.05$) than that of pigs fed the silica sand diet. The total fecal output of pigs fed the cellulose and silica sand diets were greater ($P < 0.05$) than that of pigs fed the pectin diet. The P concentration in the feces was greater ($P < 0.05$) in the pigs fed the pectin diet compared with the pigs fed the cellulose and silica sand diets. The total P output was not affected by the fiber sources. The BEL of P was 206, 350, 252, and 431 mg/kg DMI in the cellulose, pectin, silica sand, and sawdust diets, respectively. The BEL of P of the pigs fed the sawdust diet was greater ($P < 0.05$) than that of the pigs fed the cellulose diet. There were differences ($P < 0.05$) in the apparent total tract digestibility of DM, OM, CP, ether extract, NDF, ADF, and Ca among the experimental diets. In conclusion, the fiber sources in the P-free diet may have different effects on the BEL of P estimate and the apparent total tract digestibility of nutrients.

Key Words: basal endogenous loss of P, fiber, P-free diet

0963 Effects of feeding dried cabbage residues on performance, ileal and total tract digestibility, and selected microbial population in broiler chickens. A. Mustafa, B. Baurhoo, and V. Higginson*, *McGill University, Ste-Anne De Bellevue, QC, Canada.*

A study was conducted to investigate the effects of partially replacing corn and soybean meal with dried cabbage leaf residues (DCR) on broiler growth performance, apparent ileal nutrient digestibility and apparent total tract nutrient utilization. Dietary treatments include 4 levels of DCR (0, 3, 6, and 9%). Two hundred and twenty four 1-d old male broilers were randomly assigned to 1 of 4 groups (8 cage replicates; 7 birds/cage) and grown over a 35-d experimental period. Results showed that feeding DCR had no effects on daily body weight gain (average 53.4 g/d), daily feed intake (average 94.9 g/d), and feed

conversion ratio (average 1.78 g of feed/g of gain). Inclusion of DCR reduced apparent ileal DM (quadratic effect, $P < 0.001$), OM (linear effect, $P = 0.012$), and CP (quadratic effect, $P = 0.001$) digestibility of younger birds (d 21) while incremental levels of DCR had no effect on apparent ileal nutrient digestibilities of older birds (d 35). Apparent total tract digestibility of DM, OM, and CP increased (linear effect, $P < 0.001$) as the level of DCR increased. It was concluded that the inclusion of DCR in broiler diets up to 9% had no negative impact on bird performance and apparent ileal digestibility of older birds and improved apparent total tract nutrient digestibility.

Key Words: broilers, dried cabbage residues, ileal digestbility, total tract digestibility

0964 Effect of different levels of zinc and calcium on growth performance in weanling pigs. L. Blavi*, D. Solà-Oriol, S. M. Martín-Orúe, and J. F. Pérez, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra (08193), Spain.*

High Zn levels (2,500 to 3,000 mg/kg ZnO) are widely used to prevent diarrhea in piglets after weaning. The NRC recommendations of Ca levels after weaning are defined at 0.85 to 0.80% to piglets 5 to 11 kg. In a previous study we observed that piglets with low Ca in pre-starter diet (0.35% Ca) had higher BW than piglets with high levels (0.95%). Therefore, the objective of this trial was to observe the effect of Ca with addition of therapeutic ZnO or not on growth performance during pre-starter phase (0–14 d). A total of 320 pigs were used in a 2 × 2 factorial arrangement, where the main factors were: Zn levels (125 or 2,500 ppm Zn) and Ca levels (0.35% and 0.95%). Piglets were reared in 32 pens (10 pigs/pen; 8 replicates per treatment). From Day 14 onward, the Ca level was fixed at 0.77% for all diets. The pre-starter (0 to 14 d) and starter (14 to 35d) diets contained 2,520 and 2,460 Kcal NE/kg, 19.65 and 19.00% CP, 1.25 and 1.23 digestible Lys, and 0.33 and 0.25% P digestible, respectively. Feed intake and individual BW were registered on d 0, 14, and 35 post-weaning. Performance parameters were analyzed with ANOVA by using the mixed procedure of the statistical package SAS. There were a significant effect of the level of Ca and Zn on BW at d 14 and 35 ($P < 0.05$); where pigs with low Ca (0.35%) and also pigs with 125 ppm Zn showed the highest weights (values from Ca effect: 10.87 vs. 10.33 Kg d 14 and 21.20 vs. 20.37 Kg d 35; values from Zn effect: 10.97 vs. 10.24 Kg d 14 and 21.67 vs. 19.90 Kg d 35, respectively). A significant interaction was observed on average daily feed intake (ADFI) from 0 to 14d ($P = 0.04$), where piglets with 0.35% Ca and 125ppm Zn in the diet presented higher consumption compared to piglets with 0.35% Ca and 2,500 ppm Zn (327.13 vs. 261.20 g/d, respectively). In addition, an statistical trend for the interaction in FCR during pre-starter phase (0 to 14d; $P = 0.097$), where piglets with 0.95% and 2,500ppm Zn showed the highest ratios. There was no significant effect of the experimental treatments on the FCR of the starter phase (14 to 35d). It can be concluded that lower levels of Ca and Zn allow better growth of weaned piglets, suggesting that mineral supplementation has an important role on growth performance.

Key Words: calcium, pigs, zinc

0965 Evaluation of cold pressed soybean meal and pea protein as alternative amino acid sources in swine diets. J. Koepke*, *South Dakota State University, Brookings.*

Cold pressed soybean meal (CP-SBM) and a processed pea product (PP, 55% crude protein) were evaluated as potential alternative ingredients for use in swine diets. CP-SBM was produced from regular full fat soybeans that had been heat treated before cold-pressing to reduce trypsin inhibitors. 907 kg of heated soybeans produced approximately 775.6 kg of high oil (8%) meal and 131.5 kg soybean oil. Unlike solvent extracted SBM, CP-SBM can be produced on-farm and the oil byproduct sold as high commodity product. The PP was harvested from yellow peas that were mechanically milled and a portion of the dehulled split cotyledons was processed. A digestibility trial was conducted to determine the standard ileal digestibility (SID) of protein and amino acids in CP-SBM and PP in comparison to solvent extracted SBM. Six ileal-cannulated barrows (29.25 ± 1.5 kg BW) were used in crossover design with 4 collection periods of 7 d each (5 d acclimation and 2 d ileal collection of 12h/d). Pigs were randomly assigned, within period, to one of four experimental diets (CP-SBM, PP, SBM, and nitrogen-free) where CP-SBM, PP and SBM were included as the sole protein sources, respectively. Feed allowance per period was provided at 3 × maintenance energy requirement (197 kcal x $BW^{0.60}$/d) based on measured body weight at the beginning of each period. The SID of lysine (94.4 vs. 77.2 ± 1.9), arginine (96.7 vs. 83.2 ± 2.7), valine (89.3 vs. 73.6 ± 3.3), leucine (91.3 vs. 75.7 ± 2.9), isoleucine (90.9 vs. 77.4 ± 2.4) and threonine (88.3 vs. 67.0 ± 4.4) were higher ($P < 0.02$) in PP than CP-SBM. The SID of isoleucine (84.6 vs. 77.4 ± 2.4; $P = 0.107$), asparagine (82.3 vs. 72.6 ± 3.0, $P = 0.075$) and glutamine (85.9 vs. 77.4 ± 2.8, $P = 0.099$) tended to be higher in SBM compared to CP-SBM. There was no difference in SID between PP and SBM in any of the essential AA measured. Based on SID, both CP-SBM and PP may be used as an alternative amino acid source in swine diets while PP appears to be superior alternative than CP-SBM.

Key Words: cold-pressed soybean meal, pea protein, growth performance

0966 The effects of feeding low trypsin inhibitor soybean meal to broilers on growth performance. G. Hosotani*, B. Freitas, M. S. Kerley, and M. C. Shannon, *Division of Animal Sciences, University of Missouri, Columbia.*

A 21-d experiment was conducted to compare soybean meal (SBM) from low trypsin inhibitor to parent soybean cultivars on growth performance of broilers. One hundred and fifty 1-d-old male broilers (Ross 308) were randomly placed in battery cages and allocated to 6 dietary treatments with 5 replicates and 5 birds per replicate in a factorial arrangement of 3 SBM sources, solvent extracted conventional SBM (SOLV), cold-pressed conventional SBM (CON), and cold-pressed low trypsin inhibitor SBM (LTI) by laboratory-scale mechanical extraction. All SBM sources were either non-heated or heated in a forced-air oven at 120°C for 20 min. Diets were formulated to meet or exceed NRC (1994) and Aviagen nutrient requirements. Broilers were weighed and feed disappearance measured on d 7, 14, and 21. Statistical analyses were performed as a randomized complete block design using PROC GLM of SAS with significance level set at $P \leq 0.05$. Feeding sources of SBM resulted in differences in ADG, ADFI, and feed conversion ratio (FCR) in all measurements ($P < 0.05$). Overall, chicks fed LTI had intermediate ADG (36 g; $P < 0.0001$) compared to CON and SOLV (30 and 50 g, respectively), and FCR (1.38 vs. 1.54, and 1.19, respectively; $P < 0.0001$). Chicks fed LTI or HTI had lower ADFI compared to SOLV (49, 46, and 59 g, respectively; $P < 0.0001$). Heating SBM improved FCR on wks 1 and 2, resulting in overall improvement from 1.40 to 1.34 FCR ($P = 0.0017$). Interaction between SBM sources and heat treatment was not significant throughout the experiment. In conclusion, feeding LTI improved growth performance of broiler chicks compared to CON by 20% in ADG and 10% in FCR. We hypothesized that feeding LTI to broilers would result in similar growth performance of broilers fed SOLV. However, feeding either heated or non-heated LTI to broilers did not have similar growth performance as broilers fed SOLV, decreasing ADG by 28% and impairing FCR by 16%, most likely due to other anti-nutritional factors or nutritional characteristics that impaired growth performance of broiler chicks.

Key Words: broiler, performance, soybeans

0967 Nutritive value of cold-pressed camelina cake with or without supplementation of multi-carbohydrase in pig diets. T. A. Woyengo*[1], R. Patterson[2], and C. L. Levesque[1], [1]*South Dakota State University, Brookings,* [2]*Canadian Biosystems, Calgary, AB, Canada.*

Cold-pressed camelina cake (CPCC), a fibrous co-product of camelina seed pressing, is available for livestock feeding. However, information is also lacking on the effect of supplementing fiber-degrading enzymes (carbohydrases) to CPCC-based diets on nutrient utilization by pigs. Thus, the objectives were to determine the standardized ileal digestibility (SID) of AA and DE value of cold-pressed camelina cake (CPCC), and the effect of adding Multi-Carbohydrase to a CPCC-based diet for pigs. Six ileal-cannulated barrows (average initial BW = 36 kg) were fed 5 diets in 5 × 5 Latin square design with 1 added column to give 6 replicates per diet. A corn-soybean meal-soybean oil-based diet and the basal diet with corn, soybean meal, and soybean oil replaced by 25% CPCC in a 2 × 2 factorial arrangement with or without Multi-Carbohydrase (1,200 U of xylanase, 150 U of glucanase, 500 U of cellulose, 60 U of mannanase, 700 U of invertase, 5,000 U of protease, and 12,000 U of amylase/kilogram of diet; Superzyme CS, 1 g/kg). The fifth diet was N-free. The ratio of corn, SBM, and soybean oil in the basal diet was identical to the CCPC-containing diets to allow calculation of nutrient digestibility of CPCC by the difference method. On a DM basis, CPCC contained 42% CP, 10.5% ether extract, 12.2% crude fiber, 2.07% Lys, 0.73% Met, 1.64% Thr, and 0.51% Trp. The SID of Lys, Met, Thr, and Trp for CPCC were 43.5, 70.7, 44.8, and 55.3%, respectively. The DE value for CPCC was 3783 kcal/kg of DM. Multi-Carbohydrase supplementation did not affect the SID of AA and DE value for the CPCC-based diet. In conclusion, CPCC evaluated in the current study could be an alternative source of AA and energy in swine diets. However, Multi-Carbohydrase supplementation did not result in an additional benefit in nutritional value of the CPCC.

Key Words: pig, cold-pressed camelina cake, nutrient digestibility

0968 Optimization of alkali hydrolysis conditions to increase antioxidant availability in corn distillers grain. A. Daramola* and B. Min, *University of Maryland Eastern Shore, Princess Anne.*

Corn is one of the most abundant sources for antioxidants, such as phenolic compounds, among crops and they are well-concentrated into corn distillers grain (CDG) products without degradation. However, more than 70% of phenolics in CDG exist in the insoluble from bound to cell-wall-matrix, which could not be absorbed to exert their health benefits. The objective of this study was to evaluate combinations of alkali hydrolysis condition variables and determine the best combination of the variables to maximize amounts and antioxidant capacity of available phenolics in CDG for absorption. Wet distillers grains (WDG) were alkali-hydrolyzed using factorial combinations of the condition variables: NaOH concentration (0 (control), 0.6, 1.5, and 3.0 mol/kg WDG), incubation temperature (25, 50, and 80°C) and time (0.5, 2, and 4 h). WDG were mixed with NaOH solution at the ratio of 1:3 (w/v) and incubated in a temperature-controlled shaker. After incubation, the mixture was neutralized with HCl and centrifuged. Supernatants were extracted with ethyl acetate and precipitates were freeze-dried and extracted with 80%

ethanol to obtain soluble (FREE) phenolics. Residues were alkali-treated and extracted with ethyl acetate for matrix-bound (BOUND) phenolics. Antioxidant potentials (total phenolic and flavonoid contents and antioxidant capacity measured as oxygen radical absorbance capacity [ORAC]) of FREE and BOUND phenolics were evaluated. Data were analyzed by ANOVA and least square means were compared using PDIFF. Response surface analysis was used to determine the best combination of the condition variables. The antioxidant potential of FREE and BOUND phenolics in control without NaOH were not affected by incubation temperature and time ($P > 0.05$). As the condition variables increased, the antioxidant potentials increased significantly ($P < 0.05$). The biggest increases in antioxidant potentials of FREE phenolics were observed when NaOH concentration increased from 0.6 to 1.5 mol/kg WDG, incubation temperature from 50 to 80°C, and incubation time from 0.5 to 2 h, respectively ($P < 0.05$). When WDG was incubated with NaOH solution at 3.0 mol/kg WDG at 80°C for 4 h, FREE phenolics accounted for over 98% of the total amounts and antioxidant capacity in alkalized WDG. In addition, response surface analysis showed the best combination of alkali hydrolysis condition variables as NaOH concentration (2.55 mol/kg WDG), incubation temperature (69°C) and time (3.0 h) for producing alkalized WDG with maximally available bioactive phenolics, which could contribute to the improvement of farm animal health and productivity.

Key Words: corn distillers grain, alkali hydrolysis, antioxidants

0969 Effects of high protein canola meal on digestibility of phosphorus and growth performance of weanling pigs. Y. She[*1], H. H. Salgado[2], D. Li[3], and H. H. Stein[1], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]Laval Univ., Quebec City, QC, Canada, [3]CAU, Beijing, China.*

Two experiments were conducted to evaluate the nutritional value of high-protein canola meal (CM-HP) and conventional canola meal (CM-CV) in diets fed to weanling pigs. Experiment 1 was designed to compare the apparent total tract digestibility (ATTD) and the standardized total tract digestibility between CM-HP, CM-CV and soybean meal (SBM). Forty eight growing barrows (initial BW: 16.8 ± 1.18 kg) were placed in metabolism crates and allotted to a randomized complete block design using a 2 × 3 factorial arrangement with 8 replicate pigs per diet. Diets were based on CM-HP, CM-CV, or SBM, and 0 or 500 units of microbial phytase. Diets were provided for 12 d with total collection of feces over the final 5 d. Results indicated that as phytase was added to the diets, the ATTD and STTD of P increased ($P < 0.01$) from 41.9 to 57.5% and 45.1 to 60.8%, respectively, in CM-HP; from 40.8 to 60.5% and 44.5 to 64.3%, respectively, in CM-CV; and from 61.0 to 74.2% and 66.7 to 80.5%, respectively, in SBM. There were no difference in ATTD or STTD of P between CM-HP and CM-CV, but ATTD and STTD of P was greater ($P < 0.05$) in SBM than in CM-HP and CM-CV. In Exp. 2, 405 pigs (initial BW: 10.07 ± 1.41 kg) were randomly allotted to 9 dietary treatments with 9 replicate pens per treatment. There were 4 to 6 pigs per pen. The control diet was a corn-SBM diet. Four additional diets were formulated by adding 10, 20, 30, or 40% of either CM-HP or CM-CV to the control diet. Results indicated that increased inclusion rate of CM-CV increased (quadratic, $P < 0.05$) ADG of pigs. Increased inclusion rate of CM-HP or CM-CV decreased (linear, $P < 0.05$) ADFI, but increased (linear, $P < 0.05$) G:F. Pigs fed CM-CV had greater ($P < 0.05$) ADG and G:F than pigs fed CM-HP. In conclusion, there is no difference in the ATTD or STTD of P between CM-HP and CM-CV, and inclusion of up to 40% CM-HP or CM-CV has no negative effects on growth performance of weaned pigs from 2 wk post-weaning.

Key Words: canola meal, phytase, pigs

0970 Effect of heat stress on the apparent and standardized ileal digestibilities of amino acids in growing pigs. A. Morales[1], M. Perez[1], P. Castro[1], N. O. Ibarra[1], E. Avelar[1], L. H. Baumgard[2], and M. Cervantes[*1], *[1]ICA- Universidad AutÃ³noma de Baja California, Mexicali, Mexico, [2]Iowa State University, Ames.*

The exposure of pigs to heat stress (HS) impairs the small intestine digestive and absorptive capacities affecting in turn the AA digestibilities. A two 7-d periods experiment was conducted with 8 pigs (30 kg initial BW) surgically fitted with T-type cannulas at the terminal ileum to analyze the effect of HS on both the apparent (AID) and the standardized ileal digestibility (SID) of AA in pigs fed a wheat-SBM diet. A thermometer was placed inside the ileal lumen (IL) of all pigs to register the temperature at 15 min intervals. After recovery from surgery, all pigs were adapted to the diet and trained to consume the same amount of feed twice a day for 7d under thermal neutral (TN) conditions (22 ± 2°C). Following, the pigs were divided into 2 groups (4 pigs each); one was kept under TN conditions and the other group was exposed to natural HS (24 to 45°C) for 7d (period 1). In period 2, the ambient temperature conditions of the two groups were switched. Ileal digesta was continuously collected during 12 h on d 7 of each period. Chromic oxide was used as indicator of the intestinal digesta flow. The IL temperature was around 1.6°C higher in HS pigs ($P < 0.001$). The AID of AA (%) for the TN and HS pigs were: Arg, 90.6, 88.1; His, 88.7, 85.9; Ile, 84.8, 83.9; Leu, 86.9, 84.1; Lys, 86.8, 86.2; Met, 89.8, 89.1; Phe, 86.0, 84.8; Thr, 75.7, 74.1; Val, 82.8, 81.7, respectively. The SID (%) of AA for the TN and HS pigs were: Arg, 94.0, 92.0; His, 92.5, 90.2; Ile, 89.5, 88.1; Leu, 90.1, 88.6; Lys, 91.0, 90.1; Met, 94.4, 93.6; Phe, 90.4, 88.9; Thr, 86.0, 83.7; Val, 88.1, 86.5;, respectively. The AID of Arg and His was lower ($P <$

0.01) in HS pigs, and the SID of Arg and His, as well as Leu, was also lower in HS pigs. Neither the AID nor the SID of the remaining essential AA was affected by HS. In summary, these data show that ileal temperature increases in HS pigs, and that the digestibilities of essential AA are differentially affected in pigs exposed to natural HS conditions. Special attention should be given to Arg and His when formulating diets for growing pigs under HS conditions

Key Words: pigs, heat stress, amino acids, digestibility

0971 Effect of methionine sources and graded levels of sulfur amino acids on the growth performance of post-weaning piglets. F. Molist[*1], P. Buttin[2], M. Bouwhuis[1], and P. J. van der Aar[1], *[1]Schothorst Feed Research, Lelystad, The Netherlands, [2]Novus International, Brussels, Belgium.*

The aim of the experiment was to evaluate the effects of graded levels of sulfur amino acids (SAA) in the diet of weaned piglets, and to compare the effects of the source of added free-methionine (Met). The experiment was set up according to a 2 × 4 factorial arrangement, with two Met sources (DL-2-hydroxy-4(methylthio) butanoic acid, HMTBa; Novus Europe SA/NV, Belgium vs. DL-methionine, DL-Met; Adisseo, France) and four graded levels (−6, 0, +6, +12% of the requirement) of Met. All the diets were formulated to meet 2008 CVB requirements for weaning piglets for energy (NE 9.37 MJ/kg) and slightly limiting in standardized ileal digestible (SID) Lys (11 g SID Lys/kg). The basal diet (0%) was formulated at 0.6 SID SAA/SID Lys, and the different levels were obtained by the inclusion of the Met source on molar content of HMTBa compared to DL-Met in the commercial products. In total 480 piglets (Tempo × Topigs 20, Topigs Norsvin; boars and gilts) with an average BW of 7.35 ± 0.70 kg and an average age of 26 ± 1 d old entered the trial at the day of weaning. The piglets received a standard diet during the first 7 d. The experimental diets were fed ad libitum from d 7 post-weaning during 4 wk. Body weights (BW) were measured at weaning, on 7, 21, and 35 d post-weaning, and ADG, ADFI, and FCR were calculated accordingly. Data were analyzed as a 2 × 4 factorial arrangement in a randomized block design by analysis of variance (ANOVA), using GenStat® for Windows (17th edition). During d 7–21 of the trial, neither ADG nor ADFI were affected by the treatment. During d 21–35 of the trial, and overall (7–35 d), piglets supplemented with HMTBa showed a greater ADFI ($P = 0.046$), ADG ($P = 0.037$), and final BW ($P = 0.043$) with no effect of level nor interaction. In conclusion, there was no effect of level of Met or SAA on growth performance suggesting that SID Met and SID SAA were above the piglets' requirements. Piglets supplemented with HMTBa showed greater feed intake and subsequent growth than piglets receiving diets containing DL-Met.

Key Words: methionine, piglets

0972 Digestible calcium requirement for 100 to 130 kg pigs. L. A. Merriman[*1], C. L. Walk[2], C. M. Parsons[3], and H. H. Stein[3], *[1]University of Illinois, Urbana-Champaign, [2]AB Vista, Marlborough, United Kingdom, [3]University of Illinois at Urbana-Champaign, Urbana.*

An experiment was conducted to determine the digestible calcium requirement by pigs from 100 to 130 kg. Ninety pigs (average initial BW = 99.89 ± 3.34 kg) were randomly allotted to 15 experimental diets. Each diet was fed to 6 replicate pens using a randomized complete block design. Fifteen corn and soybean meal-based diets were formulated and all diets had the same concentrations of phytate and Na. Diets were formulated using a 3 × 5 factorial design with diets containing 0.11, 0.21, or 0.31% standardized total tract digestible (STTD) P and 0.12, 0.29, 0.46, 0.61, or 0.78% total Ca (0.08, 0.18, 0.29, 0.38, or 0.49% STTD Ca). The P concentrations ranged from 48 to 152% of the STTD P requirement and the Ca concentrations ranged from 27 to 173% of the total Ca requirement. Experimental diets were fed for 28 d and pigs were individually housed. Pig and feeder weights were recorded at the beginning and at the conclusion of the experiment to calculate ADFI, ADG, and G:F. On d 28, all pigs were euthanized and the right femur was extracted. Ash, Ca, and P concentrations were determined from the de-fatted, dried femurs. Results indicated that as dietary concentrations of STTD Ca increased, the ADFI and ADG decreased (main effects of Ca, $P < 0.05$), regardless of the dietary concentration of P. Models to predict ADFI [ADFI = 3.6782– 1.2722 × STTD Ca (%); $P = 0.001$] and ADG [ADG = 1.2141– 0.6230 × STTD Ca (%); $P = 0.008$] were dependent only on the concentration of STTD Ca, but not on the STTD of P. There were no effects by STTD Ca or STTD P on G:F indicating that the negative effects of STTD Ca on ADG was a result of reduced ADFI. Linear increases were observed for bone ash, bone Ca, and bone P as dietary concentrations of STTD Ca increased for all levels of STTD P (interaction, $P < 0.001$). In conclusion, results from the experiment support the current requirements (NRC, 2012) for Ca and STTD P, and feeding beyond the requirements for Ca (0.46% total Ca; 0.29% STTD Ca) or STTD P (0.21) is detrimental to growth performance of pigs.

Key Words: bone ash, calcium, pigs, phosphorus

0973 Effects of inclusion of canola meal in weanling pig diets containing different concentrations of energy. T. F. Pedersen[*1], Y. Liu[2], and H. H. Stein[3], *[1]Aarhus University, Aarhus, Denmark, [2]University of California, Davis, Davis, [3]University of Illinois at Urbana-Champaign, Urbana.*

The objective of the experiment was to determine effects of diet NE and addition of an exogenous enzyme on growth performance and physiological parameters of weanling pigs fed a corn-soybean meal (SBM) diet or diets containing high protein canola meal (CM-HP) or conventional canola meal (CM-CV). In total, 492 pigs (initial BW: 9.15 ± 0.06 kg) were used in a randomized complete block design with 9 replicate pens per treatment. A control diet based on corn and SBM and 4 diets containing 20 or 30% CM-HP or CM-CV were formulated; inclusion of choice white grease (CWG) was adjusted to maintain constant NE among diets. Four additional diets containing 20 or 30% CM-HP or CM-CV were formulated without adjusting CWG and NE in these diets was, therefore, reduced compared with the control diet. Three diets that were similar to the control diet and the diets containing 30% CM-HP or CM-CV without adjusted CWG were formulated, but a carbohydrase was included in these diets. Pigs were fed experimental diets for 22 d. Results indicated that ADG and G:F decreased (linear, $P < 0.05$) as CM-HP was included in diets with constant energy, but that was not the case if CM-CV was included in the diet or if diets were not formulated to a constant NE. There were also no differences in G:F or in final BW among pigs fed the control diet and pigs fed canola meal diets. Only minor and inconsistent effects of CM-HP or CM-CV on intestinal weight, gut fill, digesta pH, cecal VFA concentrations, and serum concentrations of urea N, total N, or albumin were observed. However, thyroid gland weight increased ($P < 0.05$) or tended to increase ($P < 0.10$) as the concentration of canola meal increased. Serum concentrations of IgG and total tract digestibility of GE were reduced (linear, $P < 0.05$) if CM-HP or CM-CV was included in the diets. No major effects of the carbohydrase were observed. In conclusion, up to 30% CM-HP or CM-CV may be used in diets fed to weanling pigs from 2 wk post-weaning without impacting growth performance and NE in diets containing canola meal does not have to be similar to that in corn-SBM diets.

Key Words: canola meal, energy concentration, pigs

0974 Effect of increasing concentrations of digestible calcium and digestible phosphorus on apparent total tract digestibility of calcium and phosphorus by pigs. J. C. González-Vega[*1], C. L. Walk[2], M. R. Murphy[1], and H. H. Stein[1], *[1] University of Illinois at Urbana-Champaign, Urbana, [2]AB Vista, Marlborough, United Kingdom.*

Two experiments were conducted to determine effects of increasing concentrations of digestible Ca and digestible P on apparent total tract digestibility (ATTD) of Ca and P in diets fed to pigs. In Exp. 1, 6 diets were formulated to contain 0.36% standardized total tract digestible (STTD) P and 0.32, 0.40, 0.48, 0.56, 0.64, or 0.72% STTD Ca, by including increasing quantities of calcium carbonate at the expense of cornstarch. Two additional diets contained 0.72% STTD Ca and 0.33% or 0.40% STTD P. A total of 80 pigs (initial BW: 13.12 ± 1.79 kg) were placed in metabolism crates and randomly allotted to the 8 diets with 10 replicate pigs per diet in a randomized complete block design. Results indicated that the ATTD of Ca and the ATTD of P decreased (linear, $P < 0.001$) as dietary STTD Ca increased. However, increasing dietary STTD P did not affect ATTD of Ca, but the ATTD of P increased (linear, $P < 0.05$) as dietary STTD P increased. In Exp. 2, 20 corn-soybean meal based diets were formulated with diets containing 4 concentrations of STTD P (0.15, 0.31, 0.39, or 0.47%) and 5 concentrations of STTD Ca (0.13, 0.27, 0.42, 0.57, or 0.72%). A total of 120 pigs (initial average BW: 29.45 ± 2.15 kg) were placed in metabolism crates and randomly allotted to the 20 diets in 6 blocks with 1 pig per diet in each block. Results indicated that ATTD of Ca in diets linearly increased ($P = 0.009$) as concentration of STTD Ca increased, but was not affected by the concentration of STTD P. However, the ATTD of P linearly decreased ($P < 0.001$) as the concentration of STTD Ca increased, but linearly increased ($P < 0.001$) as the concentration of STTD P increased. In conclusion, for pigs between 11 and 50 kg, the ATTD of Ca varies by the concentration of STTD Ca in diets, but is not affected by the concentration of STTD P. However, the ATTD of P is negatively affected by increasing concentration of STTD Ca, but increases as concentration of STTD P increases.

Key Words: calcium, phosphorus, pigs

0975 Trans-generational effect of feeding genetically modified mCry1Ac corn to laying hens and offspring on offspring growth and health. L. Chen*, R. Zhong, L. Zhang, L. Gao, and H. Zhang, *Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, China.*

The experiment was to assess the chronic effect of the transgenic corn lines containing the *mCry1Ac* gene from *Bacillus thuringiensis* strain (BT) to White Leghorn laying hens for 12 wk and their offspring from 1 d to 36 wk on offspring growth

and health. Healthy hens (n = 72 placed in cages; 3 hens/cage) were randomly assigned to 1 of 3 corn-soybean meal dietary treatments (8 cages/treatment) formulated with the following corn: 61.7% nontransgenic near-isoline control corn (CT), BT corn, and commercially available nontransgenic reference corn (RF) for 12 wk. After 12 wk, fertile eggs were collected daily and hatched for 21 d. A total of 240 offspring pullets were assigned to 3 dietary treatment for 36 wk, i.e., 1) CT corn-fed parental hens/CT corn-fed offspring pullets (CT/CT); 2) BT corn-fed parental hens/BT corn-fed offspring pullets (BT/BT); and 3) RF corn-fed parental hens/RF corn-fed offspring pullets (RF/RF). Each dietary treatment was assigned to 10 replicates with 8 offspring pullets per replicate for a total of 80 pullets per treatments. Body weight and egg quality of pullets were determined weekly. Offspring hens were harvested at the end of 36 wk (n = 8/treatment), and carcass yield and organ weights (heart, liver, spleen, lung, kidneys and ovary) were recorded; organs and intestines were sampled for histological analysis. Analysis of serum biochemistry parameters, hematology, and hormone were performed. Immune cell phenotypes of spleen and peripheral blood mononuclear cells were determined. No differences in body weight, egg quality and function of reproductive organs were observed between hens consuming the CT/CT diet and hens consuming the BT/BT diet. Intestinal histology and health were similar between the control and test groups. The relative weight of lung and kidneys of hens fed the BT/BT treatment was less than hens fed the CT/CT treatment ($P < 0.05$). Liver and kidney histology and health were not affected by the diet treatment. Offspring hens from the BT/BT treatment had greater duodenal goblet cells/villus ($P < 0.05$) and jejunal villus height/crypt depth ratios ($P = 0.06$). Similar organosomatic indices, serum biochemistry parameters, hematology, and hormone parameters did not indicate the characteristics of organ dysfunction. Immune response was not affected by the trans-generation feeding BT/BT diet. These results indicate that trans-generational consumption of the BT corn diets is not detrimental to hen growth and health.

Key Words: *Bacillus thuringiensis*, genetically modified, hen, *mCry1Ac* gene corn, trans-generational effect

0976 Effects of methionine or arginine supplementation and environmental temperature on performance, carcass traits and meat quality of finishing pigs. J. K. Htoo[*1], C. A. Garbossa[2], H. Silveira[2], L. G. Amaral[2], N. A. Barbosa[3], and V. S. Cantarelli[2], *[1]Evonik Nutrition & Care GmbH, Hanau-Wolfgang, Germany, [2]Federal University of Lavras, Lavras, Brazil, [3]Evonik Industries do Brazil, São Paulo, Brazil.*

A 46-d study was conducted to determine the effects of methionine (Met) or arginine (Arg) supplementation in a thermal-neutral (24°C) or heat stressed (32°C) environment on performance, carcass characteristics and meat quality of finishing pigs. Seventy-two mixed-sexed pigs (PIC × DanBred; initial BW of 69.1 ± 0.11 kg) were assigned to 6 diet regimes using a 2 × 3 factorial arrangement with 3 dietary treatments [a basal diet (BD), the BD + 0.15% DL-Met or the BD + 0.40% L-Arg], and 2 environmental temperatures (24°C or 32°C) having 6 pen replicates (2 pigs/pen) per treatment. Diets were formulated based on corn, soybean meal and corn gluten meal using the analyzed ingredient AA contents and published standardized ileal digestible (SID) coefficients to meet AA requirements for both finisher 1 (0.76% SID Lys; 70–90 kg) and finisher 2 (0.69% SID Lys; 90–112 kg) phases. Pigs were fed the finisher 2 diets until they reached a predetermined market weight (115 kg). At slaughter, 36 pigs (6 pigs/treatment) were selected for carcass assessment. Samples of longissimus dorsi (LD) muscle were used for meat quality assessments. Data were analyzed using the MIXED procedure of SAS. There was no diet × temperature interaction for any variables ($P > 0.05$). Compared with 24°C, ADFI, ADG and G:F were lower ($P < 0.001$) under 32°C temperature during each phase and the overall 46-d period, except for the ADFI during finisher 2 period ($P = 0.056$). Overall, supplementing with 0.15% DL-Met or 0.40% L-Arg reduced ADFI ($P = 0.033$) and increased G:F ($P = 0.012$). Compared with 24°C, 32°C temperature increased ($P < 0.05$) chilled carcass yield and 24 h pH of carcass but decreased ($P < 0.05$) drip loss after 24 and 48 h and the number days to reach 115 kg BW. The 24 h pH of carcass tended to increase ($P = 0.053$) by 0.15% DL-Met addition but all other measured carcass parameters including lean percentage and backfat thickness were not affected by dietary treatments. The concentrations of cortisol and heat shock protein 70 (HSP70) in plasma and concentrations of thiobarbituric acid reactive substances and hydrogen peroxide in LD muscle were not affected by the dietary treatments or the environment temperature. These results indicate that heat stress reduces pig performance and may affect carcass quality. Additional L-Met or L-Arg supplementation in finisher pig diets may improve feed efficiency.

Key Words: arginine, methionine, temperature

0977 A protective effect of IGF-activated plasma protein (CTCgrow) on lipopolysaccharide-induced intestinal dystrophy in rats. M. Kwak[*1], J. Kim[1], J. M. Lee[2], S. W. Jung[2], and K. Y. Whang[1], *[1]Korea University, Seoul, The Republic of Korea, [2]CTC BIO, Seoul, The Republic of Korea.*

In livestock industry, dietary plasma protein has shown the improved growth performance of weaned animals and it seems to be more than nutrient content itself. The exact mechanism of plasma protein on enhancing growth performance is not fully understood yet, but dietary insulin-like growth factors (IGFs) in plasma protein might have an important role. But it has been also suggested that IGFs with binding protein

might attenuate the growth-promoting effects of IGFs. Therefore, we conducted an experiment to determine the protective effects of commercially available IGF-activated plasma protein product (by de-binding with protein, CTCgrow) on intestinal dystrophy induced by lipopolysaccharides (LPS). Forty-two rats (4 wk-old) were allotted into six treatments in a 2 × 3 factorial design. One factor was dietary supplementation (CON, control; PP, 50 g/kg of plasma protein; and aIGFPP, 3.4 g/kg of IGF-activated plasma protein) and the other factor was LPS-challenge (PBS or LPS). Basal diet was formulated based on NIH-31 diet. During 4 wk of feeding period, rats were allowed to the diets ad libitum and growth performance was recorded weekly. On Day 28, rats were injected with either LPS or PBS and growth performance was recorded every day for 3 d. At Day 3 post-injection, rats were sacrificed and gut morphological change was investigated in jejunum samples. Before LPS-challenge, body weight and feed intake of aIGFPP group were numerically higher than those of other groups. After LPS-challenge, aIGFPP alleviated the weight loss induced by LPS-challenge and showed significantly higher feed efficiency than PP ($P < 0.05$). In non-challenged groups, there were significantly higher villus height (VH) and VH:CD ratio and lower crypt depth (CD) in aIGFPP than other groups ($P < 0.05$). And the number of goblet cells per villus was also significantly higher in aIGFPP than other groups ($P < 0.05$). And there was a tendency that LPS-challenged groups showed lower VH and higher CD than non-challenged groups in respective dietary treatment groups. In LPS-challenged groups, VH and VH:CD ratio were numerically higher in CON and aIGFPP than PP. The number of goblet cells per villus was significantly higher in LPS-challenged aIGFPP than other LPS-challenged groups ($P < 0.05$). These results indicated that aIGFPP had a growth-promoting effect by improvement of intestinal morphology before LPS-challenge. Also aIGFPP demonstrated a protective effect on gut mucosal injury induced by LPS.

Key Words: rats, intestine, gut morphology, IGF, plasma protein

0978 Effects of α-Galactosidase supplementation on the energy value of soybean meal and growth performance of weanling pigs. C. D. Espinosa*, *University of the Philippines Los Baños, Laguna, Philippines; University of Illinois at Urbana-Champaign, Urbana-Champaign.*

Two experiments were conducted to determine effects of supplementing diets with an α-galactosidase enzyme complex on the energy value of soybean meal (SBM), apparent total tract digestibility (ATTD) of nutrients in corn-SBM diets, and growth performance of weanling pigs. In Exp. 1, 40 barrows (PIC 337 × C24; initial BW 9.9 ± 1.9 kg) were randomly allotted to 5 dietary treatments with 8 pigs per diet. A basal diet consisting of 94.89% corn (as-fed basis) and 4 diets containing 70% of the basal diet and 30% (as-fed basis) SBM supplemented with 0, 100, 200, or 400 mg/kg of an α-1,6-galactosidase enzyme complex were formulated. Pigs were individually housed in metabolism crates that allowed for the total, but separate, collection of urine and fecal materials from each pig. Results indicated that addition of increasing concentrations of α-1,6-galactosidase enzyme complex increased (linear, $P < 0.05$) DE, and tended (linear, $P = 0.09$) to increase ME of SBM by approximately 300 kcal/kg (as-fed basis). The enzyme complex also improved ($P < 0.05$) the ATTD of ash and tended ($P < 0.10$) to improve the ATTD of DM, hemicellulose, OM, and crude fat. In Exp. 2, 378 pigs (PIC 337 × C24; initial BW 4.5 ± 1.8 kg) were randomly allotted to 1 of 3 dietary treatments with 21 pigs per pen and 6 pen replicates per treatment. The experiment lasted 10 d. Treatments included 2 diets (without or with the enzyme complex) formulated with the assumption that SBM contained 3344 kcal ME/kg (as-fed basis). The last diet was formulated assuming that the SBM contained 3644 kcal ME/kg if 100 mg/kg of the enzyme complex was also included in the diet. Inclusion of SBM was 18% in all diets. Results indicated that regardless of the presumed ME in SBM, addition of the enzyme improved ($P < 0.05$) total BW gain, tended ($P = 0.09$) to improve ADG, and tended ($P = 0.10$) to improve caloric efficiency when compared with the diet containing no enzyme. The cost of feed/kg of gain also tended ($P = 0.10$) to be reduced by addition of the enzyme complex to the diet. In conclusion, the α-1,6-galactosidase enzyme complex used in these experiments improved the energy value of SBM and the ATTD of nutrients, which may result in reduced cost of production per unit of gain.

Key Words: α-galactosidase, soybean meal, weanling pigs

0979 Use of crystalline amino acids in meal feeding does not affect nitrogen retention in growing pigs compared to protein-bound amino acids. S. A. Lee* and B. G. Kim, *Konkuk University, Seoul, The Republic of Korea.*

The present study was conducted to test the hypothesis that the supplementation of crystalline AA (CAA) affects the N retention for growing pigs in the meal feeding. Ten pigs with initial BW of 53.6 kg (SD = 2.7) were individually housed in metabolism crates. The pigs were allotted to 2 experimental diets according to a crossover design with 10 animals and 2 periods. Two experimental diets were formulated. A diet was mainly based on corn and soybean meal as N sources (protein-bound form-diet, PBD), and the CAA were supplemented to the PBD at the expense of 14.2% soybean meal (CAA-supplemented diet, CD). The supplementation levels of CAA were determined based on the standardized ileal digestible AA in the SBM. The daily amount of feed allowance per pig was determined as 3 times the maintenance energy of pigs within similar BW and an equal amount of the feeds was provided at 0730

and 1630 h. Total but separate collection of feces and urine was performed according to marker-to-marker and time-to-time methods, respectively. The amounts of excreted and retained N were determined based on the analyzed N contents in the fecal and urinary samples. Nitrogen intake of pigs fed the PBD and CD were 52.4 and 46.2 g/d ($P < 0.001$), respectively. The fecal N excretion (7.52 and 6.23 g/d, $P = 0.014$), digested N (44.9 and 39.9 g/d, $P < 0.001$), and retained N (24.9 and 22.2 g/d, $P = 0.014$) in the pigs fed the PBD were greater than in the pigs fed the CD. However, the apparent total tract digestibility of N and retention of N did not differ among the pigs fed 2 experimental diets. In conclusion, the use of CAA in the meal feeding did not affect the N retention in growing pigs compared to the protein-bound AA from the SBM.

Key Words: free amino acid, nitrogen retention, protein-bound amino acid

---

0980 Effects of SILOHealth 104 supplementation on the growth performance of Ross 308 broiler chickens.

A. Bedford[1], H. Yu[1], M. Hernandez[1], J. Squires[2], S. Leeson[3], and J. Gong[*1], *[1]Agriculture and Agri-Food Canada, Guelph, ON, Canada, [2]Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, [3]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Global consumption of poultry products has consistently increased over the past 30 yr, requiring producers to maintain chicken production to meet the demands. With the rising concern regarding the inclusion of antibiotics in feed, developing a viable alternative for poultry production is of a significant interest. Butyric acid, a short chain fatty acid, is the primary energy source for colonocytes and has shown potential as an alternative to in-feed antibiotics, including its antimicrobial activity and positive effects on production performance traits of broiler chickens. SILOHealth 104 (SILO S.P.A., Florence, Italy) is a commercial butyrate product mainly containing mono- and di-glycerides of butyrate with a small portion of mono- and di-glycerides of propionic, caprylic, capric, and lauric acids. Its effects on broiler performance have yet to be evaluated. Four hundred and eighty day old male Ross 308 birds were divided into different treatment groups with equal starting weights and fed a basal diet, or basal diet including 500, 1,000, 2,000, or 3,000 ppm of SILOHealth 104 for 35 d. There were no significant differences in overall average daily gain or feed:gain ratio with the addition of SILOHealth 104 to the diets ($P > 0.05$). At 5 wk of age, abdominal fat weight was reduced in birds supplemented with SILOHealth 104 in a dose responsive manner ($P < 0.05$), while breast muscle weight increased with supplementation up to 2000 ppm, with significant increases in 1000 ppm and 2000 ppm birds compared to controls ($P < 0.05$). Expression of both Forkhead box protein O4 and myostatin, two factors that can inhibit protein synthesis, were found to be significantly decreased in the breast muscle of all SILOHealth 104 birds compared to control birds ($P < 0.05$). These data suggest that the components of SILOHealth 104 can positively impact the deposition of muscle, while reducing abdominal fat deposition in broiler chickens.

Key Words: broiler, butyrate glycerides, breast muscle

0981 Effect of increasing *Buttiauxella* phytase dose to 2000 FTU/kg on phytate degradation and ileal AA digestibility in weaned pigs.

Y. Dersjant-Li[1] and G. Dusel[*2], *[1]Danisco Animal Nutrition, DuPont Industrial Biosciences, Marlborough, United Kingdom, [2]University of Applied Sciences Bingen, FB1- Life Sciences, Bingen am Rhein, Germany.*

This study determined the effect of increasing *Buttiauxella* phytase dose on phytate degradation and ileal AA digestibility in weaned pigs. Six treatments were tested including a nutritionally adequate positive control (PC); a negative control (NC) with reduction of 0.1% Ca, 0.14% digestible P and 35 kcal/kg ME vs. PC; NC supplemented with a *Buttiauxella* sp. phytase at 250, 500, 1,000 or 2,000 phytase units (**FTU**)/kg feed. One FTU was defined as the amount of enzyme required to release 1 µmol of iP per minute from sodium phytate at pH 5.5 at 37°C. Male pigs (Topigs × Pietrian, barrows, 20kg BW) were randomly allocated in metabolism crates (1 pig per crate) in 2 runs, 24 pigs in each run with a total of 8 replicates per treatment. Pelleted diets based on mixed grain (wheat, corn and barley) were fed for 9 d with 3 d adaptation, 5 d collection of feces and urine (for measuring apparent total tract digestibility [ATTD]) and 1 d to collect ileal digesta (for measuring apparent ileal digestibility [AID], TiO_2 as marker). The diets were supplied at 2.5 times energy requirement for maintenance in 2 equal meals per day, water was freely available. Treatment means were compared using Tukey's HSD, linear or nonlinear responses were determined using JMP 11 (SAS). Phytase at 2,000 FTU/kg showed greater ($P < 0.05$) nutrient digestibility vs. NC or PC for most of the parameters. Increasing phytase dose from 0 (NC) to 2,000 FTU/kg linearly improved ($P < 0.05$) ATTD of P, retainable P, Ca, DM, N, ME as well as AID of P, N, Lys, Met, Cys, Thr, Val, Ile, Leu and mean essential AA. While AID of Ca and Trp increased in a nonlinear manner. AID of phytate was 36, 39, 54, 67, 76, and 83%, respectively, for PC, NC, phytase at 250, 500, 1,000 and 2,000 FTU/kg feed ($P < 0.05$). The AID of phytate was linearly correlated with mean AID of AA ($P < 0.05$). In conclusion, increasing *Buttiauxella* phytase dose increased the level of phytate degradation, resulting in improved digestibility of AA and other nutrients. This demonstrated that increasing *Buttiauxella* phytase dose to 2,000 FTU/kg can lead to both phosphoric and extra-phosphoric effects.

Key Words: pigs, phytate degradation, AA digestibility

0982 Influence of dietary crude protein and phosphorus levels on the utilization of crude protein and phosphorus in growing pigs. P. Xue*[1] and O. Adeola[2], [1]*Purdue University, West Lafayette, IN,* [2]*Department of Animal Sciences, Purdue University, West Lafayette, IN.*

A study was conducted to determine the response of total tract utilization of CP and P to different CP and P levels in growing pigs. A total of 72 growing pigs (initial BW 20.9 ± 0.8 kg) were used in a randomized completely blocked design, with 9 treatments and four 10-d experimental periods giving 8 replicates per treatment. The pigs were blocked by BW and allotted to 9 treatments with a 3 × 3 factorial arrangement consisted of 3 CP levels (5.5, 9.7, or 13.9%) and 3 apparent total tract digestible P (ATTDP) levels (0.11, 0.19, or 0.27%). The CP level and ATTDP levels were adjusted using SBM and mono-calcium phosphate (MCP), respectively. Limestone was included to maintain the Ca: ATTDP ratio across diets. There was a 5-d adjustment period followed by a 5-d total collection period. Chromic oxide and ferric oxide were used as markers to time the initiation and termination of fecal collection, respectively. The daily feed intake was adjusted to 4% of the average BW of each block, in 2 equal daily feeding regimen at 0730 and 1730 h. Data was analyzed using PROC MIXED of SAS (9.4) and contrasts were used to test the linear and quadratic effects of increasing levels of P within each CP level, or vice versa. Digested P (g/d) was regressed against P intake (g/d) for each CP level to determine the true total tract digestibility (TTTD) of P in MCP. Digested P (g/d) increased linearly along with the increasing level of CP ($P < 0.05$). The determined TTTD of P in MCP for 5.5, 9.7, and 13.9% CP diets were 80.5, 82.6, and 87.9%, respectively. There were no statistical differences among the three TTTD estimates. In the nitrogen utilization results, increasing dietary P level decreased the urine nitrogen output ($P < 0.05$). In conclusion, the results indicated that dietary CP deficiency may limit total tract P digestion.

Key Words: crude protein, phosphorus, total tract digestibility

0983 Effects of Dakota gold and high fat commodity DDGS in a complete diet on pellet quality. A. D. Yoder*, *Kansas State University, Manhattan.*

Inclusion of dried distillers grains with solubles (DDGS) in pelleted feed is limited because of pellet quality. Including a reduced-fat DDGS instead of a higher fat DDGS may mitigate these negative effects. Thus, the objective of this experiment was to evaluate pellet quality when 2 different sources of DDGS were used in a pelleted complete feed. The experiment was set up as a 2 × 2 × 2 × 4 factorial arrangement with 2 sources of DDGS (reduced and high-fat DDGS), 2 pellet temperatures (65.6°C and 82.2°C), 2 inclusion rates (15% and 30%) and 4 Pellet Durability Methods (Standard Pellet Durability Index (PDI; ASABE S269.4, 2007), Modified PDI (three 19-mm hex nuts), Holmen NHP 100 for 60 s, and Holmen NHP 200 for 240 s) in a typical complete feed formulated for a finishing swine diet. Reduced-fat DDGS (Dakota Gold) was sourced from POET, LLC and high-fat DDGS was sourced from a local feed mill. Feed was pelleted on a 1 ton per hour pellet mill (CPM Model PM 1012–2) equipped with a 4.0 mm × 32 mm die. Throughput was held constant at 680 kg/hour. Each treatment was replicated 3 times. Data were analyzed using the GLIMMIX procedure of SAS. There was no interaction between any 2 variables of the experiment. The addition of Dakota Gold improved pellet quality by 5.2% points ($P < 0.05$). The PDI results were 88.0% and 82.8% for the Dakota Gold and 8% fat commodity DDGS, respectively. Inclusion level ($P = 0.71$) or conditioning temperature ($P = 0.103$) had no effect on PDI. The PDI method of analysis had the greatest effect on the results ($P < 0.05$). The result of Standard PDI, Modified PDI, Holmen NHP 100, and Holmen NHP 200 were 95%, 91%, 89%, and 67%, respectively. The NHP 200 method produced the lowest values primarily due to the long run time of the method. The feed industry should select the method that best models their feed manufacturing and delivery processes. The results of this experiment indicate that the addition of lower fat DDGS improves pellet quality, and the PDI method of analysis can significantly impact the results reported in the industry.

Key Words: pellet, DDGS, pellet durability index

0984 Oregano essential oil supplementation in gestation and lactation shortened birthing interval in primparous and multiparous sows. M. Renken, R. C. Thaler, and C. L. Levesque*, *South Dakota State University, Brookings.*

A total of 15 gilts and 26 sows (parity 2 to 5) were used to assess the impact of oregano EO (By-O-Reg, Advanced Ag Products) supplementation in gestation and lactation on farrowing characteristics (duration and birth interval), and sow and piglet performance. Females were assigned to 1 of 2 dietary treatments at breeding [0 or 2 g/d oregano EO supplementation]. Experimental diets were fed throughout gestation and lactation (21 d). Diets were offered once daily in gestation and twice daily in lactation, and oregano EO was added as a top dress with the AM feeding. Diets were formulated to meet or exceed nutrient requirements for sows/gilts in gestation (0.6% SID Lysine and 3280 kcal ME/kg) and lactation (0.9% SID Lysine and 3280 kcal ME/kg). Control sows (0 g/d EO) received soy hulls (the carrier for the EO) at 2 g/d. Assessment of sow performance included body weight and backfat (breeding, d 110 of gestation, d 1 of lactation, and at weaning), and lactation feed intake. Piglets were weighed at birth and at weaning. All farrowings were attended by a trained technician and farrowing duration was determined as the time between birth of the first and last piglets and piglet birth interval was

recorded. Data was analyzed as a RCB design with sow as the experimental unit. Sow performance was not affected by EO supplementation: mean body weight was 180.0 ± 8.9 kg and 233.7 ± 5.3 kg at breeding and d110, respectively and lactation feed intake was 7.09 ± 0.35. Gestation length tended to be shorter ($P = 0.11$) in EO supplemented sows (115.0 vs. 115.7 ± 0.3). Farrowing duration (3.5 ± 0.5 h) was not influenced by EO supplementation but birthing interval tended to be shorter ($P = 0.10$) in EO fed sows (14.0 vs. 20.2 ± 2.8 min/pig). Born alive (12.8 vs. 11.9 ± 0.8), stillborns (0.26 vs. 0.40 ± 0.17), piglet birth weight (1.33 vs. 1.36 ± 0.03 kg) and piglet weaning weight (7.38 vs. 7.26 ± 0.16 kg) were not influenced by maternal EO supplementation. Subsequent rebreeding interval tended to be increased ($P = 0.06$) in EO fed sows (4.7 vs. 4.5 ± 0.1 d). Oregano EO supplementation had little impact on sow and piglet performance but appeared to positively impact birthing interval and gestation length. A shorter birthing interval may reduce the risk of stillborns and limit the need for farrowing assistance.

Key Words: birthing interval, essential oil, sow

0985 Effects of casein on digestibility of amino acids in distillers dried grains with solubles fed to pigs.

C. S. Park*[1], C. Fang[1], D. Ragland[2], and O. Adeola[1], *[1]Department of Animal Sciences, Purdue University, West Lafayette, IN, [2]Department of Veterinary Clinical Sciences, Purdue University, West Lafayette, IN.*

The objective of this experiment was to determine the true ileal digestibility (TID) of CP and AA in casein and to determine the effects of inclusion of casein in experimental diet on apparent ileal digestibility (AID) and standardized ileal digestibility (SID) of CP and AA in corn distillers dried grains with solubles (DDGS) fed to pigs. Eighteen barrows with an initial BW of 50.5 ± 4.5 kg were surgically fitted with T-cannula at the distal ileum and individually housed in metabolism crates. Pigs were allotted to triplicate 6 × 3 incomplete Latin square design with 6 dietary treatments and 3 periods. The 6 dietary treatments consisted of 3 diets formulated to contain 6, 10, or 14% casein; 2 diets prepared to contain 48% DDGS or 30.8% DDGS and 6% casein; and one nitrogen-free diet to determine the basal ileal endogenous losses of CP and AA. Each period lasted 7 d consisted of 5 d of adaptation period and 2 d of ileal digesta collection period. The AID of CP and all AA in casein were linearly increased ($P < 0.01$) with increasing dietary casein. The estimated TID of CP, Lys, Met, Thr, and Trp were 101% (SE = 3.2), 99.9% (SE = 2.12), 99.2% (SE = 1.17), 97.0% (SE = 3.23), and 98.8% (SE = 3.30), respectively. The AID and SID of Arg, Lys, Phe, and Trp in diet containing DDGS were less ($P < 0.01$) than those in diet containing DDGS and casein. There were no differences between the AID of CP, His, Ile, Thr, and Val in diet containing DDGS and those in diet containing DDGS and casein. However, the SID of CP, His, and Ile in DDGS diet were less ($P < 0.05$) than those in DDGS and casein diet. In conclusion, improving protein quality in experimental diets by inclusion of highly digestible protein sources such as casein may affect the SID of CP and AA in test ingredients of lower protein quality.

Key Words: digestibility, nutrient, swine

0986 Investigations of marker and fiber effects on energy and nutrient utilization in growing pigs.

T. Wang*[1], D. Ragland[2], and O. Adeola[1], *[1]Department of Animal Sciences, Purdue University, West Lafayette, IN, [2]Department of Veterinary Clinical Sciences, Purdue University, West Lafayette, IN.*

An experiment was conducted to investigate whether the apparent ileal and total tract digestibility of nitrogen and energy, and excretion patterns of indigestible markers were influenced by the type of marker and dietary fiber. Twenty barrows surgically fitted with T-cannula at the end of ileum were used in two experimental periods consisting of a 7-d adjustment period followed by a 3-d total fecal collection period and a 3-d ileal digesta collection period. Three diets were identically formulated except for 10% of the cornstarch (CS), corn bran (CB) or oat bran (OB). All three diets contained three index markers (5 g/kg chromic oxide [Cr_2O_3], 5 g/kg titanium dioxide [TiO_2], and 20 g/kg acid-insoluble ash [AIA]). Pigs were fed at 0800 h and 1600 h with 2 equally sized meals during the experimental period. The ileal digesta were collected every 3 h from 0900 h to 1700 h with 4 time periods (TP) on ileal digesta collection days. For all 3 markers, the marker concentration of CS diet was greater than OB diet, which had greater marker concentration than CB diet ($P < 0.001$). The marker concentration of the first ileal collection day (Day1) was significantly lower than the third day (Day3) for Cr_2O_3 ($P = 0.05$), TiO_2 ($P < 0.001$) and AIA ($P < 0.01$), respectively. The 3 markers were excreted in a similar pattern over 4 TPs for ileal digesta. The highest marker concentration appeared at the second TP (1200 h to 1500 h). The apparent ileal digestibility of energy (AIDE) and nitrogen (AIDN) of CB and OB diets was not affected by markers. For all 3 diets, the apparent total tract digestibility of energy (ATTDE) and nitrogen (ATTDN) determined by total collection method was greater ($P < 0.05$) than those determined by using inert digestibility markers. The ATTDE and ATTDN of CB diet calculated based on Cr_2O_3 were lower ($P < 0.05$) than those determined by TiO_2, but for OB diet, the ATTDE and ATTDN determined by AIA were greater ($P < 0.05$) than those determined by TiO_2. In conclusion, the marker distribution varied over time periods and was affected by fiber type, and the marker type may affect the estimate of total tract but not ileal digestibility of energy and nitrogen.

Key Words: markers, fibers, digestibility

0987 Evaluation of ileal energy digestibility of diets based on different grain species fed to growing pigs. P. Rosenfelder*, H. K. Spindler, E. J. P. Strang, E. DeGiorgi, M. Eklund, and R. Mosenthin, *University of Hohenheim, Institute of Animal Science, Stuttgart, Germany.*

It is well accepted that feed energy digested until the end of the ileum is more efficiently utilized by the pig than energy fermented microbially in the hindgut. Thus, ileal rather than fecal energy digestibility values may be closer to the actual energy available for maintenance and production, but data on ileal energy digestibility of cereal grains are scarce. The objective of the present study was to determine in growing pigs the ileal energy digestibility of diets based on 8 different genotypes of barley, rye, triticale, and wheat each. Therefore, 4 experiments were conducted with 8 or 9 ileally cannulated growing pigs (initial BW of 24 to 32 kg) each. The assay diets were formulated to contain 1 of the 8 genotypes of each grain species at an inclusion level of 95% (on as-fed basis). All diets were supplemented with plant oil, minerals and vitamins, and titanium dioxide as an indigestible marker. The experiments were either arranged as a row-column design with 8 periods of 6 d each and 9 pigs (for barley and wheat), or according to an 8 × 8 Latin square design with 8 periods of 6 (rye) or 7 d (triticale) and 8 pigs. Experimental periods comprised 4 (barley, rye, and wheat) or 5 d (triticale) for adaptation, followed by 2 d for ileal digesta collection. The daily feed intake amounted to 4% of pigs' average BW, corresponding to about 3 times the animals' energy requirement for maintenance (106 kcal of ME/kg of $BW^{0.75}$). On average, ileal energy digestibility amounted to 65, 67, 78, and 73% for barley, rye, triticale, and wheat diets and was different between grain species ($P < 0.05$). Ileal energy digestibility was different within the 8 rye diets ($P < 0.05$) with values ranging between 66 and 70%, but there were no differences in ileal energy digestibility within barley, triticale, or wheat diets. Differences in ileal energy digestibility within rye diets reflect variations in contents of fiber fractions of the rye genotypes, as higher contents of NDF, ADF, and different non-starch polysaccharide fractions resulted in a linear decrease in ileal energy digestibility ($P < 0.01$). In conclusion, triticale is superior in ileal energy digestibility compared to the other grain species.

Key Words: cereal grains, ileal energy digestibility, growing pigs

0988 The relationship between the expression of genes regulating appetite control and feeding behavior in pigs divergent in feed efficiency. S. Vigors[1], J. V. O'Doherty[2], A. K. Kelly[2], and T. Sweeney*[1], [1]*School of Veterinary Medicine, University College Dublin, Belfield, Dublin 4, Ireland,* [2]*School of Agriculture and Food Science, University College Dublin, Dublin 4, Ireland.*

More efficient pigs eat less than their less efficient counterparts, however the regulation of appetite and feeding behavior in the hypothalamus and intestine has not been well researched. Therefore, the objective of this study was to examine the association between residual feed intake (RFI) and feeding behavior with both hypothalamic and gut peptides involved in appetite control. Seventy-five male pigs (initial BW 22.4 kg [SD = 2.03]) were fed a standard finishing diet (13.8 MJ DE/kg and 9.5 g standard ileal digestible [SID] lysine/kg) during a 42 d period for the purpose of calculating RFI and evaluating feeding behavior. Following the calculation of RFI on Day 112, 8 high RFI (HRFI) and 8 low RFI (LRFI) pigs (average weight 85 kg, sem 2.8 kg), were slaughtered (115 d.o). Tissue was collected from the hypothalamus and small intestine to analyze the gene expression of neuropeptides and gut peptides associated with appetite control. Behavioral analysis confirmed that LRFI pigs ate less ($P < 0.0001$), spent less time eating per day ($P < 0.05$), had smaller meals ($P < 0.05$), and spent less time eating each meal than the HRFI pigs ($P < 0.10$). In the jejunum and ileum, the HRFI pigs had increased expression of glucagon-like peptide 1 receptor (*GLP-1R*) ($P < 0.05$), with no changes in the other measured gut or hypothalamic peptides ($P > 0.10$). While RFI was unrelated to neuropeptide gene expression, the amount eaten per feeder visit was positively correlated with cocaine and amphetamine related transcript gene expression (*CART*) in the periventricular nucleus ($r = 0.63$; $P < 0.01$). The expression of pro-opiomelanocortin (*POMC*) was negatively correlated with eating rate ($r = -0.62$; $P < 0.011$). In the duodenum the amount eaten per visit was positively correlated with the expression of cholecystokinin (CCK; $r = 0.56$) and *GLP-1R* ($r = 0.54$). In conclusion HRFI pigs had increases in activity related to feeding behavior and increased gene expression of *GLP-1R.* This study identified strong relationships between feeding behavior traits and the gene expression of the hypothalamic neuropeptides *CART, POMC* and the gut peptide *CCK* suggesting these neuropeptides are important in the control of feeding behavior in pigs.

Key Words: gut peptides, neuropeptides, pigs, residual feed intake

0989 Ileal amino acid digestibility in broiler chicken fed rice bran with or without carbohydrase and phytase. C. Gallardo*, J. C. Dadalt, J. C. da Silva Maciel de Souza, and M. A. D. T. Neto, *University of São Paulo, Pirassununga, Brazil.*

Exogenous enzymes improve feedstuffs used by poultry but information on amino acid digestibility is still limited. Apparent ileal digestibility (AID) and standardized ileal digestibility (SID) of amino acids (AA) in broiler chicks fed rice bran (RB) with or without multi-carbohydrase (MC; 35 U/g α-galactosidase, 110 U/g galactomannanase, 1,500 U/g xylanase and 1,100 U/g β-glucanase) and Phytase (Phy; 10,000 FTU/g) supplementation was investigated. A total of 245 male broilers (7 birds/pen) were fed with one low-protein diet and four corn-starch-based diets containing 30% of RB as sole source of protein in 2 (MC; 0 or 200 mg/kg) × 2 (Phy; 0 or 50 mg/kg) factorial arrangement. Low-protein diet (5% casein) was used to estimate endogenous AA losses. All diets contained Chromium (0.3%) as an indigestible marker. All birds were slaughtered on 21st for ileal digesta collection. Data were analyzed using the GLM procedure of SAS (Statistical Analysis System, version 9.2) for enzyme effects and probable interaction on digestibility. Compared to diet without enzymes, single inclusion of MC or Phy showed effect ($P < 0.05$) on AID and SID of AA. Absolute increases on AID and SID of AA, from MC + Phy supplementation, exceeded the single sum of the increases from MC or Phy supplementation. Averages of 17 AA from AID and SID were: 63.03% and 74.08% for RB without enzyme; 63.73% and 75.11% for RB with MC, 64.22% and 75.41% for RB with Phy, and, 64.65% and 75.98% for RB with MC + Phy, respectively. Interaction ($P < 0.05$) from MC × Phy was observed on AID for Arg, His, Thr, Val, Glu and Ser; and SID for Arg, His, Leu, Val, Asp, Glu and Ser; and a trend on AID for Asp ($P = 0.072$), and SID for Thr ($P = 0.051$) and Pro ($P = 0.080$). The beneficial effects from MC combined with Phy may be an effective strategy to improve AID and SID of AA in RB for broiler chicks.

Key Words: apparent, standardized, enzyme

0990 Effect of dietary net energy and digestible lysine levels on performance of weaned and starter pigs fed low protein-amino acids fortified diets. J. K. Htoo*[1] and J. Morales[2], [1]*Evonik Nutrition & Care GmbH, Hanau-Wolfgang, Germany,* [2]*PigCHAMP Pro Europa, Segovia, Spain.*

Two experiments were conducted to evaluate the effect of dietary NE and standardized ileal digestible (SID) Lys levels on performance of 7 to 10 kg pigs (Exp. 1) and 9 to 17 kg pigs (Exp. 2). In Exp. 1, 288 mixed-sex pigs (PIC; initial BW of 7.0 ± 0.45 kg) were assigned to 6 diet regimes using a 2 × 3 factorial design with 2 levels of SID Lys (1.35 or 1.42%) and 3 NE levels (10.00, 10.35 or 10.70 MJ/kg) for 14 d. In Exp. 2, 288 mixed-sex pigs (PIC; initial BW of 9.2 ± 0.39 kg) were assigned to 6 diet regimes using a 2 × 3 factorial design with 2 levels of SID Lys (1.22 or 1.32%) and 3 NE levels (9.75, 10.10 or 10.45 MJ/kg) for 21 d. For both studies there were 6 pen replicates (3 barrows and 3 gilts/pen) per treatment, and diets were based on corn, soybean meal and whey powder using the analyzed ingredient AA contents to meet requirements. There was no NE x SID Lys interaction for any measured parameter ($P > 0.05$) in both Exp. 1 and 2. In both Exp. 1 and 2, ADFI was not affected ($P > 0.05$) by SID Lys or NE levels. The amount of SID Lys (g/kg of gain) was not affected ($P > 0.05$) by the treatments in both studies. In Exp. 1, pig performance seemed to maximize at 1.42% SID Lys and 10.35 MJ NE. However, ADG and G:F were not affected by the NE level. Compared with 1.35% SID Lys, 1.44% SID Lys increased G:F (0.782 and 0.833; $P = 0.035$) but did not affect ADG (233 and 244 g/d; $P > 0.05$). In Exp. 2, pig performance seemed to maximize at 1.32% SID Lys and 10.10 MJ NE. The dietary NE level did not affect ADG and G:F. Increasing dietary SID Lys from 1.22 to 1.32% increased ADG (388 and 420 g/d; $P = 0.014$) but did not affect G:F (0.592 and 0.616; $P = 0.105$). These results indicate that performance of 7 to 10 kg pigs maximized when the diet contains 1.42% SID Lys and 10.35 MJ/kg NE (SID Lys:NE of 1.37 g/MJ). For 9 to 17 kg pigs, performance maximized at the dietary SID Lys of 1.32% and NE of 10.10 MJ/kg (SID Lys:NE of 1.31 g/MJ).

Key Words: lysine, net energy, performance

0991 Relationship between the microbiota in different sections of the gastrointestinal tract, and the body weight of broiler chickens. J. Lee* and C. Kong, *Konkuk University, Seoul, The Republic of Korea.*

In the poultry industry, many efforts have been undertaken to improve the growth performance of broiler chickens and identification and modulation of body weight (BW)-related bacteria could be one of the strategies to improve productivity. However, studies regarding the relationship between BW and microbiota are scarce. The objective of the present study was to investigate the relationship between BW and microbiota in different sections of the gastrointestinal tract (GIT), and explore the BW-related bacterial groups in broiler chickens. A total of twenty 18-d-old Ross 308 male broiler chickens were selected based on BW, and samples were collected individually from the 3 different sections of the GIT, which included the crop, ileum and cecum. Bacterial genomic DNA was extracted from the samples, and the V4 region of 16S rRNA gene was amplified. All the amplicons were then sequenced on Illumina MiSeq, and microbial communities were analyzed by using QIIME. In principal coordinate analysis, bacterial communities were clustered into three groups, based on the sections of GIT. Several BW-related bacterial groups were identified from linear regression analysis with R statistical package (version 3.0.3). At the genus level, *Streptococcus*

in the ileum ($r = -0.81$, $P < 0.001$) as well as *Akkermansia* in ileum ($r = -0.51$, $P = 0.023$) and cecum ($r = -0.55$, $P = 0.022$), were negatively related to BW, whereas *Bifidobacterium* in the ileum ($r = 0.49$, $P = 0.029$) and *Lactococcus* in the cecum ($r = 0.59$, $P = 0.006$) showed a positive correlation. The results from the present study showed that particular bacterial communities in the GIT were related to BW, and the study has broadened the understanding of the intestinal microbial ecosystem in broiler chickens.

Key Words: broiler chickens, gastrointestinal tract, microbiota

0992 Nutrient profile and in vitro digestibility of cassava silages in swine. U. P. Tiwari*, and R. Jha, *University of Hawaii at Manoa, Honolulu, HI.*

Exploring and evaluating alternative feedstuffs to develop cost-effective and sustainable feeding program is of utmost need when market availability and price of conventional feedstuffs are variable. Cassava (*Manihot esculenta*) is a starchy tuber with high energy content while its leaves are rich in protein; thus combined parts of cassava can be a potential feedstuff for swine. Ensiling cassava parts may enhance its utilization in swine. Two independent studies were performed with cassava silages. First study evaluated different combinations of tubers and vines while second study evaluated different combinations of vines and molasses. In first study, 2 different lines of cassava (L_1 and L_2) and 2 sample types (100% tubers, T_{100} and 50% tubers and 50% vines, T_{50}) were ensiled over 3 periods (fresh [M_0], ensiled for 2 [M_2] and 3 [M_3] months). In second study, 2 different lines of cassava (L_1 and L_2) and 3 sample types (100% vines, V_0; 95% vines and 5% molasses, V_5; and 90% vines and 10% molasses, V_{10}) were ensiled for 2 mo. Nutrient profile of samples was analyzed using standard methods and digestibility was determined using an in vitro method (3 step enzymatic assay). With increasing the proportion of vine in the silage mix, ADF, NDF, and CP content increased ($T_{50} > T_{100}$) while starch decreased. However, ensiling resulted in a reduction of the CP, NDF, ADF and starch contents compared to the fresh samples. The CP content of L_2 (V_0M_0, V_5M_2, $V_{10}M_3$) was higher (15–18%) than L_1 (12–13%). The DM digestibility of $L_2T_{100}M_0$ (91%) and $L_1T_{100}M_0$ (86%) was higher ($P < 0.05$) than $L_2T_{50}M_0$ (76%) and $L_1T_{50}M_0$ (74%). Energy digestibility of $L_2T_{100}M_3$ (92%) and $L_1T_{100}M_3$ (87%) was higher ($P < 0.05$) than $L_1T_{50}M_3$ (69%) and $L_2T_{50}M_3$ (61%). Nutritional value of cassava silages decreased with increase in proportion of vines in the sample. However, digestibility was still at reasonable level. Thus, ensiling the combination of tubers and vines of cassava can be useful strategy to supply enough amount of feed for swine. However, ensiling period needs to be considered with combination of tubers and vines. Also, the pH of silage decreased with increase in ensiling period; feeding silage may provide gut health benefit, in addition to providing energy and other nutrients to swine.

Key Words: cassava silage, digestibility, swine

0993 Amino acid digestibility in feed ingredients fed to pigs. S. A. Lee*[1], J. Y. Ahn[2], A. R. Son[3], and B. G. Kim[1], *[1]Konkuk University, Seoul, The Republic of Korea, [2]Jeongeup, The Republic of Korea, [3]Konkuk University, Seoul, South Korea.*

The objective was to determine the standardized ileal digestibility (SID) of CP and AA in the cereal grains and various byproducts fed to growing pigs. Ten feed ingredients used in this study were barley (9.32% CP), lupin kernels (LK, 31.1% CP), and wheat (11.3% CP) as the cereal grains, and 2 sources of corn gluten feed [CGF 1 (21.6% CP) and 2 (24.6% CP)], corn gluten meal (CGM, 65.3% CP), lupin hulls (LH, 11.6% CP), rice bran (RB, 14.5% CP), soybean meal (SBM, 44.8% CP), and wheat bran (WB, 15.4% CP) as the byproducts. Eleven experimental diets were formulated to contain each ingredient as a sole source of N and an N-free diet was also prepared to estimate the basal endogenous losses of CP and AA. All diets also contained 0.5% chromic oxide as an indigestible index. The ileal digestibility of AA in the test ingredients was determined at 2 different locations. An incomplete 11 × 5 Latin square design was employed for each of 2 locations with 11 dietary treatments, 5 periods, and 11 animals. Eleven barrows with an initial BW of 62.1 ± 5.8 (location 1) and 66.7 ± 3.5 kg (location 2) were equipped with a T-cannula in the distal ileum. An experimental period consisted of a 4-d adaptation and a 2-d collection periods. Least square means were presented for the SID values. Values for the SID of CP in the barley, LK, wheat, CGF 1 and 2, CGM, LH, RB, SBM, and WB were 84.7, 90.5, 90.4, 77.4, 74.6, 89.5, 90.4, 74.4, 86.9, and 63.4% (SEM = 5.3, $P = 0.006$), respectively. Respective values for the SID of Lys were 75.5, 88.4, 83.9, 74.7, 62.4, 80.3, 83.9, 78.5, 88.0, and 71.2% (SEM = 3.3, $P < 0.001$), and the respective values for the SID of Met were 83.6, 88.7, 89.4, 85.7, 78.3, 88.9, 89.4, 85.3, 91.1, and 77.0% (SEM = 2.4, $P < 0.001$). In conclusion, the SID of Lys and Met in the barley, LK, wheat, CGF 1, CGM, LH, and RB did not differ compared to the SBM.

Key Words: amino acid, alternative feed ingredient, digestibility

0994 Evaluation and development of the prediction equation for the gross energy in feed ingredients. A. R. Son*[1] and B. G. Kim[2], *[1]Konkuk University, Seoul, South Korea, [2]Konkuk University, Seoul, The Republic of Korea.*

The objective of this study was to evaluate the accuracy of a previously published equation and to develop novel prediction equations for the GE concentration in feed ingredients. Data from 297 corn, 550 corn gluten feed, 148 copra expellers, 222 copra meal, 486 palm kernel expellers, 102 rapeseed meal, and

130 soybean meal samples were used. The mean values of the feed ingredients were 10.4 ± 2.4%, 19.8 ± 9.6%, 4.44 ± 2.71%, 5.19 ± 2.17%, and 4230 ± 265 kcal/kg on an as-is basis for the moisture, CP, ether extract, ash, and GE concentrations, respectively. The predicted GE concentration of each ingredient was calculated using the published equation based on the chemical composition. To test the accuracy of the predicted GE concentrations, the regression analysis of the determined minus predicted GE concentration against the predicted GE concentration was conducted, which was able to verify the bias in the predicted values. The correlation and multiple regression procedures of SAS were used to generate the novel prediction equations. According to the results of regression analysis for the accuracy of the published equation, the intercept (−230.3; SE = 4.8 and $P < 0.01$) and slope (0.062; SE = 0.031 and $P < 0.05$) was different from 0. The recommendable regression equations for the GE concentration (kcal/kg on an as-is basis) in the feed ingredients were: Eq. 1 = 4598– (51.6 × moisture) + (37.7 × ether extract) with root mean square error = 181, R^2 = 0.537, and $P < 0.001$; Eq. 2 = 4537– (54.2 × moisture) + (11.0 × CP) + (46.5 × ether extract)– (32.6 × ash) with root mean square error = 166, $R^2 = 0.612$, and $P < 0.001$. All independent variables are in % on an as-is basis. In conclusion, the previously published equation may overestimate the GE concentrations in the feed ingredients used in this study. On the basis of the novel prediction equations, the moisture and ether extract concentrations can be good independent variables to estimate the GE concentration in the feed ingredients.

Key Words: feed ingredient, gross energy, regression equation

0995 Effect of supplemental citrulline on thermal and production parameters during heat stress in growing pigs.

S. K. Kvidera*[1], E. A. Horst[1], E. J. Mayorga[1], J. T. Seibert[1], M. A. Al-Qaisi[1], J. W. Ross[1], R. P. Rhoads[2], and L. H. Baumgard[1], *[1]Iowa State University, Ames, [2]Virginia Tech, Blacksburg.*

Heat stress (HS) compromises intestinal barrier function, and citrulline improves gut health in rodent models. Therefore, objectives were to characterize effects of citrulline supplement (CIT) on physiological and production responses during HS. Supplements were fed twice daily at 0600 and 1800 h and consisted of 20 g of cookie dough without citrulline (CON) or with 0.13 g/kg BW L-citrulline (CIT; 99.3% purity; MP Biomedicals, Santa Ana, CA). Forty crossbred gilts (30 ± 2 kg) were assigned to 1 of 5 supplemental-environmental treatments: 1) thermoneutral (TN; 23.6 ± 0.1°C) ad libitum fed (AL) with CON (TN-AL; $n = 8$), 2) TN pair-fed (PF) with CON (PF-CON; $n = 8$), 3) TN PF with CIT (PF-CIT; $n = 8$), 4) HS AL with CON (HS-CON; $n = 8$), and 5) HS AL with CIT (HS-CIT; $n = 8$). Acclimation lasted 4d while all pigs received the CON supplement. During period 1 (P1; 7d), pigs were kept in TN and fed AL their respective diets. During period 2 (P2; 60 h), HS-CON and HS-CIT animals were fed AL and exposed to cyclical HS (33.6 to 38.3°C) while TN-AL, PF-CON, and PF-CIT remained in TN and were fed either AL or PF to their HS counterparts to negate the effect of dissimilar nutrient intake. Feed intake was measured daily and BW was obtained 1 d before P1, d7 of P1, and at P2 conclusion. Rectal temperature (Tr), skin temperature (Ts), and respiration rate (RR) were obtained once daily at 1800 h during P1 and thrice daily at 0600, 1200, and 1800 h during P2. Pigs exposed to HS had increased Tr (0.8°C), Ts (4.7°C), and RR (47 bpm) relative to TN pigs ($P < 0.01$). HS-CIT pigs had decreased RR (7 bpm, $P = 0.04$) and a tendency for decreased Tr (0.1°C, $P = 0.07$). Feed intake decreased ~15% in HS relative to TN-AL pigs ($P < 0.01$) and did not differ between HS and PF pigs ($P > 0.10$). P2 ADG decreased 18 and 62% in HS and PF pigs, respectively, relative to TN-AL pigs. PF-CIT pigs tended to have increased (0.12 kg/d; $P = 0.09$) ADG compared to PF-CON pigs. Gain:feed was similar between TN-AL and HS pigs but decreased 30% in PF relative to TN-AL pigs ($P < 0.01$). No effects of CIT on production variables during HS were detected. In summary, CIT modestly affected the thermal response but had no effect on production parameters during HS, but tended to increase ADG during limit-feeding.

Key Words: heat stress, citrulline

0996 Effect of microencapsulated blends of organic acids on growth performance, nutrient digestibility, and fecal microflora in pigs.

P. Y. Zhao*, R. X. Lan, W. C. Liu, H. S. Kim, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, South Korea.*

The microencapsulated blend of organic acids (MO) allowed slow-release of active ingredients and prevented the immediate disappearance of compounds on exiting the stomach. A total of 90 pigs [(Landrace × Yorkshire) × Duroc] with an average initial BW of 6.47 ± 0.27 kg (21 d) were used in a 154-d trial. Pigs were allotted to 3 treatments with 6 replicates/treatment and 5 pigs/pen. Dietary treatments included: 1) CON, basal diet, 2) MO1, CON + 0.1% MO (weanling phase) and 0.025% MO (growing-finishing phase), 3) MO2, CON + 0.2% MO (weanling phase) and 0.05% MO (growing-finishing phase). Individual pig BW and the feed consumption of each pen were monitored to calculate the ADG, ADFI, and G:F. Chromium oxide (2 g/kg) was added to the diets to determine the ATTD of DM, N, and GE. All data were analyzed using the GLM procedures of SAS (SAS Inst. Inc., Cary, NC). Orthogonal comparison was conducted using polynomial regression to measure the linear and quadric effects. Tukey's range test was used to compare the means of treatments, and $P < 0.05$ was considered to be significant. Pigs BW was higher ($P < 0.05$) in MO2 than CON on d 21 (14.39 vs. 13.94 kg), d 42 (25.98 vs. 27.05 kg), and d 154 (109.32 vs. 114.09 kg). From d 0 to 21, 22 to 42, 0

to 42, and 0 to 154, pigs in MO2 had higher ($P < 0.05$) ADG (377 vs. 356 g, 603 vs. 573 g, 490 vs. 464 g, 699 vs. 667 g) than CON. Increased ($P < 0.05$) G:F was detected in MO2 compared with CON from d 84 to 154 (0.369 vs. 0.343) and d 0 to 154 (0.430 vs. 0.408). Linear effect ($P < 0.05$) was observed on BW, ADG, and G:F at the same time. Pigs in MO2 had higher ($P < 0.05$) ATTD of DM (83.67 vs. 81.82%, 76.63 vs. 72.29%) than CON on d 21 and 42. Linear effect ($P < 0.05$) was also observed on the ATTD of DM on d 21 and 42. Fecal *Lactobacillus* concentration (7.70 vs. 7.45 $\log_{10}$cfu/g) was increased ($P < 0.05$) by MO2 compared with CON on d 42. Linear and quadratic effects ($P < 0.05$) were also observed on *Lactobacillus* concentration on d 42. In conclusion, the inclusion of 0.2% MO can increase BW, ADG, the ATTD of DM, and fecal *Lactobacillus* counts in weanling pigs, in addition, 0.05% MO can increase G:F in finishing pigs.

Key Words: growth performance, microencapsulation, pigs

0997 Effect of multispecies probiotic supplementation source on growth performance and meat quality traits in growing-finishing pigs.

B. Balasubramanian*, Y. H. Kim, J. W. Park, Y. H. Liu, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, South Korea.*

In South Korea, using antibiotics as growth promoters in animal feeds has been forbidden since 2011. Probiotics have received considerable attention as suitable alternatives of antibiotics to promote growth in pig industry. The study was conducted to investigate the effects of multispecies probiotic (*B. coagulance* [1×10^9 cfu/g], *B. lichenformis* [5 × 10^8 cfu/g], *B. subtilis* [1 × 10^9 cfu/g], and *Clostridium butyricum* [1 × 10^8 cfu/g]) supplementing with corn based meal on growth performance and meat quality traits in growing-finishing pigs. A total of 75 pigs ([Landrace × Yorkshire] × Duroc) with initial body weight (BW) of (23.3 ± 1.42) kg. Pigs were randomly allocated to the three treatment groups with 5 replicate pens per treatment, 5 pigs (3 barrows, 2 gilts) per pen. The following three treatments were used: CON (Basal diet), T2 (CON + 0.01% multispecies probiotic), and T3 (CON + 0.02% multispecies probiotic). These dietary treatments were given as Phase I (Week 6), Phase II (Week 12), and Phase III (Week 16) to analyze growth performance. Orthogonal polynomial contrast was conducted to measure the linear and quadratic effects for increasing the multi-species probiotic levels on all measurements. Statistical significance was considered when P value was less than 0.05. Higher level of (0.02%) multispecies probiotic supplementation had linearly increased effects on BW ($P = 0.030$) at wk 16 and also significant differences on average daily gain and gain:feed ($P < 0.05$) without effects of average daily feed intake ($P > 0.05$) in treatments with probiotic supplementation at entire experiment. Significant effects ($P < 0.05$) were observed on increased apparent total tract digestibility of dry matter (DM, $P = 0.004$), nitrogen (N, $P = 0.012$), energy (E, $P = 0.055$) at wk 16 in diets with probiotic supplementation, 0.02% multispecies probiotic inclusion in diets showed reduced level of *E. coli* ($P = 0.011$, 0.013) and increased significant difference on *Lactobacillus* counts ($P = 0.004$, 0.005) respectively at wk 6 and 16, live meat quality traits of back fat thickness ($P = 0.004$, at wk 16) and lean meat percentage ($P = 0.006$, at wk 12), blood glucose ($P = 0.028$, at wk 6) level, RBC ($P = 0.013$, at wk 16) levels, NH_3 emission ($P = 0.010$, at wk 16) and sensory evaluation of color ($P = 0.001$), firmness ($P = 0.031$). These results suggested improving effects of dietary multispecies probiotic on growth performances, apparent total tract digestibility, balancing the management of desired fecal micro biota, reduced NH_3 gas emission, and sensory evaluation of meat quality in growing-finishing pigs.

Key Words: *Bacillus* spp., *Clostridium butyricum*, pig performances

0998 Effects of dietary red ginseng on growth performance, nutrient digestibility, blood profile, meat quality, and carcass grade in growing-finishing pigs.

H. N. Tran*, Y. H. Kim, J. W. Park, S. Mohana Devi, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, South Korea.*

This study was conducted to determine the effect of dietary red ginseng on growth performance, nutrient digestibility, blood profile, meat quality, and carcass grade in growing-finishing pigs. A total of 120 crossbred pigs ([Landrace × Yorkshire] × Duroc) with an average body weight of 21.77 ± 1.88 kg were used in 22 wk experimental period. Pigs were randomly assigned to 3 treatments with 8 replications (5 pigs per replication). Dietary treatments included: 1) CON, basal diet; 2) TRT1, CON + 0.1% fermented red ginseng; 3) TRT2, CON + 0.2% fermented red ginseng. All data were analyzed as a randomized complete block design using mixed procedures of SAS. In the current study, no significant difference was observed on average daily gain (ADG), average daily feed intake (ADFI), and gain to feed ratio (G/F) among treatments at 10th, 18th and 22th weeks. However, pigs fed with TRT1 diet (657 g) had higher ADG ($P < 0.05$) than those fed with CON diet (634 g) at sixth week. Overall, a significant increase ($P < 0.05$) in ADG was observed in TRT1 treatment (550 g) compared with CON treatment (542 g), and no effect was observed on ADFI, FCR, and G/F. Apparent total tract digestibility (ATTD) of dry matter (DM) in TRT1 treatment (81.46) was higher ($P < 0.05$) than that of CON treatment (78.03). In addition, ATTD of nitrogen (N) in pigs fed with TRT1 diet (81.89) was higher ($P < 0.05$) compared with pigs fed with CON diet (76.08) and TRT2 diet (77.37). No significant difference was observed in the ATTD of energy (E) among treatments at sixth

and 10th weeks. Supplementation of red ginseng in TRT1 treatment significantly decreased ($P < 0.05$) drip loss at d 1 (1.38), d 5 (4.60) and d 7 (7.01) post slaughter. On d 9, drip loss of CON treatment (13.92) was considerably lower than TRT1 treatment (8.68) and TRT2 treatment (11.12). Meantime, drip loss of TRT2 treatment (11.12) was significantly higher than TRT1 treatment (8.68). In conclusion, results of the present study indicated that supplementation of red ginseng enhanced growth performance, nutrient digestibility and decreased meat drip loss, with no significant effect on blood profile and carcass grade in finishing pigs.

Key Words: growing-finishing pigs, growth performance, red ginseng

0999 Effect of protected organic acid blend with medium chain fatty acid on growth performance, nutrient digestibility, blood profiles, meat quality, fecal micro flora and fecal gas emission in finishing pigs. D. H. Nguyen*, T. S. Li, S. D. Upadhaya, H. N. Tran, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, South Korea.*

A total of 105 finishing pig ([Yorkshire × Landrace] × Duroc) with an average BW of 51.0 ± 3.33 kg were used in 10 wk trial to evaluate the effect of protected organic acid blend on finishing pigs. Pigs were randomly allotted to one of three dietary treatments (7 replication pens with 5 pigs per pen) in a randomly complete block design based on their initial BW. Dietary treatments were: 1) CON (basal diet); 2) MC1 (CON + 0.1% protected organic acids); 3) MC2 (CON + 0.2% protected organic acids). Protected organic acids contained 17% fumaric acid, 13% citric acid, 10% malic acid and 1.2% medium chain fatty acid (capric and caprylic acid). BW and feed were recorded at the beginning, on week 5 and week 10 of the experimental period to calculate ADG, ADFI and G:F. Fresh fecal samples were collected at sixth week and 12th week for calculation of DM, N, and energy digestibility by adding 0.2% chromium oxide before 1 wk. All data were subjected to the GLM procedures of SAS and differences among treatments were separated by Tukey's multiple range test with a $P < 0.05$ indicating a significance. In the current study, overall, the inclusion of MC1 and MC2 led to greater ADG (861, 864 vs. 827 g/d; $P < 0.05$). Administration of MC2 improved G:F compared with CON treatment (0.354 vs. 0.337; $P < 0.05$). However, no difference ($P > 0.05$) was observed in ADFI of pigs fed MC1 and MC2 compared with CON. Pigs fed MC1 and MC2 diets led to higher ($P < 0.05$) IgG concentration at the end of 5 wk. At the end of 10 wk higher concentration of IgG was seen in MC1 treatment compared with CON treatment ($P < 0.05$). Administration of MC1 and MC2 treatments led to higher *Lactobacillus* counts and lower *E.coli* counts compared with CON ($P < 0.05$). During the end of the experiment, a decrease in fecal ammonia emission was observed with MC2 treatment ($P < 0.05$). Supplementation of protected organic acid increased ($P < 0.05$) the drip loss at d5 and d7 of meat evaluation. In conclusion, protected organic acid supplementation enhanced growth performance, reduce ammonia gas emission and improve gut microbial population in finishing pigs.

Key Words: finishing pig, growth performance, protected organic acids

1000 Effect of dietary melamine concentrations on performance and tissue melamine residue in male broiler chickens. J. H. Kim[1] and D. Y. Kil[*2], [1]*Chung-Ang University, Anseong-si, The Republic of Korea,* [2]*Chung-Ang University, Anseong-si, South Korea.*

We investigated the effect of dietary melamine concentrations on performance and tissue melamine residue in male broiler chickens. A total of 504 1-d-old male broiler chicks were housed in 42 battery cages for a 5-wk feeding trial. Birds were randomly allotted to 1 of 7 dietary treatments with 6 replicated cages. Dietary melamine concentrations were set to 0, 250, 500, 750, 1,000, 5,000, or 10,000 mg/kg by adding purified form of melamine ($\geq$ 99.0%) at the expense of the sand. At the end of the experiment, 3 birds from each treatment were euthanized. Kidney and breast samples were collected for melamine residue analysis. Results indicated that the BW and BW gain for birds fed diets containing 10,000 mg/kg melamine were less ($P < 0.01$) than those fed diets containing 0, 250, 500, 750, 1,000, or 5,000 mg/kg melamine. There were no differences in feed efficiency and mortality among treatments. Kidney melamine residue for 10,000 mg/kg treatment group was greater ($P < 0.01$) than for 0, 250, 500, 750, or 1,000 mg/kg treatment groups. The 10,000 mg/kg treatment group had greater ($P < 0.01$) melamine residues in breast muscle than other treatment groups. Orthogonal polynomial contrast test revealed that increasing melamine concentrations of diets decreased BW, BW gain (linear and quadratic, $P < 0.05$), and feed intake (linear, $P < 0.01$). Increasing melamine concentrations of diets increased (linear, $P < 0.01$) melamine residues in the kidney and breast. According to food safety issue (WHO), melamine concentrations of human food should be limited less than 2.5 mg/kg. Thus, based on linear regression analysis between dietary melamine concentrations and breast melamine residue ($y = 0.0071x - 1.7956$, $R^2 = 0.89$), the upper limit of melamine concentrations of diets for male broiler chickens was estimated to be 605 mg/kg. In conclusion, 10,000 mg/kg melamine is toxic to male broiler performance. Dietary melamine concentrations for male broiler chickens should be limited approximately less than 600 mg/kg in terms of human food safety.

Key Words: dietary melamine, male broiler chicken, tissue melamine residue

1001 Effect of dietary melamine concentrations on performance and tissue melamine residue in female broiler chickens. J. H. Kim[1] and D. Y. Kil[*2], [1]*Chung-Ang University, Anseong-si, The Republic of Korea,* [2]*Chung-Ang University, Anseong-si, South Korea.*

An experiment was conducted to investigate the effect of dietary melamine concentrations on performance and tissue melamine residue in female broiler chickens. A total of 504 1-d-old female broiler chicks were housed in 42 battery cages for a 5-wk feeding trial. Birds were randomly allotted to 1 of 7 dietary treatments with 6 replicated cages. Dietary melamine concentrations were set to 0, 250, 500, 750, 1,000, 5,000, or 10,000 mg/kg by adding purified form of melamine ($\geq$ 99.0%) at the expense of the sand. At the conclusion of the experiment, 3 birds from each treatment were euthanized by CO_2, and then kidney and breast samples were collected for melamine residue analysis. Results indicated that the BW, BW gain, and feed intake (FI) for birds fed diets containing 10,000 mg/kg melamine were less ($P < 0.01$) than those fed diets 0, 250, 500, 750, 1,000, or 5,000 mg/kg melamine. There were no differences in feed efficiency and mortality among treatments. Kidney and breast melamine residue for 10,000 mg/kg treatment group were greater ($P < 0.01$) than other treatment groups. Orthogonal polynomial contrast test revealed that increasing melamine concentrations of diets decreased (linear and quadratic, $P < 0.05$) BW, BW gain and FI (linear, $P < 0.01$). Increasing concentrations of melamine in diets from 0 to 10,000 mg/kg decreased (quadratic, $P < 0.05$) feed efficiency. Increasing melamine concentrations of diets increased (linear and quadratic, $P < 0.01$) melamine residues in the kidney and breast. According to food safety issue (WHO), melamine concentrations of human food should be limited less than 2.5 mg/kg. Thus, based on linear regression analysis between dietary melamine concentrations and breast melamine residue ($y = 0.0054x - 1.3291$, $R^2 = 0.94$), the upper limit of melamine concentrations of diets for female broiler chickens was 709 mg/kg. In conclusion, 10,000 mg/kg melamine is toxic to female broiler performance. Dietary melamine concentrations for female broiler chickens should be limited approximately less than 700 mg/kg in terms of human food safety.

Key Words: dietary melamine, female broiler chicken, tissue melamine residue

1002 A plant extract with manganese, Vali MP®, decreased adipogenesis in 3T3-L1 pre-adipocytes by modulating adipogenic gene expression and cellular energy level. S. W. Choi[*1], J. Kim[1], S. W. Jung[2], and K. Y. Whang[1], [1]*Korea University, Seoul, The Republic of Korea,* [2]*CTC BIO, Seoul, The Republic of Korea.*

As animals grow, the rate of fat deposition increases and results in a decreased feed efficiency. To improve lean growth, dietary modulation (low energy and high protein) and metabolic modulator are applied for finishing pigs. One of successful metabolic modulators is a β-adrenergic agonist, which increases leanness by improving protein synthesis. However, the use of β-adrenergic agonist for pork production are banned in many counties due to bio-safety issue. Vali MP® is a natural product consisting of plant extracts and manganese and showed improved lean growth and decreased fat deposition when supplemented in finishing pig diet. However, direct effect on adipogenesis is not fully understood. We investigated effect of Vali MP® on adipogenesis by using 3T3-L1 mouse pre-adipocytes. Murine pre-adipocytes (3T3-L1) were differentiated into adipocyte by switching media (DMEM with 10% FBS, 1% antibiotics, 10 μM cortisone, 0.5 mM methylisobutylxanthine, and 1.0 ug/mL insulin) for 2 d, and then media was changed adipocyte maintenance medium (DMEM with 10% fetal bovine serum, 1% antibiotics and 1.0 μg/mL insulin) for another 2 d. Cells were maintained in DMEM with 10% fetal bovine serum and 1% antibiotics) for 4 more days. After a total of 8 d differentiation, cellular triglyceride (TG) content was determined by Oil Red-O staining, cDNA was constructed for quantitative real-time PCR and cell lysates were prepared for immunoblotting. During differentiation, Vali MP® (10% in PBS) solution was added to the final concentration of 0, 0.05, 0.10, and 0.2% through the adipocyte differentiation. TG accumulation was not affected at 0.05% Vali MP® supplementation, however 0.10% and 0.20% Vali MP® supplementation decreased TG accumulation by 25% and 90%, respectively. At 0.05% Vali MP® supplementation, gene expression level of SREBP1C was not changed, but PPAR-γ and CEBPα, and fatty acid synthase were increased ($P < 0.05$). As Vali MP® concentration was increased (0.10% and 0.20%), these gene expression levels were decreased at dose dependent manner ($P < 0.05$). Protein expression level of AMPK (cellular energy gauge) was not affected by Vali MP® supplementation, but phosphorylated AMPK was increased and resulted in increased phosphorylated acetyl-coA carboxylase (inactive form; $P < 0.05$). Collectively, these data indicate Vali MP® decreases adipogenesis by affecting adipogenic gene expression and cellular energy status (AMPK). The results suggest a possible molecular mechanism of lean growth promoting effects of Vali MP® in finishing pigs. However, the molecular mechanism of Vali MP® on myogenesis should be addressed.

Key Words: ValiMP(*R*), anti-adipogenesis, 3T3-L1

1003 Effects of dietary lysophospholipids (LipidolTM) on intestinal morphology and gene expression of inflammatory cytokines in weaned rats.

M. Kwak*[1], J. Kim[1], I. H. Hwang[2], and K. Y. Whang[1], [1]*Korea University, Seoul, The Republic of Korea,* [2]*EASY BIO, Seoul, The Republic of Korea.*

Weaning is a stressful condition for animals and negatively affects growth performance by increasing dystrophy of intestinal villi. This intestinal dystrophy attenuates nutrient absorption and barrier function. Lysophospholipids (LPLs), biosynthesis metabolites, are glycerophospholipids in which one acyl chain is lacking and thus only one hydroxyl group of the glycerol back bone is acylated. LPLs can diffuse rapidly into the lipid parts of membrane due to the relatively small hydrophobic part and increase permeability of membrane by altering fluidity of membrane. Therefore, we hypothesize that supplementation of LPLs products (Lipidol^{TM}) can modulate nutrient absorption and barrier function of intestine, and an experiment was conducted to investigate relieving effects of LPLs against weaning stress. Twenty-one rats (4 wk-old) were allotted into 3 dietary treatments (Control, NIH-31 diet; LEC, NIH-31 diet with 2 g of lecithin/kg of feed; and LPL, NIH-31 diet 2 g of LPLs/kg of feed). After 4 wk of feeding period, jejunum samples were collected and gene expression of inflammatory cytokines (IL-1, IL-4, IL-6, IL-10, IL-12β, and TNF-α) and tight junction proteins (β-catenin and ZO-1) were determined by qRT-PCR. Body weights and feed intakes were measured weekly. Serum biochemical markers (triglyceride, total cholesterol, and blood urea nitrogen) were measured. And jejunum morphology (villus heights, crypt depths, and the number of goblet cells) was also observed. Growth performance (body weight, average daily gain, average daily feed intake, and feed efficiency) was not affected by dietary treatments. There were numerically lower triglyceride and higher total cholesterol in LPL than other groups but no difference was found in blood urea nitrogen among 3 treatments. There were no differences in levels of IL-1, IL-4, IL-6, IL-10, IL-12β, and TNF-α, and ZO-1 expression among 3 treatments. But β-catenin expression was increased in LPL than other treatments ($P < 0.10$). Jejunal villus height were also numerically higher in LPL and villus heights:crypt depths ratio was significantly higher in LPL than other groups ($P < 0.05$). The number of goblet cells per villus was also significantly higher in LPL than other groups ($P < 0.05$). The results of this experiment demonstrated LPLs improved the gut health in villus heights and villus heights:crypt depths ratio after weaning. Also gut barrier function was improved with higher number of mucous producing cells. The healthier intestine should be able to absorb more nutrients with better efficiency, thus a reduced weaning-related growth check is expected.

Key Words: rats, intestine, gut morphology, lysophospholipids

1004 Effect of protected sodium butyrate and nutrient concentration on early phase of broilers.

M. Puyalto*[1], C. Sol[1], J. J. Mallo[1], and M. J. Villamide[2], [1]*NOREL S.A., Madrid, Spain,* [2]*Departamento de Produccion Agraria. ETSI Agronomos. Universidad Politecnica de Madrid, Madrid, Spain.*

The study was conducted to compare the effect of sodium butyrate protected with PFAD sodium salt (GUSTOR N'RGY) with three different nutrient concentration diets on growth performance. A 3 × 2 factorial design was used with a basal diet based on wheat, barley and soybean meal with three different nutrient concentrations and with or without additive. The tested treatments were: CON (3,000 kcal AMEn/kg, 22.02% CP and 11.6 g/kg dig Lys) and CON-1 (CON with a reduction of 60 kcal AMEn/kg and 2.3% of amino acids), CON-2 (CON with a reduction of 120 kcal AMEn/kg and 4.6% of amino acids), N'RGY (CON diet with GUSTOR N'RGY at 1kg/t), N'RGY-1 (CON-1 diet with 1 kg of N'RGY/t) and N'RGY-2 (CON-2 diet with 1 kg of N'RGY/t). A total of 252 Cobb 1-d-old males broiler chickens were used in the study. Birds were housed in 36 floor pens of seven animals, such that there were 6 replicates/treatment. The treatments were randomly distributed among the pens. Mash feeds and water were offered ad libitum. The study lasted 21 d and the weight of animals and feed from each pen were recorded at d 0 and at d 21. Data were analyzed by ANOVA using the GLM procedure of SAS. Both nutrient concentration and feed additive inclusion affected the performance variables. There were no differences between CON and CON-1 on BW, ADG and FCR. However, CON-2 had lower BW than CON-1 (BW: 831 g ab, 860 g a and 805 g b, $P = 0.03$; ADG: 37 g/day ab, 39 g/d a and 36 g/d b, $P = 0.03$) and worst FCR than CON and CON-1 (1.51 b, 1.52 b and 1.57 a, $P = 0.007$). Animals fed diets with the addition of N'RGY had higher BW (850 g vs. 813 g, $P = 0.03$), ADG (38 g/d vs. 36 g/d, $P = 0.03$), ADFI (52 g/d vs. 51 g/d, $P = 0.01$) and better FCR (1.51 vs. 1.56, $P = 0.003$). It can be concluded that the reduction of energy and amino acids reduce animal performance on its second step, and that the use of GUSTOR N'RGY is able to improve the results of performance in the early phase of chickens.

Key Words: protected sodium butyrate; nutrient concentration; broilers

1005 Use of aromatics plants in the diet on performance of broilers in Colombia. L. Bernal*, *La Salle University, Bogotá, Colombia.*

Poultry production has major challenges to streamline animal productivity, improve intestinal health, create safe and of good nutritional quality protein for human consumption. Plant diversity of Colombian tropical plant species has not evaluated in animal feed and which may have beneficial antiseptic properties in the productive parameters and intestinal health of chickens. The aim of this study was to evaluate the inclusion of the leaves of two plants from Choco, Santa Maria (*Piper peltatum*) and basil (*Ocimum basilicum*) on performance of broilers Ross 308 line in Colombia. The experiment was conducted in the San José de Guausa farm, located in the municipality of Chia, Cundinamarca Department. Two hundred chickens Ross 308 commercial line a day were used. Birds were evaluated for an experimental of 42 d. Four treatments were evaluated. Control (CON, basal diet): animals were fed a diet of corn-soybean meal without aromatics plants; treatment two, animals that received the control diet with the inclusion of 0.05% basil leaves (ABH); treatment three, animals fed with 0.05% leaves of Santa Maria (SMB) and treatment four diet by including 0.025% (ABH) and 0.025% (SMB). The production parameters evaluated were feed intake (g), weekly weight (g), feed conversion and weight gain (g). The experimental design was completely random, distributed in four treatments, five replicates per treatment, and 10 animals per repetition. Data variables were asked ANOVA, and to detect between treatment means the Tukey test was employed in the SAS statistical package. As a result of this study, significant difference ($p < 0.05$) was found between treatments for the weekly weight, bird average daily gain and feed conversion, ABH was the treatment with the best results in week seven for the weight (2362 vs. 2155, 2297, 2346 g), weight gain (79 vs. 59, 71, and 76 g) and feed conversion (2.079 vs. 2.23, 2.42, 3.74). These results suggest that the diet with the addition of 0.05% of ABH can benefit the productive parameters of chickens level weight, weight gain and feed conversion, which favors animal productivity.

Key Words: aromatics plants, growth performance, feed conversion

1006 Dietary antioxidants, chromium and betaine supplementation can improve lactation performance of sows during summer. J. J. Cottrell[1], F. Liu[1], D. J. Henman[2], K. O'Halloran[2], and F. R. Dunshea*[1], *[1]Faculty of Veterinary and Agricultural Sciences, The University of Melbourne, Parkville, Australia, [2]Rivalea Australia Pty Ltd, Corowa, Australia.*

Heat stress (HS) causes considerable losses to the global pig industry with lactating sows being particularly sensitive. There is strong evidence that nutritional supplements may provide means of ameliorating HS and so the aim of the present study was to investigate the effects of some dietary additives on lactational performance of lactating sows during summer. Eighty seven multiparous sows were fed either a wheat-based control (CON, $n = 31$) or a supra-nutritional antioxidant diet (AO, $n = 56$) for an 18 d lactation period during summer in southern Australia. All sows were housed in lactation stalls within open-sided lactation sheds. The CON diet contained NRC recommendations for all nutrients including selenium (0.15 mg/kg) and Vitamin E (44 IU/kg) while the AO diet was fortified with selenized yeast (0.4 mg/kg Se), Vitamin E (95 IU/kg), chromium picolinate (400 ppm Cr) and betaine (2 g/kg). All of these nutritional supplements have been demonstrated to ameliorate some of the physiological responses to HS in sheep and/or pigs in our laboratory. The daily temperatures during this summer study were from 15.8 ± 3.67°C to 31.9 ± 5.00°C. Sow weight and backfat were measured from 9 d before farrowing and at weaning, and individual piglet and litter weight were measured at farrowing and weaning. When the outside temperature exceeded 30°C, the respiration rate of all sows was measured in the afternoon. Appropriate blocking ensured there was no dietary effect on initial weight (301 ± 27.7 kg) on entry into the facility. Sows fed the AO diet lost less backfat (4.1 vs. 2.2 mm for CON and AO, $P = 0.047$) and live weight (−41.6 vs. −33.4 kg, $P = 0.021$) between entry into the facility and weaning than those sows fed the CON diet despite there being no effect on feed intake (5.63 vs. 5.87 kg/d, $P = 0.20$). There was also no dietary effect on litter weight at weaning (82.7 vs. 83.2 kg, $P = 0.91$) or number of piglets at weaning (10.2 vs. 9.9 piglets, $P = 0.42$) although average piglet weight at weaning tended to be greater for the sows fed the AO diet (8.05 vs. 8.47 kg, $P = 0.078$). Respiration rate increased by 4.0 breaths per min for every degree above 30°C ($P = 0.001$) but was unaffected by diet ($P = 0.88$). In conclusion, dietary Se, Cr, betaine and Vitamin E supplementation can reduce backfat and live weight loss of lactating sows during summer.

Key Words: antioxidants, lactating sow, heat stress

1007 Effects of dietary melamine on growth performance, organ weight, and blood melamine concentrations in pigs. K. R. Park* and B. G. Kim, *Konkuk University, Seoul, The Republic of Korea.*

The objective of current experiment was to determine the effects of dietary melamine on growth performance, organ weights, and blood melamine concentration for pigs. Twelve barrows with an initial BW of 19.8 kg (SD = 2.2) were randomly allotted to 4 dietary treatments in a completely randomized design. Four experimental diets were prepared to contain 0, 1, 2, or 4% of melamine based on the commercial corn and soybean meal based diet. The pigs were individually housed in metabolism crates and fed the experimental diets during 21 d of trial. Body weight and feed intake were recorded on d 7, 14, and 21. The daily feed allowance was approximately 2.7 times the estimated energy requirement for maintenance and divided into 2 equal meals at 0700 and 1600 h. The blood samples were obtained on d 7, 14, and 21 from each pig to analyze the melamine concentration. To exclude the effects of feed intake, blood melamine concentration relative to ADFI was calculated in each pig. At the end of the experimental period, all pigs were euthanized for collecting heart, kidneys, liver, and lungs. The collected organs were weighed and the organ weight relative to BW was calculated to exclude effects of BW. From d 0 to 7, the ADG, ADFI, and G:F linearly decreased ($P < 0.05$) as dietary melamine concentration increased. From d 7 to 14, linear decrease ($P < 0.05$) of ADG and ADFI and quadratic decrease ($P < 0.05$) of ADG was observed with increasing dietary melamine concentration. However, there were no linear and quadratic effects of dietary melamine concentration on G:F from d 7 to 14. During the overall period, the ADG, ADFI, and G:F linearly decreased ($P < 0.05$) as dietary melamine concentration increased. The weight of organs relative to BW was not affected by the concentration of dietary melamine. The blood melamine concentration relative to ADFI linearly increased ($P < 0.05$) as dietary melamine concentrations increased on d 7, 14, and 21. In conclusion, increasing levels of melamine in diets fed to pigs linearly decreased the growth performance and increased blood melamine concentration.

Key Words: blood, melamine, organ

1008 Effects of dietary melamine on growth performance and blood and urinary melamine concentrations in pigs. K. R. Park* and B. G. Kim, *Konkuk University, Seoul, The Republic of Korea.*

The objective of current experiment was to determine the effects of dietary melamine on growth performance and melamine concentration in blood and urine for pigs. Nine barrows with an initial BW of 35.9 kg (SD = 2.1) were randomly allotted to 3 dietary treatments in a completely randomized design. Three experimental diets were mainly based on wheat and soybean meal and were formulated to contain 0, 1, and 2% of melamine. The pigs were individually housed in metabolism crates and fed experimental diets during 12 d of trial. Body weight and feed intake were recorded at the end of the experimental period. The pigs had free access to feed and water. Blood samples were obtained on d 12 from each pig to analyze the melamine concentration. Urine was collected from 1100 h on d 7 to 1100 h on d 9, and urinary melamine concentration and average daily urinary melamine excretion were determined. To exclude effects of feed intake, melamine concentration in the blood samples, urinary melamine concentration, and average daily urinary melamine excretion relative to ADFI were calculated. The ADG and G:F were not affected by increasing dietary melamine concentrations. However, ADFI linearly decreased ($P < 0.05$) and tended to quadratically decrease ($P = 0.081$) with increasing dietary melamine concentration. The melamine concentration in the blood samples relative to ADFI linearly increased ($P < 0.05$) as dietary melamine concentration increased. The urinary melamine concentration, urinary melamine concentration relative to ADFI linearly and quadratically increased ($P < 0.05$), and the daily melamine excretion relative to ADFI linearly increased ($P < 0.05$) and tended to quadratically increase ($P = 0.071$) with increasing dietary melamine concentration. In conclusion, the addition of melamine to diets fed to growing pigs decreased feed intake and increased blood and urinary melamine concentrations.

Key Words: growth performance, swine, urine

1009 Feed additives reduced diarrhea occurrence in a medication-free postweaning pig diet. Z. Yang*[1], X. Wang[1], F. Chi[2], and S. Ching[2], *[1]College of Animal Science, Shandong Agricultural University, Tai-an, China, [2]Amlan International, Chicago, IL.*

Because of concerns about the use of antibiotics in animal diets and zinc oxide pollution in China in recent years, we conducted a trial to evaluate 2 feed additives (FA1, FA2) in an antibiotic and ZnO free diet in post-weaning pigs. One hundred-sixty newly weaned nursery pigs (30-d-old, 8.67" ± 0.35 kg body weight) were randomly allotted to 4 TRTs with 10 pigs per pen and 4 replications. The 4 TRTs were: Control (CON); CON+FA1 (0.25%); CON+FA2 (0.15%); and CON+FA1 (0.25%)+FA2 (0.15%). A mineral-based product, FA1 (MD-09™) has been shown to reduce wet droppings in poultry. The second product, FA2 (NeoPrime™) was designed to enhance gut health. The control feed was a corn-SBM basal diet formulated to meet or exceed NRC recommendations and contained no antibiotic or ZnO at levels higher than needed to meet the Zn requirement. A two-phase-feeding program with phase I from d 0 to 14 and phase II from d 15 to 28 was used in the study. Body weight and feed intake were measured weekly to determine ADG, ADFI, and FCR. Fecal scores were recorded daily using a 0 to 5 scale (0-solid to 5-watery). Fecal

samples were collected at 14 and 28 d post-weaning and fecal microorganisms were analyzed. Data were analyzed using ANOVA procedure of SAS (SAS 9.2) with pen as the experimental unit. Post-weaning pigs supplemented with FA1 and FA2 had numerically higher ADG (0.42 and 0.45 vs. the CON 0.33) and significantly increased ADFI (0.67 and 0.71 vs. the CON 0.56) ($P < 0.05$) during the 4-wk experimental period resulting in better FCR 1.64 and 1.61 vs. the CON 1.68. Feeding FA1 or FA2 significantly reduced ($P < 0.05$) the diarrhea index from a 4.31 score in the CON to 0.84 and 0.93, respectively. Fecal samples of pigs fed the diet with FA1 had higher *Lactobacilli* counts on both d-14 and d-28 ($P < 0.05$), lower *E. coli* on d-14, and lower *Salmonella* on d-28 ($P < 0.05$). Supplementing FA2 to post-weaning pigs significantly reduced *E. coli* and increased*Lactobacilli* on both d-14 and d-28 of tested period ($P < 0.05$). Fecal *Salmonella*counts were numerically lower in the FA2 group on both d-14 and d-28. In conclusion, FA1 or FA2 can be used as feed additives to reduce diarrhea, improve growth performance, and improve microorganism profiles in the intestine of post-weaning pigs.

Key Words: gut health, growth performance, diarrhea, post-weaning pigs

1010 Optimization of B vitamins for improving the quality of fermented feed with response surface methodology. Z. Yang*[1] and X. M. Wang[2], *[1]College of Animal science, Shandong Agricultural University, Taian, China, [2]College of Animal science, Shandong Agricultural University, Tai-an, Shandong, Taian, China.*

To investigate the optimization of vitamin B_1, B_2 and B_{12} that were inoculated to improve the quality of fermented feed. Central composite design of response surface methodology (RSM) was employed to optimize vitamin B_1 content (X_1: 0.6~1.0 mg/kg), vitamin B_2 content (X_2:0.6~1.8 mg/kg) and vitamin B_{12} content (X_3: 9~15 μg/kg). After 72 h solid-state fermented (SSF), samples from three fermented feed/pen and 6 replicate pens/treatment were obtained to evaluate the pH value, dry matter recovery (DMR) and reducing-sugar content. Results indicated that the data of pH value, DMR and reducing-sugar were adequately fitted into 3 s-order polynomial models ($P < 0.05$). The vitamin B_1, B_2 and B_{12} were found to have significant linear, quadratic and interaction effects on the pH value, DMR and reducing-sugar ($P < 0.05$). The optimal extraction conditions were predicted to be vitamin B_1 content of 0.65 mg/kg, vitamin B_2 content of 1.29 mg/kg and vitamin B_{12} content of 12.02μg/kg. The pH value, DMR and reducing sugar were predicted by RSA to be 4.09, 91.57, and 6.46%, respectively. These detection indexes what obtained through the verification experiment were close to the predicted values significantly ($P < 0.01$). The establishment of such a model provides a good experimental basis with employing RSM for optimizing the inoculation amount of vitamin B_1 (0.65 mg/kg), vitamin B_2 (1.29 mg/kg) and vitamin B_{12} (12.02μg/kg) to improve the quality of fermented feed.

Key Words: B vitamins, pH, dry matter recovery, reducing-sugar, fermented feed

1011 Changes in pH of digestive tract and cecal microflora composition in broilers fed with probiotic and prebiotic supplementation (SynerAll). A. Ipek* and A. Sozcu, *Faculty of Agriculture, Department of Animal Science, Uludag University, Bursa, Turkey.*

This study was conducted to investigate the changes in the pH of the digestive tract and cecal microflora composition in broilers fed a combination of probiotic and prebiotic supplementation (PPS) (SynerAll; Global Nutritech LLC, Richmond, VA). A total of 720 1-d-old Cobb 500 broiler chicks were randomly assigned to four treatment groups: Control (no PPS), Group 1 (0.5 kg PPS/ton), Group 2 (1 kg PPS/ton), and Group 3 (2 kg PPS/ton). The combination of probiotics and prebiotics included live *Saccharomyces cerevisiae* (strain NCYC R618), mannan, and glucan. Each experimental group consisted of six replicates, each containing 30 chicks (15 female and 15 male). At 42 d of age, the pH and dry matter of the digestive tract (crop, proventriculus, gizzard, ileum), the pH of feces, and cecal microflora composition (*Lactobacillus* spp. and total *E. coli* spp.) were determined. Data were analyzed using the GLM Procedure of SAS. The crop and gizzard had the lowest ($P < 0.05$) pH values in Group 2 (4.35 and 2.24, respectively) compared to the Control (5.90 and 3.28, respectively), Group 1 (4.88 and 2.91, respectively), and Group 3 (4.63 and 2.78, respectively). The pH of the ileum was higher ($P < 0.01$) for the Control (6.64) than for Group 1, Group 2, and Group 3 (5.38, 5.18, and 5.42, respectively). Dry matter and pH of feces were similar among the treatment groups ($P > 0.05$). The count of *Lactobacillus* spp. increased more in Group 2 (7.97 log CFU/g wet digesta) and Group 3 (6.90 log CFU/g wet digesta) than the Control (1.30 log CFU/g wet digesta) and Group 1 (1.43 log CFU/g wet digesta; $P < 0.01$). Total *E. coli* spp. count was higher ($P < 0.05$) in the Control and Group 1 (8.90 and 7.67 log CFU/g wet digesta, respectively) compared to Group 2 and Group 3 (3.47 and 4.20 log CFU/g wet digesta, respectively). Increasing the dose of SynerAll resulted in increased counts of *Lactobacillus* spp. and decreased counts of total *E. coli* spp. in the cecal microflora. In conclusion, supplementation of SynerAll to broiler diets had a positive effect on the pH of digestive organs and cecal microflora composition, which may increase the performance of broilers.

Key Words: broiler, probiotic, prebiotic, pH, cecal microflora

1012 Effects of dietary inclusion of probiotics and prebiotics (SynerAll) on growth performance and serum biochemical parameters in broilers.
A. Ipek*[1], A. Sozcu[1], and V. Akay[2], [1]*Faculty of Agriculture, Department of Animal Science, Uludag University, Bursa, Turkey,* [2]*Global Nutritech Biotechnology LLC, Richmond, VA.*

This study was conducted to investigate the effects of the dietary inclusion of probiotics and prebiotics (PPS) (SynerAll; Global Nutritech LLC, Richmond, VA) on broiler growth performance and serum biochemical parameters. A total of 720 1-d-old Cobb 500 broiler chicks were randomly assigned to four treatment groups: Control (no PPS), Group 1 (0.5 kg PPS/ton), Group 2 (1 kg PPS/ton), and Group 3 (2 kg PPS/ton). The combination of probiotics and prebiotics included live *Saccharomyces cerevisiae* (strain NCYC R618), mannan, and glucan. Each experimental group consisted of six replicates, each containing 30 chicks (15 female and 15 male). Growth performance, live weight gain, and feed conversion rate were determined between d 1–21 and d 22–42. At 42 d of age, serum biochemical parameters (heterophil (H), lymphocytes (L), monocytes, eosinophils, basophils) were analyzed and the H:L ratio was calculated. Data were analyzed using the GLM Procedure of SAS. Final live body weight on d 42 was the highest ($P < 0.01$) for Group 2 (3238.6 g) and the lowest ($P < 0.01$) for the Control (2818.5 g). Final body weight was 6.8%, 14.9%, and 5.8% higher ($P < 0.01$) for Group 1, Group 2, and Group 3, respectively, when compared to the Control. Feed consumption was lower ($P < 0.01$) for Group 2 and Control (1683.5 and 1727.2 g/bird, respectively) compared to Group 1 and Group 3 (1926.3 and 1935.4 g/bird, respectively). Dietary inclusion of PPS affected the feed conversion ratio ($P < 0.01$). The feed conversion ratio was the highest for the Control (2.04) and the lowest for Group 2 (1.72). It was intermediate for Group 1 and Group 3 (1.88 and 1.97, respectively). Mortality rate was not statistically significant among treatment groups ($P > 0.05$). Serum biochemical parameters and H:L ratio were similar among treatment groups ($P > 0.05$). These findings demonstrated that SynerAll can be used in broiler diets to improve weight gain and profitability.

Key Words: broiler, probiotic, prebiotic, live weight, blood parameters

1013 Changes in pH of digestive tract and cecal microflora composition in broilers fed with probiotic and prebiotic supplementation, SynerAll.
A. Ipek* and A. Sozcu, *Faculty of Agriculture, Department of Animal Science, Uludag University, Bursa, Turkey.*

This study was conducted to investigate the changes in pH of the digestive tract and cecal microflora composition in broilers fed a combination of probiotic and prebiotic supplementation (PPS) (SynerAll; Global Nutritech LLC, Richmond, VA). A total of 720 1-d-old Cobb 500 broiler chicks were randomly assigned to four treatment groups: Control (no PPS), Group 1 (0.5 kg PPS/ton), Group 2 (1 kg PPS/ton), and Group 3 (2 kg PPS/ton). The combination of probiotics and prebiotics included live *Saccharomyces cerevisiae* (strain NCYC R618), mannan, and glucan. Each experimental group consisted of six replicates, each containing 30 chicks (15 female and 15 male). At 42 d of age, the pH and dry matter of the digestive tract (crop, proventriculus, gizzard, ileum), the pH of feces, and cecal microflora composition (*Lactobacillus* spp. and total *E. coli* spp.) were determined. Data were analyzed using the GLM Procedure of SAS. Crop and gizzard had the lowest ($P < 0.05$) pH values in Group 2 (4.35 and 2.24, respectively) compared to the Control (5.90 and 3.28, respectively), Group 1 (4.88 and 2.91, respectively), and Group 3 (4.63 and 2.78, respectively). The pH of the ileum was higher ($P < 0.01$) for the Control (6.64) than Group 1, Group 2, and Group 3 (5.38, 5.18, and 5.42, respectively). Dry matter and the pH of feces were similar among treatment groups ($P > 0.05$). The *Lactobacillus* spp. count increased more in Group 2 (7.97 log CFU/g wet digesta) and Group 3 (6.90 log CFU/g wet digesta) than the Control (1.30 log cfu/g wet digesta) and Group 1 (1.43 log CFU/g wet digesta; $P < 0.01$). The total *E. coli* spp. count was higher ($P < 0.05$) in the Control and Group 1 (8.90 and 7.67 log CFU/g wet digesta, respectively) compared to Group 2 and Group 3 (3.47 and 4.20 log CFU/g wet digesta; respectively). Increasing the dose of SynerAll resulted in increased counts of *Lactobacillus* spp. and decreased counts of total *E. coli* spp. in the cecal microflora. In conclusion, supplementation of SynerAll to broiler diets had a positive effect on the pH of digestive organs and cecal microflora composition, which may increase the performance of broilers.

Key Words: broiler, probiotic and prebiotic, pH, cecal microflora

1014 Supplementation of chestnut tannins in artificially infected weaned piglets. G. Bee*, S. Thanner, G. Marion, and A. Gutzwiller, *Agroscope Institute for Livestock Sciences, Posieux, Switzerland.*

Weaning is a critical stage for piglets that is associated with disturbances in the intestinal microflora and pre-disposes them to gastrointestinal tract infections such as enterotoxic *E. coli* F4 (ETEC) infections and the development of post-weaning diarrhea. The continuous use of large amounts of antibiotics in animal production has led to the increased occurrence of resistances, so alternative solutions become urgent. Hydrolyzable tannins (HT) are known to have antimicrobial properties. The aim of this study was to determine the effect of HT from chestnut added to a standard starter diet on the prevalence of diarrhea in weaned piglets artificially infected with ETEC. The trial was arranged as a 2 × 2 factorial design and was performed with 72 piglets, weaned at 23 to 31 d of age. Piglets were allocated within weaning body weight and litter to the treatments and housed as pairs in pens. From the day of weaning, piglets had ad libitum access to either a control (**C**) or a 1% tannin (T) supplemented diet. Four days after weaning, 18 C and 18 T piglets received a 5-mL ETEC suspension of 10^8 CFU/ml orally, while the other 18 C and 18 T piglets received 5 mL of a PBS solution. For 14 d after infection, fecal score was assessed daily using the following score scheme: 1 = dry, pelleted feces; 2 = molded feces; 3 = moist, cow-dung appearance; 4 = diarrhea; 5 = watery diarrhea. Once per week, the piglets were weighed and the feed disappearance per pen was determined. In the first week after infection, the fecal score and the number of days in diarrhea were reduced ($P < 0.01$) in the T group (2.7 ± 1.24 and 2 ± 1.9 d, respectively) compared with the C group (3.1 ± 1.32 and 3 ± 2.4 d, respectively). However, average daily weight gain and feed disappearance were similar ($P > 0.05$) between the infected groups in the first week after infection (T: 0.4 ± 0.70 kg/piglet/d; C: 0.2 ± 0.27 kg/piglet/d; T: 517 ± 157.5 g/pen/d; C: 488 ± 193.7 g/pen/d) as well as in the second week after infection (T: 0.9 ± 1.25 kg/piglet/d; C: 0.6 ± 0.69 kg/piglet/d; T: 1043 ± 385.4 g/pen/d; C: 946 ± 347.5 g/pen/d). There was no difference in the frequency of antibiotic treatment between the C and T groups (2 out of 36 T piglets and 2 out of 36 C piglets suffering from watery diarrhea for 4 d received antibiotic treatment), and none of the T and C piglets died. In conclusion, the HT extract reduced the severity of diarrhea in the first week after infection but had no effect on growth performance.

Key Words: ETEC infection, post-weaning diarrhea, piglet

1015 Curcumin prevents hepatotoxic effects of Aflatoxin B1 associated with inhibition of cytochrome P450 isozymes genes in chick liver. L. Sun*, N. Zhang, M. Zhu, L. Zhao, and D. Qi, *College of Animal Science and Technology, Huazhong Agricultural University, Wuhan, China.*

The involvement of cytochrome P450 (CYP450) isozymes in curcumin-mediated protection against aflatoxin B_1 (AFB_1)-induced adverse effects in broilers remains unclear. This study was designed to establish if curcumin could alleviate AFB_1-induced hepatotoxic effects and then to determine if these effects were due to changes in the CYP450 isozymes expression in the livers of chicks. 120 1-d-old male Avian broilers were assigned to 4 groups with 5 replicates of 6 birds to be included in a 2 by 2 factorial trial, in which the main factors included supplementation of AFB_1 (<5 vs. 100 μg/kg) and curcumin (0 vs. 150 mg/kg) in a corn/soybean-based diet for 4 wk. The liver histology, antioxidant enzymes, and mRNA of CYP450 isozymes in liver were analyzed. Administration of AFB_1 induced liver injury, which was indicated by induced hepatic necrosis and bile duct hyperplasia at wk 2. AFB_1 also decreased ($P < 0.05$) hepatic activities of catalase and glutathione peroxidase, while increasing ($P < 0.05$) exo-AFB_1–8,9-epoxide (AFBO)-DNA concentration. Curcumin supplementation was found to prevent the changes induced by AFB_1 in broilers. Moreover, the mRNA of the enzymes responsible for the bioactivation of AFB_1 into AFBO, which included CYP1A1, CYP1A2, CYP2A6, and CYP3A4, were induced ($P < 0.05$) in liver microsomes after 2 wk exposure to AFB_1. These alterations induced by AFB_1 were prevented by curcumin supplementation. In summary, dietary curcumin supplementation protected chicks from the AFB_1-induced liver injury, potentially through the synergistic actions of increased antioxidant capacities, and inhibition of the pivotal CYP450 isozyme-mediated activation of AFB_1 to toxic AFBO.

Key Words: curcumin, aflatoxin B_1, CYP450, AFBO-DNA, chicks

1016 Effects of humic acid supplementation on pig growth performance, Nitrogen digestibility, odor, and ammonia emission. C. H. Ponce[*1], C. Arteaga[2], and A. Flores[2], [1]*Escuela de Medicina Veterinaria, Colegio de Ciencias de la Salud, Universidad San Francisco de Quito USFQ, Quito, Ecuador,* [2]*Departamento de Ciencias de la Vida y Agricultura, Universidad de las Fuerzas Armadas ESPE, Sangolqui, Ecuador.*

An experiment was conducted to evaluate the effects of the level of supplementation of humic acid salts (HF) on pig performance, nitrogen digestibility, odor, and ammonia emissions from manure. A total of 150 piglets were used in a completely randomized block design (10 pens/treatment and 5 piglets/

pen) and assigned into 3 experimental treatments: 1) control, without HF supplementation (0HF), 2) supplementation of 2 g/pig/day of HF (Huminfeed; 2HF), and 3) supplementation of 4 g/pig/day of HF (Huminfeed; 4HF). Commercial diets were fed ad libitum in a pellet form in 2 phases, from weaning (21 d) to d 49 (pre-starter) and from d 49 to 70 (starter). Growth parameters were measured weekly. Total fecal and urine samples were collected form 3 pens/treatment on d 14 of the experiment for 5 consecutive days to measure nitrogen digestibility. On d 20 of the experiment, fecal samples mixed with urine samples (1:2) were placed into plastic containers to measure ammonia emissions over 48 h. Additionally, fecal samples were collected to measure odor characteristics. Overall, body weight, ADFI, ADG, and the G:F ratio were not altered by HF supplementation ($P > 0.59$). Nitrogen intake and N fecal excretion were linearly decreased as HF increased ($P < 0.01$). Apparent total nitrogen digestibility increased linearly as HF increased ($P = 0.02$). However, N retention was not different across treatments ($P > 0.37$). There was a tendency toward decreased NH_3 emission from manure from the 4HF treatment over 48 h ($P = 0.09$). Odor hedonic tone and odor intensity from manure were significantly reduced by HF supplementation ($P < 0.01$). Results from this experiment suggest that there are benefits of HF supplementation on odor parameters, NH_3 emissions, and N digestibility without altering pig growth performance.

Key Words: ammonia emissions, growth performance, humic acids

1017 A standardized blend of capsicum and turmeric oleoresins given during late gestation improves the performance of sows vaccinated against *E. coli*.

C. Oguey[*1], I. Riu[2], C. Quintilla[3], and S. Lopez[4], *[1]Pancosma, Geneva, Switzerland, [2]Avena Nutrició, La Garriga, Spain, [3]Copinsa, Altorricon, Spain, [4]Pancosma SA, Le Grand Saconnex, Switzerland.*

Previous research projects have demonstrated that a standardized protected blend of capsicum and turmeric oleoresins (XT, Xtract® Nature, Pancosma, Switzerland) had an immune-modulating effect and could potentiate and complement the effects of vaccines in poultry. However, similar data were not available in swine. The objective of this trial was to evaluate if the supplementation of XT in late gestation could improve the performance of sows vaccinated against *E. coli* during farrowing and lactation. A total of 1531 sows vaccinated against *E. coli* at 80 d of gestation and regrouped in 3 successive bands were involved. Sows in phases 1 and 3 were fed an unsupplemented basal diet (CT, $N = 529$ and 329, respectively), whereas animals in the second phase were provided the same basal diet supplemented with 200 g/t XT ($N = 673$) from 80 until 110 d of gestation. In terms of sow performance, the proportion of piglets born/litter was recorded at farrowing as well as piglets' mortality during lactation. Colostrum was also collected at birth ($N = 14$ and 16, respectively, for the XT and CT groups) for analysis of total protein, albumin, and globulins. Data were analyzed by analysis of variance, considering the effect of the treatment for colostrum quality, and the effects of the treatment, parity, and their interaction for performance outcomes. Results showed that XT increased the levels of total proteins by +5.0% in colostrum ($P = 0.04$), and this was mainly driven by a greater concentration in globulins (+5.0%, $P = 0.08$). XT enhanced the proportion of piglets born alive per litter (92.6% vs. 90.7%, respectively, for XT and CT; $P < 0.01$). This effect was more pronounced in sows of parity 1 or 2 (+2.2%, $P = 0.02$) than in sows of parity 3 or more (+1.9%, $P = 0.06$). The treatment did not affect the piglets' mortality during suckling, but there was a treatment*parity effect on this outcome: litters in primiparous and parity 2 sows had reduced mortality when fed XT compared to CT (10.1 vs. 12.5%, $P = 0.01$). These results suggest that XT supplementation to vaccinated sows during late gestation has the potential to improve nutrient supply to the progeny, litter performance at farrowing, and litter size at weaning.

Key Words: performance, vaccinated sows, Xtract

1018 Evaluation of biodegraded and undegraded plantain peels as replacement to wheat offal in broiler production.

F. A. Aderemi[*1], O. M. Alabi[2], and A. Awe[2], *[1]Bowen, Ibadan, Nigeria, [2]Bowen University, Iwo, Nigeria.*

This study evaluated the replacement of wheat offal with biodegraded and undegraded plantain peels in raising broilers. Plantain peels were biodegraded using fungus, and three diets were formulated. Diet I with 12% wheat offal was the control, and in diets II and III, wheat offal was replaced with undegraded and biodegraded plantain peels. Ninety day old broilers were randomly assigned to these diets, which were replicated thrice and lasted for 8 wk. During this feeding trial, data on the performance characteristics of the birds were collected. Blood samples were also taken at the eighth week for analysis, and all data generated were subjected to analysis. Results revealed that body weight gain was similar ($P = 0.05$) across the diets at both starter and finisher phases, implying that the energy and protein content of the diets were not below the maintenance requirements. The broilers fed control diets had a similar feed intake to those on the degraded plantain peel diet, but it was significantly ($P < 0.05$) higher than those on the undegraded plantain peel diet at the starter phase, while at the finisher phase the intake was similar across the diets possibly due to age. Feed conversion ratio had a similar pattern to intake at both phases. Among the serum metabolites observed, the glucose, total protein, cholesterol, urea, creatinine, and the enzymes were all significantly affected by the diets and were mostly within normal range. Morphological analysis of the birds revealed significant effects of treatments on the

heart, proventriculus, gizzard, lung, spleen, liver, and intestine. The carcass analysis revealed that the shank, wing, back, and the head of the control and those fed diet II were similar and higher than those fed diet III, but the breasts of broilers on diet III were better than those on diets I and II. The mortality that occurred could not be traced to diets. Biodegraded or undegraded plantain peels could be used as a replacement for wheat offal weight for weight in broiler production without adversely affecting performance characteristics, morphology, blood parameters, and carcass analysis.

Key Words: plantain peels, broilers, performance characteristics

1019 Effect of lysophospholipids supplementation in different energy diets on growth performance, nutrient digestibility, milk composition, litter performance, and fecal score in lactating sows.

P. Y. Zhao*, S. O. Jung, I. C. Hwang, B. R. Kim, J. W. Shin, M. K. Shim, D. K. Kang, J. Y. Kim, H. B. Kim, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, South Korea.*

Emulsifiers are substances that stabilize mixtures and prevent oil and water from separating, which is good for the digestion of lipids. This study was conducted to evaluate the effect of dietary emulsifier (lysophospholipids, LPL) supplementation with different energy diets in lactating sows. A total of 32 multiparous sows (Landrace × Yorkshire) were used in a 21-d experiment. On d 110 of gestation, sows were weighed and moved into the farrowing facility, randomly assigned in a 2 × 2 factorial arrangement with two levels of Lipidol (0 and 0.1%; Lipidol contains 3% LPL) and two level of metabolizable energy (3265 and 3165 kcal/kg) according to their BW. Individual sows were weighed and scanned for backfat thickness to determine weight and backfat loss. Chromium oxide (0.2%) was added to the diet as an indigestible marker to determine ATTD of DM, N, and GE. Milk crude fat (Method 960.39; AOAC, 2007) was measured according to the Association of Official Analytical Chemists. Lactose was assayed using an enzymatic method. Data were analyzed as a randomized complete block design with a 2 × 2 factorial arrangement using the GLM Procedure of SAS (SAS Inst. Inc., Cary, NC). A probability level of $P < 0.05$ was considered to be significant. Body weight loss (18.6 vs. 15.1 kg) and backfat thickness loss (2.4 vs. 1.9 mm) were decreased ($P < 0.05$) by LPL supplementation. Backfat thickness (17.0 vs. 14.5 mm) at weaning was higher ($P < 0.05$) in sows fed LPL supplementation diets. The ATTD of DM (84.4 vs. 83.2%), N (83.6 vs. 82.5%), GE (82.9 vs. 82.1%), and crude fat (80.1 vs. 79.2%) in sows fed LPL diets was increased ($P < 0.05$) compared with those fed non-LPL diets. Sows fed the high energy diets had higher ($P < 0.05$) milk fat (11.3 vs. 10.0%) on d 10 and milk lactose (4.6 vs. 3.9%) on d 20 than those fed the low energy diets. Milk fat (11.3 vs. 9.9%) and lactose concentrations (4.6 vs. 4.0%) in LPL supplementation treatments were increased ($P < 0.05$) compared with non-LPL treatments on d 10 and d 20, respectively. Interactive effects ($P < 0.05$) between energy and LPL were observed on milk fat concentration on d 10. In conclusion, LPL addition decreased body weight loss and backfat thickness loss and improved nutrient digestibility and milk fat as well as milk lactose concentrations. Additionally, LPL and energy can interactively increase milk fat concentration in lactating sows.

Key Words: growth performance, lysophospholipids, sow

1020 Effect of crystalline silicon dioxide in piglet feed on growth performance with different levels of growth promoters.

Y. Martel-Kennes[*1], J. Lévesque[1], and C. Decaux[2], *[1]Centre de Recherche en Sciences Animales de Deschambault, Deschambault, QC, Canada, [2]Ceresco Nutrition, Saint-Urbain-Premier, QC, Canada.*

Silicon dioxide is a common mineral that can be found under different forms (crystalline or amorphous) and is also found in many clays and diatomaceous earth. The purpose of this trial was to assess, in a factorial 2×2 arrangement, the growth performance of piglets reared with a feeding program including, or not, a crystalline silica-based feed supplement (SI) with or without antibiotics as growth promoters (AGP; chlortetracycline and high levels of Cu and Zn in Phase 1 and chlortetracycline in Phase 2). All diets were formulated to be iso-caloric and iso-nitrogenous. An ANOVA was performed on zootechnical parameters with the pen as the experimental unit for all analyses. Effects of AGP, SI, block (based on sex and body weight), and interaction between AGP and SI were included in the statistical model. A total of 252 piglets with body weights of 7 kg were reared until 24 kg of body weight and allocated into 36 pens. According to these results, groups fed with AGP showed improved weight gain, feed intake, and feed conversion during Phase 1, while no significant effect was observed during Phase 2. Concerning the effect of SI, feed intake was improved by 4.13% during the overall nursery period, compared to groups without SI (729 versus 700 g/day; $P < 0,05$). In addition, groups fed SI showed an average daily gain of 3.26% higher than animals without SI during the same period (607 versus 588 g/day; $P < 0.05$). This effect leads to an improvement of 2.2% in piglet's weight at the end of the post-weaning phase (24.52 versus 23.99 kg; $P < 0.05$). It was concluded that under our trial conditions, adding crystalline silicon dioxide to piglet feed (0.02%) increase feed intake, growth rate, and piglet weight at the end of the nursery period. This mineral additive could offer potential economic benefits to swine producers.

Key Words: silicon, silica, piglet

BEEF CATTLE NUTRITION SYMPOSIUM: A LOOK AT THE LATEST BEEF CATTLE NRC RECOMMENDATIONS

1021 Overview of the process and changes in the eighth edition of the Nutrient Requirements of Beef Cattle. M. L. Galyean*, *Texas Tech University, Lubbock.*

The National Research Council's (NRC) series on *Nutrient Requirements of Beef Cattle* has been an essential information resource for practicing nutritionists and academicians for decades. Standards set by NRC publications have improved the economic and environmental sustainability of the beef industry, and each revision has provided a stimulus for further research. The committee responsible for the eighth edition invested more than 2 yr in producing a revision that would meet the high standards set by previous publications in the series. Following the Statement of Task, the committee updated the seventh revised edition by reviewing the scientific literature on the nutrition of beef cattle for all life phases and various production settings. Several new sections were added, including beef cattle production systems, food quality, and safety; ruminant anatomy and digestion; carbohydrates; lipids; compounds that modify digestion and metabolism; nutrition and the environment; and byproduct feed ingredients. Chapters from the seventh edition were updated, with substantial effort to provide improved prediction equations for modeling nutrient supply and metabolism. Specifically, new equations for predicting microbial protein synthesis and recycled nitrogen that is incorporated into microbial products were added. New information was included relative to the role of sulfur in beef cattle production, particularly as it relates to high-sulfur byproduct feeds. Greater clarity is provided on recommendations for provision of vitamin E in various production settings, and new equations were provided for the prediction of feed intake by growing/finishing beef cattle. The body condition score-based system was changed to include a fixed percentage of shrunk BW change per unit of BCS, and updated guidelines for adjustments to dietary ME values associated with the use of ionophores are provided. A new chapter is devoted to the potential effects of livestock operations on the environment, and prediction equations for nutrient excretion and enteric methane production are included. Byproduct feeds are described in much greater detail, and a statistically based evaluation of a feed composition data from commercial laboratories is provided. The new computer model, with options for empirical and mechanistic solutions, is more intuitive and user-friendly than software provided with the seventh edition. The eighth edition of the *Nutrient Requirements of Beef Cattle* is a major revision that should have a significant effect on beef cattle research and production over the next decade.

Key Words: beef cattle, nutrient requirements, revision

1022 The eighth revised edition of the Nutrient Requirements of Beef Cattle: maintenance and growth. J. S. Caton*[1], C. R. Krehbiel[2], M. L. Galyean[3], and L. O. Tedeschi[4], *[1]Department of Animal Sciences, North Dakota State University, Fargo, [2]Oklahoma State University, Stillwater, [3]Texas Tech University, Lubbock, [4]Texas A&M University, College Station.*

The objectives of this review are to discuss updates to maintenance and growth components of the eighth revised edition of the Nutrient Requirements of Beef Cattle. From an energy supply standpoint, the traditionally held relationship of DE to ME (ME = DE × 0.82) needs to be reassessed. Maintenance requirements are computed by adjusting the base NEm requirement for breed, lactation, and heat loss vs. heat production (HE), which is ME intake minus retained energy (RE). Adjustments for animal insulation and environmental conditions are considered. The NEm requirement is computed based on the basal metabolism coefficient (a1) and adjustment factors for previous temperature (a2), breed (BE), lactation(L), gender, and previous plane of nutrition (COMP) as follows: NEm = $SBW^{0.75}$ × (a1 × BE × L × COMP × SEX + a2), where a1 = 0.077 and is the basal metabolism coefficient in Mcal/$kg^{0.75}$ daily, BE is breed factor, L is lactation factor, COMP = 0.8 + (BCS – 1) × 0.05 and is the NEm adjustment for previous nutrition, SEX is gender effect (1.15 bulls vs. 1 for others), a2 = 0.0007 × (20 – Tp) with a2 being the acclimatization factor in Mcal/$kg^{0.75}$ daily, and Tp is the previous temperature in °C. The seventh revised edition of the Beef NRC adjusted the a1 coefficient by 10% for all *Bos indicus* cattle; in the revised edition, this adjustment is removed for Nellore cattle. Previous adjustments to NEm for cold or heat stress are retained in the revised version, but users are cautioned on applying current equations, and this is an area of research need. Previous adjustments for the physical activity of grazing have been removed in the eighth revised edition, and additional research is needed on energetic costs of physical activity. Methods to estimate MP for maintenance remain unchanged. Growth equations from the previous NRC were retained. Additional data were used to evaluate equations for predicting retained energy and protein, with resulting satisfactory accuracy for predicting RE, but improvements are needed for predicting retained protein. Serial slaughter data measuring body composition in modern cattle with and without growth technologies are needed. Problems and barriers associated with accurately predicting NE and protein requirements for growth were delineated and discussed.

Key Words: energy, maintenance, protein

1023 The eighth revised edition of the Nutrient Requirements of Beef Cattle: reproduction.

R. P. Lemenager[*1], J. S. Caton[2], M. L. Galyean[3], and L. O. Tedeschi[4], *[1]Purdue University, West Lafayette, IN, [2]Department of Animal Sciences, North Dakota State University, Fargo, [3]Texas Tech University, Lubbock, [4]Texas A&M University, College Station.*

The eighth Revised Edition includes updates to the calculation of body energy (BE) and protein reserves in beef females, empty BW (EBW, kg) change per BCS, and Mcal of BE change per BCS. Energy and protein requirements for the maintenance and growth of bulls, heifers, and cows and for milk production remain largely unchanged from the seventh Revised Edition. Replacement heifer target weights at the beginning of the breeding season are unchanged from the seventh Revised Edition (55% for dual purpose or dairy breeds, 60% for *Bos taurus*, and 65% for *Bos indicus*), but the eighth Revised Edition model allows the user to change this variable. A more complete description of BCS 1 through 9 has been created, and a BCS decision tree has been added. A discussion regarding the effect of cow nutrition on fetal and developmental programming has been added to the narrative. While the previous body reserves model assumed a variable BW change per BCS, the new body reserves model assumes a fixed BW change per BCS, and it is computed as 7.105% of the empty body weight at BCS 5. Within the model, the user can modify the 7.105% adjustment. For primiparous females, based on limited data, an adjustment factor of 1.6 × 7.105% is suggested for the EBW change needed to increase 1 BCS. Similarly, it is suggested that an adjustment factor of 0.4 × 7.105% be used for EBW change needed to lose 1 BCS for primiparous females. Energy content of 1 kg cow weight gain in the eighth Revised Edition has been changed from a constant of 5.826 Mcal/kg of SBW to a variable number ranging from 3.69 for a BCS 1 cow to 7.99 Mcal/kg of SBW for a BCS 9 cow. The estimated DMI calculation for cows in the model remains unchanged, but a DMI calculation based on neutral detergent fiber (NDF) intake, as a percentage of BW, has been added to the model output for user evaluation of DMI. It is often suggested that 1.1% be used for low- to medium-quality forages. Only minor adjustments have been made to the vitamin and mineral (Co) requirements for reproducing beef females.

Key Words: beef cattle, reproduction, requirements

1024 The eighth revised edition of the Nutrient Requirements of Beef Cattle: protein and metabolic modifiers.

J. H. Eisemann[*1], M. L. Galyean[2], K. A. Beauchemin[3], C. R. Krehbiel[4], and L. O. Tedeschi[5], *[1]North Carolina State University, Raleigh, [2]Texas Tech University, Lubbock, [3]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [4]Oklahoma State University, Stillwater, [5]Texas A&M University, College Station.*

The eighth Revised Edition includes updates to the proteins and digestive and metabolic modifiers sections of the report reflecting new information since the seventh Revised Edition was published. The MP system was adopted in the seventh Revised Edition. It accounts for rumen degradation of dietary protein and separates requirements into the needs for ruminal microorganisms and the needs of the animal. Rumen degradable protein (RDP) provides ruminal microorganisms with various sources of nitrogen (N). In contrast, ruminally undegraded protein (RUP) is not hydrolyzed in the rumen. The amount of RDP required is based on prediction of synthesis of microbial CP (MCP). Published data from studies using cattle fitted with intestinal cannulas were used to develop and evaluate empirical equations for the prediction of MCP based on total digestible nutrient intake (TDNI), fat-free TDNI (FFTDNI), and CP intake as independent variables. Equations based on TDNI and FFTDNI are provided to estimate MCP depending on the ether extract percentage of the diet. The MP supply is absorbed amino acids from protein digested in the intestine and supplied by microbial protein and RUP. Reported values for RUP digestibility are variable, but most estimates for forages are less than 60%. The digestibility of RUP for forages was decreased from 80% to 60%. Regression analysis of literature data based on the dual-labeled urea isotopic approach was used to update equations to estimate urea N kinetics. A more complex rumen model is needed to include recycling directly in the beef cattle nutrient requirements model. A number of feed additives and other compounds that improve animal health and the efficiency of nutrient use, increase growth rate, and decrease the environmental impact of beef cattle were reviewed. These include compounds that alter rumen fermentation, additional aspects of gastrointestinal tract function, or post-absorptive metabolism. Review of feed additives with the potential to provide an alternative to inclusion of dietary antibiotics, such as plant secondary metabolites, direct-fed microbials, and feed enzymes, was included. Ionophores change microbial populations in the rumen and improve feed efficiency. Predicted DMI is decreased by 3% when monensin is fed. In addition, dietary ME was increased by 2.3 or 1.5% for monensin or lasalocid, respectively, to account for improvements in ADG and feed efficiency when feeding ionophores.

Key Words: beef cattle, ionophores, microbial protein synthesis, urea recycling

1025 The eighth revised edition of the Nutrient Requirements of Beef Cattle: minerals, vitamins, and water. T. E. Engle*[1], J. S. Caton[2], M. L. Galyean[3], L. O. Tedeschi[4], N. A. Cole[5], C. R. Krehbiel[6], G. E. Erickson[7], K. A. Beauchemin[8], R. P. Lemenager[9], and J. H. Eisemann[10], *[1]Colorado State University, Fort Collins, [2]Department of Animal Sciences, North Dakota State University, Fargo, [3]Texas Tech University, Lubbock, [4]Texas A&M University, College Station, [5]USDA Agricultural Research Service, Bushland, TX, [6]Oklahoma State University, Stillwater, [7]University of Nebraska, Lincoln, [8]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [9]Purdue University, West Lafayette, IN, [10]North Carolina State University, Raleigh.*

The objective of this review is to briefly discuss the updates made to the minerals, vitamins, and water sections contained in the eighth revised edition of the Nutrient Requirements of Beef Cattle publication. Relevant data for determining mineral, vitamin, and water requirements for beef cattle published since the seventh revised edition as well as recommendations from recently published NRC publications were added where appropriate. Although long identified as essential components in the diets of beef cattle and required for many biochemical reactions, the interactions among minerals, vitamins, water, and metabolic processes are extremely complex. The minerals chapter provides an update of macro- and micro-mineral requirements for beef cattle and discusses factors that can affect mineral requirements as well as mineral-specific diseases that can influence beef cattle production. New information has been added relative to the role of sulfur in beef cattle production that focuses on factors affecting sulfur requirement and maximum tolerable concentrations of sulfur. Dietary cobalt requirements were increased from 0.10 to 0.15 mg Co/kg DM for all classes of beef cattle, and maximum tolerable concentrations of certain minerals were adjusted based on published data. The vitamins chapter provides an update of beef cattle vitamin nutrition, with new information regarding fat- and water-soluble vitamins. Of special note is the greater clarity that has been provided with respect to recommendations for provision of vitamin E in various production settings. The review articulates issues associated with specific deficiencies and excesses and suggests areas for additional research. New research focusing on the influence of diet type, physiological status, and stress would be useful to more accurately predict the vitamin and mineral requirements of beef cattle. Of the six essential nutrient classes, water is the single most important nutrient for beef cattle. The water chapter provides an update of equations to predict water intake by beef cattle and discusses certain factors that influence water intake, including the role of water quality in beef cattle production. In Chapter 19, the water intake model includes a response surface regression to predict water requirements for different effective temperature indexes for growing and finishing beef cattle.

Key Words: beef cattle, minerals, vitamins, water

1026 The eighth revised edition of the Nutrient Requirements of Beef Cattle: environmental issues. N. A. Cole*[1], K. A. Beauchemin[2], G. E. Erickson[3], L. O. Tedeschi[4], and M. L. Galyean[5]. *[1]USDA-ARS Conservation and Production Research Laboratory (retired), Bushland, TX, [2]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [3]University of Nebraska, Lincoln, [4]Texas A&M University, College Station, [5]Texas Tech University, Lubbock.*

Since publication of the of seventh Revised Edition of the *Nutrient Requirements of Beef Cattle*, (1996/2000), there has been growing concern among producers, regulators, and the general public about the impacts of livestock operations on the environment. Beef cattle typically retain less than 20% of the nutrients they consume. The remainder is lost via feces, urine, or respiration. The effects of these excreted nutrients, as well as pharmacologically active compounds (PAC) and pathogens on ground waters, surface waters, air quality, global climate change, environmental sustainability, land use, biodiversity, and quality of life are potentially affected by nutritional and management programs used by producers. Although environmental concerns normally revolve around concentrated animal feeding operations, some effects can also be a concern in extensive systems, such as pasture-based cow-calf and stocker operations. This new chapter in the eighth Revised Edition summarizes the environmental concerns associated with beef production in North America and reviews the latest scientific approaches to mitigation. Possible dietary effects on surface and ground water and air quality are discussed. Water quality concerns include the loss of nutrients, such as nitrates and phosphorus and PAC, to ground and surface waters. Air quality issues of greatest concern include emissions of ammonia and the greenhouse gases methane and nitrous oxide. Empirical equations are provided to estimate the excretion of organic matter, nitrogen, and phosphorus and for emissions of ammonia and enteric methane. A nonlinear equation is recommended to calculate the proportion of total nitrogen that is excreted in urine. Enteric methane production of cattle is highly dependent on factors such as forage quality, forage concentration, DMI, dietary fat, ionophores, and grain processing; therefore, multiple empirical equations are proposed to estimate enteric methane production from cattle fed high-forage, medium-forage, and low-forage diets. The effects of many co-products, such as distiller's grain, on enteric methane are variable and dependent on the control diet composition. By more precisely feeding and supplementing

livestock to meet their nutrient requirements, excess nutrient losses can be decreased. Under practical conditions, however, the use of precision feeding systems to manage environmental impacts is limited and challenged by factors such as: 1) inherent biological inefficiencies in the animal, 2) variability in animal performance and/or nutrient requirements, 3) variability in composition of feed ingredients, 4) high nutrient concentrations in many co-products, and 5) other factors.

Key Words: environment, beef cattle, nutrients, greenhouse gas, ammonia

---

1027 The eighth revised edition of the Nutrient Requirements of Beef Cattle: byproducts and feed composition.

K. A. Beauchemin*[1], G. E. Erickson[2], H. Tran[3], J. S. Caton[4], N. A. Cole[5], J. H. Eisemann[6], T. E. Engle[7], M. L. Galyean[8], C. R. Krehbiel[9], R. P. Lemenager[10], and L. O. Tedeschi[11], *[1]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]University of Nebraska, Lincoln, [3]National Animal Nutrition Program, University of Kentucky, Lexington, [4]Department of Animal Sciences, North Dakota State University, Fargo, [5]USDA-ARS Conservation and Production Research Laboratory (retired), Bushland, TX, [6]North Carolina State University, Raleigh, [7]Colorado State University, Fort Collins, [8]Texas Tech University, Lubbock, [9]Oklahoma State University, Stillwater, [10]Purdue University, West Lafayette, IN, [11]Texas A&M University, College Station.*

Byproduct feeds are important in beef cattle production, often providing cost-effective energy and protein. The focus of the review in the eighth revised edition was on corn and soy byproducts, as corn and soybean production are the two largest crops produced in the U.S. Use of distillers grains plus solubles, distillers solubles, corn gluten feed, Sweet Bran (Cargill corn milling, Blair, NE), soybean hulls, and glycerin was reviewed. The focus for grain milling byproducts (distillers and gluten feed) was on protein characteristics and use as a protein or an energy supplement and to replace grain in finishing diets. Effects of initial grain used to produce ethanol on distillers grains characteristics was also reviewed. The associative effects of using grain milling byproducts was reviewed to illustrate the important interactions of corn processing, roughage inclusion, and dietary inclusions relative to energy content realized from distillers grains and corn gluten feed. Similar to the seventh Revised Edition of the Beef NRC, a comprehensive feed composition review was conducted. Data were summarized from 3 commercial laboratories that included 170 feeds. Nutrient data on DM, ash, TDN, DE, ME, NEm, NEg, sugar, starch, fat, NDF, ADF, lignin, CP, RDP, RUP, soluble CP, ADIN, and minerals (Ca, P, Mg, K, Cl, S, Co, Cu, I, Fe, Mn, Mo, Se, and Zn) were provided. Considerable effort was made to ensure feeds had proper nomenclature and to avoid duplication by evaluating normal distribution, mean, and SD. Feeds with less than 20 entries were removed from the database. Likewise, nutrient values greater or less than 3.5 SD were removed from the database but only for that nutrient within a particular feed. Once the final data were available, mean, SD, and sample size were calculated and reported, and composition data for these 170 feeds was included in the computer model database. Feed composition data should only be used as a guide in the absence of feed analysis and to indicate which nutrients are variable and may require assay before formulation. These data can also be used to compare analyzed nutrients to a known database. Additionally, grazed forages from different regions were provided from the literature and focused on masticate collections when available. Grazed forage data only include TDN, NDF, and CP but illustrate how season and region can affect grazed forage quality.

Key Words: beef cattle, byproducts, feed composition

1028 The eighth revised edition of the Nutrient Requirements of Beef Cattle: development and evaluation of the mathematical model.

L. O. Tedeschi*[1], M. L. Galyean[2], K. A. Beauchemin[3], J. S. Caton[4], N. A. Cole[5], J. H. Eisemann[6], T. E. Engle[7], G. E. Erickson[8], C. R. Krehbiel[9], and R. P. Lemenager[10], *[1]Texas A&M University, College Station, [2]Texas Tech University, Lubbock, [3]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [4]Department of Animal Sciences, North Dakota State University, Fargo, [5]USDA-ARS Conservation and Production Research Laboratory (retired), Bushland, TX, [6]North Carolina State University, Raleigh, [7]Colorado State University, Fort Collins, [8]University of Nebraska, Lincoln, [9]Oklahoma State University, Stillwater, [10]Purdue University, West Lafayette, IN.*

The beef cattle nutrient requirements model (BCNRM) is a spreadsheet-based computer software program compatible with Microsoft Excel 2007 or earlier versions. The BCNRM contains two levels of solutions (empirical = ELS and mechanistic = MLS) to compute the supply of energy and nutrients to the animal. The calculation of animal requirements for energy and nutrients is the same for ELS and MLS. In the ELS, users can choose to use tabular values for ME and NE or compute NE, ME, and DE from tabular TDN. Methane (CH_4) is computed based on empirical equations that combine animal and dietary chemical information. In contrast, the MLS computes TDN based on: 1) rumen digestibility of five carbohydrate pools (CA = sugars, CB1 = starch, CB2 = pectin, CB3 = available NDF, and CC = unavailable carbohydrate) and three protein pools (PA = NPN, PB = soluble CP, and PC = ADIN), assuming their fractional degradation rates (kd, %/h) and a fractional passage rate (kp, %/h) for each feed; 2) intestinal

digestibilities for CB1, CB2, and PB for each feed; and 3) endogenous matter production for each feed. Then, similar to ELS, NE, ME, and DE are computed from TDN. In the MLS, CH_4 is computed based on the stoichiometric relationship of VFA produced in the rumen. The BCNRM includes an optimizer to assist with diet formulation and balancing, an ability to perform stochastic modeling, and a table generator that allows the user to create tables of nutrient requirements through an optimization procedure. The BCNRM was compared with NRC (1996, 2000) levels of solution 1 (L1) and 2 (L2) using data from 20 experiments (n = 2539 pen-fed animals). For ME-allowable gain, ELS and L1 predictions were nearly identical (r^2 of 0.999, root of mean square error (RMSE) of 0.018 kg/d, and accuracy (Cb) of 0.998). The MLS predictions tended to be greater than L2 predictions by approximately 0.158 kg/d, though there was a strong correlation between them (r^2 of 0.999 and Cb of 0.9). The opposite was observed for MP-allowable gain, and MLS and L2 predictions were nearly identical (r^2 of 0.999, RMSE of 0.023 kg/d, and Cb of 0.998) while ELS and L1 predictions differed by 0.234 kg/d (r^2 of 0.975 and Cb of 0.9). A stochastic simulation (n = 5000) predicted 122 and 97 g CH_4/d for ELS and MLS, respectively, with a 67% prediction overlap.

Key Words: computer, modeling, simulation, spreadsheet

NON-NUTRITION: THE FUTURE OF NUTRITION?

1029 Why the intersection of microbiology and neurobiology matters to animal health: microbial endocrinology as a means to examine the host-microbiota interface. M. Lyte*, *Iowa State University, Ames.*

Microbial endocrinology represents the intersection of two seemingly disparate fields, microbiology and neurobiology, and is based on the shared presence of neurochemicals that are exactly the same in structure in the host as well as in the microorganism. The ability of microorganisms not only to respond to but also to produce many of the same neurochemicals that are produced by the host, such as during periods of stress, has led to the introduction of this evolution-based mechanism that has a role in the pathogenesis of infectious disease as well as the microbiota-gut-brain axis. Production of neurochemicals by microorganisms usually employs the same biosynthetic pathways as those utilized by the host, indicating that acquisition of a neurochemical-based signaling system in the host may have been acquired due to lateral gene transfer from microorganisms. Such recognition of a common shared signaling system suggests that there is a common mechanistic pathway by which the host may interact with the microbiota in a bi-directional fashion influencing aspects of both disease and health. In the case of infectious disease pathogenesis, the consideration of a microbial endocrinology-based mechanism in which infectious bacteria can directly respond to host-derived neurochemicals, such as those present during periods of stress, has demonstrated, for example, that the prevalent use of catecholamine-based synthetic drugs in the clinical setting contributes to the formation of biofilms in indwelling medical devices, leading to increased morbidity and mortality. At the same time, the ability of the microbiota to produce neurochemicals that constitute the host's own neuronal signaling systems means that a common pathway exists for the microbiota to influence host neurophysiology. One of the most prevalent examples by which neurochemical production by microbiota may influence the host's brain and ultimately behavior can be seen with the increasing use of probiotics as a means to influence behavior. Numerous probiotics in current use produce large amounts of neurochemicals, such as GABA, which are known to have well-recognized roles in behavior. That both the host and microorganism produce and respond to the same neurochemicals means that there is bi-directionality contained within the theoretical underpinnings of microbial endocrinology. Such a shared pathway argues for a role of microbiota-neurochemical interactions in animal health.

Key Words: gut endocrinology, microbiome

1030 The gut microbiome as a virtual endocrine organ: implications for host physiology and behavior. G. Clarke*, *University College Cork, Cork, Ireland.*

The gut microbiome exerts a marked influence on multiple aspects of host physiology including not just host metabolism and body composition but also brain function and behavior. This impact relates to its ability to produce or indirectly control a large range of hormonal agents that can play a regulatory role in the activity of local and distal systems and organs. Dysfunction of the hypothalamic–pituitary–adrenal (HPA) axis in particular has been a striking consequence to disrupting the gut microbiota in preclinical studies. The translational relevance of these findings is apparent in stress-related disorders, such as irritable bowel syndrome. Unlike other endocrine organs, however, the gut microbiota exhibits compositional plasticity and can itself be subject to fluctuation as a result of stressors or dietary factors with implications for the associated functionality. This includes stress experienced prenatally, postnatally, and during adulthood. Farm animals regularly encounter a variety of such stressors related to handling practices, weaning, housing systems, and transport that potentially affect welfare and productivity. While optimizing nutrition to promote the gold standard assembly and maturity of the microbiota is one option to counteract the detrimental impact of stress exposure, more targeted interventions may be necessary at various critical points of control across the lifespan. Understanding how best to manipulate the gut microbiota to control host physiological

and behavioral responses could have important implications in multiple settings, including the prevention or treatment of stress-related disorders. Expanding this research to farm animals may pave the way for new strategies to enhance animal health and to meet farm production targets.

Key Words: endocrinology, gut physiology, microbiome

1031 Threats to gut health in production animals.

J. Furness*[1], D. M. Bravo[2], and J. J. Cottrell[3], *[1]University of Melbourne, Parkville, Australia, [2]Pancosma, Geneva, Switzerland, [3]Faculty of Veterinary and Agricultural Sciences, The University of Melbourne, Parkville, Australia.*

Demand for meat protein is steadily increasing due to an expanding population and increasing wealth in populous nations. With finite supplies of arable land under increasing pressure, productivity gains through increased efficiency of animal production are essential for future food security. However, regulations and public opinion have restricted the use of hormone supplements and antibiotics for growth enhancement. There is thus a focus on other non-nutrient additives, including phytonutrients. The gastrointestinal mucosa is a major determinant of feed conversion efficiency, as it represents the first line of defense against enteric pathogens and is susceptible to disruption by events, such as weaning, environmental (notably heat) stress, and infection. Heat stress is increasing with global warning and a shift of agricultural production into tropical regions; in feedlot cattle and in intensive pig faming, it can cause decreases in feed intake and growth, and in extreme cases may result in death. The gut leakiness of heat exposure is associated with oxidative stress in the intestine, which is manifested by compromised glutathione peroxidase activity and increased levels of oxidized glutathione. A further threat to gut health is rapid and early weaning. Rapid weaning is required to maintain breeding productivity and effective herd management. However, it causes stress that is not associated with gradual weaning, which occurs for animals in the wild. The weaning transition in farmed pigs is accompanied by adverse changes in intestinal morphology, including villus atrophy, increased crypt depth, reduced absorptive capacity, and reduced brush border enzyme activity. The weaned animals lose weight, some animals die, and those that lose significant weight lag behind their litter mates in weight gain. In pigs, first litters show greater post-weaning deficits. The third major threat, which is exacerbated by heat or post-weaning stress and by intensification of production, is reduced resistance to enteric pathogens. Intestinal bacterial infections can reduce average growth rates by as much as 40%. The major hormone that promotes mucosal growth and repair is glucagon-like peptide 2 (GLP-2), which is released from L-type enteroendocrine cells. These cells bear receptors that are potential targets for food additives. In addition, a number of phytonutrients and other food additives have antioxidant or mucosal protective qualities, for example cinnamaldehyde and selenium. There is need to further advance understanding of mucosal biology and the actions of non-nutrient additives in production animals to improve gut health, animal health, and productivity.

Key Words: gut health, mucosal integrity, heat stress, weaning, enteritis

1032 The gut microbiome and its role in the development and function of newborn calf gastrointestinal tract.

N. Malmuthuge[1], G. Liang[2], P. J. Griebel[3], and L. L. Guan*[1], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]Vaccine and Infectious Disease Organization, University of Saskatchewan, Saskatoon, SK, Canada.*

Microbial colonization plays important roles in neonatal gut health. However, studies on gut microbial composition and how it can shape host function during early life in ruminants are limited. Here, we report some of our recent efforts in studying host-microbial interactions in neonatal calves focusing on small intestines collected from animals from soon after birth to 6 wk of age. The use of molecular-based approaches revealed extensive colonization of the gut with active microbiota during birth. Composition of the newborn gut microbiota was significantly different from the maternal microbiota in the birth canal and the environmental microbiome. Further differences in diversity were observed between tissue-attached (epimural) and content-associated microbiomes. Epimural communities consisted primarily of *Pseudomonadaceae* and *Propionibacteriaceae*, whereas *Propionibacteriaceae*, *Prevotellaceae*, *Ruminococcaceae*, *and Lachnospiraceae* dominated luminal contents. Within the first week of life, *Veillonellaceae* and *Lachnospiraceae* dominated epimural communities, while *Bacteroidaceae*, *Clostridiaceae*, and *Lactobacillaceae* dominated content communities. Investigation of calf small intestinal transcriptomes using RNA-seq revealed that the expression of immune-related genes at birth was different from three other developmental stages (week 1, 3, & 6) in the jejunum and ileum. The expression of genes related to tight junction proteins, antimicrobial peptides, NOD-like receptors, regulatory T cell markers, and cytokines underwent dynamic changes within the first week of life along with the observed changes in microbiome. This suggests that the first week postpartum is a critical developmental period for the intestinal epithelial barrier, and development of the mucosal immune system may be responding to the changing microbial composition. This conclusion is supported by evidence of strong correlations between expression of mucosal immune-related genes and total bacterial population in different gut regions at different ages. This study provides evidence that the establishment of the small intestinal-specific microbiota begins during

birth, and its composition deviates significantly from the dam's microbiota. This process may be modulated primarily by host selection. The establishment of such "individualized" gut microbiota may be an important regulator of gut tissue and immune function development. Our findings provide fundamental knowledge regarding host-microbial interactions in neonatal calves and may support future development of more effective strategies to improve neonatal gut health.

Key Words: calf, gut health, mucosal immunity

1033 From pre- to post-weaning: the adaptations of the gastrointestinal tract of the young calf.

M. Steele*[1], S. J. Meale[2], K. Wood[3], and G. B. Penner[4], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]INRA, Unité Mixte de Recherches sur les Herbivores, St Genès Champanelle, France, [3]Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, [4]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

The ruminant gastrointestinal tract (GIT) faces the challenge of protecting the host from luminal contents and pathogens while supporting the absorption and metabolism of nutrients for growth. The GIT of the calf in early-life undergoes some of the most rapid microbial and structural changes documented in nature, and it is these adaptations in GIT function that make the young calf susceptible to gastrointestinal disease and disorders. Despite these challenges, the GIT of the calf has a certain degree of plasticity and can sense nutrient supply and respond to bioactive ingredients. For example, the pre-weaned calf can adapt to meal size by altering abomasal emptying as a means of controlling nutrient delivery to the intestine, thereby stabilizing blood metabolites. Despite this plasticity, research has historically focused on the transition during weaning and characterizing ruminal papillae development using microscopy. Through the use of molecular-based approaches, we have recently shown that delaying the age of weaning and providing a step-down weaning protocol is associated with a more gradual shift in ruminal microbiota to a post-weaned state. In addition to ruminal adaptations during weaning, nutrient flow to the lower gut changes dramatically during weaning, coinciding with a wide array of structural and microbiological changes. A study examining structural and gene expression changes suggests that the lower gut of the dairy calf undergoes alterations that may reduce barrier function when solid feeds are consumed. Additionally, a recent in vivo calf study revealed that the weaning transition increases total gut permeability of the calf. Interestingly, some evidence suggests that the upper and lower gut are able to communicate with the forestomach, meaning that a nutrient can be sensed in the lower gut and cause subsequent adaptations in the forestomach. An improved understanding of how diet, microbiota, and functional ingredients interact to impact growth and barrier function of the intestinal tract would greatly benefit the industry. A mechanistic understanding of such adaptations would also aid in the formulation of specific management regimens and provision of the functional ingredients required to support or enhance gut function in young calves.

Key Words: calf, gastrointestinal tract, weaning, functional nutrition

---

1034 Metabolic effects of dietary pungent spices on the gut in animal models.

K. Srinivasan*, *Department of Biochemistry and Nutrition, CSIR-Central Food Technological Research Institute, Mysore, India.*

The beneficial influence of pungent spices was examined in experimental rats on (i) the fluidity of intestinal brush border membrane (BBM), (ii) the activity of intestinal membrane bound enzymes, and (iii) ultrastructural alterations in the intestinal epithelium. Groups of Wistar rats were maintained on dietary black pepper (0.5%), red pepper (3.0%), ginger (0.05%), and spice bioactive compounds—piperine (0.02%) and capsaicin (0.01%)—for 8 wk. A membrane fluidity study using an apolar fluorescent probe showed increased BBM fluidity in all of the spice fed animals. This was corroborated by decreased cholesterol: phospholipid ratio in jejunal and ileal regions of the intestine. These dietary spices stimulated the activities of BBM enzymes—glycyl-glycine dipeptidase, leucine amino peptidase, and γ-glutamyl transpeptidase in jejunal mucosa, suggesting a modulation in membrane dynamics due to the apolar spice bioactive compounds interacting with surrounding lipids and hydrophobic portions in the protein vicinity. Scanning electron microscopy of the intestinal villi in these spice treatments revealed alteration in the ultrastructure, especially an increase in microvilli length and perimeter, which would mean a beneficial increase in the absorptive surface of the small intestine, providing for an increased bioavailability of micronutrients. Thus, dietary spices—black pepper, red pepper, and ginger were evidenced to induce alteration in BBM fluidity and passive permeability property, associated with the induction in the increased microvilli length and perimeter, resulting in an increased absorptive surface of the small intestine. Everted segments of duodenum, jejunum, and ileum portions of small intestines isolated from rats fed piperine, capsaicin, and ginger containing diets for 8 wk were examined for ex vivo uptake of iron, zinc, and calcium from incubations containing digesta of finger millet. A higher uptake of iron, zinc, and calcium by the intestinal segments from spice-fed animals was observed. The increase in the mineral uptake was the highest for calcium with >100%. Higher in vitro absorption of β-carotene in the intestines was evidenced in all spice-fed animals. Dietary piperine and ginger increased the uptake of β-carotene by 147 and 98%, respectively, while increases in absorption were 59 and 27% in black pepper and red pepper fed animals, respectively. An

animal study conducted to evaluate the influence of dietary spice compounds—piperine, capsaicin, and ginger—on the absorption of orally administered β-carotene and its conversion to vitamin A revealed significantly increased β-carotene concentration in the serum, liver, and intestine of piperine and ginger fed rats, suggesting improved absorption of β-carotene. Retinol concentration was not however changed in these animals, suggesting that bioconversion of β-carotene to vitamin A was not similarly influenced. The higher intestinal uptake of iron, zinc, and β-carotene as a result of consumption of pungent spices could encourage a strategy to reduce the deficiency of these micronutrients prevalent in populations dependent on plant-based foods.

Key Words: gut health, nutrient absorption, spices

1035 Phytonutrients as non-nutritive feed additives to enhance growth and host immunity in broiler chickens. H. Lillehoj*[1] and S. Oh[2], [1]*ARS USDA, Beltsville, MD,* [2]*USDA, Beltsville, MD.*

The gut represents a continuously evolving ecosystem where a dynamic interaction between host immune, neuroendocrine, and enteroendocrine cells and the gut microbiota influences normal physiological development and homeostasis. New antibiotic regulatory policies and cage-free rearing systems in poultry production now challenge animal scientists to think outside of the box to develop alternative strategies for sustainable animal agriculture. This presentation will discuss using dietary phytonutrients to enhance poultry growth and modulate innate immunity against enteric pathogens. Phytochemicals are non-nutritive, plant-derived chemicals, many with disease-preventing properties. A growing body of scientific evidence has demonstrated that many of the health-promoting activities of phytochemicals are mediated through their ability to improve host defense against microbial infections and tumors. During the last 10 yr, our research has provided science-based evidence for the beneficial effects of certain phytochemicals in the poultry immune system. Many of these phytonutrients are now commercially used to increase poultry growth and reduce disease-associated losses. Furthermore, our latest study demonstrated that dietary phytonutrients influence the intestinal microbiome through "crosstalk" with the host immune system to maintain gut homeostasis and gut health. These studies collectively suggest that dietary feeding of certain phytonutrients reduces the negative consequences of enteric diseases, in part, through alteration of the gut microbiome.

Key Words: plant extracts, poultry, immunity

1036 Phytonutrients as additives in ruminants: the unexpected target organ. J. Oh[1], E. H. Wall[2], D. M. Bravo[2], and A. N. Hristov*[3], [1]*The Pennsylvania State University, University Park,* [2]*Pancosma, Geneva, Switzerland,* [3]*Department of Animal Science, The Pennsylvania State University, University Park.*

Plants produce an extensive array of organic compounds derived from secondary metabolism that may be useful in animal nutrition because of their chemical makeup. These plant-derived bioactive compounds, also referred to as phytonutrients or phytobiotics, have been shown to express antimicrobial activities against a wide range of bacteria, yeast, and fungi and have been investigated as rumen modifiers in animal nutrition. Reports have concluded that phytonutrients may inhibit deamination of amino acids and methanogenesis in the rumen and shift fermentation toward propionate and butyrate. Responses, however, have been highly variable. Most of the experiments have been conducted in vitro. Although in vitro data are useful for screening purposes, the true value of phytonutrients for altering rumen microbial fermentation and ultimately enhancing animal production must be assessed in vivo and in long-term experiments. Some phytonutrients, due to their phenolic nature, are likely less susceptible to microbial degradation in the rumen and, similar to observations in monogastric species, may exhibit activities postruminally. For example, depending on dose, 15 to 30% of capsaicin from capsicum oleoresin administered intraruminally was estimated to escape ruminal degradation. Thus, phytonutrients, such as garlic, curcumin, and capsicum, which have modulatory effects on both the innate and adaptive immune systems in monogastric animals, may exhibit similar properties in ruminants if protected from ruminal fermentation. This opens a new area of research on the effects of phytonutrients on the immune system, physiology, and health of ruminant animals. Studies with dairy cows have shown that some phytonutrients delivered postruminally increase subtype T cells in peripheral blood (CD4+) related to adaptive immunity. More recent reports indicated that capsicum increased energy-corrected milk yield and facilitated immune cells related to acute phase responses in high-producing dairy cows. In another study with dairy cows, a rumen-protected capsicum product tended to increase milk yield and increased feed efficiency. Increased insulin sensitivity during a glucose tolerance test in that study suggested that capsicum may redirect glucose for lactose synthesis and milk production. Data also suggest that capsicum may be enhancing fat mobilization in early lactation. Further research is needed to elucidate the effect and mode of action of phytonutrients on immune function and animal energetics. Overall, the effects of phytonutrients on immunity, health, and productivity of ruminant animals observed in short-term, crossover studies are encouraging but need to be confirmed in

long-term, production experiments.

Key Words: phytonutrients, postruminal effect, immune response, insulin sensitivity, dairy cow

1037 Non-nutrients in swine health and production.

Y. Liu*, *University of California, Davis.*

Demand for animal proteins in human food consumption is rising globally at an unprecedented rate. Swine products occupy an important position in the structure of animal proteins. Thus, the improvement of swine health in future swine production systems will be critical to increase global food production. A group of health technologies have been applied to powerfully improve swine health and production, including age segregation, all-in/all-out pig flow, biosecurity measures, sanitation, vaccination, and others. In addition, the regular use of antibiotics in pig diets has been proven to improve health and productive performance, as shown by volumes of scientific literature and decades of practical experience. Recently, a novel concept, non-nutrients, was illuminated to describe a group of dietary compounds, which has no nutrient contribution to animals but has physiological activities beyond provision of bioavailable nutrients. Antibiotics are also counted in the category of non-nutrients. Emerging evidence suggested that these non-nutrients provided benefits for animal health and production through different modes of action: regulating nutrient digestibility or absorption and modulating microbial ecology in the digestive tract and/or immune responses. For example, dietary supplementation of artificial sweeteners prevents enteric disorders and enhances the growth and performance of early weaned pigs by increasing the expression of the intestinal glucose transporter SGLT1 and glucose absorption. Different types of exogenous enzymes, such as phytase, xylanases, proteases, etc., may be used in swine diets to improve nutrient digestibility of all stages of pigs when certain endogenous enzymes are insufficient. Interest is growing in the use of probiotics and/or prebiotics to increase the populations of desired microbes in the digestive tract and thereby provide benefits on pig health and performance. They may achieve this goal either by continuously introducing the target microbes into the digestive tract or by providing substances that specifically favor the growth of the target microbes over competitors. Moreover, plant extracts can be additional tools that producers use to keep pigs healthy and reduce the impacts of disease. Dietary supplementation of certain plant extracts may enhance the disease resistance of pigs by improving gut mucosal integrity and optimizing immune response. In the near future, the importance of using non-nutritional dietary components for maintaining pig health will be increased, as such use of antibiotics will be progressively restricted in many countries.

Key Words: health, non-nutrients, pigs

1038 Manipulation of gut morphology and gut immunity in swine using novel, naturally sustainable bioactives.

T. Sweeney*[1] and J. O'Doherty[2], [1]*School of Veterinary Medicine, University College Dublin, Dublin, Ireland,* [2]*School of Agriculture and Food Science, University College Dublin, Dublin, Ireland.*

As health and environmental regulations increase the constraints on the use of in-feed antibiotics and minerals in swine husbandry, the search for novel bioactives from sustainable natural resources increases. A wealth of chemodiversity in nature has arisen from plants and animals developing protective molecules to survive in varying complex biosystems. Many of these molecules have anti-inflammatory, antimicrobial, and/or antioxidant properties, which help the host to survive a wide spectrum of environmental challenges. We hypothesize that these non-nutritive molecules can be used in the diet to support the developing gastrointestinal tract of the piglet. The mammalian gastrointestinal tract is a dynamic environment, where a symbiotic relationship exists between the immune system, the resident microbiota, and the digestive system. The development of the immune system begins in-utero and is further developed following the colonization of the GIT with microbiota during birth and postnatal life. The early establishment of this relationship is fundamental to the development and long-term maintenance of gut homeostasis, with unfavorable alterations in the composition of the microbiota, known as dysbiosis, being implicated in many conditions. The weaning period of the piglet under modern husbandry conditions is very prone to dysbiosis in the gastrointestinal tract, resulting in a period of post-weaning diarrhea. It involves complex dietary, social, and environmental stresses that interfere with gut development and is characterized by a reduction in feed intake and growth, atrophy of small intestine architecture, up-regulation of intestinal inflammatory cytokines, alterations in GIT microflora, diarrhea, and heightened susceptibility to infection. In this review, we discuss advances in our understanding of the immune mechanisms by which the dynamic interplay of the intestinal microbiota and its host normally favors a homeostatic, symbiotic relationship, and how feeding novel, naturally sustainable bioactives from marine flora and fauna and milk can be utilized to support this symbiotic relationship in times of challenge. The overall aim of our research program is to provide dietary support to ensure an appropriate level of immune reactivity in the gut to accommodate the presence of beneficial and dietary microorganisms, while allowing effective immune/inflammatory responses to clear pathogens. A variety of natural sustainable bioactives has been identified that target different components of the gastrointestinal tract environment. Modes of action vary from commensal microbial stimulants, targeted antimicrobial activity, gut barrier repair, mucosal structure (villous architecture, absorptive capacity, nutrient transporters), and mucosal anti-inflammatory

activity. Interestingly, ingestion of combinations of these bioactives can enhance bioavailability lower down in the colon.

PHYSIOLOGY AND ENDOCRINOLOGY

1039 WS Influence of sampling location and pregnancy on composition of the microbiome associated with the reproductive tract of the ewe.

K. E. Smith*, A. L. Garza, C. Robinson, R. L. Ashley, and S. L. Ivey, *New Mexico State University, Las Cruces*.

The objective of this study was to investigate the microbiome of the vagina, uterus, and embryo and determine the effects of pregnancy status and a maternal pregnancy recognition antagonist treatment. We hypothesized that location, pregnancy status, and maternal pregnancy recognition antagonist treatment would result in significant differences in the bacterial microbiome of the reproductive tract in sheep. Mini osmotic pumps were placed surgically into the uterus and loaded with control (PBS, $n = 9$) or treatment (AMD3100, $n = 7$). AMD3100 is an antagonist for maternal pregnancy recognition. Samples were collected for microbiome analysis from the vagina, uterus, and embryo. AMD3100 and PBS had no effect on microbiome composition ($P > 0.98$). Sampling location had the greatest effect on bacterial population ($P > 0.01$). *Firmicutes*, *Proteobacteria*, and *Actinobacteria* were the most predominant phyla ($P < 0.01$) present in the vagina while *Proteobacteria*, *Firmicutes*, and *Actinobacteria* were present in the uterus ($P < 0.01$). The genus of bacteria present in the uterus and vagina supported the phylum data. *Corynebacterium* was more prevalent than *Finegoldia* in the vagina ($P < 0.01$), while the prevailing genus in the uterus was *Bradyrhizobium* ($P < 0.01$). The pregnancy status of ewes did not differ by phylum; however, the genus *Finegoldia* was greatest in nonpregnant ewes ($P < 0.01$). Treatment effects were not observed on embryo microbiome phylum ($P < 0.90$) or genus ($P < 0.88$). Results show further research is needed to understand the relationship between the reproductive tract microbiome and ewe fertility.

Key Words: metagenome, sheep, uterus, vagina

1040 Use of doppler ultrasound and infrared thermography to evaluate scrotal insulation in Braford bulls.

F. A. Barca Junior[1], C. Koetz Junior[*1], G. R. Pereira[2], S. R. Menegassi[2], F. Morotti[3], J . O. Barcellos[2], L. A. Claus[3], and M. M. Seneda[3], *[1]UNOPAR, Arapongas, Brazil, [2]NESPRO/UFRGS-Federal University of Rio Grande do Sul, Porto Alegre, Brazil, [3]UEL- Universidade Estadual de Londrina, Londrina, Brazil.*

The objective of this study was to evaluate the flow dynamics of scrotal surface temperature (SST) by infrared thermography in Braford bulls submitted to scrotal insulation. In addition, bulls were also evaluated for velocity parameters (V), pulsatility index (PI), and resistance index (RI) using Doppler ultrasound. All procedures were approved by the Ethical Committee for Care and Use of Experimental Animals (Project 19656/2014/58, CEUA/UEL). All animals had a breeding soundness examination at the beginning of the experiment. Eight Braford bulls were used at the age of 18 mo and randomly divided into four different groups, as follows: the control group not subjected to insulation (CON; $n = 2$), scrotal insulated bulls for 72 h (G72, $n = 2$), scrotal insulated bulls for 96 h (G96, $n = 2$), and scrotal insulated bulls for 120 h (G120, $n = 2$). Infrared thermography and Doppler data were collected at four different periods: after removal of scrotal insulation (M0), 10 min after removal of scrotal insulation (M10), 30 min after removal of scrotal insulation (M30), and 60 min after removal of scrotal insulation (M60). Data were analyzed using ANOVA, *t* test (paired), and Pearson correlation with a significance level of 5%. No differences were observed between insulated treated groups. Rectal temperature (38.5 ± 0.4) was higher compared to scrotal surface (32.7 ± 0.8; $P < 0.05$). Scrotal insulated animals showed higher testicular temperature at M0 (33.0 ± 0.7) compared to M10, M30, and M60 periods (30.2 ± 1.3, 31.6 ± 1.5, 30.6 ± 1.0, respectively; $P < 0.05$). We observed no difference in PI and RI indexes between evaluation periods after scrotal insulation. However, blood flow velocity (cm/sec) showed differences between M10 (17.1 ± 4.22) compared to the M0, M30, and M60 periods (12.5 ± 5.1, 14.3 ± 4.5, 14.3 ± 2.9, respectively; $P < 0.05$). A positive correlation (93.1%) was observed between PI and RI ($P < 0.05$) variables. The scrotal insulation changes the temperature and the blood flow velocity; however, after 60 min of insulation, these parameters are already reestablished. We conclude that Doppler ultrasound can be used to evaluate scrotal blood flow variations during scrotal heat stress induction in Braford bulls.

Key Words: Doppler ultrasonography, infrared thermography, scrotal insulation

1041 Diurnal vaginal temperature cycles of Senepol and crossbred beef heifers with different hair coat types and colors under tropical conditions.

H. L. Sánchez-Rodríguez*[1], Z. Contreras-Correa[1], K. Domenech-Pérez[2], G. Rivera-Collazo[2], A. Casas-Guérnica[1], and G. Muñiz-Colón[1], *[1]University of Puerto Rico, Mayagüez Campus, Mayagüez, Puerto Rico, [2]University of Nebraska, Lincoln, Lincoln.*

This study evaluated the influence of hair coat type and color on vaginal temperature (VT) regulation of beef heifers. The VT was recorded in five slick haired, red colored Senepol (SENEPOL); six slick haired, light colored crossbred (SLICK); and four wild-type long haired, light colored crossbred (REGULAR) heifers, every 5 min for four consecutive days. Crossbred heifers were obtained from Charbray × Senepol × Charolais crosses. Air temperature and relative humidity were recorded in synchrony with VT, and the thermal humidity index (THI) was determined. Heifers were kept in a large paddock with access to natural shade. After averaged by hour, data were analyzed by the GLIMMIX and CORR procedures of SAS. To study the possible lag time in the relationship between the THI and the TV, the correlations were performed taking into consideration the THI recorded previous to the VT in 1-hour intervals (from 1 to 24 h earlier). Hair type-color interacted with the time of day to affect VT, with REGULAR heifers presenting greater VT values than SLICK and SENEPOL from 2200 to 2400 h (39.33 ± 0.03, 38.84 ± 0.01, and 38.74 ± 0.02°C, respectively). During the remaining daily time period (0100 to 2100 h), similar VT values were observed in the REGULAR, SLICK, and SENEPOL heifers (38.75 ± 0.01, 38.62 ± 0.01, and 38.51 ± 0.01°C, respectively; $P > 0.05$). The greatest positive correlations between THI and VT were obtained when evaluating the THI value from 7 h earlier in SENEPOL ($r = 0.25$; $P < 0.0001$) and SLICK ($r = 0.30$; $P < 0.0001$) and from 8 h earlier in REGULAR ($r = 0.32$; $P < 0.0001$) heifers. Regardless of coat color, the slick hair phenotype allowed heifers to minimize their daily increase in body temperature in comparison with their long haired counterparts. We suggest introducing genes for the slick phenotype of the Senepol into other Puerto Rican beef breeds as a means of reducing the negative impact of heat stress.

Key Words: coat color, slick hair, vaginal temperature

1042 Associations between the environmental conditions and vaginal temperature in wild-type and slick-haired Puerto Rican Holstein cows.

H. L. Sánchez-Rodríguez*[1], Z. Contreras-Correa[1], M. Pagán-Morales[2], J. Curbelo-Rodríguez[1], A. Mesonero-Morales[1], C. Cabrera-Cabrera[3], and G. Muñiz-Colón[1], *[1]University of Puerto Rico, Mayagüez Campus, Mayagüez, Puerto Rico, [2]Department of Animal Science, University of Puerto Rico, Mayaguez Campus, Mayaguez, Puerto Rico, [3]Universidad ISA, Santiago, Dominican Republic.*

The physical barrier created by the hair coat between the skin and the environment has been reported to reduce heat dissipation in wild-type-haired (WT) *Bos taurus* cattle exposed to hot and humid weather. However, slick-haired (SLICK) cattle have demonstrated the ability to maintain lower body temperatures under similar conditions. Thus, the present study aimed to evaluate if the air temperature (AT), relative humidity (RH), thermal humidity index (THI), solar radiation (SR), wind speed (WS), and gust speed (GS) have a different relationship with vaginal temperature (VT) in Holstein cows with different hair coat types during the summer in Puerto Rico. Twenty-four lactating cows [11 WT; 176.31 ± 32.65 d in milk (DIM); 2.06 ± 1.44 lactations and 13 SLICK; 175.62 ± 42.78 DIM; 2.19 ± 0.96 lactations] were evaluated. The WT and SLICK classifications were confirmed in previous genotyping studies. Data loggers (Onset Computer Corporation, Bourne, MA, USA) recorded environmental variables as well as VT values in synchrony every 5 min for 7 consecutive days. After averaged by hour, data were analyzed by the GLIMMIX procedure of SAS. The CORR procedure of SAS was used to analyze the data collected every 5 min. Time and hair type interacted ($P = 0.0026$) to affect VT. From 1800 to 0700 h and from 0900 to 1600 h, the WT cows presented, on average, 0.31°C greater VT values than their SLICK counterparts ($P = 0.0032$). During the 0800 h ($P = 0.0584$) and 1700 h ($P = 0.0619$) VT values tended to be, on average, 0.20°C greater in WT than in SLICK cows. In WT cows VT was correlated with AT ($r = 0.43$; $P < 0.0001$), RH ($r = –0.38$; $P < 0.0001$), THI ($r = 0.45$; $P < 0.0001$), SR ($r = 0.16$; $P < 0.0001$), WS ($r = 0.38$; $P < 0.0001$), and GS ($r = 0.38$; $P < 0.0001$). In the SLICK group, greater correlation coefficients were obtained between VT and AT ($r = 0.50$; $P < 0.0001$), RH ($r = -0.44$; $P < 0.0001$), THI ($r = 0.53$; $P < 0.0001$), SR ($r = 0.24$; $P < 0.0001$), WS ($r = 0.46$; $P < 0.0001$), and GS ($r = 0.46$; $P < 0.0001$). Our results suggest that the slick-haired phenotype allows cows to have a more direct relationship between their skin and the environment, providing for greater heat dissipation and a lower body temperature.

Key Words: heat stress, slick-haired, vaginal temperature

1043 Impact of heat stress and metabolic endotoxemia on porcine ovarian function. M. J. Dickson*, K. L. Bidne, B. J. Hale, C. L. Hager, J. T. Seibert, L. H. Baumgard, J. W. Ross, and A. F. Keating, *Iowa State University, Ames.*

Heat stress (HS) results from an imbalance of thermal energy, and economic losses due to HS cost the U.S. swine industry approximately $900 million annually. HS negatively influences a variety of parameters affecting reproduction: spontaneous abortion, longer wean-to-estrus interval, delayed puberty, reduced litter size, and total number born, all of which culminate in seasonal infertility. Additionally, HS compromises intestinal integrity ultimately leading to metabolic endotoxemia (ME) and increased systemic lipopolysaccharide (LPS), an endotoxin originating from the cell wall of gram-negative bacteria. Toll-like receptor 4 (TLR4) is a membrane bound receptor protein that binds LPS, initiating a signaling cascade that involves phosphorylated nuclear factor kappa B (pNFκB) and pro-inflammatory cytokine release. Acyloxyacyl hydrolase (AOAH) cleaves the lipid A moiety from LPS and is thereby involved in LPS detoxification. We hypothesized that ME contributes to seasonal infertility in swine. The study objectives were to characterize the impact of HS and ME on ovarian function. Twelve post-pubertal gilts (126.0 ± 21.6 kg) were synchronized for 14 d by orally administering Matrix® to ensure that gilts were heat-stressed during the follicular phase of the estrous cycle. Immediately after Matrix® withdrawal, gilts were split in two groups ($n = 6$) and exposed to cyclical HS or thermal neutral (TN) conditions for 5 d and then sacrificed. Gilts were exposed to either constant TN conditions (20.3 ± 0.5°C) or cyclical HS (25.4– 31.9°C) to imitate a diurnal heat load pattern. Ovaries were collected at the end of the experimental period and TLR4, pNFκB, and AOAH protein abundance were quantified in whole ovarian lysate. Relative to TN ovaries, HS increased ($P < 0.05$) TLR4 (16%) and pNFκB (11%) protein abundance. There was no difference in AOAH abundance ($P > 0.05$) between TN and HS ovaries. This data suggests that the ovary is responsive to ME and that HS can induce a pro-inflammatory environment in the ovary, which could contribute to compromised fecundity in heat-stressed swine. This work was supported by the National Pork Board.

Key Words: heat stress, immune function, ovary

1044 Heat stress induces distinct lipidomic profile in differentiating porcine adipocytes. H. Qu[1] and K. M. Ajuwon*[2], *[1]Purdue University, West Lafayette, IN, [2]Department of Animal Sciences, Purdue University, West Lafayette, IN.*

Heat stress results in enhanced lipid deposition in pigs. However, the effects of heat stress (HS) on adipocyte lipidome and metabolome are largely unknown. Understanding the effects of heat stress on the lipid profile will increase understanding of heat stress sensing and signaling mechanisms. To study this, we applied a combination of liquid chromatography-mass spectrometry (LC-MS) based metabolomic and lipidomic profiling approaches to identify and characterize the lipid classes in differentiating pig adipocytes. Porcine preadipocyte (stromovascular cells) were differentiated either under control (37°C) or HS (41.5°C) temperature conditions for 9 d. HS increased triglycerides and decreased monoacylglycerols ($P < 0.05$) accumulation. HS also increased concentrations of glycerophosphocholines, glycerophosphoserines, glycerophosphoglycerols, and glycerophosphoinositols than in control ($P < 0.05$). The specific lipidomic signatures in HS indicates that metabolic pathways centered around diacylglycerol (DAG) metabolism may be impacted by HS in pig adipocytes, perhaps as part of an adaptive mechanism. The observed changes in phospholipid composition may help to regulate cellular metabolism, membrane characteristics, and signal transduction pathways for enhanced adaptation to HS. Overall lipidomic analysis revealed that HS induces a unique lipidomic profile in adipocytes.

Key Words: pig adipocytes lipidomics LC-MS

1045 Impact of temperature fluctuations in cooled-fresh semen on fertility of lactating dairy cows. A. H. Souza*[1], H. J. Bessoff[2], and E. Danzeisen[3], *[1]Ceva Animal Health, Libourne, France, [2]Dairy Management Solutions, Tulare, CA, [3]Global AG Alliance, Tulare, CA.*

The objective of this study was to evaluate whether deviations from ideal semen storage temperature of cooled-fresh semen could affect conception results (CR) in lactating dairy cows. A temperature recording system (LogTag® analyzer, Trix8 data logger model) was placed in the semen shipping-container from its initial shipping to the dairy (located in the Central California Valley) and continuously until breeding time. Temperature was recorded for breedings that took place from June 2015 to December 2015 at every 30 s interval with a 0.01°C of accuracy. Ideal storage temperature for fresh semen was assumed to be from 1.7 to 7.2°C. Then, the cumulative amount of time within the 24 h before AI in which semen temperature deviated to below the lower limit and/or above the high temperature limit was utilized in the Glimmix (SAS 9.3) logistic model to evaluate the impact of temperature fluctuations on

CR. A total of 2306 AI records were available for CR analysis. Variables considered in the logistic regression model were herd, parity number of the cow, days in milk at AI, year-month of AI, service sire, AI technician, temperature deviations from below and above ideal limits, and cow-within herd, which was included in the model as a random variable. As expected, most deviations from ideal storage temperature were due to above threshold temperature faults; and those were more common in summer months, particularly during months of June and August, occurring more commonly from 8AM to 1PM. Interestingly, semen storage deviations to above temperature limits appeared to have less impact ($P > 0.10$) on CR than when temperature deviated to below the lower limits ($P = 0.03$). As a result, CR was 36.2% when the temperature deviated less than 5% of the daily time above the temperature threshold limit and had a nonsignificant minor decrease to 35.1% when temperature deviated over 20% of the daily time above the upper temperature limits. In contrast, CR significantly decreased from 35.8% when semen deviated less than 5% of the time toward below lower temperature limits, to 31.3% when temperature deviated more than 20% of the daily time to below the lower temperature limit. In conclusion, it appears that exposing cooled-fresh semen to colder temperatures below 1.7°C was more detrimental to the fertility of dairy cows.

Key Words: fresh semen, storage temperature, fertility

1046 Effects of a 48 h feed withdrawal on intraperitoneal core body temperature in growing pigs. J. S. Johnson*[1], N. M. Chapel[2], and C. J. Byrd[2], *[1]USDA-ARS Livestock Behavior Research Unit, West Lafayette, IN, [2]Purdue University, West Lafayette, IN.*

In response to increasing ambient temperatures, pigs often reduce their feed intake (FI) to decrease metabolic heat production and maintain euthermia. Although the effects of reduced FI on swine body composition, metabolism, growth rate, and reproductive parameters are well-documented, little is known regarding the direct effects of feed withdrawal on core body temperature response. Therefore, the study objective was to determine the effects of a 48 h feed withdrawal on the intraperitoneal core body temperature response in growing pigs. Eight barrows (35.9 ± 1.9 kg BW) were housed in TN conditions (22.30 ± 0.22°C) and exposed to four 24 h periods: 1) PT (pre-treatment ad libitum feeding), 2) FW1 (1–24 h feed withdrawal), 3) FW2 (25–48 h feed withdrawal), and 4) RF (ad libitum re-feeding). Barrows were used in an effort to reduce the body temperature variability associated with gonadal steroid production. Intraperitoneal core body temperature (T_{core}) was recorded in 10 min intervals using implanted Thermochron temperature recorders. Data were analyzed using the PROC MIXED procedure in SAS 9.4. Overall, T_{core} was reduced ($P < 0.01$) during FW1 (40.30°C) and FW2 (40.28°C) compared to PT (40.59°C) and RF (40.60°C), but no differences were observed between the FW1 and FW2 or the PT and RF periods. Minimum T_{core} was reduced ($P < 0.01$) during FW1 (39.86°C) and FW2 (39.81°C) compared to PT (40.34°C) and RF (40.28°C), but no differences were observed comparing the FW1 and FW2 or the PT and RF periods. No maximum T_{core} period differences ($P = 0.32$) were observed. During FW1, a linear reduction ($P < 0.01$; −0.03°C/h) from maximum (h1) to minimum (h21) T_{core} was observed. Between h 24 of the FW2 period and h 1 of the RF period, T_{core} was linearly increased ($P < 0.01$) by 0.66°C. Feed withdrawal increased ($P < 0.01$) the T_{core} variance and range during FW1 (0.07 and 0.96°C, respectively) and FW2 (0.07 and 0.90°C, respectively) compared to the PT period (0.02 and 0.50°C, respectively) and during the FW1 compared to the RF period (0.02 and 0.69°C, respectively). No T_{core} variance or range differences were detected between the PT and RF periods or the FW1 and RF periods. In summary, a 48 h feed withdrawal directly reduced T_{core} in growing pigs, and this T_{core} reduction recovered within the first hour of re-feeding.

Key Words: pigs, feed withdrawal, core body temperature

1047 The effect of exercise on heat tolerance and first lactation in pregnant Holstein heifers. J. Johnson*, P. L. Steichen, and T. G. Rozell, *Kansas State University, Manhattan.*

A primary source of stress for dairy cattle is associated with the environment, particularly heat, and therefore a considerable amount of research has been done in an attempt to find ways of reducing heat stress. Exercise improves heat regulation in humans and horses; thus, the objectives of this study were to determine if an exercise regimen could improve thermo-tolerance and subsequent milk production during the hot part of the summer in Kansas. Pregnant Holstein heifers ($n = 24$) were randomly assigned to 2 treatment groups: exercise (EX; $n = 12$), and exercise-control (EC; $n = 12$; walked with exercise heifers to exerciser but held in a holding pen). An exercise regimen was implemented through May and June, 4 d per wk in the afternoon for approximately 30–45 min using a motorized 8-panel walker. Data were collected on fitness test d 0, 28, and 56 of the experiment in which heifers were exercised for 23 min, 10 of which were spent at a greater intensity (5.63 KPH). Intra-vaginal temperature, skin temperature, respiration rates, and heart rate were recorded. Weekly measurements of skin temperature, respiration rates, and rectal temperatures were also recorded and post-parturition milk production and milk components were determined. All data were analyzed using PROC MIXED. Respiration rates and heart rates were not affected by exercise treatment on fitness test days or during weekly measurements ($P > 0.10$). Time spent in body temperature zone 3 (> 40.0°C) during the 23-min fitness test and 1 h following fitness test tended to be greater for EC than EX (87% vs. 76%; $P < 0.10$). Average

body temperature of the hour following fitness tests was significantly less in EX than EC (40.48°C vs. 40.83°C; $P < 0.05$) on d 28. On fitness test Day 28, EX heifers tended to have reduced skin temperatures at the thurl post-exercise compared with EC ($P < 0.10$). Exercised heifers had reduced skin temperatures of the cheek, withers, and thurl compared with EC during week 7 ($P < 0.05$). Exercise resulted in greater milk protein % and solids-not-fat % ($P < 0.05$) compared with EC, but there was no difference in monthly milk production in the first 150 d of lactation ($P > 0.10$). These results indicate that exercise in pregnant dairy heifers may improve heat tolerance, and improve milk quality during first lactation.

Key Words: exercise, heat tolerance, milk quality

1048 Effect of exercise on ovarian function in cycling gilts.

A. M. Mesa*[1], A. M. Adkin[1], A. L. Dias[2], D. Y. Kim[3], P. J. Hansen[1], C. J. Mortensen[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]University of Alberta, Edmonton, AB, Canada, [3]Gachon University, Gyeonggi-do, Korea, The Republic of*

Exercise can alter reproductive function in the mare. To identify this phenomenon in other species, the effects of daily exercise on ovarian function was evaluated in cycling gilts. A total of 18 gilts (mean age = 225 ± 8.3 d) were treated orally with a synthetic progestin, and subsequently injected with a gonadotropin to synchronize estrous cycles. Gilts were then trained to follow a target and run voluntarily along an 80 m track. Thereafter, gilts were randomly assigned to either an exercise or control group. Exercised pigs were worked twice daily for 6 min each period, during the last 10 d of the estrous cycle. Each exercise period consisted of an average distance of 0.25 km at an average speed of 6.0 km/h. Rectal temperatures increased from values of 38.5 ± 0.3°C at rest to a mean of 38.8 ± 0.4°C immediately after exercise ($P < 0.05$). Respiration rates also increased from 30.8 ± 3.5 to 59.7 ± 12.6 breaths/min ($P < 0.05$). Cortisol was measured in saliva the day before the exercise protocol started and 5 and 9 d later. Cortisol concentrations were higher ($P < 0.05$) in exercised pigs at 5 and 9 d compared to controls. Gilts were slaughtered 2 d after the onset of estrus and reproductive organs were collected. No differences were found among treatments in the total number of follicles, corpus hemorragica, or corpora lutea. Exercised gilts had more medium (18.5 vs. 7.6; $P < 0.01$) and small (24.6 vs. 20.1; $P < 0.05$) sized follicles compared to control gilts. Cumulus-oocyte complexes were aspirated from small follicles (< 2 mm in diameter), medium follicles (3–6 mm) and large follicles (> 6 mm) and classified by quality based on a qualitative scale considering the number of layers of compact cumulus cells and ooplasm homogeneity. However, there were no effects of treatment on oocyte complex quality. Data indicated that exercise of pigs is associated with a stress response and can influence ovarian follicle development.

Keywords: exercise, follicular development, stress

1049 The effect of exogenous glucose infusion on early embryonic development in lactating dairy cows.

S. Leane*[1,2], M. M. Herlihy[1], N. Forde[3], M. C. Lucy[4], P. Lonergan[5], S. Butler[1], *[1]Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Co. Cork, Ireland, [2]School of Agriculture and Food Science, University College Dublin, Dublin, Ireland, [3]University of Leeds, Leeds, United Kingdom, [4]University of Missouri, Columbia, MO, [5]School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland*

The objective of this study was to examine the effect of glucose infusion in late lactation (276 ± 17.3 d in milk) dairy cows on early embryonic development. Estrous cycles were synchronized using a progesterone ovsynch protocol ($n = 12$ cows). On Day 7 after synchronized estrus, cows were randomly assigned to either intravenous glucose infusion (750 g/d; 78 mL/h of 40% glucose, GLUC) or intravenous saline infusion (78 mL/h of 0.9% saline solution, CTRL) for 7 d ($n = 6$/treatment). In vitro produced Day 7 blastocysts (15 per cow) were transferred into all cows on Day 7 of the estrous cycle at the same time as the infusion commenced. Blood samples were collected at 0600 and 1800 every day for glucose, NEFA, BHB and progesterone determination, and transrectal ultrasound was used to measure corpus luteum (CL) volume every second day. All cows were slaughtered on Day 14. Reproductive tracts were recovered and flushed with phosphate-buffered saline containing 5% FCS. The number and dimensions (length and width) of recovered embryos were recorded. Endometrial tissue was dissected and snap frozen for later determination of mRNA abundance of glucose transporters (GRT3, GTR8, SLC2A1, SLC2A3, SLC35A4 and SLC5A1) using qPCR. There was no effect of treatment on milk yield (14.1 ± 1.3 vs. 14.7 ± 1.3 kg/d) or dry matter intake (15.0 ± 1.6 vs. 14.4 ± 0.8 kg/d). Glucose infusion increased mean (± SE) circulating glucose concentration (4.7 vs. 4.15 ± 0.1 mmol/l, $P < 0.001$) and reduced circulating BHB concentration (0.51 vs. 0.70 ± 0.01; $P < 0.001$); plasma NEFA concentrations were not affected (0.13 vs. 0.14 ± 0.01). Mean circulating progesterone concentration (6.8 vs. 6.8 ± 1.0 ng/ml) and CL volume were not affected by treatment. There were no effects of treatment on either uterine lumen fluid glucose concentration or mRNA abundance of glucose transporters. Embryo development was decreased in the GLUC cows compared with CTRL cows (length: 11.5 vs. 18.3 ± 3.05 mm; width: 1.3 vs. 1.7 ± 0.15 mm; area: 15.0 vs. 28.7 ± 3.5 mm^2, all $P < 0.05$). A greater proportion of embryos recovered from CTRL cows had elongated to ≥ 16mm in length compared with GLUC cows (0.16 vs. 0.51 ± 0.12; $P = 0.07$).

These results indicate that increasing circulating glucose concentration during the period of conceptus elongation before maternal recognition of pregnancy had an adverse effect on early embryonic development.

Key Words: embryo development, endometrium, glucose

1050 Influence of cattle temperament on blood serum fatty acid content. T. Gardner[*1], J. F. Legako[1], N. C. Burdick Sanchez[2], P. R. Broadway[2], J. A. Carroll[2], R. C. Vann[3], *[1]Utah State University, Logan, UT, [2]Livestock Issues Research Unit, USDA-ARS, Lubbock, TX, [3]MAFES-Brown Loam, Mississippi State University, Raymond, MS*

Cattle temperament has been reported to influence blood metabolites. Specifically, temperament was related with increased circulation of serum NEFA, decreased blood urea nitrogen, and reduced insulin sensitivity. Metabolic alterations such as these may impact cattle immune function, performance traits, carcass traits, and meat tenderness. Presently, little work has been performed to determine the impacts of temperament on fatty acid content within blood serum. For this study blood and resulting serum was obtained from Angus-cross steers ($n = 31$; 216 ± 6 kg BW), previously assessed to be Temperamental ($n = 15$) or Calm ($n = 16$). Temperament score was calculated as an average of exit velocity and pen score measured at weaning. Serum fatty acid content (mg/mL) was determined via gas chromatography and flame ionization detection. Serum from Temperamental steers contained greater ($P \leq 0.050$) concentrations of linoleic (18:2 n-6; 2.56 mg/mL), α-linolenic (18:3 n-3; 0.34 mg/mL), dihomo-γ-linolenic (20:3 n-6; 0.12 mg/mL), and eicosapentanoic acid (20:5 n-3; 0.26 mg/mL) compared with Calm steers (2.02, 0.25, 0.09, and 0.21 mg/mL, respectively). Furthermore, serum cumulative PUFA of Temperamental steers (4.47 mg/mL) was greater ($P = 0.003$) than Calm steers (3.69 mg/mL). Previous work in other fields of study have used PUFA as markers for stress responsiveness and inflammation in tissues. In agreement with those previous studies, markers of stress and inflammation were related with an increase in overall PUFA concentration in blood in the present study. These findings add to the current body of work regarding cattle temperament and associated alterations of metabolic components. It is not clear if elevated blood PUFA are directly impacting cattle immunity, performance, carcass traits, and/or meat quality among temperamental cattle. However, it is widely known that alteration of fatty acid composition in the final product has numerous organoleptic impacts. Future research is required to determine if circulating lipids in blood ultimately impact overall meat quality.

Key Words: blood metabolites, cattle, fatty acids, PUFA, temperament

1051 Effects of intrammamary LPS infusions on inflammation and reproductive parameters of dairy cows. C. C. Campos[*1], A. C. C. Fernandes[2], I. Hartling[3], M. Kaur[2], R. M. Dos Santos[4], R. L. A. Cerri[3], *[1]FAMEV-UFU, Uberlândia, Brazil, [2]Faculty of Land and Food Systems- University of British Columbia, Vancouver, BC, Canada, [3]Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada, [4]Universidade Federal de Uberlândia, Uberlândia, Brazil*

The objective was to determine the effects of LPS induced mastitis on systemic inflammatory response and early embryo development in lactating Holstein cows. Cows at 35 ± 7 DIM ($n = 20$) were submitted to a modified Double-Ovsynch program (10 d interval between protocols with CIDR and two PGF injections in the second protocol) and timed AI (d0). Cows were randomly assigned (block design) to two treatments: 1) LPS group- cows received an intrammamary infusions (d5 and d10) of 25 μg of LPS (strain 0111:B4) diluted in 10 mL of sterile saline at morning milkings; and 2) Control group- cows received infusion with saline. Blood samples were taken at different time intervals during the study to determine plasmatic concentrations of haptoglobin (Hp), tumoral necrosis factor α (TNF-α) and progesterone (P_4). Milk samples were collected every 2 d for somatic cell count (SCC) and body temperature was recorded using a rumen-reticular bolus logger and summarized for every hour during the period. On Day 15 after AI, uterine flushing for embryo recover and interferon-tau (IFN-τ) measurement, as well as endometrium biopsy were performed. Data were analyzed using the MIXED procedure of SAS. Hp was greater in LPS compared with Control group (0.80 ± 0.06 vs. 0.45 ± 0.07; $P < 0.01$), but TNF-α concentration was similar ($P = 0.72$) between treatments. Milk production from d0 to d15 was greater for Control cows (37.5 ± 1.5 vs. 33.5 ± 1.3 kg/d; $P < 0.01$), whereas SCC was higher in LPS treated cows for about 48 h after each infusion ($P < 0.01$). Likewise, reticular temperature of LPS cows was elevated for 12 h ($P < 0.01$) after each infusion. Progesterone did not differ among treatments at all time collections ($P = 0.72$). However, pregnant cows had greater concentrations of progesterone on d 6, 9, and 10 post-AI ($P < 0.01$). The recovery rate was 55% and the length of recovered embryos (3.6 ± 0.9 vs. 2.4 ± 0.7 cm; $P = 0.56$) and IFN-τ concentration in the luminal uterine flushing ($P = 0.44$) were similar between treatments. In summary, the intrammamary infusion of LPS was able to trigger a systemic inflammatory response during post-AI period, but unable affect conceptus recovery and length, and intraluminal uterine IFN-t concentration.

Key Words: embryo development, inflammation, LPS, mastitis

1052 Relationships of calf vigor at birth with calf size and circulating metabolites in fall-born beef calves. J. M. Larson*[1], B. L. Vander Ley[2], A. M. Meyer[1], [1]*Division of Animal Sciences, University of Missouri, Columbia, MO,* [2]*Department of Veterinary Medicine and Surgery, University of Missouri, Columbia, MO*

To evaluate the relationship of neonatal calf vigor with calf size and circulating metabolites, 66 beef cows and heifers (average age = 4.4 ± 0.5 yr; average BCS = 5.2 ± 0.1; average calving date = September 11, 2015) were monitored during calving. Calf time to stand was determined from the time of birth until the time the calf successfully stood for 5 consecutive seconds (n = 30). Gestation length, birth weight, and body measurements (crown to rump length, shoulder to rump length, heart girth, abdominal girth, and cannon bone circumference) were measured. Jugular blood samples were obtained from 8 bull and 16 heifer calves from this subset at 0, 6, 12, 24, 48, and 72 h postnatally for plasma glucose and serum blood urea nitrogen (BUN), NEFA, albumin, total protein, and globulin analysis. Serum fructose was determined in 0 h samples only. Samples at 0 h were obtained before colostrum intake but after standing. Correlations were determined between time to stand (min) and all neonatal parameters. Birth weight had a moderate positive correlation (P = 0.01) with time to stand. Crown to rump length, shoulder to rump length, abdominal girth, and heart girth tended to have a weak positive correlation ($P \leq 0.11$) with time to stand. Gestation length and cannon bone circumference were not correlated ($P \geq 0.33$) with time to stand, and calf sex did not affect (P = 0.39) calf vigor. Time to stand had a moderate negative correlation with serum NEFA at 24 h (P = 0.04) and 72 h (P = 0.07). Circulating albumin at 0 h tended to have a moderate negative correlation (P = 0.06) with time to stand, and had a moderate or strong negative correlation ($P < 0.02$) with time to stand at the remaining sampling times. Plasma glucose from 12 through 72 h tended to have a weak or moderate positive correlation ($P \leq 0.15$) with time to stand. Time to stand had a moderate or strong positive correlation ($P \leq 0.05$) with BUN at 6 through 48 h. Total protein, globulin, and fructose concentrations were not correlated ($P \geq 0.25$) with time to stand. In conclusion, calf size may play a role in beef calf vigor at birth. Pre-suckling circulating metabolites appear to be poor predictors of vigor, but several neonatal metabolites after colostrum intake were related to vigor in this study.

Key Words: neonates, parturition, vigor

1053 Effect of pregnancy on steroid and eicosanoid metabolizing enzymes in bovine reproductive tissues. M. P. T. Coleson*[1], E. J. Northrop[2], J. J. J. Rich[2], G. A. Perry[2], C. G. Hart[1], K. J. McCarty[1], C. O. Lemley[1], [1]*Mississippi State University, Mississippi State, MS,* [2]*Department of Animal Science, South Dakota State University, Brookings, SD*

The objective was to determine the effects of pregnancy status on steroid and eicosanoid metabolizing enzymes in Angus cross cattle (between 3 and 13 yr) 16 d post-insemination within corpora lutea (**CL**) or endometrial (caruncle; **CAR** and inter-caruncle; **IC**) tissues. Cattle were fixed-time artificially inseminated. Cattle were further classified as either exhibiting or not exhibiting estrus based on estrus activity (confirmed with peripheral concentrations of estradiol). Sixteen d after AI cattle were euthanized and reproductive tracts collected from 18 non-pregnant and 10 pregnant cows (pregnancy determined by presence of an embryo). Activity of cytochrome P450 1A (**CYP1A**) and UDP-glucuronosyltransferase (**UGT**) enzymes were determined using specific luminogenic substrates. Activities were expressed relative to mg of protein or g of tissue. In addition, total activity of the CL was calculated by multiplying activity per g of tissue by CL weight. Data were analyzed using MIXED procedure of SAS and the model statement included pregnancy status, display of estrus, and the respective interaction. In the CL, activity of CYP1A relative to mg of protein, g of tissue, and CL total was not different ($P > 0.19$) between pregnant and non-pregnant cattle, as well as cattle that exhibited or failed to exhibit estrus. In CAR and IC, activity of CYP1A relative to mg of protein and g of tissue was not different ($P > 0.40$) between pregnant and non-pregnant cattle, as well as cattle that exhibited or failed to exhibit estrus. In the CL, activity of UGT relative to mg of protein was not different ($P > 0.14$) between pregnant and non-pregnant cattle, as well as cattle that exhibited or failed to exhibit estrus. However, in CL the activity of UGT relative to g of tissue and CL total decreased ($P < 0.05$) in pregnant vs. non-pregnant cattle which exhibited estrus, while it was not different in pregnant vs. non-pregnant cattle that did not exhibit estrus. In CAR and IC the activity of UGT relative to mg of protein and g of tissue was not different ($P > 0.15$) between pregnant and non-pregnant cattle, as well as cattle that exhibited or failed to exhibit estrus. In conclusion, activity of UGT was decreased in the CL of pregnant vs. non-pregnant cattle that exhibited estrus. This alteration in CL UGT activity could affect steroid and eicosanoid metabolism during early pregnancy.

Key Words: corpus luteum, cytochrome P450, pregnancy

1054 Effect of exogenous β-hydroxybutyrate in the lateral ventricle on circulating serum metabolites and luteinizing hormone in castrated lambs.

E. R. Cope*[1], B. H. Voy[1], B. K. Whitlock[1], J. D. Hobbs[1], Z. D. Mcfarlane[1], S. Das[1], J. T. Mulliniks[2], *[1]University of Tennessee, Knoxville, TN, [2]University of Tennessee, Crossville, TN*

Metabolic dysfunctions are known to have negative impacts on reproduction. It has been well established that during periods of fasting or nutrient restriction, reproduction is inhibited due to the suppression of pulsatile luteinizing hormone (LH) secretion. The manifestation of metabolic dysfunction through elevated β-hydroxybutyrate (BHB) concentrations could be an indication of poor adaptation to negative energy balance (NEB) and modulate reproductive incompetence in livestock. Therefore, the objective of this study was to evaluate the effect of a central injection of exogenous BHB into the lateral ventricle on circulating metabolic markers and LH secretion in lambs. Ten wether lambs were individually housed and fed once a day at a rate of 1.1 kg/d of a 13.5% CP and 72.5% TDN complete feed ration. Before experimental treatments, lambs were fitted with lateral ventricle intracerebroventricular brain cannulas. Lambs were centrally injected with 1 mL into the lateral ventricle with one of two treatments: (1) β-hydroxybutyric acid sodium salt solution (BHB; 12,800 μmol/L) or (2) saline solution (CON). Serum blood samples were collected every 10 min for 60 min before treatment injection and every 10 min for 120 min after infusions. Serum glucose concentrations increased ($P < 0.01$) with BHB injection, indicating stimulation of gluconeogenesis. Infusion of BHB also increased serum non-esterified fatty acid levels ($P < 0.01$). In addition, serum BHB concentrations also increased ($P < 0.01$) in lambs when infusion of BHB in the lateral ventricle occurred. Injection of BHB in the lateral ventricle tended ($P = 0.08$) to inhibit overall LH secretion (mean LH). Number of LH peaks during the 2 h sampling period after injection of treatments did not differ ($P = 0.18$) between lambs injected with BHB or CON. However, lambs injected with BHB had significantly decreased ($P < 0.01$) LH amplitudes. The results of this study suggest that elevated β-hydroxybutyrate in the brain mimics a negative energy signal leading to an increase in the mobilization of glucose and non-esterified fatty acids, while suppressing luteinizing hormone.

Key Words: β-hydroxybutyrate, energy sensing, metabolism, reproduction

1055 WS Comparisons of two short duration estrous synchronization protocols on pregnancy rates to fixed-time AI.

J. B. Hall*[1], M. C. Roberts-Lew[2], *[1]Department of Animal & Veterinary Sciences, University of Idaho, Moscow, ID, [2]University of Idaho Nancy M. Cummings Research, Extension Education Center, Carmen, ID*

The objective of the current experiment was to compare pregnancy rate and estrus response between a 5-d or 6-d CO-Synch + CIDR synchronization protocol. Multiparous cows ($n = 238$) were assigned to either a 5-d CO-Synch + CIDR (5-Day) or a PG 6-d CIDR (6-Day) groups based on body weight and body condition score (BCS). Cows assigned to the 5-d protocol were given GnRH (100 μg i.m., Factrel) at the time of insertion of a controlled internal drug releasing device (CIDR; Eazi-Breed CIDR). Five d later CIDR was removed and PGF2α (25 mg i.m., Lutalyse) was given with an additional injection of PGF2α 8 h after CIDR removal. Cows assigned to the 6-d protocol were given an injection of PGF2α and three d later a CIDR was inserted and an injection of GnRH was given. Six d later CIDR were removed and PGF2α was given. Estrus detection aids were applied at CIDR removal. Cows were inseminated by fixed-time AI (FTAI) with conventional semen 72 h after CIDR removal, and GnRH was administered at the time of AI. At insemination, estrus status was categorized as positive (YES), unknown (NR) or negative (NO). Cows were divided into three groups and bulls were introduced 14 d post-insemination at a 1:50 ratio. Bulls were removed 60 d after FTAI and pregnancy was determined by transrectal ultrasound. Pregnancy diagnosis was confirmed by palpation 60 d after the bulls were removed. The AI and final pregnancy rates averaged 62.6% and 95.0%, respectively, and were similar ($P < 0.7$) between 5-Day and 6-Day protocol. There was no difference ($P = 0.11$) in the percentage of cows expressing estrus between the treatments (42.4% and 54.9% for 5-Day and 6-Day, respectively). Expression of estrus before FTAI increased ($P < 0.05$) AI pregnancy rates by 21%; however, it did not increase ($P = 0.32$) final pregnancy rates. There was no interaction ($P = 0.11$) among synchronization protocols and expression of estrus on AI pregnancy rates. In conclusion, expression of estrus increased pregnancy rates; however, there was no difference in pregnancy rates between synchronization protocols.

Key Words: beef cows, estrous synchronization, fixed-time AI

1056 WS Effect of prostaglandin administration after ram exposure on ewe reproductive efficiency.
S. L. Rosasco*, J. K. Beard, M. C. Herrington, D. M. Hallford, A. F. Summers, *Animal and Range Science Dep., New Mexico State University, Las Cruces, NM*

A 2-yr experiment was conducted to determine the effect of a single injection of prostaglandin after ram turnout on ewe estrous synchronization. Rambouillet ewes (n = 100; yr 1 = 52; yr 2 = 48) at New Mexico State University West Sheep Unit were stratified by age and BW and assigned to 1 of 3 treatments: untreated (**CON**; n = 33); 12-d CIDR insert (**CIDR**; n = 33); or 1 injection of prostaglandin at d 2.5 (**1PG**; n = 34) after rams were placed with ewes. Ewes were exposed to rams at CIDR insert removal (d 0) for a 35-d breeding season. Ewes were observed twice daily to determine estrus. A greater ($P \leq$ 0.01) number of CIDR ewes were bred in the first 3 d of the breeding season (82%), compared with 1PG (35%) or control (21%) ewes. Moreover, there was an increased ($P \leq 0.01$) number of CIDR ewes bred in the first 4 d (94%) compared to 1PG (50%) ewes, both of which had an increased ($P \leq 0.01$) number of ewes bred compared to control ewes (21%). Both CIDR (94%) and 1PG (73.5) ewes had an increased number ($P \leq 0.01$) of ewes bred in the first 5 d compared to control (33%) ewes. As expected, CIDR-treated ewes had a shorter time (2.2 d) to breeding, than 1PG treat ewes (4.9 d) and control ewes took longer to breed than both CIDR and 1PG ewes (8.1 d) ($P \leq 0.01$). Lambing and weaning data have not yet been collected for yr 2. In yr 1 the number of lambs born per ewe and kg of lamb weaned per ewe was not different ($P \geq$ 0.33) between treatments. Based on these data, utilizing a single injection of PG 2.5 d after ram turnout resulted in similar pregnancy rates at d 5 of the breeding season when compared with CIDR-treated ewes suggesting in a confinement setting the 1PG synchronization protocol could potentially be utilized as a less expensive method of synchronization. Additional information will be collected to determine the effects of synchronization protocol on post-lambing data to determine efficacy of the treatments. Moreover, more research is needed to determine the efficacy of the proposed synchronization protocol in a range production environment.

Key Words: reproduction, sheep, synchronize

1057 The association between Anti-Mullerian Hormone concentrations, antral follicle count and fertility measures in dairy cows.
M. Gobikrushanth[*1], P. A. Dutra[1], C. A. Felton[2], A. Ruiz-Sanchez[1], T. C. Bruinjé[1], M. G. Colazo[2], S. Butler[3], D. J. Ambrose[1,2], *[1]Department of Agricultural Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]Livestock Research Branch, Alberta Agriculture and Forestry, Edmonton, AB, Canada, [3]Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Co. Cork, Ireland*

The objectives were to (1) characterize variations in plasma concentrations of Anti-Müllerian Hormone (AMH) within a population of dairy cows, and (2) determine associations between AMH categories and AFC, first service conception rate, number of services and days open. Lactating Holstein cows (35 primiparous, 65 multiparous) were subjected to blood sampling (for plasma AMH; AnshLite Bovine AMH CLIA, Ansh Labs, Webster, TX) and transrectal ultrasonography (for AFC; 7.5 MHz linear array transducer; Aloka Co Ltd., Tokyo, Japan) at 75 ± 1 d postpartum (approximately 48 h after the second GnRH of an Ovsynch protocol). Cows were ranked in a descending order based on AMH concentrations and those in the top and bottom thirds were categorized into HIGH- (n = 33) and LOW-AMH (n = 33), respectively. The continuous variables (plasma AMH concentrations, AFC, number of services and days open) were analyzed using MIXED procedure of SAS. The association between AMH and AFC was tested using REG procedure, and the effect of categories of AMH and parity groups on first service conception rate was analyzed using GLIMMIX procedure. Plasma AMH concentrations (pg/mL) ranged from 38.2 to 774.1 (CV 63.4%) with an overall mean (± SEM) of 224.8 ± 14.3. Plasma AMH was greater in the HIGH-AMH than in the LOW-AMH category cows (386.2 ± 14.9 vs. 95.8 ± 15.2 pg/mL; $P < 0.01$). Mean AFC was also significantly greater in HIGH-AMH than those in LOW-AMH category cows (28.1 ± 1.4 vs. 16.7 ± 1.4; $P < 0.01$). Plasma AMH concentrations were linearly associated with AFC (R^2 = 37.5; $P < 0.01$). First service conception rate did not differ between AMH categories (HIGH-AMH vs. LOW-AMH: 35.3 vs. 36.4; $P > 0.05$). However, cows in the HIGH-AMH category tended to have fewer number of services (2.1 ± 0.2 vs. 2.7 ± 0.2; $P = 0.08$) and days open (133.6 ± 11.5 vs. 162.3 ± 11.7 d; $P = 0.09$) than those in LOW-AMH category. Parity did not influence plasma concentrations of AMH, AFC, first service conception rate, number of services or days open ($P >$ 0.05). In summary, plasma AMH concentrations were highly variable and associated with AFC; however, AMH categories did not influence first service conception rates although cows in the HIGH-AMH category had a tendency for fewer days

open and reduced number of services.

Key Words: anti-Müllerian hormone, antral follicle count, fertility

1058 Natural patterns of early postpartum luteal activity and their association with insemination outcomes in dairy cows.

T. C. Bruinjé*[1], M. Gobikrushanth[1], D. J. Ambrose[1,2], *[1]Department of Agricultural Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]Livestock Research Branch, Alberta Agriculture and Forestry, Edmonton, AB, Canada*

The objective of this study was to investigate associations between different patterns of luteal activity early postpartum, up to first service, and insemination (AI) outcomes. Milk progesterone (P4) concentrations measured through in-line milk analysis (Herd Navigator, DeLaval Inc) from 785 Holstein cows were assessed from two dairy herds. Progesterone > 5ng/mL was indicative of luteal activity (LA). Milk P4 was determined at set intervals starting 20d postpartum and cows that initiated LA at ≤ 35d and > 35d were considered to have ovulated early (Early-Ov) and late (Late-Ov), respectively. Luteal activity, until first service, lasting 7d to 19d was defined as normal and LA lasting < 7d or > 19d as abnormal. Outcomes of first and second AI were: pregnant (LA > 45d; 1stAI n = 237; 2ndAI n = 133), open (LA ≤ 19d; 1stAI n = 428; 2ndAI n = 337), or pregnancy loss (LA > 20d but ≤ 45d; 1stAI n = 120; 2ndAI n = 62). From calving to 1stAI, luteal phases were classified as at least one normal LA (1NormLA), at least two normal LA (2NormLA), at least one abnormal LA (1AbnLA) and at least two LA whether normal or abnormal (2TotLA). Each of the four categories of luteal phases were analyzed as binomial variables against AI outcomes, Early-Ov or Late-Ov, parity and interactions, using mixed-effects logistic regression (GLMER of R-3.2.3) with herd as random factor. Cows in 1NormLA had increased odds of being pregnant at 1stAI (odds ratio [OR]: 3.21, P = 0.001) and cows in 2NormLA had increased odds of being pregnant at first and 2ndAI (OR: 1.63, P < 0.03). AbnLA1 decreased the probability of pregnancy (OR: 0.66, P = 0.01) and tended to be associated with pregnancy loss at 2ndAI (66%, P = 0.08). Cows having 2TotLA had increased probability of being pregnant at first and 2ndAI (OR: 2.41 and 1.80, respectively, P < 0.01). Cows that were open at 1stAI had twice the odds to suffer pregnancy loss at 2ndAI than cows that suffered pregnancy loss at 1stAI (OR: 1.99, P < 0.03). Primiparous cows were more likely to become pregnant at 1stAI than multiparous cows (OR: 1.56, P < 0.01), while multiparous cows had higher odds of delayed ovulation (32.58%, P = 0.04). Early-Ov cows had higher odds of having 2TotLA (98%, P < 0.001) and lower odds of suffering pregnancy losses at 2ndAI (OR: 0.70, P = 0.05). In summary, an early onset, and an increased frequency of normal luteal activity preceding first AI postpartum benefits insemination outcomes.

Key Words: estrous cycle, fertility, milk progesterone profiles

1059 Circulating LH concentrations after intravaginal instillation of GnRH in lactating dairy cows.

R. Wijma*, M. L. Stangaferro, M. A. Elmetwally, F. Amovilli, J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY*

Our objective was to evaluate circulating LH concentrations after intravaginal (**IVG**) instillation of GnRH in dairy cows. Lactating primiparous (n = 6) and multiparous (n = 27) Holstein cows received two luteolytic doses of PGF2α 12 h apart 7 d after the Ovsynch protocol (GnRH-7d-PGF2α-56h-GnRH). Forty 8 h after the first PGF2α treatment cows were stratified by parity and randomly allocated to five different treatments: 2 mL of saline solution IVG (**SAL-IVG**, n = 6), 100 µg of GnRH i.m. (**G100-im**, n = 5), 100 (**G100-IVG**, n = 7), 500 (**G500-IVG**, n = 8), or 1000 µg of GnRH IVG (**G1000-IVG**, n = 7). For all GnRH treatments Gonadorelin diacetate tetrahydrate (Cystorelin) was used. Blood was collected using indwelling jugular catheters at −1 h, 0 h, every 15 min up to 4 h, and every 30 min from 4 to 6 h after treatment. Data for progesterone, estradiol, and LH concentrations were analyzed by ANOVA with (LH only) or without repeated measures using PROC MIXED of SAS. Concentrations of progesterone and estradiol did not differ (P > 0.10) among groups at time 0. Concentrations of LH were affected by treatment (P < 0.001), time (P < 0.001) and treatment by time interaction (P < 0.001). Cows in G100-im had greater (P < 0.05) mean LH than the IVG treatments from 15 to 195 min after treatment whereas the G1000-IVG group had greater (P < 0.05) mean LH than the SAL-IVG and the other IVG GnRH groups from 45 to 240 min (except at 60, 75, and 90 min) after treatment. Mean LH for SAL-IVG, G100-IVG, and G500-IVG did not differ (P > 0.05) at any time point. The greatest (P < 0.001) area under the curve (**AUC**) was observed for G100-im (1149 ± 51 ng) followed by G1000-IVG (546 ± 108 ng) which had greater AUC than the other IVG treatment groups (242 ± 40, 271 ± 34 and 247 ± 24 ng for SAL-IVG, G100-IVG, and G500-IVG, respectively). Mean LH peak was greater (P < 0.001) for G100-im (6.9 ± 0.4 ng/mL) than G1000-IVG (2.8 ± 0.6 ng/mL) whereas the SAL-IVG, G100-IVG, and G500-IVG groups did not have a discernible LH surge after treatment (maximum LH: 1.2 ± 0.2, 1.3 ± 0.2 and 1.2 ± 0.1 ng/mL for SAL-IVG, G100-IVG and G500-IVG respectively). We conclude that IVG instillation of 1000 µg of GnRH induced more LH release than IVG instillation of saline solution and a 100 or 500 µg dose of GnRH. Also, the amount of LH released after IVG treatment with 1000 µg of GnRH was less than that released after i.m. treatment with 100 µg of GnRH.

Key Words: intravaginal, GnRH, LH

1060 Effect of dose and timing of prostaglandin $F_{2\alpha}$ treatments during a Resynch protocol on luteal regression and fertility to timed artificial insemination in lactating Holstein cows.

R. V. Barletta, P. D. Carvalho, L. F. Mello, M. Luchterhand, C. E. Consentini, A. L. Jones, A. S. Netto, P. M. Fricke*, *Department of Dairy Science, University of Wisconsin, Madison, WI*

Our objective was to evaluate the effect of a second $PGF_{2\alpha}$ treatment (25 mg dinoprost) or a double dose of $PGF_{2\alpha}$ (50 mg dinoprost) during a Resynch protocol on luteal regression and pregnancies per artificial insemination (P/AI) in dairy cows. Lactating Holstein cows (n = 1438) were randomly assigned at a nonpregnancy diagnosis to receive: 1) Ovsynch (Control: GnRH; 7 d, $PGF_{2\alpha}$; 56 h, GnRH); 2) Ovsynch with a second $PGF_{2\alpha}$ treatment (GPPG: GnRH; 7 d $PGF_{2\alpha}$; 24 h, $PGF_{2\alpha}$; 32 h, GnRH); or 3) Ovsynch with a double dose of $PGF_{2\alpha}$ (GDPG: GnRH; 7 d, 2x$PGF_{2\alpha}$; 56 h, GnRH). All cows received TAI ~16 h after the second GnRH treatment (G2). Pregnancy diagnosis was performed by transrectal palpation 38 ± 3 d after TAI, and pregnancy status was reconfirmed 28 d later. Blood samples were collected at the first $PGF_{2\alpha}$ treatment and at G2 from a subset of cows (n = 546) and assayed for progesterone (P4). Data were analyzed by logistic regression using the GLIMMIX procedure of SAS. At 38 d after TAI, GPPG cows tended to have more (P = 0.12) P/AI than Control cows [37% (181/495) vs. 33% (154/463)], whereas P/AI for GDPG cows [34% (164/480)] did not differ (P = 0.34) from Control cows. Pregnancy loss from 38 to 66 d did not differ (P = 0.46) among treatments and was 8% (38/475). The percentage of cows with complete luteal regression (P4 $\leq$ 0.3 ng/mL at G2) tended to differ (P = 0.06) among treatments and was greater for GPPG cows than for GDPG and Control cows (94% vs. 88% vs. 88%, respectively). Overall, cows with P4 < 1 ng/mL at the first $PGF_{2\alpha}$ treatment had fewer (P < 0.01) P/AI than cows with P4 $\geq$ 1 ng/mL [28% (40/145) vs. 41% (148/365)], whereas cows with P4 > 0.3 ng/mL at G2 had fewer (P < 0.01) P/AI than cows with P4 $\leq$ 0.3 ng/mL [14% (7/51) vs. 39% (167/425)]. We conclude that addition of a second $PGF_{2\alpha}$ treatment during a Resynch protocol tended to increase P/AI to TAI by increasing the percentage of cows with complete luteal regression at G2, whereas doubling the dose of $PGF_{2\alpha}$ did not. *Supported by USDA NIFA Hatch project 1006519*

Key Words: dairy cow, resynchronization, timed AI

1061 Fertility of lactating Holstein cows after synchronization of ovulation and timed artificial insemination versus artificial insemination after detection of estrus at a similar DIM range.

V. G. Santos[1], P. D. Carvalho[1], C. Maia[2], B. Carneiro[2], A. Valenza[3], P. M. Fricke*[1], *[1]Department of Dairy Science, University of Wisconsin, Madison, WI, [2]Diessen Servicos Veterinarios Lda, Evora, Portugal, [3]Ceva Animal Health, Libourne, France*

Our objective was to compare pregnancies per artificial insemination (P/AI) at first service after synchronization of ovulation and timed artificial insemination (TAI) with artificial insemination (AI) after detection of estrus at a similar DIM range. Lactating Holstein cows (n = 408) were randomly assigned to receive their first TAI after a Double-Ovsynch protocol [TAI; Pre-Ovsynch (GnRH; 7 d, $PGF_{2\alpha}$; 3 d, GnRH) followed 7 d later by Breeding-Ovsynch (G1; 7 d $PGF_{2\alpha}$; 24 h, $PGF_{2\alpha}$; 32 h, GnRH; 16 h, TAI)] or to receive first AI after estrus induced using $PGF_{2\alpha}$(Estrus; $PGF_{2\alpha}$; 14 d, $PGF_{2\alpha}$; 24 h, $PGF_{2\alpha}$). Cows were inseminated using frozen-thawed semen from 4 AI sires with proven high fertility (sire conception rate > 0). Overall, 92% (374/408) of cows received their first insemination from 74 to 81 DIM. Estrus cows inseminated > 7 d after the last $PGF_{2\alpha}$ treatment (n = 34) were excluded from the analysis of P/AI but were included in the calculation of insemination rate. Pregnancy status was determined 33 ± 3 d after AI, and pregnancy status was reconfirmed 63 ± 3 d after AI. Data were analyzed by ANOVA and logistic regression using MIXED and GLIMMIX procedures of SAS. DIM at AI did not differ (P = 0.37) between treatments (76.9 ± 0.2 vs. 76.7 ± 0.3 for TAI vs. Estrus cows, respectively). More (P < 0.01) TAI cows received AI within 7 d after the VWP than Estrus cows (100% vs. 83%). At 33 d after AI, primiparous cows had more (P < 0.01) P/AI than multiparous cows [58% (81/139) vs. 37% (87/235)], and TAI cows had 50% more (P < 0.01) P/AI than Estrus cows [51% (109/212) vs. 34% (59/162)]. No parity by treatment interaction was detected (P = 0.20). At 63 d after AI, TAI cows had 39% more (P = 0.02) P/AI than Estrus cows [46% (69/149) vs. 33% (38/116)], and pregnancy loss from 33 to 61 d after AI did not differ (P = 0.16) between treatments [14% (11/81) vs. 5% (2/41) for TAI vs. Estrus cows]. In conclusion, synchronization of ovulation and TAI for first service increased the percentage of cows inseminated within 7 d after the VWP, and TAI cows had greater fertility at first service than Estrus cows at a similar DIM range. *Supported by USDA NIFA Hatch project 1006519 and CEVA Sante Animale*

Key Words: estrus, fertility, timed AI

1062 Increasing estrus expression in lactating dairy cows. J. A. Sauls*, B. E. Voelz, S. L. Hill, J. S. Stevenson, *Kansas State University, Manhattan, KS*

Using an activity monitoring system (AMS) equipped with an accelerometer, 2 experiments were conducted to test the hypotheses that: (1) altering progesterone before inducing luteolysis or (2) exposing cows to estradiol cypionate (ECP) or testosterone propionate (TP) after luteolysis would increase occurrence and intensity of estrus. In experiment 1, cows (n = 154) were fitted with an AMS collar and a pressure-sensitive device (HW) and assigned to 3 treatments: 1) CL only; 2) no CL + progesterone insert (CIDR); or 3) CL + 2 CIDR to achieve different concentrations of progesterone. Progesterone 24 h post-treatment was greatest ($P < 0.01$) in CL + 2 CIDR, followed by CL, and no CL + CIDR cows. Estrus occurred 11 to 12 h earlier ($P < 0.01$) in no CL + CIDR compared with CL-bearing cows. Estrus intensity was greater ($P \leq 0.05$) after CL + 2 CIDR than CL only cows. The AMS and HW determined 68 and 62% of the qualifying cows to be in estrus (estrus was defined: follicle $\geq$ 10 mm at $PGF_{2\alpha}$ and progesterone $\leq$ 0.5 ng/mL 72 h later), respectively. In experiment 2, cows (n = 203) were equipped with an AMS and a friction-activated patch (Estrotect patch; P) and assigned to receive 1 mg ECP, 2 mg TP, or control 24 h after $PGF_{2\alpha}$. Estradiol 24 h post treatment was greater ($P <$ 0.01) in ECP compared with controls. Estrus expression detected by P in all cows tended ($P = 0.10$) to be greater for ECP compared with controls. More ($P < 0.05$) qualifying cows were detected in estrus after ECP compared with controls. Compared with controls and in response to ECP, estrus occurred 17 to 20 h earlier ($P < 0.01$) and was of greater ($P < 0.05$) intensity. The AMS and P determined 71% and 74% to be in estrus, respectively. Of cows exposed to the AMS, HW, or P, 62 to 74% were detected in estrus and more than 94% ovulated. In contrast, of the residual cows not detected in estrus, 60 to 76% ovulated in the absence of detected estrus. Only ECP was successful in inducing more estrus expression, but proportions never exceeded 80%. Given the large proportion of cows ovulating in the absence of estrus, further research is warranted to determine if conception is achievable by inseminating cows not detected in estrus by 72–80 h post-PGF_{2a}.

Key Words: estrus, estradiol, progesterone

1063 The characterization of estradiol concentration before insemination and its effect on fertility in dairy cattle. M. Gobikrushanth*[1], P. A. Dutra[1], C. A. Felton[2], T. C. Bruinjé[1], M. G. Colazo[2], S. Butler[3], D. J. Ambrose[1,2], *[1]Department of Agricultural Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]Livestock Research Branch, Alberta Agriculture and Forestry, Edmonton, AB, Canada, [3]Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Co. Cork, Ireland*

The objectives of this study were to: (1) characterize variations in plasma concentrations of estradiol (E2) within a population of dairy cows, and (2) determine associations between E2 categories, LH, ovulatory response, first service conception rate, number of services and days open. Lactating Holstein cows (35 primiparous, 65 multiparous) received one injection of $PGF_2\alpha$ (cloprostenol, 500 µg, d 0) followed by GnRH (gonadorelin, 100 µg, d 3; Presynch) and were subjected to an Ovsynch protocol starting on d 10, with timed-AI (TAI) occurring at ~75 d postpartum. Blood samples were collected immediately before (0h) and 2h after the second GnRH of Ovsynch to determine plasma E2 and LH concentrations, respectively. Cows were ranked based on plasma E2 concentrations, from highest to lowest, and those in the top (n = 33) and bottom (n = 33) thirds were classified into HIGH- and LOW-E2 categories. The continuous variables were analyzed using MIXED procedure of SAS and the binomial data were modeled against E2 categories and parity and analyzed using the GLIMMIX procedure of SAS. Plasma E2 concentrations (pg/mL) ranged from 0.1 to 9.2 (CV 78.7%) with an overall mean (± SEM) of 2.0 ± 0.1. The plasma E2 was greater for cows in HIGH-E2 category than those in LOW-E2 category (3.7 ± 0.2 vs. 0.5 ± 0.2 pg/mL; $P < 0.01$). Similarly, cows in the HIGH-E2 category had greater concentrations of plasma LH than cows in the LOW-E2 category (13.5 ± 1.0 vs. 5.9 ± .1.0 ng/mL; $P < 0.01$). The categories of E2 did not influence ovulatory response to the second GnRH of the Ovsynch ($P <$ 0.05). The first service conception rate tended to be greater for cows in HIGH-E2 category than those in LOW-E2 category (44.1 vs. 24.2; $P = 0.10$). Further, cows in the HIGH-E2 category had a tendency for fewer number of services (2.2 ± 0.2 vs. 2.7 ± 0.2; $P = 0.10$) and lesser days open (138.6 ± 11.6 vs. 171.5 ± 11.7 d; $P = 0.06$) than cows in LOW-E2 category. Parity did not influence plasma concentrations of E2 and LH, ovulatory response to the second GnRH of Ovsynch, number of services or days open ($P > 0.05$). However, primiparous cows tended to have greater first service conception rate than multiparous cows (50.0 vs. 25.6%; $P = 0.06$). In summary, plasma E2 concentrations were highly variable in a tested population of dairy cows and cows in the HIGH-E2 category had a tendency for greater first service conception rate and

fewer number of services and lesser days open.

Key Words: estradiol concentration, fertility, variability

1064 Resynchronization of ovulation strategies including or not including GnRH treatment before non-pregnancy diagnosis. R. Wijma*, M. L. Stangaferro, M. Masello, G. E. Granados, J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY*

Our objectives were to evaluate ovarian dynamics and reproductive performance of cows managed with two different resynchronization protocols for second and greater AI services. After each AI, cows were randomly assigned to receive (**G25** group; $n = 649$) or to not receive GnRH (**NoG25**; $n = 656$) 25 ± 3 d after AI and 7 before non-pregnancy diagnosis (**NPD**) by transrectal ultrasonography. Non-pregnant cows in G25 ($n = 353$) and NoG25 ($n = 353$) received the same protocols as follows: cows with a corpus luteum (**CL**) $\geq$ 15 mm received two PGF treatments 24 h apart, GnRH 32 h later, and timed AI (**TAI**) 16 h after GnRH whereas, cows without a CL $\geq$ 15 mm at NPD received the CIDR-Ovsynch protocol (GnRH+CIDR-7d-CIDR-removal+PGF-24h-PGF-32h-GnRH-16h-TAI). Cows in both groups were inseminated to estrus (**AIE**) any time after AI. Circulating concentrations of progesterone (**P4**) were determined and ovarian ultrasonography was performed thrice weekly from 18 ± 3 d after AI until NPD in 44 and 46 cows for G25 and NoG25, respectively. Binomial outcomes were analyzed by logistic regression and continues outcomes using ANOVA. Overall, more cows ovulated ($P < 0.01$) spontaneously or in response to GnRH for G25 (69.9%) than NoG25 (36.4%) from 18 ± 3 d after AI to NPD, the proportion of cows with a CL tended ($P = 0.06$) to be greater for G25 (89.1%) than NoG25 (72.7%), and the proportion of cows with P4 > 1 ng/mL at NPD was similar ($P = 0.14$) for G25 (67.4%) and NoG25 (61.4%). A similar ($P = 0.74$) proportion of cows had an active follicle (**AF**, > 10 mm in the growing or static phase) at NPD (G25 = 91.3% and NoG25 = 95.5%) but size of the AF was greater ($P = 0.02$) for NoG25 (16.5 ± 0.6 mm) than G25 (15.0 ± 0.4 mm). For all cows enrolled, more ($P = 0.04$) non-pregnant cows after AI received AIE in NoG25 (55.8%, 169/353) than G25 (47.9%, 197/353) but more cows had a CL ($P = 0.01$) at NPD for G25 than NoG25 [83.7% (154/184) vs. 72.4% (113/155)]. Pregnancies per AI were similar for G25 and NoG25 for cows AIE [36.5% (51/167) vs. 38.7% (74/191); $P = 0.77$], cows with a CL at NPD [40.0% (58/145) vs. 33.0% (35/106; $P = 0.26$], cows without a CL at NPD [37.9% (11/29) vs. 39.0% (16/41); $P = 0.0.92$] or for all services combined [38.1% (130/341) vs. 36.9% (125/338); $P = 0.69$]. We conclude that despite differences in ovarian function, fertility after TAI and overall P/AI was similar for cows that received or not received GnRH 25 ± 3 d after AI.

Key Words: dairy cow, resynchronization, timed AI

1065 Effects of modification of proestrus length and duration of progesterone exposure on automated measurements of estrous expression in lactating Holstein cows. B. F. Silper*, T. A. Burnett, P. F. M. P. Souto, M. S. Baylao, A. P. O. Santos, R. L. A. Cerri, *Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada*

Objectives were to investigate if longer proestrus, via longer exposure to pre-ovulatory estradiol concentrations, would induce behavioral estrus of greater intensity, and to investigate if longer exposure to progesterone would offset possible effects of shorter proestrus on estrous behavior. Three treatments consisting of different intervals between GnRH-PGF (5 or 7 d) and PGF-ECP (1 or 3 d) on a Heatsynch program were applied to lactating Holstein cows ($n = 48$). All cows were fitted with three activity monitors (Heatime, SmartDairy, and AfiActII) and enrolled into pre-synchronization at 40 ± 3 DIM, followed by random allocation to treatments at 57 ± 3 DIM. Treatments were 5d3d (GnRH-5d-PGF-3d-ECP), 5d1d (GnRH-5d-PGF-1d-ECP), and 7d1d (GnRH-7d-PGF-1d-ECP). The AI was performed at a fixed time 48 h after ECP, except for those detected in high activity before timed-AI. Ovarian ultrasonography and blood samples were performed at injection days, day of AI, and 2, 5, and 7 d after timed-AI. Rates of estrous detection, ovulation (until 84 h after ECP) and presence of CL 7 d after timed-AI were not different among treatments ($P > 0.05$). Although the goal of 5d3d was to increase proestrus length, 6 of the 10 cows that showed high activity in this treatment did so before or at the day of ECP. Consequently, proestrus length was not different among treatments (3.0 ± 0.2, 3.2 ± 0.2, and 2.7 ± 0.2 d, for 5d1d, 5d3d, and 7d1d, respectively; $P > 0.05$). Pre-ovulatory follicle diameter was not significantly different among treatments and was 20.9 ± 0.7 mm (multiparous) and 19.2 ± 0.9 mm (primiparous). Odds of estrous expression were not influenced by parity, BCS, or progesterone concentration and follicle diameter at the PGF injection. Parity and BCS were the factors most frequently associated with measurements of estrus. Cows in 5d1d had estrus of greater duration (Heatime) than 7d1d (13.9 ± 0.9 vs. 11.1 ± 0.9 h; $P = 0.04$), whereas intensity of estrus (AfiActII) was greater for 5d3d cows (377.3 ± 43.0; $P = 0.04$) and tended to be greater for 7d1d (350.8 ± 41.3; $P = 0.09$), both in comparison with 5d1d (243.3 ± 45.8). Although estrous detection rate and proestrus length were not different among treatments, the use of a Heatsynch program with different GnRH-PGF or PGF-ECP intervals was capable of altering duration and intensity of estrus, likely due to changes in the endocrine profile during the estrous cycle.

Key Words: automated estrous detection, estradiol, proestrus

1066 Effect of GnRH removal at CIDR insertion in the 5 d CO-Synch + CIDR ovulation synchronization protocol on ovarian function in beef cows.

T. M. Grussing*[1], T. C. Grussing[2], P. J. Gunn[1], *[1]Department of Animal Science, Iowa State University, Ames, IA, [2]Department of Animal Science, South Dakota State University, Brookings, SD*

The objective of this experiment was to evaluate the effects of GnRH removal at controlled internal drug release (CIDR) insertion in the 5-d CO-Synch + CIDR protocol (5dCO) on ovarian follicle growth and circulating steroid hormone concentrations. Non-pregnant, non-lactating beef cows (n = 15) were used in a 3 × 3 Latin square design and assigned to treatment by age and BCS to receive either: 1) standard 5dCO hormone administration including 100 μL of GnRH at CIDR insert and 2 concurrent 25-mg doses of $PGF_{2\alpha}$ (PG) delivered at CIDR removal (G2PG), 2) no GnRH at CIDR insert and 2 concurrent, 25-mg doses of PG at CIDR removal (NoG2PG), or 3) no GnRH at CIDR insert and a single, 25-mg dose of PG at CIDR removal (NoG1PG). All cows were monitored for estrous for 72 h after CIDR removal at which time 100 μL of GnRH was administered. Cows underwent transrectal ultrasonography to record ovarian structures and blood samples were taken for progesterone and estradiol analyses at CIDR insertion, CIDR removal, final GnRH administration, and d 5 and 10 post PG administration. An additional blood sample was collected on cows that displayed estrus between PG and GnRH. Data were analyzed using the MIXED and GLIMMIX procedures of SAS for the continuous and binary response variables, respectively. Dominant follicle diameter did not differ between treatments at CIDR removal or final GnRH ($P \geq 0.61$). Percentage of animals that regressed their corpus luteum (CL) in response to PG, estrus detection aid score, and CL volume 10 d following PG administration did not differ between treatments ($P \geq 0.18$). Post ovulation plasma progesterone did not differ between treatments ($P \geq 0.29$), and plasma estradiol was not different at CIDR removal or final GnRH administration ($P \geq 0.59$). However, peak plasma estradiol concentrations were greater ($P = 0.01$) in NoG2PG than NoG1PG (5.85 and 2.93 ± 0.55 pg/mL, respectively), with G2PG intermediate (3.31 ± 0.55 pg/mL). In conclusion, follicle and CL growth as well as subsequent progesterone concentrations were not negatively affected by removal of the initial GnRH in the 5-d CO-Synch + CIDR protocol; however fluctuations in estradiol concentrations merit implementation of a field trial to elucidate protocol impacts on fertility.

Keywords: 5-d CO-Synch, GnRH, Synchronization

1067 Effect of eCG and P4 level in timed AI programs in bos indicus and bos indicus x bos taurus heifers.

A. D. P. Rodrigues*[1], R. F. G. Peres[1], M. L. Day[2], J. L. M. Vasconcelos[3], *[1]Departamento de Produção Animal- FMVZ-UNESP, Botucatu, Brazil, [2]Department of Animal Science, University of Wyoming, Laramie, WY, [3]Departamento de ProduÂ§Ã£o Animal- FMVZ-UNESP, Botucatu, Brazil*

This study evaluates the effects of P4 level and eCG treatment in timed-AI in Bos indicus (Nellore) and Bos indicus x Bos taurus (crossbred) heifers. Heifers used in the study (n = 1989) included Nellore (n = 992) and Crossbred (n = 997) that were 14–24 mo of age (BCS: 3.08 ± 0.01, BW: 329.09 ± 0.66 kg). Ovarian ultrasonography was performed twice (7 d apart) in all heifers at start of the study to identify heifers with a CL. Heifers with a CL were submitted to estrous synchronization and timed AI. Heifers without a CL in either ultrasonography were submitted to a puberty induction protocol (Rodrigues et al., 2014). Heifers with a detectable CL 12 d after puberty induction remained in the study. Timed-AI program was as follows: D0– Insertion of an intravaginal P4 device (CIDR 1.9 g; Zoetis, Sao Paulo, Brazil) and 2 mg of estradiol benzoate (Gonadiol; Zoetis); D7– 12.5 mg of dinoprost tromethamine (Lutalyse; Zoetis); D9– CIDR withdrawal and 0.5 mg of ECP (ECP; Zoetis). At D9 heifers were randomly assigned to receive either 0 (Control; 994) or 200 IU (eCG; 995) of eCG (Novormon; Zoetis); D11– timed AI was performed. On Days 9 and 11, a subgroup of heifers were evaluated by ultrasonography to record the largest follicular diameter. Continuous variables were analyzed using the PROC MIXED and binomial variables using the PROC GLIMMIX, both from SAS. Included in the models were effects of breed, group, eCG and serum P4 level (determined by ROC curve). Significance set when $P < 0.05$. Follicle diameter at D9 was greater for crossbred heifers (10.1 ± 0.01 mm) than Nellore heifers (9.5 ± 0.01) and in LowP4 (10.0 ± 0.01) compared to HighP4 (9.5 ± 0.01). Follicle diameter at D11 were not affected by tested variables. Ovulation rate was greater for eCG compared to Control (92.3% vs. 87.5%, respectively). Crossbred heifers had greater conception rate (63.7% vs. 56.3%) and greater pregnancy rate than Nellore (58.2% vs. 50.7%). eCG treatment (62.3%) tended to have greater conception than Control (55.3%). LowP4 heifers have greater conception and pregnancy rate than HighP4 (64.8, 59.6% and 55.3, 49.4%, respectively). Differences between Crossbred and Nellore heifers synchronized with the same timed AI program were observed, regardless of breed low P4 environments resulting in increased pregnancy rates. Acknowledgment: FAPESP process n° 2014/05270–9.

Keywords: bos indicus, bos taurus x bos indicus, timed-AI

1068 Gonadal and extra-gonadal sperm characteristics of rabbit bucks fed raw or fermented cottonseed cake– cased diets supplemented with ginger (Zingiber officinale Roscoe). A. A. Olajide*, *Ladoke Akintola University of Technology (Lautech), Ogbomoso, Nigeria*

The potential of cottonseed cake (CSC) as a veritable source of protein, energy and fiber for farm animals has been demonstrated. However, its use is limited to ruminant feeding due to the presence of gossypol, a polyphenolic compound of significant physiological implications. Fermentation is one of the biotechnological options for detoxifying a variety of feed ingredients. This study was conducted to investigate the effect of raw or fermented CSC– based diets (with or without ginger supplementation) on gonadal and extra-gonadal sperm characteristics of rabbit bucks. Thirty (30) cross-bred (New Zealand White X Chinchilla) rabbit bucks, 6 −7 wk old and averagely weighing 768.54 g, were randomly assigned to five dietary treatments (n = 6 per treatment) in a 2 × 2 factorial within a completely randomized design (CRD). The CSC replaced soyabean meal (SBM) at 0% (control) and 100% (Raw or Fermented) with or without ginger supplementation (30mg/kg feed). Animals were fed for 12 wk after which they were slaughtered; and their reproductive organs removed and processed for sperm evaluation. Raw CSC without ginger supplementation resulted in lower ($p < 0.05$) sperm count, Gonadal Sperm Reserve (GSR), Daily Sperm Production (DSP); and higher ($p < 0.05$) dead sperm than other treatments. The sperm count (69.33×10^6), motile sperm (79.97%), GSR (66.44×10^6) and extra-gonadal sperm reserve (109.98×10^6) were highest for bucks that were fed with fermented CSC with ginger supplementation. This study shows that total replacement of SBM with raw CSC reduced sperm quality in rabbit bucks. This adverse effect was corrected by a combination of fermentation and ginger supplementation.

1069 Supplementation with a Lactobacillus acidophilus fermentation product alters the metabolic response following a lipopolysaccharide challenge in weaned pigs. N. C. Burdick Sanchez*[1], J. A. Carroll[1], P. R. Broadway[1], B. E. Bass[2], J. W. Frank[2], *[1]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [2]Diamond V, Cedar Rapids, IA*

This study was designed to determine if feeding a *Lactobacillus acidophilus* fermentation product to weaned pigs would alter the metabolic response following a lipopolysaccharide (LPS) challenge. Pigs (n = 30; 6.4 ± 0.1 kg BW) were housed individually with ad libitum access to feed and water. Pigs were weighed on arrival, assigned to 1 of 3 groups (n = 10/treatment), and fed for 18 d: 1) Control, fed a non-medicated starter diet; 2) Control + *Lactobacillus acidophilus* fermentation product at 1 kg/MT (SGX1; Diamond V SynGenX, Cedar Rapids, IA), and 3) Control +*Lactobacillus acidophilus* fermentation product at 2 kg/MT (SGX2). Pigs were anesthetized on d 7 and 14 for insertion of an i.p. temperature device and jugular catheter, respectively. On d 15, pigs were challenged i.v. with LPS (25 μg/kg BW LPS from *E. coli* O111:B4). Blood samples were collected at 0.5 h intervals from −2 to 8 h and at 24 h relative to LPS administration at 0 h and serum isolated for glucose, NEFA, and blood urea nitrogen (BUN) analysis. There was a treatment x time interaction ($P < 0.001$) for serum glucose; Control pigs had greater glucose than SGX1 and/or SGX2 pigs at 0.5, 1.5, 2.5, 4, 5, and 6.5h post-LPS ($P \leq 0.04$), while SGX2 had greater glucose than SGX1 at 3.5 h ($P = 0.02$). Baseline (−2 to 0h) NEFA was affected by treatment ($P < 0.001$) such that SGX1 pigs had the greatest (0.12 ± 0.01mmol/L) followed by Control (0.10 ± 0.01 mmol/L) and SGX2 pigs (0.08 ± 0.01 mmol/L). Thus, NEFA were analyzed as the change relative to baseline values. There were treatment ($P = 0.006$) and time ($P < 0.001$) effects for the change in NEFA; Control (0.23 ± 0.02 mmol/L) and SGX2 (0.27 ± 0.02 mmol/L) pigs had a greater change in NEFA than SGX1 pigs (0.15 ± 0.02 mmol/L). Baseline serum BUN was affected by treatment ($P < 0.001$); Control (12.62 ± 0.41 mg/dL) and SGX2 (13.26 ± 0.35 mg/dL) pigs had greater BUN than SGX1 pigs (10.86 ± 0.40 mg/dL); thus serum BUN were analyzed as the change relative to baseline values. There was a treatment x time interaction ($P = 0.004$) for the change in BUN; SGX1 pigs had greater BUN than Control and/or SGX2 at 0.5, 4, 5 to 6, 7, 7.5, and 24 h post-LPS challenge. These data demonstrate that feeding a *Lactobacillus acidophilus*fermentation product to weaned pigs may alter the redistribution of energy stores in response to an immune challenge which may expedite recovery.

Key Words: *Lactobacillus acidophilus* fermentation product, lipopolysaccharide, metabolism

1070 Non-targeted metabolomic evaluation of the uterine milieu during the transitional period of embryo elongation in the pig. J. R. Miles*[1], E. C. Wright-Johnson[1], T. D. Laughlin[2], C. D. Broeckling[3], L. A. Rempel[1], A. K. Pannier[2], *[1]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [2]Department of Biological Systems Engineering, University of Nebraska, Lincoln, NE, [3]Proteomics & Metabolomics Facility, Colorado State University, Fort Collins, CO*

Alterations in the signaling of critical molecular factors within the uterine milieu lead to deficiencies in embryo elongation. The objective of this study was to identify metabolites within the uterine environment that are present as porcine embryos transition between spherical, ovoid, and tubular embryos at Day 9, 10, and 11 of gestation, respectively. White crossbred

gilts (n = 9) were bred at standing estrus (designated d 0) and again 24 h later and randomly assigned to collection group. At Day 9, 10, or 11 of gestation (n = 3 per day), reproductive tracts were collected immediately following harvest and flushed with 40 mL of RPMI-1640 media. Embryo morphologies were assessed for each pregnancy to ensure gilts were assigned to the correct gestation day treatment group (i.e., Day 9 contained only spherical conceptuses, Day 10 contained only ovoid conceptuses, and Day 11 contained a mixture of ovoid and tubular conceptuses). Subsequent uterine flushings were submitted for non-targeted profiling by GC–MS and UPLC-MS techniques. Raw spectral data was processed using XCMS package in R and features were clustered using RAMclustR. Unsupervised multivariate principal component analysis (PCA) was performed in R using pcamethods package and univariate ANOVA was performed in R with a Benjamini-Hochburg false discovery rate (FDR) adjustment. Multivariate analysis of both the GC–MS and UPLC-MS spectral data demonstrated sample grouping that reflected the day of gestation. Maximum separation for the GC–MS data over time was observed with PC1 vs. PC2 accounting for 90% of the variance and PC2 identified several significant (P = 0.03) putative metabolites that changed over time. For the UPLC-MS data, separation over time was not as obvious but PC2 vs. PC6 did account for 28% of the variance and PC2 identified some significant (P = 0.04) metabolites that changed with time. After FDR adjustment of the GC–MS and UPLC-MS data, only C553, an unknown compound, was significantly (P = 0.02) greater in Day 11 uterine flushings compared to Day 9 and 10. However, several annotated compounds were trending toward differences, including aminomalonic acid which tended to be increased (P = 0.07) in Day 11 uterine flushings compared to Day 9 and 10. In conclusion, these data illustrate putative metabolites that change within the uterine milieu as porcine embryos transition between spherical, ovoid, and tubular embryos. USDA is an equal opportunity provider and employer.

Key Words: embryo elongation, metabolome, uterine milieu

1071 Effect of neuromedin u on pig immune regulation.

Z. Lei*, *Nanjing Agricultural University, nanjing, AZ, China*

Neuromedin U (NMU) is a conserved mammalian neuropeptide discovered in the 1980s, and found in two forms, NMU-25 and NMU-8. Wide distribution of NMU in animal organs suggests that NMU is involved in multiple physiological functions, including immue regulation. However, the role of NMU in pig immune regulation is still largely unknown. To study the effect of NMU on pig immune regulation, we cloned and detected the expression of NMU and its receptors in pig lymphatic organs and immune cells. We also investigated the effect of NMU on cytokine secretion after injection of (0, 5, 15, 45 nmol) NMU via intracerebral ventricle (i.c.v) into 16 pigs (n = 4 within each group), and the effect of (0.1 × 1000 nM) NMU on cytokine secretion in cultured dendritic cells and natural kill (NK) cells using ELISA and RIA methods. The results were as follows: 1. NMU and its receptors are expressed in lymphatic organs, cultured dendritic cells and NK cells. 2. Compared with the control group, NMU stimulated (P < 0.05) IL-1β, IL-6, IL-8, TNF-α and IL-10 secretion post-injection in a time- and dose-dependent manner. 3. NMU increased IL-8, IL-6 and IL-13 secretion and reduced IL-10 secretion (P < 0.05) in cultured dendritic cells. 4. NMU enhanced the killing activity of cultured NK cells, stimulated IFN-γ secretion and inhibited IL-10 secretion (P < 0.05) in NK cells in a time- and dose-dependent manner. Results from this study suggest that NMU has a role in pig immune regulation through its effect on cytokine secretion and increasing killing activity of NK cells.

Key Words: cytokine, immune regulation, NMU

1072 Evaluation of immune function of circulating leukocytes during the transition period in dairy cows.

A. Minuti*[1], N. Jahan[2], F. Piccioli-Capelli[1], L. Bomba[1], S. Capomaccio[3], J. J. Loor[4], P. Ajmone-Marsan[1], E. Trevisi[5], *[1]Università Cattolica del Sacro Cuore, Piacenza, Italy, [2]IUBAT- International University of Business Agriculture and Technology, Dhaka, Bangladesh, [3]Università degli Studi di Perugia, Perugia, Italy, [4]University of Illinois, Urbana, IL, [5]UniversitaÂ Cattolica del Sacro Cuore, Piacenza, Italy*

The aims of the study were to determine immune function circulating leukocytes using an ex vivowhole blood stimulation assay (WBA) with lipopolysaccharide (LPS) and assess gene expression profiles by RNA sequencing in the transition period of dairy cows. The WBA was performed on whole blood of 6 Holstein multiparous cows at −20, −3, 3, 7 d from parturition (DFP) using 0, 0.01 and 5 μg LPS/mL. The plasma collected after stimulation was used to analyze IL-1β and IL-6 concentration via ELISA. The data were analyzed as a factorial design with repeated measures, using PROC MIXED in SAS. At the same day of the WBA test, RNA was isolated from whole blood and sequenced on a Hiseq1000 (Illumina, USA). Differential gene expression analysis was conducted with the edgeR package, and a general linear model was applied considering −20 DFP as the baseline. A threshold of 1.5-fold change and P < 0.05 were used to define differentially expressed genes (DEG), which were subsequently analyzed through the Dynamic Impact Approach (DIA) using the Kyoto Encyclopedia of Genes and Genomes (KEGG) database. The IL-1b and IL-6 released after LPS stimulation was higher at −3 DFP (P < 0.05) in comparison with −20 DFP. After calving, the response of IL-1β to stimulation of LPS decreased markedly, while the IL-6 response was unchanged up to 3 DFP (P < 0.01 vs. -20 DFP) and then declined at 7 DFP. The most-impacted and activated KEGG pathways highlighted by the DIA

analysis at −3 vs. −20 DFP were: PPAR signaling, adipocytokine signaling, hematopoietic cell lineage, ECM-receptor interaction and phagosome. After calving (3 and 7 DFP) the impact and activation of the above listed pathways was strongly increased, but there also was a strong inhibition of arachidonic acid metabolism (in particular enzymes regulating leukotrienes synthesis) as well as glycine, serine and threonine metabolism. Overall, the WBA and transcriptomic data confirmed changes in immune-competence of the circulating leukocytes around calving and, in particular, indicate mainly an increase of their activity and function. These data support the idea that the dairy cow's immune system is dysfunctional but not immunosuppressed around calving.

Key Words: Immune system, transition period dairy cows, transcriptomics, whole blood stimulation assay

1073 Branched-chain amino acids (BCAA) in serum and skeletal muscle and mRNA expression of BCAA catabolizing enzymes in muscle of dairy cows around parturition.

Y. Yang[1], H. Sauerwein[1], C. Prehn[2], J. Adamski[2], J. Rehage[3], S. Dänicke[4], H. Sadri[*1], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Bonn, Germany, [2]Institute of Experimental Genetics, Genome Analysis Center, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany, [3]University for Veterinary Medicine, Foundation, Hannover, Germany, [4]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Braunschweig, Germany*

The BCAA (Leu, Ile, and Val), besides being substrates for protein synthesis or generation of energy, also act as signaling molecules and modulate overall AA and protein metabolism. The BCAA are mainly catabolized in skeletal muscle by transamination, followed by an irreversible oxidative decarboxylation by the action of branched-chain α-keto acid dehydrogenase complex (BCKDH). In view of the substantial mobilization of muscle protein during the transition period and the specific requirements of BCAA for milk protein synthesis and for supporting immune functions, our objective was to investigate the changes in the expression of BCAA catabolizing enzymes in conjunct with BCAA profiles during late gestation and the subsequent lactation in dairy cows. Biopsies from *M. semitendinosus* and blood were collected from 11 multiparous German Holstein cows on d −21, 1, 21, and 70 relative to calving. The BCAA profiles in muscle and serum were determined by LC-MS/MS profiling through targeted metabolomics using the Biocrates Absolute IDQ p180 Kit. The mRNA abundance of BCKDHA and BCKDHB was quantified by qPCR. Data were analyzed using the MIXED procedure of SAS. The concentrations of Leu, Ile, and Val in muscle increased from d −21 to d 1 ($P < 0.001$), remained unchanged until d 21 and then declined (except in case of Val) on d 70 ($P < 0.001$). In serum, the concentrations of Val and Ile changed over time ($P < 0.01$ and 0.06, respectively), whereas Leu remained stable. The mRNA abundance of BCKDHA decreased ($P = 0.03$) from d −21 to d 1, followed by a 1.9-fold increase ($P < 0.01$) on d 21 and then again declined thereafter ($P < 0.01$). The abundance of BCKDHB mRNA decreased 1.7-fold from d −21 to d 1 ($P < 0.01$), remained at this level on d 21, and then increased ($P < 0.01$) to nearly prepartum values on d 70. Negative correlations ($P < 0.01$) between BCKDHB mRNA abundance and muscle concentrations of Leu, Ile, and total BCAA ($r = −0.48$, −0.53, and −0.44, respectively) were observed across all time-points. Reduced abundance of BCKDHA and BCKDHB mRNA coincided with greater muscle concentrations of BCAA, suggesting an attenuation of BCAA oxidation in skeletal muscle shortly after parturition. This would favor sparing of BCAA for milk protein synthesis and other metabolic processes.

Key Words: branched chain amino acids, dairy cow, skeletal muscle

1074 Incidence and risk factors related to anovulation in dairy cows.

P. L. J. Monteiro Jr[*1], B. Gonzales[2], J. N. Drum[1], A. B. Prata[1], S. Soriano[3], J. E. P. Santos[4], M. C. Wiltbank[5], R. Sartori[1], *[1]University of São Paulo- ESALQ/USP, Piracicaba, Brazil, [2]Large Animal Veterinary Practitioner- Campestre Dairy, Sao Pedro, Brazil, [3]Fazenda Colorado, Araras, Brazil, [4]University of Florida, Gainesville, FL, [5]University of Wisconsin, Madison, WI*

This study evaluated incidence and risk factors associated with anovulation in lactating dairy cows. Primiparous ($n = 357$) and multiparous ($n = 585$) Holsteins (43.6 ± 11.0 kg/d of milk and body condition score at 35 ± 3 days in milk [DIM] of 2.9 ± 0.3 [mean ± sd) had ovaries scanned at 35 ± 3 and 49 ± 3 DIM at PGF2α treatments of the Presynch to determine presence of corpus luteum and diameter of the largest follicle. Cows without corpus luteum at both examinations were considered anovular and classified in phenotypes according to follicle diameter: 4 to 8 mm; 9 to 14 mm; 15 to 24 mm; and ≥ 25 mm. The following information was collected until 49 ± 3 DIM. Dry period, incidence of retained placenta, metritis, ketosis, mastitis, lameness, respiratory and digestive problems. Cows detected in estrus until 5 d after the second PGF2α of the Presynch were inseminated, and the other cows were subjected to a fixed-time artificial insemination (FTAI) protocol. Categorical data were analyzed by logistic regression using the GLIMMIX procedure of SAS, and continuous data were analyzed using of the MIXED procedure ($P < 0.05$). The incidence of anovulation was 28.5% (268/942), and the distribution of phenotypes was 4.1% (11/268), 27.6% (74/268), 59.7% (160/268), and 8.6% (23/268) for 4 to 8 mm, 9 to 14 mm, 15 to 24 mm, and ≥ 25 mm, respectively. There was

a positive linear effect of dry period, and a negative linear effect of BCS on the incidence of anovulation. Milk production level was not associated with anovulation. Less healthy cows were anovular as compared to cows with history of one or multiple diseases (17.9%[c] [61/341], 29.8%[b] [94/315], and 39.5%[a] [113/286], respectively). All evaluated diseases were associated with increased incidence of anovulation when analyzed separately. A lower proportion of anovular cows was inseminated by estrus detection (27.1% [49/181] vs. 63.5% [344/542]) and, regardless of AI type, anovular cows were inseminated later (73.0 vs. 62.0 DIM) than cyclic cows. There was no difference in pregnancy per AI (P/AI) on d 60 of cows inseminated after estrus detection between anovular and cyclic cows (16.7% [8/48] vs. 18.1% [62/342], respectively). Nevertheless, when inseminated by FTAI, anovular cows had lower P/AI on d 60 than cyclic cows (16.3% [22/135] vs. 25.6 [50/195]). In conclusion, peri-parturient diseases were highly associated with increased anovular condition. Additionally, anovular cows had delayed first postpartum AI and lower P/AI when submitted to FTAI.

1075 Increasing fatty acid oxidation improves insulin sensitivity in primary differentiated bovine adipocytes. J. E. Rico*, F. Seck, M. V. Pinti, J. W. McFadden, *West Virginia University, Morgantown, WV*

Dairy cows develop insulin resistance during the transition from gestation to lactation. Because insulin is an anti-lipolytic hormone, insulin resistance promotes adipose tissue lipolysis. Increasing fatty acid oxidation (FAox) is a means to improve insulin sensitivity in monogastrics. Therefore, our objective was to evaluate the effects of a pharmacological stimulator of FAox on insulin sensitivity in bovine adipocytes. To test our objective, we utilized subcutaneous adipose tissue collected from Angus steers. Stromal-vascular cells were grown from explants in DMEM/F12 growth medium containing 17.5 mM glucose and 10% fetal bovine serum (FBS). Cells were harvested by trypsinization and replated. Once confluent, cells were differentiated using DMEM/F12 medium containing 17.5 mM glucose, 5 mM acetate, 1 mM octanoate, 5% FBS, 1.72 mM insulin, 0.25 mM dexamethasone, 0.5 mM isobutylmethylxanthine, and 2 mM rosiglitazone. Following d 8 of differentiation, cells were cultured in DMEM/F12 treatment medium containing 5 mM glucose, 1 mM acetate, 1% FBS, and 1.2 nM insulin. Differentiated adipocytes were treated with C75 (stimulator of carnitine palmitoyltranserase 1 and FAox; 0 to 100 μM) or palmitic acid (C16:0; 0 to 800 μM) complexed with bovine serum albumin for 3 to 18 h. Control cells did not receive C75 or C16:0 treatment. A minimum of two independent experiments with three replicates per experiment were performed. The statistical model included the fixed effects of treatment, experiment, and their interaction. Replicate within experiment was the random effect. Triacylglycerol (TAG) accumulation and cell viability were determined using colorimetric and fluorescence assays, respectively. Measurement of FAox and insulin sensitivity were measured using radiolabeled 2-deoxyglucose (2DOG) and C16:0. Relative to undifferentiated adipocytes, TAG accumulation was 736% greater in differentiated adipocytes ($P < 0.01$). Following differentiation, treatment with C16:0 or C75 for 18 h did not impair cell viability. Interestingly, 100 μM C75 improved cell viability by 40%, relative to control ($P < 0.01$). Treatment of adipocytes with 100 μM C75 for 3 h increased FAox, as demonstrated by a 122% increase in the recovery of radiolabeled acid-soluble products as well as a 30% increase in radiolabeled CO_2 ($P < 0.05$). Although C16:0 did not modify insulin 2DOG uptake following an 18 h treatment, treating adipocytes with 100 μM C75 for 18 h increased 2DOG uptake by 141%, relative to control ($P < 0.01$). We conclude that the stimulation of FAox enhances insulin-stimulated glucose uptake in primary differentiated bovine adipocytes.

Key Words: C75, fatty acid oxidation, insulin sensitivity

1076 Global gene expression in the endometrium of primiparous dairy cows during the early-luteal phase of the estrous cycle. A. L. Astessiano Dickson*[1], F. Peñagaricano[2], A. Meikle[3], and M. Carriquiry[1], *[1]Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay, [2]University of Florida, Gainesville, [3]Facultad de Veterinaria, Montevideo, Uruguay.*

The uterine endometrium plays a central role in early conceptus-maternal communication for the establishment and maintenance of pregnancy. Primiparous Holstein dairy cows were used in a randomized block design to evaluate gene expression changes in the endometrium during the early-luteal phase of the estrous cycle induced by two different feeding strategies: total mixed ration (TMR) vs. pasture + TMR applied during early lactation. In particular, during the first 65 d of lactation, cows were fed either [i] TMR ad libitum (17 kgDM/d offered; 70% forage, 30% concentrate; T1) or [ii] grazing of alfalfa (*Medicago sativa*; 6-h am grazing in 3-d strips; pasture allowance = 20 kgDM/d) plus TMR (70% of ad libitum TMR; 12 kgDM/d offered; T2). At 45 ± 1 d, cows were synchronized and at d 7 of the estrous cycle (d 0 = estrous) endometrial biopsies were obtained. A total of 10 endometrium samples (5 cows per treatment) were analyzed using RNA sequencing. Sequence reads were mapped to the bovine reference genome (bosTau7) using Tophat and the resulting alignments were used to reconstruct transcript models using Cufflinks. Gene expression differences were tested using edgeR package. From the 14,753 genes detected

in the transcriptome, 102 genes were differentially expressed (FDR = 0.10; fold change $\geq$ 2) between T1 vs. T2. Specifically, 20 genes were significantly upregulated in T1 while 82 genes were upregulated in T2. Many of these genes are involved in biological processes such as regulating enzymatic activity (e.g., phospholamban, secretoglobin family 1A member 1), protein binding (e.g., caveolin 3, α-2-HS-glycoprotein), and immune response (e.g., immunoglobulin heavy constant epsilon, major histocompatibility complex class II DQ β, myelin protein P0-like). Functional enrichment analysis, using both Gene Ontology and KEGG databases, revealed significant terms associated with cell and tissue development, cell adhesion, endopeptidases, calcium ion transport, calcium signaling, tryptophan metabolism, among others, with most of the genes being upregulated in T2 compared to T1. Overall, this study characterized genes and pathways expressed in the endometrium of dairy cows at Day 7 of the estrous cycle, and evidenced a differential endometrial environment according with a nutritional management during early lactation in which most of the genes differentially expressed were upregulated in grazing cows.

Key Words: dairy cows, nutrition, transcriptome

1077 Influence of reproductive indicators and genetic parameters on lactation curves.

H. Jeong*[1], D. Gonzalez-Pena[2], T. M. Goncalves[1], P. J. Pinedo[3], J. E. P. Santos[4], G. M. Schuenemann[5], G. J. M. Rosa[6], R. O. Gilbert[7], R. C. Bicalho[7], R. Chebel[4], K. N. Galvão[8], C. M. Seabury[9], W. W. Thatcher[10], and S. L. Rodriguez Zas[1], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]Zoetis, Kalamazoo, MI, [3]Colorado State University, Fort Collins, [4]University of Florida, Gainesville, [5]Department of Veterinary Preventive Medicine, The Ohio State University, Columbus, [6]University of Wisconsin-Madison, Madison, [7]Cornell University, Ithaca, NY, [8]Department of Large Animal Clinical Sciences, University of Florida, Gainesville,, [9]Texas A&M University, College Station, [10]Department of Animal Sciences, University of Florida, Gainesville.*

Low levels of reproduction indicators in dairy farms are linked to low net returns associated with low milk production and replacement levels and high breeding and veterinary costs. The objectives of this study were to assess the association between lactation curve and reproductive efficiency and to evaluate the genetic variability. A novel reproductive indicator that combines pregnancy status after first (Prg first AI) and second artificial insemination (Prg second AI) and subsequent pregnancy loss after first (Non-Prg first AI) and second artificial insemination (Non-Preg second AI) was developed. The lactation curve was described using Wilmink's and Wood's functions that were incorporated into nonlinear mixed effects models that included the effect of sire, contemporary group, lactation number, the novel reproductive indicator, months open after calving, and cyclicity status at Day 35 after calving. Data on more than 50,000 test-day milk records from more than 6000 U.S. Holstein cows were considered. Cyclicity status was not associated with any lactation curve parameter. Higher months open was associated with higher persistency in milk yield. Estimates from the Wilmink function indicated that cows positive for Prg first AI and negative for Non-Prg first AI and cows negative for Prg first AI, positive for Prg second AI, and negative for Non-Prg second AI had significantly higher levels of milk yield during lactation, higher milk yield at peak production, and lower persistency than cows positive for Non-Prg first and 2ndAI. The Wood's parameter estimates confirmed the higher milk yield immediately after calving, higher incline in milk yield after calving, and higher persistency of the former relative to the latter reproductive groups. The ratio of sire to residual variance estimates was 0.4 and was consistent across models. The novel reproductive indicator that integrates reproduction-related variables intrinsic to the cow combined information on pregnancy and pregnancy loss at the first two AI events and together with genetic parameter estimates offers insights into the factors influencing the lactation curve. These findings contribute to a long-term multistate project database (USDA-NIFA-AFRI-003542) for direct measures of fertility.

Key Words: lactation curves, nonlinear mixed models, reproductive efficiency

1078 Hematocrit, milk yield, and production related parameters comparisons between slick and wild-type-haired Puerto Rican Holstein cows.

Z. Contreras-Correa*[1], G. Muñiz-Colón[1], M. Pagán-Morales[2], A. Mesonero-Morales[1], J. Curbelo-Rodríguez[1], and H. L. Sánchez-Rodríguez[1], *[1]University of Puerto Rico at Mayagüez, Mayagüez, Puerto Rico, [2]Department of Animal Science, University of Puerto Rico, Mayagüez, Puerto Rico.*

Previous research has suggested the presence of a slick hair coat as well as greater hematocrit values (HCT) as adaptations resulting in the thermoregulatory superiority of *Bos indicus* in comparison with *Bos Taurus* cattle. However, although it is well established that wild-type-haired (WT) Holstein cows have inferior thermoregulatory capacity than their slick-haired (SLICK) counterparts, there has been no research comparing both phenotypes in terms of HCT values in the Puerto Rican dairy cattle population. Therefore, the present study compared the HCT values (recorded in triplicate) from 29 SLICK and 35 WT lactating Puerto Rican Holstein cows. The SLICK and WT classifications were previously confirmed in a genotyping experiment. Additionally, to determine the uniformity of the evaluated groups the body weight (BW), days in milk (DIM), number of lactations, and production (averaged from the week

before the sampling) were compared between phenotypes. Data, averaged by cow, were analyzed using the GLIMMIX procedure of SAS. No differences were found in BW (538.25 ± 11.77 vs. 570.31 ± 15.61kg; $P = 0.5098$), DIM (187.57 ± 16.25 vs. 186.90 ± 18.17; $P = 0.9992$), and lactation number (1.94 ± 0.25 vs. 2.17 ± 0.22; $P = 0.9984$) between WT and SLICK cows, respectively. However, WT cows exhibited lower milk production values than their SLICK counterparts (17.11 ± 0.63 vs. 20.26 ± 1.28 kg/d; $P = 0.0288$, respectively). Nevertheless, there were no differences ($P = 0.4040$) in HCT values between the WT and SLICK cows (29.30 ± 0.46 vs. 29.79 ± 0.49, respectively). Although there was a difference in milk production, our results suggest that greater HCT values are not part of the adaptations to hot environments present in the Puerto Rican slick-haired Holstein cattle.

Key Words: heat stress, hematocrit, milk yield, slick-haired

1079 Effect of milk yield genotype on hepatic metabolic gene expression and repeated lipopolysaccharide (LPS) administration. G. T. Cousillas[*1], W. J. Weber[1], B. Walcheck[1], R. Chebel[1], D. E. Kerr[2], T. H. Elsasser[3], and B. A. Crooker[1], *[1]University of Minnesota, Saint Paul, [2]University of Vermont, Burlington, [3]USDA, Agricultural Research Service, Beltsville, MD.*

Objectives were to determine effects of milk yield genotype on hepatic expression of genes related to the somatotropic axis and glucose and lipid metabolism during an LPS challenge. Multiparous cows ($n = 12$/genotype) from unselected (stable milk yield since 1964, UH) and contemporary (CH) Holsteins that differed by more than 4500 kg milk/305-d were housed together and fed the same diet ad libitum for more than 4 mo before being blocked (2/genotype) by DIM and randomly assigned within genotype to receive saline or 0.25 μg/kg BW of LPS (*Escherichia coli* 055:B5). Cows were synchronized to be at Day 8 of their estrous cycle for the first challenge (C1) at 70–84 DIM. Liver biopsies were collected at 0, 4, and 24 h relative to treatment. A second identical challenge (C2) and sampling was conducted 4 d later. RNA was extracted and expression of 23 genes associated with metabolism were determined by digital multiplexed analysis (nanoString nCounter). Expression was normalized to the positive control and the geometric mean of 4 internal control genes. Data were transformed (square root) and analyzed by repeated measures using PROC MIXED (SAS) with time as the repeated effect. Means differed when $P < 0.05$. Sixteen genes presented a time by treatment interaction due to changes in expression after LPS. Expression of INSR, INSR-b, and IGFBP2 was greater and GHR-1A was less in CH than UH, expression of these genes decreased in response to LPS in both challenges, but the response did not differ between genotypes. There was a time by challenge interaction for IGFBP2 as it was decreased at 24 h in C1 but not in C2. There were challenge effects for IGF1 and GHR-1A due to greater expression in C1 than in C2 but the response did not differ between genotypes. There were time by treatment interactions for PC1, PCK1, PPARa, and PPARd. In response to LPS expression of PC1 and PPARd increased, and PCK1 and PPARa decreased at 4 h in both challenges, but the response did not differ between genotypes. Results indicate that LPS administration altered hepatic expression of genes related to the somatotropic axis, glucose, and lipid metabolism and that these responses were similar for the low and high milk yield genotypes.

Key Words: bovine genotype, gene expression, lipopolysaccharide, metabolism

1080 Milk yield genotype impacts expression of hepatic innate immune genes during the transition period in Holsteins. *G. T. Cousillas[*1], W. J. Weber[1], B. Walcheck[1], D. E. Kerr[2], T. H. Elsasser[3], and B. A. Crooker[1], [1]University of Minnesota, Saint Paul, [2]University of Vermont, Burlington, [3]USDA, Agricultural Research Service, Beltsville, MD.*

Objectives were to determine effects of milk yield genotype on hepatic expression of genes related to innate immunity. Multiparous cows from unselected (stable milk yield since 1964; UH; $n = 10$) and contemporary (CH; $n = 10$) Holsteins that differed in milk yield by more than 4500 kg milk/305-d were housed together, fed the same diet ad libitum, and milked 2X/d. Liver biopsies were collected at −14, 3, 14, and 42 d in milk (DIM). RNA was extracted and expression of 44 genes was determined by digital multiplexed analysis (nanoString nCounter). Expression was normalized to the positive control and the geometric mean of 4 internal control genes. Data were transformed (square root) and analyzed by repeated measures using PROC MIXED (SAS) with DIM as the repeated effect. Means differed when $P < 0.05$. Expression of 19 genes was altered by DIM. Expression of 9 genes was greater and 9 genes was less in CH than UH. There were genotype by DIM interactions for CD14 and C/EBPd. Expression of CD14 was lower in CH than UH. In both genotypes, expression of CD14 decreased at 3 DIM, but remained lower in CH through 42 DIM, while CD14 expression recovered at 14 DIM in UH. C/EBPd expression was greater in CH than UH. In CH expression of C/EBPd increased at 3 DIM and returned to prepartum values at 42 DIM. Expression of C/EBPd in UH did not decrease until 42 DIM. LBP and XBP1 were greater in CH than UH, increased at 3 DIM and recovered by 14 DIM. TLR4 decreased at 3 DIM and although it was increasing, remained less than prepartum expression through 42 DIM for both genotypes. TLR2 and ICAM1 were less in UH than CH, decreased at 3 DIM and remained decreased by 42 DIM. XDH was greater in CH than UH, increased at 14 DIM and remained increased by 42 DIM. IL-1b was greater in UH than CH, but its receptor (IL1bR1) was less in UH than CH

and there was no effect of DIM. Results indicate expression of genes involved with cytokine production, inflammation, cell differentiation and activation were altered in both genotypes during the transition period and that there was a less robust response in the contemporary cow.

Key Words: gene expression, Holstein genotype, innate immunity

1081 Effect of milk yield genotype on hepatic metabolic gene expression during the transition period.

G. T. Cousillas*[1], W. J. Weber[1], B. Walcheck[1], D. E. Kerr[2], T. H. Elsasser[3], B. and A. Crooker[1], *[1]University of Minnesota, Saint Paul, [2]University of Vermont, Burlington, [3]USDA, Agricultural Research Service, Beltsville, MD.*

Objectives were to determine effects of milk yield genotype on hepatic expression of genes related to the somatotropic axis and carbohydrate and lipid metabolism. Multiparous cows from unselected (stable milk yield since 1964; UH; $n = 10$) and contemporary (CH; $n = 10$) Holsteins that differed in milk yield by more than 4500 kg milk/305-d were housed together, fed the same diet ad libitum, and milked 2X/d. Liver biopsies were collected at −14, 3, 14, and 42 d in milk (DIM). RNA was extracted and expression of 23 genes was determined by digital multiplexed analysis (nanoString nCounter). Expression was normalized to the positive control and the geometric mean of 4 internal control genes. Data were transformed (square root) and analyzed by repeated measures using PROC MIXED (SAS) with DIM as the repeated effect. Means differed when $P < 0.05$. Expression of 17 genes was altered by DIM. Liver expression of 8 genes was greater and 5 genes was less in CH than UH. There was a genotype by DIM interaction for STAT5A as it decreased at 3 DIM and recovered by 42 DIM in CH but did not change in UH. GHR-1A and IGF-1 were less and STAT3 greater in CH than UH but expression of JAK2 and STAT5B did not differ. There was a genotype by DIM interaction for PC1 as it increased at 3 DIM in both genotypes and remained increased by 42 DIM in CH; in UH PC1 returned to prepartum values at 42 DIM. INSR, PCK1, and PPARGC1A were greater in CH than UH, increased at 3 DIM and remained increased by 42 DIM. PPARa did not differ between genotypes, decreased at 3 DIM and returned to pre-partum values by 14 DIM. PPARd did not differ between genotypes or DIM. Results are consistent with postpartum reduction in hepatic sensitivity to somatotropin which lasted longer in CH cows. During the postpartum interval, expression of INSR and genes for enzymes related to gluconeogenesis were greater in CH than UH which is consistent with their greater need for lactose synthesis in the contemporary cow.

Key Words: gene expression, milk genotype, transition

1082 Gene expression and secretion of chemerin in bovine mammary epithelial cells.

Y. Suzuki*[1], S. Chiba[1], S. Haga[2], and S. Roh[1], *[1]Lab of Animal Physiology, TOHOKU University, Sendai, Japan, [2]NARO Institute of Livestock and Grassland Science, Nasushiobara, Japan.*

A variety of cytokines are secreted in a paracrine manner within the bovine mammary gland to maintain the microenvironment of the tissue. Our previous study showed that treatment with chemerin induced the expression of genes related to lactogenesis in immortalized bovine mammary epithelial cells (MAC-T cells). This suggested that chemerin is a secreted protein with chemotactic ability to antigen presenting cells has a regulatory effect on the function of mammary gland. However, what type of cell in mammary glands expresses chemerin and what kind of factor regulates its expression are not clear. In this study, we investigated the chemerin protein expression in bovine mammary tissues, milk, and cultured MAC-T cells. Mammary tissues were sampled from Holstein dairy cows in the lactation and dry-off periods, and chemerin protein expression was determined immunohistochemically. Chemerin protein was also detected in fresh milk and cell lysate of MAC-T cells by western blotting. Further, the effect of TNF-α on chemerin mRNA expression was investigated in MAC-T cells. MAC-T cells were grown until confluence and then treated with TNF-α (0.1, 1, and 10 nM) for 24 h. Chemerin gene expression was analyzed by Q-RT-PCR. Statistical analysis was performed using Tukey's HSD test. The results showed that chemerin protein was expressed in epithelial cells and stromal cells of bovine mammary gland from Holstein dairy cows and in cultured MAC-T cells. In addition, secreted chemerin protein was also detected in fresh milk. TNF-α significantly induced chemerin mRNA expression in MAC-T cells ($p < 0.05$). These results indicate that chemerin is secreted within the mammary gland in an auto/paracrine manner and that chemerin expression is upregulated by inflammatory cytokine. This study suggests the roles of chemerin as a chemoattractant that might attract immune cells to eliminate infectious bacteria or apoptotic cells in the mammary gland, as well as its role in lactogenesis.

Key Words: chemerin, inflammatory cytokine, mammary epithelial cells

1083 Proteomic analysis reveals increased Nrf2-mediated oxidative stress response in adipose tissue of late pregnant dairy cows during summer heat stress. M. Zachut[*1], G. Kra[1], G. Friedlander[2], and Y. Levin[3], *[1]Institute of Animal Science, Volcani Center, Bet Dagan, Israel, [2]The Ilana and Pascal Mantoux Institute for Bioinformatics, Weizmann Institute of Science, Rehovot, Israel, [3]The Nancy and Stephen Grand Israel National Center for Personalized Medicine, Weizmann Institute of Science, Rehovot, Israel.*

Nuclear factor erythroid 2-related factor 2 (Nrf2) is a critical regulator of key aspects of the antioxidant defense pathway under chronic stress. Oxidative stress and Nrf2 affect adipose tissue (AT) function. Heat stress at late pregnancy affects the physiology and performance in subsequent lactation. We investigated the effects of seasonal heat load on the proteome of adipose tissue in late pregnant dairy cows. Adipose tissue biopsies were obtained from 18 multiparous late pregnant dry cows at 14 d before expected calving during summer (S, n = 10) or winter (W, n = 8). Cows were also divided retrospectively according to BW loss during the first month postpartum to HWL–high weight loss (n = 9), and LWL–low weight loss (n = 9). Blood samples were collected twice a week for oxidative stress marker malondialdehyde (MDA) and cortisol concentrations. Proteins were analyzed by intensity based, label-free quantitative shotgun proteomics at Weizmann Institute of Science (Rehovot, Israel). Proteins were extracted and subjected to in-solution tryptic digestion, followed by nanoflow liquid chromatography coupled to high-resolution tandem mass spectrometry (nanoLC-MS/MS). Quantitative data were extracted using Genedata Expressionist data analysis package and proteins identified using Mascot search engine. Proteomics data, after logarithmic transformation, were analyzed by two-way ANOVA for effects of season (S vs. W), subgroup (HWL vs. LWL), and their interaction. Both pre- and postpartum, S cows had higher plasma MDA and cortisol concentrations compared with W (P < 0.005). Proteomic analysis quantified 1496 proteins in AT, from which the abundance of 132 (8.8%) proteins was differential in S vs. W [Fold change (FC) ± 1.5 and P < 0.05]. One of the top canonical pathways affected by season was Nrf2-mediated oxidative stress response (Ingenuity Pathway Analysis, Qiagen); the abundance of ubiquitin-conjugating enzyme E2 K (P < 0.006) and stress-induced-phosphoprotein 1 (P < 0.001) was elevated, while mitogen-activated protein kinase kinase 1 (P < 0.02), ferritin (P < 0.02), glutathione S-transferase Mu 1 (P < 0.04) and microsomal glutathione S-transferase 1 (P < 0.02) decreased in S vs. W adipose. These findings imply that Nrf2-mediated oxidative stress response plays a main role in the reaction of AT to counterbalance the increased oxidative stress under heat stress conditions in late pregnant dairy cows.

Key Words: adipose, heat stress, proteomics, transition

1084 Cholesterol deficiency associated APOB mutation affects lipid metabolism in Holstein cattle. J. J. Gross[*1], A. C. Schwinn[1], F. Schmitz-Hsu[2], F. Menzi[3], C. Drögemüller[3], C. Albrecht[4], and R. M. Bruckmaier[1], *[1]Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland, [2]Swissgenetics, Zollikofen, Switzerland, [3]Institute of Genetics, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [4]Institute of Biochemistry and Molecular Medicine, University of Bern, Bern, Switzerland.*

During the last months, the number of reports on Holstein calves suffering from incurable idiopathic diarrhea dramatically increased. Affected calves showed severe hypocholesterolemia, and mostly died within days up to a few months after birth. This new autosomal monogenic recessive inherited fat metabolism disorder termed cholesterol deficiency (CD) is caused by a loss of function mutation of the bovine *APOB* gene. The objective of the present study was to investigate specific components of the lipid metabolism in 6 CD affected homozygous for the *APOB* mutation (CDS) and six normal Holstein calves with different *APOB* genotypes. Independent of sex, CD affected calves (CDS) had significantly lower plasma concentrations of total cholesterol (TC), free-cholesterol (FC), high density lipoprotein-cholesterol (HDL-C), low density lipoprotein-cholesterol (LDL-C), very low density lipoprotein-cholesterol (VLDL-C), triacylglycerides (TAG), and phospholipids (PL) compared to homozygous wild-type calves (P < 0.05). Furthermore, we studied the effect of the *APOB* genotype on cholesterol metabolism in adult Holstein breeding bulls of Swissgenetics. Among a total of 254 adult males the homozygous mutant genotype was absent, 36 bulls were heterozygous carriers (CDC), and 218 homozygous wild-type (CDF). In CDC bulls, plasma concentrations of TC, FC, HDL-C, LDL-C, VLDL-C, TAG, and PL were lower compared to CDF bulls (P < 0.05). The ratios of FC:cholesteryl esters (CE), and FC:TC were higher in CDC compared to CDF bulls, whereas the ratio of CE:TC was lower in CDC compared to CDF bulls (P < 0.01). In conclusion, the cholesterol deficiency associated *APOB* mutation was shown to affect lipid metabolism in affected Holstein calves and adult breeding bulls. Besides cholesterol also the concentrations of PL, TAG, and lipoproteins were distinctly reduced in homozygous and heterozygous carriers of the *APOB* mutation. Beyond malabsorption of dietary lipids, deleterious effects of apoB deficiency on hepatic lipid metabolism, steroid biosynthesis, and cell membrane function can be expected, which may result in unspecific symptoms of reduced fertility, growth, and health.

Key Words: cholesterol deficiency, hypobetalipoproteinemia, hypocholesterolemia

1085 Characterization of changes in temporal concentrations of fibroblast growth factor 21 (FGF21) before and after parturition in multiparous beef cows. L. Prezotto*[1], J. F. Thorson[1], J. Dafoe[1], M. R. Herrygers[2], and J. G. Berardinelli[2], *[1]Montana State University, Havre, [2]Montana State University, Bozeman.*

The objectives of this experiment were to characterize the secretion of Fibroblast Growth Factor 21 (FGF21) in beef cows during the last month of gestation, parturition, and early lactation and correlate these concentrations with metabolites. Pregnant, multiparous cows (n = 30) fed a TMR to meet or exceed NRC requirements were weighed and blood samples collected on days −14, −7, 0, 14, 28, and 60 relative to parturition. Samples were assayed for concentrations of FGF21, glucose, BUN, and NEFA. Individual average daily gain (ADG) was calculated for the experimental period. As previously shown in dairy cows, concentrations of FGF21 increased as parturition neared with concentrations of FGF21 increasing (P = 0.003) from day −14 (447 ± 120 pg/ml; mean ± SE) to 0 (790 ± 87 pg/ml). After parturition, concentrations of FGF21 decreased (P < 0.0001) by Day 14 (299 ± 88 pg/ml) to concentrations no different than day −14. Concentrations of FGF21 were maintained (P = 0.85) after parturition to Day 28 (288 ± 88 pg/ml). At Day 60, concentrations of FGF21 tended (P = 0.08; 391 ± 87 pg/ml) to increase compared to concentrations on Day 28. Concentrations of FGF21 and ADG tended (P = 0.09) to be negatively correlated on Day 56. Concentrations of glucose increased (P = 0.002) between day −14 and 0 and then decreased (P = 0.04) between Day 0 and 14. Concentrations of BUN increased (P = 0.0006) from day −14 to 0, decreased (P = 0.03) between Day 0 and 14, then continued to decrease (P < 0.0001) from Day 28 to 60. Finally, concentrations of NEFA decreased (P < 0.0001) from day −14 to 0 then increased (P = 0.04) by Day 14 to concentrations maintained (P = 0.94) to Day 28. There was no correlation (P ≥ 0.42) between metabolites and FGF21 on Day 0. However, on Day 60 concentrations of FGF21 tended (P = 0.09) to be negatively correlated with concentrations of glucose, positively correlated with concentrations of BUN (P = 0.0004), and not correlated with concentrations of NEFA (P = 0.30). These data indicate that FGF21 can be used as a biomarker to indicate reproductive and nutritional status in the beef cow.

Key Words: metabolites, parturition, performance

1086 Effect of investigational kisspeptin/metastin analog, TAK-683, on luteinizing hormone secretion at different stages of the luteal phase in goats. L. P. Rahayu*[1,2], M. E. Behiry[3], N. Endo[1,2], and T. Tanaka[1,2], *[1]Tokyo University of Agriculture and Technology, Tokyo, Japan, [2]United Graduate School of Veterinary Sciences, Gifu University, Gifu, Japan, [3]Visiting Research Scientist from Egypt, Tokyo University of Agriculture and Technology, Tokyo, Japan.*

Our previous study showed differential changes in luteinizing hormone (LH) secretion after administration of an investigational kisspeptin/metastin analog, TAK-683, between the endocrine conditions of the follicular and luteal phases in goats (Anim. Reprod. Sci. 2015). The present study aimed to examine the response of LH secretion to TAK-683 treatment and its association with ovarian changes during different stages of the luteal phase in goats. Nine cycling Shiba goats (4.4 ± 2.3 yr old) were assigned into 3 groups: early luteal phase (ELP, n = 4), mid-luteal phase (MLP, n = 4), and a control (n = 5) group. The ELP and MLP groups were administered 50 µg of TAK-683 intravenously on the 5 d after ovulation and on Days 7–14 after ovulation, respectively. The control group received vehicle on Days 7–14 after ovulation. Blood samples were collected at 10-min (hours 2–6) or 2 h (hours 6–24) intervals, and at 48 h after treatment for analysis of endocrine profiles. Ovarian ultrasonographic images and estrous behavior were assessed daily or every other day until the subsequent ovulation for analysis of effects on follicular and luteal dynamics and the length of the estrous cycle. LH concentration increased with a relatively small amplitude within 6 h of treatment with a mean peak value of 1.9 ± 0.6 ng/ml in the MLP group. Meanwhile, in the ELP group, TAK-683 treatment initially induced a sustained rise in the LH concentration with a relatively small amplitude, and then a surge-like release of LH with the highest values of 18.4 and 12.8 ng/ml, and with a peak time at 12 h and 14 h after treatment, respectively, in 2 goats. There is no significant difference in the progesterone concentration between pre- and post-treatment periods in all groups. Ovulation was detected within 2 d of the administration of TAK-683 in 2 goats showing a surge-like release of LH. Time-course of the LH response to TAK-683 treatment in the 2 goats showing a surge-like release of LH in the ELP group support our previous study that initial secretory response of LH to TAK-683 treatment is characterized as a small amplitude increase, and the secretion pattern of LH subsequently changes to a robust increase. It is suggested that responses of pulsatile and surge mode secretions of LH to the treatment of a kisspeptin analog depend on the stage of luteal phase in cycling goats.

Key Words: kisspeptin, luteal phase, luteinizing hormone

1087 MAC-T cell as in vitro evaluation system for casein gene expression involving glucose level.
H. Y. Jeong*[1], Y. T. Heo[2], H. S. Kang[1], E. T. Kim[1], and H. Song[2], *[1]Dairy Science Division, National Institute of Animal Science, RDA, Cheonan-si, Korea, [2]Konkuk University, Seoul, Korea.*

Glucose is essential fuel in energy metabolism and synthesis pathways of all mammalian cells. In lactating animals, glucose is the major precursor for lactose and is a substrate for the synthesis of milk proteins and fat in mammary secretory (alveolar) epithelial cells. However, clear utilization level of glucose in mammary cell during lactogenesis is still unknown due to lack of in vitro analyzing model. Therefore, objective of this study is to test reliability of mammary alveolar (MAC-T) cell as in vitro study model for glucose metabolism and lactating system. Undifferentiated MAC-T cells were cultured in three types (Non-glucose: 0 g/L, low glucose: 1 g/L, and High glucose: 4.5 g/L) of DMEM for 8 days, and then differentiation was induced. Cell proliferation and expression levels of apoptotic genes, IGF1 receptor, Oxytocin receptor, αS1, αS2, and β casein genes were analyzed at 1, 2, 4, and 8 d after differentiation. Proliferation of MAC-T cells with high glucose treatment was significantly higher. Expression of apoptotic genes was not affected by any groups. However, expression levels of mammary development related gene IFG1 r and lactating related gene Oxytocin r were significantly higher in low glucose group. Expressions of αS1-casein, αS2-casein, and β-casein were also higher in low glucose treated group compared with none and high glucose groups. Results demonstrated that although high glucose environment to MAC-T cells increase cell proliferation, low glucose treatment to MAC-T cells induce higher expression of casein genes. Our results may suggest that MAC-T cell can be in vitro model to analyze mammary cell development and lactation connect with precise biological effects.

Key Words: casein, glucose, IGF1, mammary alveolar (MAC-T) cell, oxytocin

1088 mRNA abundance of steroid hormone metabolizing enzymes (17β-HSD isoforms and CYP19) in adipose tissue of dairy cows during the periparturient period.
A. Alizadeh[1,2,3], H. Sadri[1], J. Rehage[4], S. Dänicke[5], and H. Sauerwein*[1], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Bonn, Germany, [2]Department of Animal Science, Saveh Branch, Islamic Azad University, Saveh, Iran, [3]Department of Embryology, Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran, [4]University for Veterinary Medicine, Foundation, Hannover, Germany, [5]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Braunschweig, Germany.*

Besides being a storage organ for lipophilic compounds such as steroids, adipose tissue (AT) is now recognized in humans as being also capable of synthesizing and interconverting steroid hormones. In view of the comprehensive changes in body fat content of dairy cows during the lactation cycle, effects on steroid metabolism and release and potentially on fertility are conceivable. With this background, our research objectives were (1) to assess the mRNA expression of 17β-hydroxysteroid dehydrogenases (17β-HSD), i.e., the enzymes catalyzing the interconversion between the active and inactive forms of specific steroid hormones (focusing on subtypes 17β-HSD-1, −3 and −12), and of P450-aromatase (CYP19), converting androgens to estrogens, in bovine AT, (2) to characterize the time course of their mRNA abundance during late pregnancy and early lactation and (3) to compare this time course in a subcutaneous versus a visceral fat depot. From 20 Holstein cows, biopsies were collected from the subcutaneous (sc) and the retroperitoneal fat depot (rpAT) on d −42 and d 1, 21, and 100 relative to calving. The mRNA abundance of the target genes was assessed in the tissue samples by qPCR and normalized by using the 4 most stable reference genes. Data were analyzed using the MIXED procedure of SAS. Among the 4 target genes studied, only 17β-HSD-12 mRNA was detectable with the protocol used herein (suitability of the protocols was confirmed using ovary as positive control). The mRNA abundance of 17β-HSD-12 in scAT was highest on d −42, followed by a substantial decline on d 1 and 21 (7.5- and sixfold, respectively), and an increase on d 100 ($P < 0.001$). In rpAT, the peripartal changes of 17β-HSD-12 mRNA abundance were largely analogous to the ones observed in scAT; i.e., the values on d −42 and 100 were greater than on d 1 and 21 ($P < 0.001$). Our results indicate that aromatization of androgens to estrogens via CYP19 is not taking place in bovine AT, but estradiol-17β might be formed in AT by 17β-HSD-12 from estrone taken up from the circulation.

Key Words: 17β-HSD, adipose tissue, dairy cows

1089 Mitochondrial biogenesis and DNA content in metabolically tissues of lactating cows with divergent milk production. R. Weikard* and C. Kühn, *Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany.*

An appropriate metabolic adaptation of key tissues important for bioenergetic homeostasis and lactogenesis is required in cows to adjust for changes in energy demands and physiological conditions during the lactation period. Mitochondria are recognized to be central for meeting energy demands and maintaining metabolic homeostasis, and mitochondrial DNA (mtDNA) content reflects the capacity of cells for energy generation. The focus of our study was to elucidate, if mtDNA content and mitochondrial biogenesis were associated with lactation performance of cows characterized by a divergent genetic background regarding milk production. Therefore, we took advantage of cows from a resource population with a combined genetic dairy and beef background (Charolais x German Holstein cross, CHxGH) and compared them to purebred German Holstein (GH) dairy cows regarding mtDNA content and mRNA expression of important nuclear encoded genes controlling mitochondrial biogenesis in in two metabolically active tissues, liver and mammary gland. Genomic DNA and total RNA were isolated from tissue samples of 30 cows separated into three experimental groups based on their milk production during the week before slaughtering (each $n = 10$). Analysis of expression of genes involved in mitochondrial biogenesis, replication/transcription and translation of mtDNA and determination of mtDNA content were performed using quantitative real-time PCR. The study revealed a tissue-specific variation of mtDNA content that is higher in liver than in mammary gland, which agrees to the higher hepatic metabolic activity. When comparing high-lactating GH cows to cows with medium lactation performance (CHxGH-M), the mtDNA content was similar in liver but clearly reduced in mammary gland in GH cows. Unexpectedly, the mtDNA levels in mammary gland of GH cows resembled those of low-lactating cows (CHxGH-L). Gene expression analysis revealed lower transcript levels of genes involved in mitochondrial biogenesis, replication/transcription and translation in the liver of GH cows compared to CHxGH-M cows. In the mammary gland of GH cows, the gene expression levels pointed to a reduced mitochondrial biogenesis and mtDNA translation compared to CHxGH-M cows, whereas transcript levels related to mtDNA transcription/replication did not differ between both cow groups. The results suggest that the hepatic and mammary mitochondrial biogenesis processes are differentially modulated in high-lactating dairy cows and lactating cows from a CHxGH cross population indicating toward impaired mitochondrial biogenesis during high lactation and obviously reflecting genetic differences in coping with metabolic and physiological changes during lactation.

Key Words: gene expression, lactation, liver, mammary gland, mitochondrial DNA, mitochondrial biogenesis

1090 Lipopolysaccharide exposure in swine alters ovarian toll-like receptor 4 expression. K. L. Bidne*, M. J. Dickson, S. K. Kvidera, L. H. Baumgard, J. W. Ross, and A. F. Keating, *Iowa State University, Ames.*

Heat stress (HS) is associated with decreased fertility and endotoxemia as evidenced by increased systemic lipopolysaccharide (LPS) arising from decreased intestinal integrity. Across multiple species, LPS is associated with reduced female fecundity; phenotypic responses similar to HS-induced infertility, including spontaneous abortion and increased wean-to-estrus interval length. LPS binds to toll-like receptor 4 (TLR4), a membrane bound receptor, to initiate a signaling cascade culminating in the phosphorylation of nuclear factor kappa-B (pNFκB) and pro-inflammatory cytokine production. Acyloxyacyl hydrolase (AOAH) participates in LPS detoxification by cleaving the lipid A moiety, rendering the deacylated LPS unable to effectively bind TLR4. We hypothesized that endotoxemia could impact ovarian function in swine. Postpubertal gilts were synchronized to the follicular phase of their estrous cycle using Matrix® administered orally for 14 d. Immediately following Matrix® removal, gilts were treated with vehicle control (CT; 3 mL sterile saline; $n = 6$) or LPS (0.1 μg/kg BW; *E. coli* 055:B5; $n = 6$) via jugular catheter four times daily (0000, 0600, 1200, 1800 h) for 5 d during the follicular phase preceding estrus. Six hours after the final LPS infusion, animals were euthanized and ovaries collected. Whole ovarian protein homogenates were prepared and western blotting performed to quantify abundance of TLR4 and AOAH protein. Relative to CT, ovaries from LPS treated gilts had reduced ($P < 0.05$) abundance of TLR4 protein. No effect ($P > 0.05$) of LPS infusion on AOAH abundance was observed. These data demonstrate that the ovary to be responsive to chronic, low-level LPS exposure, and that endotoxemia potentially contributes to seasonal infertility in swine. Funded by the Global Food Security Consortium.

Key Words: endotoxemia, heat stress, ovary

1091 Milk yield genotype affects hepatic expression of innate immune genes when challenged with lipopolysaccharide (LPS).

1092 WS Mycobacterium avium subspecies paratuberculosis serum lipid profile analysis through Fourier transform ion cyclotron resonance mass spectrometry. A. L. Salazar*[1], J. M. Jarvis[1], N. M. Sudasinghe[1], S. Kumar[1], M. Song[1], J. Stabel[2], T. Thacker[2], S. L. Ivey[1], and T. Schaub[1], *[1]New Mexico State University, Las Cruces, [2]USDA-ARS, Ames, IA.*

Mycobacterium avium subspecies paratuberculosis (MAP) is responsible for Johne's disease (paratuberculosis; paraTB) in bovine which elicits serve enteritis in the lower intestinal tract; similar to Crohn's disease in humans. The objective of our study was to observe lipid changes in serum extracts of cattle infected with MAP using ultra-high resolution mass spectrometry. We hypothesized through the use of Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR MS) the identification of unique lipid biomarkers induced by MAP infection will be observed. Field samples from cattle infected with MAP (INF; $n = 10$) were provided by the National Animal Disease Center (NADC). Uninfected serum (SC2012 and SC2015) from cattle with no history of paraTB came from two sources provided by the NADC. Negative controls used to test cross reactivity, with no MAP infection or previous exposure, included serum extracts from cattle challenged with lipopolysaccharide (LPS) and cattle infected with *Mycobacterium bovis* (bTB). Spectral differences were observed in the INF treatment compared to all other samples. Heteroatom class distribution, in positive ion mode, showed higher relative lipid abundance in the INF treatment in O_5Na_1, O_3, O_9Na_1, $O_{10}Na_1$, O_8Na_1, N_1, O_7Na_1, and N_1O_1 compounds whereas $N_1O_8P_1$ and $N_1O_7P_1$, were higher abundance in both control treatment groups. In negative-ion mode, O_3compounds were greater relative abundance in the INF treatment and both control treatments had higher relative abundance of $N_1O_{11}P_1$ and $O_{13}S_1$compounds. Assigned elemental compositions were searched in the Lipidomic Gateway Databased to identify relative abundance of lipid classes. The majority of compounds classified in the glycerophospholipid, polyketide, or sterol class. Bioinformatics showed forty-five unique compounds ($P < 0.05$), twenty-six in positive-ion mode, and nineteen in negative-ion mode, purely present in MAP infected cattle; no cross reactivity observed. The shift in heteroatom class distribution provides specific lipids may be present only in paraTB infected cattle, which is confirmed by the compounds identified solely in MAP infected cattle.

Key Words: Johne's disease, lipidomics, *Mycobacterium avium* subspecies *paratuberculosis*, paratuberculosis, ultra-high resoltuion mass spectrometry

1093 WS Insulin-associated and insulin-independent impacts of β adrenergic agonists and pro-inflammatory cytokines on glucose metabolism in primary rat soleus muscle. C. N. Cadaret*, K. A. Beede, H. E. Riley, and D. T. Yates, *University of Nebraska-Lincoln, Lincoln.*

Recent studies show that catecholamines and pro-inflammatory cytokines may help regulate skeletal muscle growth and metabolism even at sub-stress levels. The objective of this study was to determine the acute effects of β1 and β2-specific adrenergic agonists as well as TNFα and IL-6 on muscle glucose uptake and oxidation under basal and insulin-stimulated conditions. Primary soleus muscle was collected from adult Sprague-Dawley rats, separated tendon-to-tendon into 25–45 mg strips, and incubated in KHB spiked with or without insulin, and/or ractopamine HCl (β1 agonist), zilpaterol HCl (β2 agonist), TNFα, and IL-6. Glucose uptake was determined from cellular content of [^{3}H]-2-deoxyglucose after 20 min. Glucose oxidation of [^{14}C-U] glucose was determined after 2 h. Phospho-Akt/total Akt (p-Akt/Akt) was determined from protein isolated after 1 h. Compared to muscle incubated in un-spiked (basal) media, incubation with insulin increased ($P < 0.05$) glucose uptake by ~47%, glucose oxidation by ~32%, and p-Akt/Akt by ~238%. Muscle incubated with β2 agonist exhibited ~20% less ($P < 0.05$) glucose uptake but ~32% greater ($P < 0.05$) glucose oxidation than basal. Moreover, incubation with β2 agonist+insulin increased ($P < 0.05$) glucose oxidation and p-Akt/Akt over insulin alone. Muscle incubated with β1 agonist did not differ from basal for any output. Likewise, β1 agonist+insulin incubations did not differ from insulin alone. Glucose oxidation was ~23% and ~33% greater ($P < 0.05$), respectively, in muscle incubated with TNFα and IL-6 compared to basal, yet glucose uptake and p-Akt/Akt did not differ. Glucose uptake, glucose oxidation, and p-Akt/Akt were similar among muscle incubated with TNFα+insulin, IL-6+insulin, and insulin alone. In addition, glucose oxidation in muscle incubated with TNFα+insulin and IL-6+insulin did not differ from TNFα alone or IL-6 alone. These results show that acute β2 stimulation had opposite effects on glucose uptake and glucose oxidation in muscle, and that acute β1 stimulation had no evident impact on muscle metabolism. Moreover, β2 stimulation was synergistic with insulin, as glucose oxidation and Akt phosphorylation were greater with the two products together than with either individually. Lastly, acute stimulation with TNFα or IL-6 increased glucose oxidation rates independently of insulin or Akt phosphorylation. Together, our findings demonstrate that adrenergic and inflammatory mediators can have insulin-associated or insulin-independent effects on glucose metabolism and that these

effects may differ for glucose uptake and oxidation.

Key Words: β-agonist, glucose metabolism, stress hormones

1094 WS Relationship between current temperament measures and physiological responses to handling of feedlot cattle. A. F. Williams*[1], J. A. Boles[1], M. R. Herrygers[1], J. G. Berardinelli[1], M. C. Meyers[2], and J. M. Thomson[1], *[1]Montana State University, Bozeman, [2]Idaho State University, Pocatella.*

Interest in beef cattle temperament has increased due to growing consumer awareness of animal welfare. Researchers have defined temperament as behavioral responses to a perceived stressor. Subjective chute scoring has been used by many researchers for temperament, however, the subjectivity and associated variability among observers has been questioned. The most practical objective method of assessing temperament is exit velocity. Corresponding chute side measures to physiological markers are important. Faster exit velocities have been related to both increased cortisol and increased plasma lactate. The objectives of this study were to compare temperament differences between feedlot steers and heifers and to confirm chute side measures relationship to physiological responses to stress. Body temperature, serum and plasma lactate, serum glucose, salivary and serum cortisol concentrations were measured on mixed breed and sex feedlot cattle (n = 197). Fast, medium, and slow classifications were developed from exit velocities. Plasma lactate was significantly different between all classes. Sex had a significant effect on exit velocity and physiological measures. Heifers had higher exit velocities (P = 0.003), plasma lactate concentrations (P = 0.03), and cortisol concentrations (P = 0.001). Simple correlations among these variables indicated body temperature (heifers r = 0.44, P < 0.0001; steers 0.45 P < 0.0001), plasma lactate (heifers r = 0.52 P < 0.0001; steers r = 0.63 P < 0.0001), serum lactate (heifers r = 0.53 P < 0.001; steers r = 0.59 P < 0.001) and glucose (heifers r = 0.54 P < 0.001; steers r = 0.32 P < 0.003) were all correlated to exit velocity in both steers and heifers. Cortisol measures were not correlated to exit velocity in steers but were in heifers. Linear models constructed and evaluated using Akaike information criterion indicated that plasma lactate in combination with body temperature were strong candidates to predict exit velocity. Using the discriminate function analysis, the model categorized fast and slow classifications 69.23% and 61.54% respectively, indicating that in combination with exit velocity simple objective chute side measures of body temperature and plasma lactate can potentially increase accuracy of temperament identification.

Key Words: cortisol, lactate, temperament

1095 Cardiovascular performance of modern swine does not comply with allometric scaling laws. G. van Essen*, *University Medical Center Rotterdam, Rotterdam, Netherlands.*

In view of long-standing concerns about possible consequences regarding the cardiovascular capacity and adaptability of modern pigs we investigated the proportionality and performance of porcine hearts over a wide range of body weights (25– 225 kg), according to allometric scaling laws. Specifically, we tested the hypothesis that both heart mass (HM) and cardiac output (CO) scale with body mass (M) to the power of 0.75 (HM or CO = a.M0.75), stroke volume (SV), and left ventricular end-diastolic volume (LVEDV) to the power of 1.00. For this purpose, 21 Yorkshire x Landrace pigs were instrumented under anesthesia to measure CO and SV and LVEDV. Subsequently, animals were sacrificed and hearts were excised and weighed and tissue samples of the LV anterior myocardial wall analyzed for collagen content. Using a linear mixed model, the scaling coefficients of the relations between M and CO, SV, HM, and LVEDLV were determined. The 95% confidence intervals of the power-coefficient b for HM were 0.67– 0.88, encompassing the predicted value of 0.75, indicating that HM increased proportionally to M. In contrast, the 95% confidence intervals of power-coefficient b for CO amounted 0.40–0.65, thus failing to encompass the predicted value of 0.75. This was principally due to the lack of proper scaling of SV as the confidence interval of 0.52–0.83 failed to encompass the predicted value of 1.0, which in turn appeared to be due to a lack of scaling of LVEDV as its confidence interval of b values amounted 0.57–0.99, thus failing to encompass the predicted value of 1.0. The increase of HM without a proportional increase of LV volume, was accompanied by a doubling of collagen content in the LV of swine > 150 kg compared to swine < 75 kg (p < 0.05). In conclusion, cardiac geometry and function of modern swine fail to obey allometric scaling laws, likely due to an increased extracellular matrix deposition preventing physiological remodeling during growth.

Key Words: allometric scaling laws, cardiovascular system, swine

1096 DL-methionine increases glutathione concentration and alleviates inflammatory responses in primary bovine hepatocytes. Q. Zhang*[1], D. N. Luchini[2], and H. M. White[1], *[1]University of Wisconsin-Madison, Madison, [2]Adisseo S.A.S., Alpharetta, GA.*

Supplementation of rumen-protected methionine (Met) to dairy cows during the peripartal period improves postpartal performance and may decrease oxidative stress. The aim of the present study was to determine the effects of increasing concentrations of DL-Met on hepatic inflammatory responses and oxidative status. Hepatocytes isolated from 4 calves less

than 7 d old were maintained as monolayer cultures for 24 h before addition of treatments. Treatments included 0, 10, or 40 μM DL-Met added to Met-free media containing 100 μM Lys (0MET100LYS, 10MET100LYS, or 40MET100LYS), and 10 μM DL-Met added to Met-free media containing 25 μM Lys (10MET25LYS). Both 40MET100LYS and 10MET25LYS had a Met:Lys of 1:2.5. Cells were exposed to each treatment in triplicate for 16 h and then challenged with either 0 or 100 ng/mL lipopolysaccharide (LPS) for 8 h. Cell lysates were collected for quantification of glutathione (GSH) by fluorometic assay and quantification of gene expression by quantitative PCR. Abundance of mRNA was normalized to the mean of 3 reference genes. Cell media was collected for quantification of reactive oxygen species (ROS) by fluorometric assay. Data were analyzed using PROC MIXED of SAS 9.3. The model included treatment, LPS, their interaction, and random effect of calf. Data are reported as LSMEANS ± SE. There was an interaction ($P < 0.05$) of treatment and LPS on GSH concentration which increased ($P < 0.01$) as Met concentration increased (107.5, 114. 5 vs. 131. 5 ± 23.5 μM) without LPS challenge, and 40MET100LYS had greater ($P < 0.01$) GSH than 10MET-25LYS (131. 5 vs. 97.5 ± 23.5 μM). With LPS challenge, GSH concentration was not different ($P > 0.10$) among treatments. Hepatocytes challenged by LPS showed an inflammatory response with increased ($P < 0.001$) expression of tumor necrosis factor (1.425 vs. 2.257 ± 0.344 arbitrary unit (AU)) independent of treatment. However, there was an interaction ($P < 0.01$) of treatment and LPS on interleukin *(IL)-6* expression, which was increased by LPS in cells receiving 10MET-100LYS (1.086 vs. 3.851 ± 0.643 AU) and 10MET25LYS (0.918 vs. 2.296 ± 0.643 AU), but was not increased by LPS in cells receiving 40MET100LYS (0.912 vs. 1.770 ± 0.643 AU). Cell culture media ROS concentration was not different ($P > 0.10$) among treatments with or without LPS. The data suggest that a stress model can be established using primary bovine hepatocytes with LPS challenge. Increasing Met concentration enhances intracellular antioxidant production and alleviates inflammatory responses, although ROS released from the cells was not affected. The treatment effects were attributed to increase in Met concentration, not the Met:Lys.

Key Words: glutathione, interleukin, lipopolysaccharide

1097 Elevated hepatic lipid peroxidation and oxidative stress in underperforming piglets. *T. G. Ramsay*, M. J. Stoll, L. A. Blomberg, and T. J. Caperna, USDA, ARS, BARC, Beltsville, MD.*

The present study was designed to determine if normal weight pigs that grow poorly during the pre-weaning period have altered hepatic metabolism, as previously reported for intrauterine growth retarded pigs relative to littermates with normal growth rates. Eight pairs of average birth weight pigs (1.57 ± 0.05 kg) were identified that diverged in weight by a minimum of 50 g/day until 21 d of age. At 21 d, slow growing (SG) pigs weighed 5.47 ± 0.22 kg while control littermates weight 6.98 ± 0.28 kg ($P < 0.001$). Livers were collected for analysis at Day 21 for analysis of enzyme activity, glycogen content, and gene expression. Metabolomic analysis of the liver tissue was performed by Metabolon (Durham, NC). No changes with growth rate were detected in liver enzyme activity per mg tissue protein for enzymes in glycolysis, lipogenesis, or the pentose phosphate shunt ($P > 0.05$). Liver glycogen content (mg/gm liver protein) was similar between SG piglets and control littermates ($P = 0.908$). The mRNA abundance for the two genes regulating peroxisomal fatty acid oxidation: acyl CoA oxidase 1 (ACOX1; $P < 0.001$) and peroxisome proliferator-activated receptor α (PPARα; $P < = 0.003$), superoxide dismutase 2 ($P = 0.021$), lactate dehydrogenase ($P = 0.016$), insulin-like growth factor 2 (IGF2; $P = 0.002$), IGF binding protein 2 (IGFBP2; $P = 0.004$), and IGFBP3 ($P = 0.015$) were increased in the liver of the SG piglet relative to liver of piglets experiencing normal growth, as measured by real-time quantitative PCR. The increases in PPARα and ACOX1 mRNA abundance suggest that the liver of the SG piglet has the capacity to oxidize an increased proportion of long chain fatty acids relative to the control piglet through peroxisomal β-oxidation. The parallel increase in SOD2 mRNA abundance suggests that SOD2 may function to reduce the oxidative stress caused by an increase in peroxisomal β-oxidation. Metabolomic analysis of the liver from these SG piglets confirmed an increase in mono- and dihydroxy-fatty acids indicative of increased lipid peroxidation and oxidative stress relative to liver from control littermates ($p < 0.05$). These data indicate that the SG piglet utilizes alternative pathways for fatty acid oxidation during the preweaning period which may be a predictor for poor postnatal growth or a target for treatment to improve growth.

1098 Yeast supplementation altered the metabolic response to a combined viral-bacterial challenge in feedlot heifers. A. B. Word[*1], P. R. Broadway[2], N. C. Burdick Sanchez[2], K. P. Sharon[3], S. L. Roberts[4], J. T. Richeson[4], P. J. Defoor[5], M. D. Cravey[6], J. R. Corley[7], M. A. Ballou[1], and J. A. Carroll[2], *[1]Texas Tech University, Lubbock, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]Department of Animal and Food Sciences, Texas Tech University, Lubbock, [4]Department of Agricultural Sciences, West Texas A&M University, Canyon, [5]Cactus Feeders, Canyon, TX, [6]Phileo Lesaffre Animal Care, Milwaukee, WI, [7]Phileo Lesaffre Animal Care, Cedar Rapids, IA.*

Two treatments were evaluated in feedlot heifers to determine the effects of feeding a yeast supplement on metabolic responses to a combined viral-bacterial respiratory disease

challenge. Thirty-two beef heifers (325 ± 19.2 kg) were selected and randomly assigned to one of two treatments: 1) Control (CON), receiving a standard feedlot ration with no yeast supplement, or 2) yeast, (YEAST) control ration plus a combination live yeast (2.5 $g \cdot hd^{-1} \cdot d^{-1}$) and yeast cell wall (2.5 $g \cdot hd^{-1} \cdot d^{-1}$) supplement (Phileo-Lesaffre Animal Care, Milwaukee, WI). Cattle were maintained on treatments for 31 d. On d −3 all cattle were challenged intra-nasally with 1 x 10^8 PFU of bovine herpesvirus-1 (BHV-1) and then allowed to rest in outdoor pens for 3 d. On d 0, each heifer was challenged intra-tracheally with approximately $3x10^7$ CFU of *Mannheimia haemolytica*, was fitted with an indwelling jugular catheter and indwelling vaginal temperature recording device, and was moved into individual stanchions in an environmentally-controlled barn. Whole blood samples were collected at the time of BHV-1 challenge, at 1-h (serum) or 2-h (complete blood cell counts) intervals from 0 to 8 h, and at 12, 24, 36, 48, 60, and 72 h following the *M. haemolytica* challenge. Data were analyzed using the mixed procedure of SAS specific for repeated measures with fixed effects of treatment, time, and their interaction. Cattle in the YEAST group had a greater glucose concentration following *M. haemolytica* challenge (121.38 ± 2.91 vs. 109.86 ± 2.90 mg/dL, respectively; $P < 0.01$) and decreased serum concentrations of blood urea nitrogen compared to CON (11.82 ± 0.53 vs. 10.12 ± 0.53 mg/dL, respectively; $P = 0.03$). There was no difference in serum NEFA concentration between YEAST (0.14 ± 0.01 mg/dL) and CON (0.15 ± 0.01mg/dL; $P = 0.37$). These data indicate that feeding a combination live yeast and yeast cell wall product may modulate energy stores by reducing muscle catabolism to provide energy for the activated immune system in response to a respiratory disease challenge. The reduction in catabolism has the potential to improve live animal performance when an animal is exposed to respiratory diseases.

Key Words: feedlot health, respiratory disease challenge, yeast

1099 In vivo production, quality and pregnancy of bovine embryos from cows with high or low intake of dry matter or energy. R. Sartori*[1], R. S. Surjus[2], A. B. Prata[2], P. L. J. Monteiro Jr.[1], M. C. C. Mattos[3], F. C. Mattos[4], G. B. Mourao[5], and F. A. P. Santos[6], *[1]University of São Paulo-ESALQ/USP, Piracicaba, Brazil, [2]ESALQ/USP, Piracicaba, Brazil, [3]CEVA Animal Health, Paulinea, Brazil, [4]Ourofino Animal Health, Cravinhos, Brazil, [5]Department of Animal Science, University of São Paulo/ESALQ, Piracicaba, Brazil, [6]University of São Paulo, Piracicaba, Brazil.*

This study evaluated the influence of dry matter (DM) or energy intake on in vivo embryo production and quality. Non-lactating Nelore cows ($n = 32$, 4 to 10 y old) weighing 489.5 ± 11.3 kg and with BCS of 3.3 (1 to 5) were used. After 15 d on a maintenance diet [1.2% of DM per kg of body weight (BW)], cows were randomly divided into four groups. Maintenance (M), 0.7M, and 1.5M received the equivalent of 70, 100, and 150% of the M diet, respectively. The fourth group (Energy; E) received a diet with DM similar to the M group, but with an energy level equivalent to the 1.5M group. Cows were fed individually and offered all diets in a Latin-square arrangement every 42 d. Cows were submitted to a conventional superovulation protocol. Superovulatory response was assessed by ultrasonography and embryo quality was evaluated according to the IETS guidelines, as well as by pregnancy per fixed-time transfer (P/ET) of 274 vitrified embryos to Nelore recipients. Pre-prandial blood plasma insulin was performed by RIA at the onset of superovulation. Data were analyzed by PROC GLIMMIX of SAS ($P < 0.05$). Circulating insulin was greater in the E group (8.7 ± 0.9 μIU/mL) compared with groups 0.7 M (4.6 ± 0.9) and M (5.3 ± 0.85), not differing from group 1.5M (6.6 ± 0.9). Superovulation (CL number) was lower in donors fed high energy (9.7 ± 1.2) compared with cows receiving the standard diet [0.7M (13.0 ± 1.3), M (14.2 ± 1.2) or 1.5M (13.9 ± 1.2)] due to the negative correlation between circulating insulin and CL number ($r = -0.32$). Nevertheless, there was no difference between groups for number of ova/embryos (~6), viable (~3), or freezable embryos (~2.7). Regardless of treatment, circulating insulin was negatively correlated with the number of viable embryos ($r = -0.22$). There was lower P/ET at 60 d in the 97 cows receiving embryos from donors fed high energy (E; 29.4%) compared with the 177 cows receiving embryos from donors fed the standard diet (0.7M, M or 1.5M; 43.3%). Moreover, probability of P/ET at 60 d evaluated by logistic regression decreased as circulating insulin of donor cows increased from 0.64 to 25.0 μIU/mL. In conclusion, there was effect of diet on the superovulatory response and P/ET. Additionally, high circulating insulin of the donors was associated with lower superovulatory response, less viable embryos and less P/ET at 60 d. Financial support from FAPESP and CNPq. We also thank InVitro Brasil and Hildergard Pritzelwitz Experimental Station.

Key Words: cattle, fertility, insulin, nutrition

1100 Body condition score affects milk yield and energy balance of dairy cows after a short or no dry period. A. van Knegsel* and B. Kemp, *Adaptation Physiology Group, Wageningen University, Wageningen, Netherlands.*

Shortening or omitting the dry period of dairy cows is of interest because it limits the negative energy balance in early lactation, mainly due to a reduction in milk yield postpartum. Moreover, there are indications that individual cow characteristics, like parity or genotype, affect the response of dairy cows to a short or no dry period. The objective of this study was to evaluate the effects of prepartum BCS on the response of cows in milk yield, energy balance (EB), and plasma metabolites to a short or no dry period, compared with

a conventional dry period. Holstein-Friesian dairy cows (n = 167) were assigned randomly to three dry period lengths: 0 (no), 30 (short), or 60 d (conventional). Across treatments, cows were classified on prepartum BCS as lean (BCS < 3.0; n = 64), normal (3.0 ≤ BCS < 3.5; n = 60) or fat (BCS ≥ 3.5; n = 43). Feed intake and milk yield were recorded daily from week −8 till 14 relative to calving and averaged per week. Energy balance was calculated weekly. Blood was sampled weekly. Repeated measures ANOVA was performed to analyze the data. Data are expressed as LSMEANS ± SEM. Postcalving, milk production, EB, plasma free-fatty acids, and β-hydroxybutyrate concentration were affected by BCS-class*dry period length interaction (P < 0.05). More specifically, in fat cows milk yield and EB were similar between dry period lengths (milk: 39.9 ± 0.8 kg/d; EB: −113 ± 15 kJ/kg$^{0.75}$*d). In lean cows, however, shortening or omitting the dry period reduced milk yield (short: 38.5 ± 1.0 kg/d; no: 31.1 ± 1.1 kg/d) and improved the EB (short: −56 ± 19 kJ/kg$^{0.75}$*d; no: 89 ± 20 kJ/kg$^{0.75}$*d) compared with a conventional dry period. In normal cows, shortening or omitting the dry period reduced milk yield (short: 38.9 ± 1.2 kg/d; no: 30.1 ± 1.1 kg/d), compared with a conventional dry period. Between lean and normal cows, there were no differences in milk yield reduction or EB improvement due to dry period length. Results for plasma metabolites were in line with results for EB. In conclusion, prepartum BCS affects milk yield and EB of dairy cows after a short or no dry period. This might imply that the optimal dry period length for dairy cows depends on prepartum BCS. Currently, studies are ongoing to develop a decision support tool for dry period length based on individual cow characteristics, like parity and BCS, to optimize milk yield and cow health.

Key Words: energy balance, individual variation, metabolic status

1101 The effect of stocking rate and cow breed on resumption of cyclicity, blood indicators of energy status, uterine health and reproductive parameters in pasture-based dairy systems.

S. Leane*[1,2], P. Lonergan[3], J. Kenneally[1], and S. Butler[1], *[1]Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Ireland, [2]School of Agriculture and Food Science, University College Dublin, Dublin, Ireland, [3]School of Agriculture and Food Science, University College Dublin, Belfield, Dublin, Ireland.*

Identifying the optimum stocking rate (SR) and cow breed for pasture-based systems is essential to maximize output/ha without compromising reproductive performance. The objective of this study was to compare the performance of two different breeds (Holstein Friesian, HF, and Jersey crossbreds, JEX; n = 69 per breed) on one of three different SR (Low: 2.5 cows/ha; Medium: 2.9 cows/ha; and High: 3.3 cows/ha; n = 46 per treatment). The study was performed over 3 consecutive years. Milk samples were collected three times per week from parturition until week 5 post AI for progesterone analysis. Ten blood samples/cow/year were collected (weeks −2, 1, 2, 3, 4, 6, 8, 10, 14, and 18 relative to parturition) to determine circulating concentrations of glucose, non-esterified fatty acids (NEFA), β-hydroxybutyrate (β-HBA) and insulin-like growth factor-1 (IGF1). Uterine cytology samples were collected on Week 6 after parturition from 252 cows during Years 2 and 3 of the study to determine the proportion of cows with sub-clinical endometritis. The fertility performance of each herd was monitored during a 12-wk breeding season across 3 yr of the study. Days to resumption of cyclicity was not affected by SR or breed (25.2, 24.5, and 25.1 ± 1.2 d for Low, Med, and High SR; 24.7, vs. 25.2 ± 1.7 d for HF vs. JEX, respectively, P > 0.05). Mean plasma glucose (72.9, 71.9, and 72.4 ± 0.9 mg/dl), BHBA (0.61 ± , 0.61, and 0.62 ± 0.01, mmol/l), NEFA (0.46, 0.48, and 0.47 ± 0.01 mmol/l), and IGF1 (93.7, 92.9, and 98.9 ± 4.3, mmol/l) concentrations were not affected by SR (Low, Med, and High, respectively; P > 0.05). Mean glucose concentrations were greater in JEX than HF (73.5 ± 0.7 vs. 71.3 ± 0.8, mg/dl; P < 0.05, respectively), but concentrations of NEFA, β-HBA, and IGF1 were not affected by breed (P > 0.05). Neither SR nor breed affected the proportion of cows with sub-clinical endometritis at Week 6 postpartum (SR: 0.15, 0.14, and 0.27 of cows for low, medium and high SR, respectively; Breed: 0.18 and 0.18 of HF and JEX cows, respectively) or 42d pregnancy rate and final in-calf rate (all P > 0.05). In conclusion, under the conditions of this study, there was no major effect of increased SR or cow breed on reproductive performance. It is important that farm SR allows nutritional requirements to be met and that cows are genetically suited to seasonal-calving pasture based systems.

Key Words: breed, fertility, stocking rate

1102 Implications of acute or chronic pasture restriction on indicators of metabolic status in grass-based dairy cows.

F. Curran*[1,2], E. Kennedy[1], E. Lewis[1], P. Lonergan[2], and S. Butler[1], *[1]Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Ireland, [2]School of Agriculture and Food Science, University College Dublin, Dublin, Ireland.*

Annual variation in pasture growth rate has a major effect on grass availability for grazing dairy cows, especially at the onset of lactation in early spring. The objective was to determine the effect of imposing acute (2 wk) or chronic (6 wk) periods of varying levels of pasture restriction on indicators of metabolic health and hepatic gene expression in early lactation dairy cows. Holstein Friesian and Jersey crossbred cows (n = 96) were randomly assigned to one of four daily herbage allowances (DHA: 60, 80, 100, and 120% of intake capacity) for either two or 6 wk (12 cows per treatment) during early

lactation for 2 consecutive years. During the experimental period no supplemental concentrates were fed. Milk samples were collected three times per week for progesterone analysis to determine effects on estrous cyclicity. Blood was collected once weekly during the study to determine circulating concentrations of glucose, non-esterified fatty acids (NEFA), and β-hydroxybutyrate (β-HBA). In Year 2 of the study, liver biopsies were collected from a subset of cows assigned to the 60% DHA for 2 wk, 60% DHA for 6 wk, and the 100% DHA for 6 wk treatments at experimental weeks 0, 2, and 6. Reverse-transcription quantitative PCR (RT-qPCR) analysis was used to determine the mRNA abundance of 24 target genes related to energy metabolism. Data were analyzed using PROC MIXED of SAS. The DHA treatments had no effect on resumption of cyclicity, mean plasma glucose, or NEFA concentrations. Mean plasma β-HBA concentrations during the treatment periods were increased in cows on the restricted DHA treatments for 2 wk (1.25 ± 0.09, 1.08 ± 0.1, 1.03 ± 0.1, 0.9 ± 0.09 mmol/l; $P < 0.05$; 60%, 80%, 100%, and 120%, respectively) and 6 wk (1.43 ± 0.09, 1.32 ± 0.1, 1.06 ± 0.1, 1.04 ± 0.09 mmol/l; $P < 0.05$; 60%, 80%, 100% and 120%, respectively). At week six, 60% DHA increased mean expression of *glucose-6-phosphatase, pyruvate carboxylase, carnitine palmitoyltransferase 1A, acyl-CoA synthetase long-chain 1* and decreased mean expression of *fatty acid synthase and acetyl-CoA-carboxylase.* DHA had no effect on mRNA abundance of *IGF-1*, but 60% DHA for 6 wk increased expression of *insulin-like growth factor binding protein-2*. We conclude that imposing acute periods of restricted DHA had only modest effects on metabolic health in early lactation dairy cows.

Key Words: gene expression, metabolites, restriction

1103 The effects of ketosis, feed restriction, and an endotoxin challenge on circulating serotonin (5-HT) in lactating dairy cows. E. A. Horst*[1], S. K. Kvidera[1], M. Abuajamieh[1], E. J. Mayorga[1], M. A. Al-Qaisi[1], H. B. Green[2], K. M. Schoenberg[2], W. E. Trout[3], and L. H. Baumgard[1], *[1]Iowa State University, Ames, [2]Elanco Animal Health, Indianapolis, IN, [3]Elanco Animal Health, Greenfield, IN.*

Circulating serotonin (5-HT) is thought to be associated with various metabolic disorders and hypocalcemia during the transition period. Objectives were to evaluate the effect of ketosis, feed restriction, or endotoxin challenge (models where energetic and calcium metabolism is markedly altered) in lactating cows on circulating 5-HT. Blood samples were obtained from three separate experiments and circulating BHBA, NEFA, and glucose were measured in all three experiments while ionized calcium was only measured in the endotoxin challenge. Data were analyzed using PROC MIXED and PROC CORR of SAS 9.4. In the ketosis study, blood samples from cows clinically diagnosed with ketosis ($n = 10$) or classified as healthy ($n = 9$) were obtained from a commercial dairy farm at d −7, 3, and 7 relative to calving (Abuajamieh et al., 2015 JDS. 98[2]:876). There was no effect of health status on circulating 5-HT. Circulating 5-HT was negatively correlated with NEFA ($r = -0.47$, $P = 0.04$); however, no other relationships existed between 5-HT and the other metabolites. In the feed restriction experiment (Stoakes et al., 2015 JDS. 98[2]:274), mid-lactation cows were either fed ad libitum ($n = 3$) or restricted to 20% of their ad libitum intake ($n = 5$). There were no effects of feed restriction on circulating 5-HT, and energetic metabolites were not correlated with circulating 5-HT. In a model of endotoxemia (Stoakes et al., 2015 JDS. 98[2]:509), mid-lactation cows were either challenged with lipopolysaccharide (LPS; 1.5 μg/kg BW; $n = 6$) or sterile saline (CON; $n = 6$). LPS decreased blood ionized Ca^{2+} (56%; $P < 0.05$), but had no effect on circulating 5-HT. No relationships existed between circulating 5-HT and energetic metabolites or ionized Ca^{2+}. In summary, ketosis, feed restriction, nor endotoxemia affected circulating 5-HT. Circulating 5-HT was moderately correlated with NEFA in the transition cow experiment, but no other relationships existed between 5-HT and energetic metabolites and calcium in these experimental conditions.

Key Words: feed restriction, ketosis, lipopolysaccharide, serotonin

1104 Transcriptome analysis reveals fundamental differences between liver of neonatal calves and transition dairy cows. F. Batistel*, M. Vailati Riboni, A. Agrawal, and J. J. Loor, *University of Illinois, Urbana.*

Primary hepatocytes isolated from neonatal calf liver have been used to infer aspects of liver metabolism of dairy cows, with the assumption that physiological responses of neonatal hepatocytes mimic those of cows. To evaluate more directly the usefulness of calf hepatocytes as model to study cow responses, in particular during the early postpartal period, liver RNA from 7 Holstein cows (20 d in milk) and 7 Holstein calves (4-d old) was used for transcriptome analysis. Individual samples were used to determine expression of 7 key metabolic genes via quantitative RT-PCR. Data were $\log_2$ normalized and subjected to ANOVA using the Proc MIXED procedure of SAS. Compared with calves, the expression of genes related with lipoprotein synthesis (*APOB,* $P = 0.01$; *MTTP,* $P = 0.01$), gluconeogenesis (*FBP1*, $P = 0.07$), fatty acid oxidation (*CPT1A,* $P = 0.01$), and methionine metabolism (*MAT1A,* $P = 0.03$; *BHMT,* $P = 0.07$) was lower in calves than cows. Samples were pooled by type (calves or cows) and co-hybrized onto the 44K-Agilent bovine (V2) gene expression microarray chips (Agilent Technologies Inc.). This allowed for a direct comparison of transcriptomes in calves and cows. Out of 14,772 unique annotated genes detected by the array, 354 (2.39%) differentially expressed genes with expression ratio ≥ (calf specific) or ≤ (cow specific) than mean

± 2 SD were considered highly-expressed in calves or cows and used for pathway analysis using the Dynamic Impact Approach (DIA) with the KEGG database. Within this set, 221 (1.49%) had at least 40-fold greater expression in cows (e.g., *ACSL6, APOBEC3A, IGF2BP1, PFKFB3, SLC11A1, VLDLR*) or calves (e.g., *AOX1, CYP1A1, CYP7A1, SLC27A2*). Instead, expression of 73 genes was equal among cows and calves. The 25 most-impacted pathways from the DIA analysis indicated that critical metabolic processes involving amino acid, lipid, carbohydrate, and vitamin metabolism (e.g., branched-chain amino acid degradation; primary bile acid biosynthesis; fatty acid elongation in mitochondria; and glycolysis/gluconeogenesis) were biologically more important and highly-activated in calves than cows. In contrast, signaling pathways related to immunity (e.g., NOD-like receptor, Toll-like receptor, and chemokine), as well as cofactor metabolism (e.g., folate, pantothenate, and CoA biosynthesis) were highly-activated in cows than calves. Overall, results indicate that liver of calves and cows have unique transcriptome profiles, hence, hepatocytes isolated from calves might not be a suitable model to study hepatic function/metabolic responses of cows.

Key Words: calf, dairy cow, liver transcriptome

1105 ADSA®-EAAP speaker exchange presentation: Effect of rumen content exchange on gene expression in rumen epithelium of lactating cows.

J. Vilkki[*1], D. Fischer[1], I. Tapio[1], S. Ahvenjärvi[1], and K. J. Shingfield[2], *[1]Natural Resources Institute Finland, Jokioinen, Finland, [2]Aberystwyth University, Aberystwyth, United Kingdom.*

The ruminal epithelium may adapt to changes in diet either by adjusting the absorptive capacity and surface area of papillae or through acute cellular functional adaptations. To test this hypothesis, an experiment involving total rumen content exchange between 3 pairs of lactating cows fed the same diet was performed to investigate the influence of variation in rumen contents and microbial populations therein on gene expression in rumen papillae. Papillae samples were taken during and 1 wk after digesta exchange from the ventral sites of rumen. Sequencing libraries were prepared according to Illumina TruSeq® Stranded mRNA and TruSeq® Small RNA sample preparation. Paired-end sequencing with Illumina HiSeq3000 with 2 × 150 bp read length was used for mRNA (average 50.6 M reads per sample) and single-read sequencing with 1 × 50 bp read length for miRNA (average 2.5 M reads per sample). From mRNA 67.8% of reads were mapped, of which 53.5% were located to known genes, the remaining reads mapping to unannotated regions of the bovine genome. Each animal was analyzed for differential gene expression (DE) between the two time points using edgeR. The *p*-values of DE genes were used for hierarchical clustering to identify groups with different responses. Using this approach experimental animals ($n = 6$) formed two clusters. DE analysis within the clusters revealed 170 genes differentially expressed at FDR < 0.1 in cluster 1 and two genes differentially expressed in cluster 2. The gene set was analyzed with Ingenuity®Pathway analysis (Qiagen). The top five affected canonical pathways were Acyl-CoA hydrolysis, xenobiotic metabolism signaling, dermatan sulfate biosynthesis, chrondroitin sulfate biosynthesis, and IGF-1 signaling. Twelve phenotypes were significantly different between the two clusters before exchange (ANOVA, $p < 0.1$ by permutation test), with cows in cluster 1 having higher milk protein content, lower total tract N digestibility, greater fecal N excretion, and higher molar acetate and lower valerate proportions in rumen VFA. From miRNA libraries 36.3% of reads were uniquely mapped. From 811 annotated miRNAs, 382 miRNAs were expressed. Analyses of miRNA expression between the two clusters revealed miRNAs with large differences before and after the exchange, five of which have been recently reported to be correlated with N efficiency in cows fed low quality forage diets. To conclude, the transfer of digesta contents was associated with alterations in the expression of key genes and gene networks in rumen epithelium.

Key Words: dairy cow, rumen epithelium, transcriptomics

1106 Identification of effects of different forage source on metabolism and function of liver from dairy cows using systematic approaches.

H. Z. Sun[*1,2], H. Y. Liu[1], D. M. Wang[1], L. L. Guan[2], and J. X. Liu[1], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Liver occupies a unique role in nutritional physiology of lactating dairy cows, but the effects of forage source on its metabolism and function have not been well examined. This study was conducted to investigate the effects of different forage source on liver metabolites and key gene functions in dairy cows using gas chromatography–time of flight/mass spectrometry (GC-TOF/MS) based metabolomics and RNA-seq analysis. A total of 12 multiparous Holstein dairy cows were fed 2 diets with different forage source: Alfalfa hay (AH, $n = 6$) and corn stover (CS, $n = 6$). The multivariate statistical analysis (PCA, PLS-DA, and OPLS-DA) showed a clear separation of metabolomics profiles between AH and CS groups. A total of 270 metabolites were identified in the liver with 28 of them significantly different between the 2 diets (VIP > 1&$P < 0.05$). In AH, 71 up-regulated metabolites ($\log_2$(z-score) > 1 & $P < 0.05$) were associated with gluconeogenesis, vitamin and mineral metabolism, amino acid metabolism, propanoate metabolism, cell death and survival, carbohydrate metabolism, and energy production. In CS, 64 up-regulated metabolites were involved in cellular growth and proliferation, organismal development, cell-to-cell signaling and interaction, molecular transport and lipid metabolism. Three

metabolites, leucine, cystine, and hippuric acid were further identified as biomarkers based on the analysis (AUC value, predicted class probabilities, and predicted accuracy) of different combinations of significantly different metabolites. In addition, expression of 11,781 genes was detected (more than 50% of samples with CPM > 1) in the liver. One gene module containing 122 genes had a significantly strong positive correlation ($R = 0.82$, $P = 0.001$) with cystine abundance by weighted gene co-expression network analysis (WGCNA). The main functions represented by these genes were gluconeogenesis, pyruvate metabolic process, monosaccharide biosynthetic process, carbohydrate homeostasis, glucose homeostasis, hexose biosynthetic process, chemical homeostasis, and vitamin-related metabolic process which were all up-regulated in the AH group. Our results suggest that various metabolites, pathways, and gene functions were significant changed in response to forage source. These can be used for further characterization of the regulatory mechanisms of forage-related milk performance in dairy cows.

Key Words: dairy cow, gene function, liver metabolomics

1107 Early postpartum administration of sodium salicylate to multiparous dairy cattle is associated with alterations in feeding behavior up to 120 d in milk.

A. J. Carpenter*, C. M. Ylioja, and B. J. Bradford, *Kansas State University, Manhattan.*

Previous research has indicated that the use of non-steroidal anti-inflammatory drugs such as sodium salicylate following calving can alter milk yield later in lactation. In the current experiment, sodium salicylate was administered following calving, and cattle were observed through 120 d in milk (DIM). Cows in their second parity and greater were blocked by parity and alternately enrolled into 1 of 2 treatments following calving, receiving either drenches of water (CON) or drenches of 125 g of sodium salicylate dissolved in a similar volume of water (SAL) at approximately 24, 48, and 72 h postpartum. A total of 28 animals per treatment were enrolled in this experiment, and 42 of these animals ($n = 21$ cows/treatment) were included in feeding behavior measurements. Of these, 16 cows were in their third parity and greater, and 26 were in their second parity. Feeding behavior was measured by feed bunks suspended from load cells that continuously monitored bunk weight. For all feeding behavior responses, variables (meal weight, meal length, number of meals/d, and intermeal interval) were averaged by day, and daily responses were averaged by week for statistical analysis. No differences were detected due to treatment for milk yield, energy-corrected milk (ECM), or DMI; however, a significant parity by treatment interaction was observed ($P = 0.03$), where SAL decreased intake in second parity cows but not cows in their third parity and greater. This resulted in a tendency for a treatment by parity interaction for milk yield:DMI ($P = 0.08$) and a significant interaction between treatment and parity on ECM:DMI ($P = 0.02$). Similarly, a significant interaction between parity and treatment was observed for average meal weight ($P = 0.04$), with no difference between treatments in second parity animals but increased average meal weight for older cows receiving SAL. Treatment with SAL was associated with fewer daily meals and greater average meal length ($P = 0.03$). A tendency for an interaction between treatment and week was also observed for intermeal interval ($P = 0.06$). For all feeding behavior variables measured, responses to treatment were delayed by at least 5 wk following administration. In conclusion, despite a failure to detect differences due to treatment in milk production or intake, postpartum treatment with sodium salicylate resulted in subtle and prolonged differences in feeding behavior in multiparous cows.

Key Words: feeding behavior, inflammation, sodium salicylate

1108 Proteomic analysis reveals increased abundance of inflammation-related proteins in adipose tissues from postpartum dairy cows treated with sodium salicylate.

M. Zachut[1], S. R. Montgomery[2], Y. Levin[3], L. Mamedova[2], and B. J. Bradford[*2], *[1]Institute of Animal Science, Volcani Center, Bet Dagan, Israel, [2]Kansas State University, Manhattan, [3]The Nancy and Stephen Grand Israel National Center for Personalized Medicine, Weizmann Institute of Science, Rehovot, Israel.*

The objective was to investigate the effects of sodium salicylate (SS) on the proteome of adipose tissue in early lactating dairy cows. Holstein cows in parity 3+ were assigned alternately at time of calving to either control or SS treatments. CON treatment received a molasses carrier in drinking water while the SS received 2.5 g/L SS with the molasses carrier in drinking water for 7 d after parturition. Adipose tissue biopsies were obtained from control cows ($n = 5$) and cows treated with SS ($n = 5$) at 7 DIM. Proteins were analyzed by intensity based, label-free quantitative shotgun proteomics at Weizmann Institute of Science (Rehovot, Israel). Proteins were extracted and subjected to in-solution tryptic digestion, followed by nanoflow liquid chromatography coupled to high-resolution tandem mass spectrometry (nanoLC-MS/MS). Quantitative data were extracted using Genedata Expressionist data analysis package and proteins identified using Mascot search engine. PCA analysis revealed two distinctive clusters, therefore proteomics data, after logarithmic transformation, were analyzed by two-way ANOVA for effects of treatment (control vs. SS), cluster (1 vs. 2) and their interaction. Only proteins that were different at $P < 0.05$ for effect of treatment and $P > 0.05$ for effect of interaction, as well as having a fold change (FC) of ± 1.5 were further considered. Proteomic analysis quantified 1422 proteins in adipose tissue, from which the abundance of 80 (5.6%) proteins differed in SS vs. control.

The top canonical pathways affected by SS treatment (IPA, Ingenuity) were the complement system, IL-10 signaling and acute phase response signaling. The abundance of several proteins related to these pathways was altered; for example, complement C1q subcomponent subunit B (C1QB, FC = 360, $P < 0.002$), complement component 1-r subcomponent (C1R, FC = 1.6, $P < 0.04$), flavin reductase (NADPH; BLVRB, FC = 1.6, $P < 0.05$) and lipopolysaccharide-binding protein (LBP, FC = 2.3, $P < 0.004$) were increased in SS adipose compared to controls. These findings imply that SS treatment up-regulates some inflammation-related proteins in adipose tissue, perhaps to maintain the desired inflammatory tone during the subacute inflammation in postpartum cows.

Key Words: adipose, immune, proteomics, sodium salicylate

1109 WS Effect of delayed insemination of non-estrual beef heifers following a 7-d-CO-Synch plus controlled internal drug release (CIDR) insert timed artificial insemination protocol.

D. C. Shaw*, K. E. Fike, and D. M. Grieger, *Kansas State University, Manhattan.*

Synchronizing estrus before AI is an effective way to shorten the calving season, and increasing the number of pregnancies per AI may lead to greater use and acceptance of synchronization protocols among beef producers. Our objective was to determine if pregnancy rates to fixed-time AI (FTAI) would be improved by delaying insemination in heifers not expressing estrus before FTAI in a 7-d CO-Synch + controlled internal drug release (CIDR) estrous synchronization protocol. Four hundred sixty-five yearling beef heifers across three locations of commercial and purebred herds were given 100 μg of GnRH (Cystorelin; Merial) i.m. and a CIDR insert (Zoetis; 1.38 g of progesterone) on d 0. On d 7 CIDR inserts were removed and all heifers received 25 mg of $PGF_{2\alpha}$ i.m. (Lutalyse; Zoetis) and were fitted with an estrous detection patch (Estrotect; Rockway, Inc.). Heifers were placed in one of three treatment groups based on estrous detection patch color at 48 h after $PGF_{2\alpha}$: 1. Estrus-Red 48 h (n = 180)—heifers displayed estrus as indicated by red estrous detection patch and were given GnRH (100 μg i.m. Cystorelin) and inseminated at 48 h after $PGF_{2\alpha}$, 2. Non-Estrus-Gray 48 h (n = 137)—heifers did not display estrus by 48 h after $PGF_{2\alpha}$ and were given GnRH (100 μg i.m. Cystorelin) and inseminated at 48 h after $PGF_{2\alpha}$, and 3. Non-Estrus Delayed-Gray 56 h (n = 148)—heifers did not display estrus by 48 h after $PGF_{2\alpha}$ and were given GnRH (100 μg i.m. Cystorelin) at 48 h and inseminated at 56 h after $PGF_{2\alpha}$. Pregnancy data were analyzed using SAS PROC GLIMMIX with treatment as a fixed effect, herd as a random variable, and heifer as the experimental unit. By 48 h after $PGF_{2\alpha}$, 38.7% of all heifers were in estrus (as indicated by a red estrous detection patch). Pregnancy rate to AI was greatest for Estrus-Red 48 h heifers (67.8%; $P < 0.0001$) as compared to heifers in the Non-Estrus-Gray 48 h (39.4%) and Non-Estrus Delayed-Gray 56 h (42.6%) groups. Among heifers not expressing estrus before FTAI, delayed insemination achieved a similar (P = 0.83) percent of pregnancies (Non-Estrus Delayed-Gray 56 h; 42.6%) as compared to Non-Estrus-Gray 48 h heifers (39.4%). Delaying insemination by 8 h in heifers not displaying estrus by 48 h after $PGF_{2\alpha}$ did not improve pregnancy rates to AI.

Key Words: beef heifers

1110 GnRH increased pregnancy risk in suckled beef cows that did not display estrus when subjected to a split-time artificial insemination program.

S. L. Hill*[1], D. M. Grieger[1], K. C. Olson[1], J. R. Jaeger[2], C. R. Dahlen[3], M. R. Crosswhite[3], N. Negrin Pereira[3], S. R. Underdahl[3], B. W. Neville[4], J. K. Ahola[5], M. C. Fischer[5], G. E. Seidel[5], and J. S. Stevenson[1], *[1]Kansas State University, Manhattan, [2]Western Kansas Agricultural Research Center, Kansas State University, Hays, [3]North Dakota State University, Fargo, [4]North Dakota State University, Streeter, [5]Colorado State University, Fort Collins.*

We hypothesized GnRH would induce ovulation in a split-time AI program by increasing pregnancy risk (PR) when estrus was not detected. A total of 1236 suckled beef cows at 12 locations in 3 states (CO, KS, and ND) were enrolled. Before applying the fixed-time AI program, BCS was assessed. Cows were treated on d −7 with a CIDR insert concurrent with 100 μg GnRH and on d 0 with 25 mg $PGF_{2\alpha}$ plus removal of the insert. Estrotect patches were affixed to cows at CIDR insert removal. Estrus was defined to have occurred when an estrus-detection patch was > 50% colored (activated). Cows in estrus by 65 h (n = 758; 61.3% of all cows) were allocated randomly to 2 treatments: 1) GnRH and early AI at 65 h (E+G; n = 373), or 2) AI only at 65 h (E–G; n = 385). Remaining cows were allocated randomly to 2 treatments: 1) GnRH injection at 65 h and late AI at 84 h (L+G; n = 252), or 2) AI only at 84 h (L–G; n = 226). Pregnancy was determined 35 d after AI via transrectal ultrasound. Pregnancy risk did not differ (P = 0.68) between E+G and E–G cows (61.9 vs. 60.4%), respectively. Conversely, for cows inseminated at 84 h, PR was greater (P = 0.01) in cows that received GnRH at 65 h compared with their herd mates not receiving GnRH (41.7 vs. 30.8%), respectively. Of those cows not in estrus by 65 h, 57.7% displayed estrus by 84 h for a total expression of estrus by all cows of 77.6%. Pregnancy risk was greater ($P < 0.01$) in cows not detected in estrus by 84 h when treated with GnRH at 65 h compared with no GnRH (+G = 33.4% [n = 146] vs.–G = 15.0% [n = 128]), whereas no difference in PR was detected for cows detected in estrus (+G = 65.3% [n = 103] vs.–G = 61.7% [n = 97]). Neither estrus expression by 65 or 84 h nor pregnancy risk was influenced by BCS, parity, or days postpartum at AI. Cows had greater PR when they displayed estrus before AI and cows

that did not display estrus by 65 h benefited from an injection of GnRH at 65 h before insemination occurred at 84 h.

Key Words: beef cows, GnRH, split-time AI

1111 Comparison of long- versus short-term CIDR-based protocols to synchronize estrus before fixed-time AI in primiparous 2-yr-old beef cows.

J. M. Abel*, B. E. Bishop, J. M. Thomas, M. R. Ellersieck, S. E. Poock, M. F. Smith, and D. J. Patterson, *University of Missouri, Columbia.*

This experiment was designed to compare the 14-d CIDR-PG (14-d) and 7-d CO-Synch + CIDR (7-d) protocols on the basis of estrous response, pregnancy rates resulting from fixed-time AI (FTAI), and final pregnancy rates at the end of the breeding season in primiparous 2-yr-old beef cows. Cows assigned to the 14-d treatment (n = 355) received a CIDR insert on d 0 with removal on d 14. Cows assigned to the 7-d treatment (n = 349) received GnRH and CIDR inserts on d 23. On d 30 CIDRs were removed from cows assigned to the 7-d treatment and $PGF_{2\alpha}$ was administered to cows in both treatments. On d 33 GnRH was administered concurrent with FTAI at 66 and 72 h after $PGF_{2\alpha}$ for 7-d and 14-d treated cows, respectively. Estrus response at FTAI was higher for 7-d compared to 14-d treated cows (7-d = 74%; 14-d = 43%; $P < 0.0001$); however, pregnancy rates resulting from FTAI were similar between treatments (7-d = 64%; 14-d = 63%; $P = 0.52$). Furthermore, 87% and 88% of 14-d and 7-d treated cows conceived within the first 30 d of the breeding season, and final pregnancy rates at the end of the breeding season did not differ between treatments (7-d = 96%; 14-d = 95%; $P = 0.93$). To understand similarities between treatments in pregnancy rates resulting from FTAI, despite differences in estrous response rates before FTAI, ovaries were mapped and serum estradiol-17-β (E_2) concentrations were evaluated among a subset of cows in each treatment. The 14-d treated cows had smaller diameter dominant follicles at $PGF_{2\alpha}$ ($P = 0.04$) and FTAI ($P = 0.002$) compared to 7-d treated cows (10.9 ± 0.3; 13.0 ± 0.3; vs. 11.9 ± 0.4; 14.5 ± 0.3); however, serum E_2 concentrations at $PGF_{2\alpha}$ ($P = 0.06$) and FTAI ($P = 0.001$) were greater for 14-d vs. 7-d treated cows (3.7 ± 0.4; 8.0 ± 0.7 vs. 2.5 ± 0.4; 4.2 ± 0.8). These differences suggest that dominant follicles of 14-d treated cows remain in an active growth stage at the time FTAI is performed compared to 7-d treated cows in which growth of dominant follicles may have plateaued. This theory is supported from previous studies that report decreased aromatase activity in granulosa cells when growth of dominant follicles plateau compared to actively growing follicles. In summary, these data suggest that the 14-d CIDR-PG and 7-d CO-Synch + CIDR protocols may be used to effectively synchronize estrus before FTAI in primiparous 2-yr-old beef cows.

Key Words: artificial insemination, estrus synchronization, primiparous 2-yr-old beef cow

1112 Comparing split-time AI pregnancy rates among non-estrous heifers based on administration of GnRH at AI.

B. E. Bishop*, J. M. Thomas, J. M. Abel, M. F. Smith, M. R. Ellersieck, S. E. Poock, and D. J. Patterson, *University of Missouri, Columbia.*

This experiment was designed to evaluate split-time artificial insemination (STAI) in beef heifers following administration of the 14-d (d) controlled internal drug release (CIDR)-prostaglandin $F_{2\alpha}$ (PG) protocol and to compare pregnancy rates among non-estrous heifers based on administration of GnRH at AI. Estrus was synchronized for 1138 heifers across six locations. Heifers received a CIDR insert (1.38 g progesterone) on Day 0 with removal on Day 14. Estrus detection aids (Estrotect) were applied at PG (25 mg) 16 d after CIDR removal on Day 30. Treatments were balanced across locations for heifers using reproductive tract score and weight. Split-time AI was performed at 66 and 90 h after PG, and estrus was recorded at these times. Heifers in both treatments that exhibited estrus by 66 h were inseminated at that time and did not receive GnRH, whereas AI was delayed 24 h until 90 h after PG for heifers that failed to exhibit estrus by 66 h. For heifers in treatment 1 that were inseminated at 90 h, GnRH (100 μg) was administered concurrent with AI at 90 h. Heifers in treatment 2 that were inseminated at 90 h did not receive GnRH. Estrous response did not differ between treatments at 66 h after PG (1 = 70%; 2 = 71%; $P = 0.58$) or during the 24 h delay period (1 = 59%; 2 = 52%; $P = 0.21$). There was no effect of treatment on total AI pregnancy rate (1 = 54%; 2 = 56%; $P = 0.60$) or on AI pregnancy rate for heifers inseminated at 66 h (1 = 58%; 2 = 62%; $P = 0.86$) or 90 h (1 = 44%; 2 = 39%; $P = 0.50$) after PG. Ovulation was confirmed via ultrasonography for a subset of heifers that failed to exhibit estrus before 90 h after PG. For heifers that failed to exhibit estrus by 90 h, ovulation rate did not differ between treatments (1 = 52%; 2 = 50%; $P = 0.64$) nor did AI pregnancy rate (1 = 24%; 2 = 15%; $P = 0.97$). In summary, when split-time AI was used in conjunction with the 14-d CIDR-PG protocol in heifers, comparable pregnancy rates were achieved without administering GnRH.

Key Words: beef heifer, gonadotropin-releasing hormone, split-time artificial insemination

1113 Comparing fixed-time artificial insemination to split-time artificial insemination with delayed administration of GnRH in postpartum beef cows. B. E. Bishop*, J. M. Abel, J. M. Thomas, M. F. Smith, S. E. Poock, M. R. Ellersieck, and D. J. Patterson, *University of Missouri, Columbia.*

This experiment was designed to compare pregnancy rates in postpartum beef cows following split-time (STAI) or fixed-time (FTAI) artificial insemination. Estrus was synchronized for 671 cows at seven locations following administration of the 7-d CO-Synch + CIDR protocol (100 μg GnRH + CIDR insert [1.38 g progesterone] on d 0; 25 mg prostaglandin $F_{2\alpha}$ [PG] at CIDR removal on d 7). Cows were assigned to treatments that were balanced across locations based on age, body condition score, and days postpartum at the time treatments were initiated. All cows in treatment 1 (n = 333; FTAI) were inseminated at 66 h after PG and GnRH was administered concurrent with insemination regardless of estrus expression. For cows in treatment 2 (n = 338), STAI was performed at 66 and 90 h after PG, and estrus was recorded at these times. Cows in the STAI treatment that exhibited estrus by 66 h were inseminated at that time and did not receive GnRH, whereas AI was delayed 24 h until 90 h after PG for cows that failed to exhibit estrus by 66 h. Gonadotropin-releasing hormone (100 μg) was administered concurrent with AI at 90 h only to cows failing to exhibit estrus. Estrus expression that occurred during the 24 delay period among cows assigned to the STAI treatment increased the total proportion of cows that expressed estrus before insemination (1 = 60%; 2 = 86%; P < 0.001). Pregnancy rates for cows inseminated at 66 h that exhibited estrus did not differ between treatments (1 = 58%; 2 = 58%; P = 0.93); however, pregnancy rates among non-estrous cows at 66 h was improved (1 = 35%; 2 = 51%; P = 0.01) among cows assigned to the STAI treatment when insemination was postponed by 24 h. Consequently, total AI pregnancy rate tended to be higher for cows that received STAI (1 = 49%; 2 = 56%; P = 0.06). In summary, following administration of the 7-d CO-Synch + CIDR protocol, total estrous response increased and pregnancy rates resulting from AI tended to be higher among cows assigned to STAI versus FTAI treatments.

Key Words: beef cow, fixed-time artificial insemination, split-time artificial insemination

1114 Split-time artificial insemination following synchronization of estrus with the 14-d CIDR-PG protocol in primiparous 2-yr-old beef cows. J. M. Abel*, B. E. Bishop, J. M. Thomas, M. R. Ellersieck, S. E. Poock, M. F. Smith, and D. J. Patterson, *University of Missouri, Columbia.*

This experiment was designed to test the hypothesis that estrous response and pregnancy rate following synchronization of estrus with the 14-d CIDR-PG protocol in primiparous 2-yr-old beef cows would be improved using split-time AI (STAI) compared to fixed-time AI (FTAI). Estrus was synchronized for 523 primiparous, postpartum beef cows at five locations. Cows received a CIDR insert (1.38 g progesterone) on d 0 with removal on d 14. On d 30, 16 d after CIDR removal, cows were administered $PGF_{2\alpha}$ (25 mg) and estrus detection aids (Estrotect) were applied. All cows were administered GnRH (100 μg) on d 33, 72 h after $PGF_{2\alpha}$ administration. Treatments were equally represented across locations, and cows within each location were assigned to one of two treatments based on days postpartum and body condition score. Cows assigned to the FTAI treatment (n = 266) were inseminated at a fixed-time concurrent with GnRH administration at 72 h after $PGF_{2\alpha}$ regardless of estrus expression, while cows assigned to the STAI treatment (n = 257) were inseminated based on estrus expression observed at 72 h. Cows assigned to STAI that expressed estrus by 72 h were inseminated; however, AI was delayed 24 h until 96 h after $PGF_{2\alpha}$ for cows that failed to express estrus before the standard fixed time. Estrus detection aids remained attached following GnRH at 72 h for all non-estrous cows assigned to the STAI treatment, and estrus expression during the delayed time period was recorded. Estrous response at 72 h did not differ between treatments (FTAI = 42%; STAI = 40%; P = 0.33). Delayed insemination to 96 h after $PGF_{2\alpha}$ of STAI treated cows that failed to exhibit estrus before the standard FTAI at 72 h increased total estrous response (FTAI = 42%; STAI = 64%; P < 0.0001); however, pregnancy rates resulting from AI were similar between treatments (FTAI = 56%; STAI = 55%; P = 0.60). In summary, estrus expression was increased when STAI was used following synchronization of estrus with the 14-d CIDR-PG protocol in primiparous 2-yr-old beef cows; however, this strategy did not result in significant improvements in AI pregnancy rates compared to FTAI.

Key Words: artificial insemination, estrus synchronization, primiparous 2-yr-old beef cow

1115 The 9-d CIDR-PG protocol: Incorporation of prostaglandin pretreatment into a long-term, CIDR-based estrus synchronization protocol improves timed AI pregnancy rates in postpartum suckled beef cows. *J.* M. Thomas*, B. E. Bishop, J. M. Abel, J. W. Locke, S. E. Poock, M. F. Smith, and D. J. Patterson, *University of Missouri, Columbia.*

An experiment was designed to test the hypothesis that pregnancy rates after fixed-time artificial insemination (FTAI) among postpartum suckled beef cows would be improved by incorporating pretreatment with prostaglandin $F_{2\alpha}$ (PG) into a long-term, CIDR-based estrus synchronization protocol. The 9-d CIDR-PG protocol, a modified protocol in which PG is used to facilitate a decreased length of progestin treatment, was compared to the 14-d CIDR-PG protocol. Protocols were compared on the basis of initial estrus response following

CIDR removal, final estrus response following the administration of PG, and pregnancy rate resulting from FTAI. Estrus was synchronized for 321 cows across three locations. Treatments were represented across locations, and cows within each location were randomly assigned to one of the two protocols based on age and body condition score (BCS). Cows assigned to the 14-d CIDR-PG treatment received a CIDR insert (1.38 g progesterone) on d 0 with removal of CIDR on d 14; 25 mg PG 16 d after CIDR removal on d 30; and 100 μg GnRH on d 33, 72 h after PG. Cows assigned the 9-d CIDR-PG treatment received 25 mg PG and a CIDR insert (1.38 g progesterone) on d 5; 25 mg PG and removal of CIDR on d 14; 25 mg PG 16 d after CIDR removal on d 30; and 100 μg GnRH on d 33, 72 h after PG. Estrus response following CIDR removal on d 14 did not differ between treatments (87% versus 85%, $P = 0.71$), and there was no difference in final estrus response following the administration of PG on d 30 (53% versus 50%, $P = 0.69$). A significant effect of treatment was found on pregnancy rate resulting from FTAI, with cows assigned to the 9-d CIDR-PG protocol achieving greater FTAI pregnancy rates than cows assigned to the 14-d CIDR-PG protocol (63% versus 53%, $P < 0.05$). Across treatments, greater pregnancy rates ($P = 0.06$) tended to be achieved by cows that expressed estrus before FTAI (69% for 9-d CIDR-PG, 57% for 14-d CIDR-PG) than were achieved by cows that failed to express estrus (57% for 9-d CIDR-PG, 48% for 14-d CIDR-PG). In summary, when using a long-term, CIDR-based estrus synchronization protocol among mature, suckled beef cows, FTAI pregnancy rates are improved through use of the 9-d CIDR-PG protocol.

Key Words: artificial insemination, beef cow, estrus synchronization

1116 Requirement of GnRH administration at the onset of the 5 d CO-Synch + CIDR protocol in suckled beef cows.

T. M. Grussing*[1], M. L. Day[2], B. J. Funnell[3], B. R. Harstine[4], E. J. Northrop[5], G. A. Perry[5], J. J. J. Rich[5], D. W. Shike[6], K. R. Stewart[7], and P. J. Gunn[1], *[1]Department of Animal Science, Iowa State University, Ames, [2]Department of Animal Science, University of Wyoming, Laramie, [3]Department of Veterinary and Clinical Sciences, Purdue University, West Lafayette, IN, [4]The Ohio State University, Columbus, [5]Department of Animal Science, South Dakota State University, Brookings, [6]University of Illinois, Urbana, [7]Purdue University, West Lafayette, IN.*

The objective of this experiment was to evaluate the requirement of GnRH administration at controlled internal drug release (CIDR) insertion in the 5-d CO-Synch + CIDR protocol (5dCO). Postpartum, suckled beef cows ($n = 2159$) from 11 herds at 5 universities were assigned by age, BCS, and days postpartum to receive either: 1) standard 5dCO hormone administration including 100 μL of GnRH at CIDR insert and 2 concurrent 25-mg doses of $PGF_{2\alpha}$ (PG) at CIDR removal (G2PG), 2) no GnRH at CIDR insert and 2 concurrent, 25-mg doses of PG at CIDR removal (NoG2PG), or 3) no GnRH at CIDR insert and a single, 25-mg dose of PG at CIDR removal (NoG1PG). Estrous response between PG and timed-AI (TAI) was determined using estrous detection aids. All cows were TAI 72 h after CIDR removal, concurrent with administration of 100 μL of GnRH. Estrous cyclicity before synchronization was determined using a combination of 2 blood samples collected 10 d apart and estrus detection aids administered approximately 24 d before CIDR insert. Transrectal ultrasonography was used on a subset of cows at both CIDR insert and removal to record all ovarian structures as well as to detect pregnancy 31 to 42 d after TAI. Data were analyzed using the MIXED and GLIMMIX procedures of SAS for continuous and binary response variables, respectively. Herd nested within university was included as a random effect. Number of total follicles and size of the largest 2 follicles at CIDR insertion were not different ($P \geq 0.34$). However, the largest follicle at CIDR removal was greater ($P = 0.02$) in NoG2PG than G2PG and NoG1PG (13.2, 11.5, and 12.1 ± 0.5 mm, respectively). Though estrus response was not different ($P = 0.99$) before TAI, detection aid activation was more advanced ($P = 0.01$) in NoG1PG than G2PG and NoG2PG. However, pregnancy to TAI did not differ ($P = 0.66$) among G2PG (55.4%), NoG2PG (52.8%), and NoG1PG (50.5%) treatments. Cows exhibiting estrus before TAI had greater ($P < 0.001$) TAI pregnancy rates (58.1%) than those not exhibiting estrus (39.3%) and cows determined to be cyclic at synchronization initiation had greater ($P < 0.001$) TAI pregnancy rates (53.6%) than non-cyclic cows (37.1%). In conclusion, TAI pregnancy rates were not negatively affected by removal of initial GnRH in the 5-d CO-Synch + CIDR protocol.

Key Words: 5-d CO-Synch, GnRH, synchronization

1117 Comparison of follicular dynamics and subsequent progesterone profiles in Brahman cows with either two or three ovarian follicular waves.

R. A. d'Orey Branco*[1,2], D. A. Neuendorff[3], A. W. Lewis[1], R. C. Vann[4], T. H. Welsh, Jr.[5], and R. D. Randel[3], *[1]Texas A&M AgriLife Research, Overton, [2]Department of Animal Science, Texas A&M University, College Station, [3]Texas A&M AgriLife Research, Texas A&M University System, Overton, [4]MAFES-Brown Loam Experiment Station, Mississippi State University, Raymond,[5]Texas A&M AgriLife Research and Department of Animal Science, College Station.*

The objective of this study was to identify differences in follicular dynamics in a *Bos indicus* bovine estrous cycle with 2 or 3 follicular waves (2FW or 3FW) and the subsequent progesterone profiles. Daily ultrasonography was performed on 15 multiparous Brahman cows through a complete estrous

cycle. Blood samples were collected daily from the coccygeal vein throughout the subsequent estrous cycle to determine serum progesterone concentrations by RIA. The ultrasound images were collected using a SonoSite M-Turbo ultrasound with a 7.5 MHz L52X transducer. Follicular data were analyzed using Proc Mixed procedures and serum progesterone data were analyzed using Proc Mixed procedures specific for repeated measures using SAS v9.3. The first FW from cows with 2 or 3 FW estrous cycles were compared and the ovulatory FW were compared. Size and day (d) of the dominant and largest subordinate follicle did not differ between 2 or 3 FW estrous cycles during either the first or ovulatory FW. As expected the length of the FW differed ($P < 0.01$) during the first (2FW = 11.90 ± 0.73; 3FW = 7.00 ± 1.03) and ovulatory FW (2FW = 10.80 ± 0.90; 3FW = 6.00 ± 1.27) between groups, respectively. The d the largest follicle appeared differed ($P < 0.01$) in the first (2FW = 9.5 ± 0.48; 3FW = 5.6 ± 0.67) and ovulatory FW (2FW = 9.8 ± 1.05; 3FW = 5.6 ± 1.47). The greatest number of antral follicles found differed during the first (2FW = 14.20 ± 1.60; 3FW = 6.00 ± 2.25) ($P < 0.01$) and ovulatory FW (2FW = 21.0 ± 2.00; 3FW = 12.5 ± 2.83) ($P = 0.025$). The serum progesterone profile of the following estrous cycle was normalized by analyzing the first 10 d after estrus (CL growth phase) and the 10 d before the succeeding estrus (CL regression phase). There was a tendency ($P = 0.08$) for an interaction between day and number of FW for the CL regression phase of the estrous cycle. The 3FW cows tended to have greater progesterone concentrations during the last 7d of the regression phase compared with the 2FW. These results suggest that cows with 2FW have greater a number of antral follicles within the first and ovulatory FW and the 3FW cows had increased serum progesterone concentrations during the CL regression phase of the subsequent estrous cycle.

Key Words: Brahman cows, follicular dynamics, serum progesterone.

1118 Effect of a progesterone-based estrous synchronization program for timed AI (TAI) on reproductive performance in a seasonal pasture-based dairy production system.

F. Randi[1,2], J. M. Sanchez[1], M. M. Herlihy[3], D. A. Kenny[4], A. Valenza[5], S. Butler[*3], and P. Lonergan[6], *[1]School of Agriculture and Food Science, University College Dublin, Dublin, Ireland, [2]Teagasc Grange, Meath, Ireland, [3]Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Ireland, [4]Teagasc Grange, Dunsany Co. Meath, Ireland, [5]Ceva Animal Health, Libourne, France, [6]School of Agriculture and Food Science, University College Dublin, Belfield, Dublin, Ireland.*

The aim of this study was to investigate the effect of progesterone-based TAI programs on fertility in seasonal-calving pasture-based dairy herds. At 10 d before the mating start date (MSD), 840 lactating dairy cows on 3 seasonal-calving farms were blocked based on days in milk (DIM) and parity and randomly allocated to one of three treatments: (i) Control: no treatment, inseminated at detected estrus; (ii) P4-Ovsynch: cows received a 7-d progesterone-releasing intravaginal device (PRID®Delta) with 100 mg of GnRH analog (Ovarelin®) at PRID insertion, 25 mg injection of PGF2α (Enzaprost®) at PRID removal, GnRH at 56 h after device removal and TAI 16 h later; (iii)P4-Ovsynch+eCG: same as P4-Ovsynch, but cows received 500 IU equine chorionic gonadotropin (eCG; Syncrostim®) at PRID removal. At trial initiation all cows that were $\geq$ 30 DIM were ultrasound scanned to assess presence/absence of a corpus luteum (CL) and Body Condition Score (BCS) was also recorded. Pregnancy diagnosis was performed by transrectal ultrasonography 30–35d after insemination. Binary data were analyzed using the GLIMMIX procedure of SAS, and time-dependent data were analyzed using survival analysis. Overall, conception rate was not different between groups (51.0%, 52.0%, and 51.8% for Control, P4-Ovsynch, and P4-Ovsynch+eCG, respectively; $P = 0.9$), but the 21-d pregnancy rate was increased by the synchronization protocols (38.6%, 58.6%, and 53.6%; $P < 0.0001$). Supplementation with eCG at PRID removal did not affect pregnancy rate (53.3 vs. 52.5, P4-Ovsynch vs. P4-Ovsynch+eCG, respectively; $P = 0.9$). Compared to the Control group, synchronization treatments significantly reduced the interval from MSD to conception (36.7, 24.0, and 27.1 d, respectively; $P < 0.001$), and consequently reduced the average days open (87.0, 75.0, and 78.0 d, respectively; $P < 0.001$). Across all treatment groups, DIM at start of synchronization had a significant effect on conception rate (44.3%, 51.1%, and 59.5% for < 60, 60–80, and > 80 DIM, respectively; $P < 0.05$), but parity (49.7%, 51.5%, and 53.9% for parity 1, 2, and $\geq$ 3, respectively; $P = 0.7$), BCS (44.9%, 51.6%, and 58.6% for $\leq$ 2.50, 2.75–3.25, and $\geq$ 3.50, respectively; $P = 0.2$) and presence of a CL (51.7% vs. 51.7%; $P = 0.9$) did not have significant effects on the likelihood of pregnancy per AI. Additionally, there were no two-way interactions detected ($P > 0.05$) between treatment and DIM, parity, BCS, or CL status category. In conclusion, the use of TAI accelerated pregnancy establishment of cows in a pasture-based system by reducing days open, but eCG supplementation at PRID removal did not affect pregnancy rate.

Key Words: eCG, progesterone, synchronization, timed AI

1119 Hepatic gluconeogenic enzymes are differentially altered by methyl-donors choline and methionine in bovine primary hepatocytes. T. L. Chandler*[1], S. J. Bertics[1], B. A. Barton[2], and H. M. White[1], [1]*Department of Dairy Science University of Wisconsin, Madison,* [2]*Balchem Corporation, New Hampton, NY.*

Tricarboxylic acid cycle (TCA) and gluconeogenic carbon flux are controlled by balances of pyruvate carboxylase (*PC*) and phosphoenolpyruvate carboxykinase (*PEPCK*). The lipotropic action of choline and methionine may alter fatty acid (FA) oxidation and gluoneogenic carbon availability. The objective of this experiment was to examine regulation of genes controlling gluconeogenesis in response to increasing concentrations of choline chloride (CC), DL-methionine (DLM), and added FA. Primary hepatocytes isolated from 4 Holstein calves were maintained as monolayer cultures for 24 h in media containing optimal concentrations of essential amino acids and 1.25 m*M* pyruvic acid. Treatments of physiologically relevant concentrations of CC (33, 100, 2000, 4500 μ*M*) and DLM (16, 30, 100, 300 μ*M*), with or without a 1 m*M* FA cocktail, were added to a methionine-free media in a factorial design. After 24 h of treatment, cells were harvested for RNA isolation, cDNA generation, and quantification of gene expression by quantitative PCR. Abundance of mRNA was normalized to the geometric mean of three reference genes. Data were analyzed using PROC MIXED of SAS 9.4 with linear and quadratic contrasts in a model accounting for fixed effect of treatment and random effect of calf and reported as least squares means ± SE. Expression of *PC* tended to be linearly increased ($P = 0.06$) by CC (1.28, 1.42, 1.43, 1.50 ± 0.21 arbitrary units (AU)) and was unaffected ($P > 0.15$) by DLM (1.39, 1.51, 1.38, 1.35 ± 0.21 AU). Although, *mitochondrial PEPCK* (*PEPCKm*) expression was unaffected ($P \geq 0.15$) by CC (1.64, 1.58, 1.60, 1.59 ± 0.5 AU) or DLM (1.49, 1.57, 1.65, 1.69 ± AU), *cytosolic PEPCK* (*PEPCKc*) tended to be linearly increased ($P = 0.11$) by CC (1.03, 1.19, 1.30, 1.57 ± 0.32 AU) and decreased ($P = 0.08$) by DLM (1.60, 1.31, 1.21, 0.97 ± 0.32). Expression of *glucose 6-phosphatase* (*G6P*) was quadratically affected ($P = 0.009$) by CC (1.14, 1.42, 0.99, 1.13 ± 0.30) and unaffected ($P > 0.15$) by DLM (1.14, 1.17, 1.19, 1.17 ± 0.30). Treatment with FA increased ($P < 0.001$) expression of *PC* (1.11 vs. 1.70 ± 0.20 AU), *PEPCKc* (0.55 vs. 2.0 ± 0.27 AU), *PEPCKm* (1.36 vs. 1.84 ± 0.48 AU), and *G6P* (0.93 vs. 1.41 ± 0.29 AU). Coordinated increases in *PC* and *PEPCKc* with increasing CC suggests increased capacity for gluconeogenesis. Conversely, decreased *PEPCKc* without altered *PC* may indicate that DLM may increase TCA capacity but not gluconeogenic capacity. Choline and methionine appear to differentially regulate TCA cycle and gluconeogenesis.

Key Words: gluconeogenesis, methyl-donors, primary hepatocytes

1120 Expression of the putative gonadotropin-inhibitory hormone receptor, NPFFR1, in the anterior pituitary gland of the gilt is affected by age and sexual maturation. C. A. Lents*, J. F. Thorson, and D. J. Nonneman, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE.*

Gonadotropin-inhibitory hormone (GnIH) purportedly suppresses secretion of luteinizing hormone (LH) by acting through a G protein coupled receptor (NPFFR1) in the anterior pituitary gland and hypothalamus. The objective of these studies was to determine if expression of mRNA for NPFFR1 in the reproductive neurosecretory axis of gilts differed with age or sexual maturation. In Exp. 1, the anterior pituitary gland was collected from gilts at 24 (weaning), 60, 100, and 140 d of age ($n = 14$ to 16 per age). In Exp. 2, the anterior pituitary gland and medial basal hypothalamus were collected from gilts at 240 d of age. Gilts were classified ($n = 12$ to 14 per classification) as prepubertal, peripubertal, or cyclic (midluteal phase) based on estrus records and ovarian morphology at slaughter. Relative abundance of LHβ, FSHβ, CGA, GnRHR1, and NPFFR1 mRNA in pituitary glands from Exp. 1 and 2 and NPFFR1, GnRH1, NPY, POMC, and RFRP in hypothalami from Exp. 2 was measured with qPCR. Data were analyzed by ANOVA with age or reproductive classification as fixed effects. In Exp. 1, age did not affect expression of GnRHR1 or CGA. Expression of FSHβ at weaning was not different from 60 d of age but was greater ($P < 0.05$) than expression at 100 and 140 d of age. Compared to weaning, expression of LHβ was less ($P < 0.05$) at 60 d of age and greater ($P < 0.05$) at 100 d of age, but not different at 140 d of age. Pituitary expression of NPFFR1 was greater ($P < 0.05$) at 100 d of age compared with all other ages. In Exp. 2, prepubertal gilts had less pituitary expression of LHβ ($P < 0.02$) and greater pituitary expression of FSHβ ($P < 0.04$), CGA ($P < 0.001$), GnRHR1 ($P < 0.01$), and NPFFR1 ($P < 0.001$) than cyclic gilts. Expression of LHβ and GnRHR1 was intermediate in peripubertal gilts. Expression of FSHβ, CGA, and NPFFR1 in the pituitary did not differ between peripubertal and cyclic gilts. Expression of NPFFR1 in the hypothalamus of peripubertal gilts was less ($P < 0.05$) than in cyclic gilts. Reproductive classification did not affect hypothalamic expression of GnRH1, NPY, POMC, or RFRP. Increased expression of NPFFR1 in prepubertal gilts indicates an increased sensitivity to GnIH inhibition of LH secretion. Support: NIFA AFRI 2011–67015. USDA is an equal opportunity provider and employer.

1121 Role of focal adhesion molecules in maternal recognition of pregnancy in the mare.
K. Klohonatz, L. Nulton, A. Hess, G. J. Bouma, and J. E. Bruemmer*, *Colorado State University, Fort Collins.*

The mechanism responsible for maternal recognition of pregnancy (MRP) in the mare remains unknown. During early pregnancy the equine conceptus and endometrium communicate to attenuate prostaglandin $F2_{\alpha}$(PGF) secretion thus sparing the corpus luteum and maintaining progesterone production. Based on previous experiments we identified focal adhesion molecules (FAM) as potentially playing a key role in this process. We hypothesize that contact of an embryo with equine endometrium causes (i) a change in FAM transcription and (ii) decrease PGF secretion. We designed an in vitro experiment to test this hypothesis. Endometrial biopsies were obtained from mares in a crossover design, with each mare providing samples from a pregnant and non-pregnant (non-mated) control cycle (n = 3/sample day) on d 9 and 11 post-ovulation, a critical time immediately before and during MRP. Pregnancy was confirmed by ultrasonography and presence of an embryo following uterine lavage. Mares were matched by day and embryos collected were used in co-culture experiment. Endometrial samples were divided and placed in culture with or without contact by an equine embryo for 24 h. Total RNA from endometrial biopsies was evaluated by qPCR using primers designed to detect 22 equine-specific FAM transcripts and ELISA was used to assay PGF content in medium. All comparisons were made within day between groups and pregnancy status. Differential expression of 4 and 6 FAM were noted in samples collected on d 9 ($P \leq 0.02$) and 11 ($P \leq 0.05$), respectively, when compared by pregnancy status alone. No changes were detected in FAM expression in samples collected from pregnant mares due to the presence or absence of an embryo, while 1 and 4 FAM differed when embryos were co-cultured with endometrial samples from non-mated mares at d 9 (P = 0.04) and 11 ($P \leq 0.04$), respectively. Secretion of PGF was not attenuated with embryo contact on d 9 regardless of pregnancy status. Embryo contact resulted in dramatic decreases (P < 0.003) in PGF secretion in samples collected from both pregnant and non-pregnant mares 11 d post-ovulation. These data support our hypothesis that FAM expression is altered with the presence of an embryo and implicates FAM in the modulation of PGF secretion. Together these provide new insight into a potential mechanism for MRP in mares.

Key Words: embryo, endometrium, equine, focal adhesion molecule, maternal recognition of pregnancy

1122 Modification of embryonic resistance to heat shock in cattle by melatonin and genetic variation in HSPA1L.
M. S. Ortega*[1], N. A. D. S. Rocha Frigoni[2], G. Z. Mingoti[2], Z. Roth[3], and P. J. Hansen[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]University of Sao Paulo State (UNESP), Araçatuba, Brazil, [3]The Hebrew University, Rehovot, Israel.*

Seeking for new methods to reduce the effect of heat stress on fertility we examined 1) whether melatonin blocks inhibition of embryonic development caused by heat shock and 2) whether frequency of a thermoprotective allele for *HSPA1L* is increased in blastocysts formed from heat-shocked zygotes as compared to blastocysts from control zygotes. It was hypothesized that melatonin prevents effects of heat shock on development by reducing accumulation of reactive oxygen species (ROS). Effects of 1 μM melatonin on ROS were determined in Exp. 1 and 2. Zygotes were cultured at 38.5 or 40°C for 3 h in the presence of CellROX® reagent. Culture was in a low [5% (v/v)] oxygen (Exp. 1) or low or high [21% (v/v)] oxygen environment (Exp. 2). Heat shock and high oxygen increased ROS; melatonin decreased ROS. In Exp. 1, for example, fluorescent intensity at 38.5°C was 346 ± 54 and 451 ± 51 and 769 ± 47 and 361 ± 50 at 40°C for control and melatonin-treated embryos (interaction, $P < 0.0001$). Development was assessed in Exp. 3–5. In Exp. 3 and 4, zygotes were cultured in low oxygen + 1 μM melatonin and exposed to 38.5 or 40°C for 12 (Exp. 1) or 24 h (Exp. 2) beginning 8 h after fertilization. Melatonin was not thermoprotective in either experiment. Exp. 5 was performed similarly except that temperature treatments (38.5 or 40°C, 24 h) were performed in a low or high oxygen environment (2 x 2 x 2 factorial design with temperature, melatonin, and oxygen concentration as main effects). Heat shock decreased (P = 0.003) percent of zygotes developing to the blastocyst stage (26 ± 1.5 vs. 20 ± 1.5%) independent of melatonin or oxygen concentration. For Exp. 5, blastocysts were genotyped for a deletion (D) mutation (C®D) in the promoter region of *HSPA1L* associated with thermotolerance. Genotype was affected by temperature (P = 0.002). The percent of blastocysts CC, CD, or DD was 43.3, 28.5, and 28.2% for blastocysts from control zygotes and 32.4, 36.0, and 31.6% for blastocysts from heat-shocked zygotes. It was concluded that 1) lack of effect of melatonin or oxygen concentration on embryonic development means that the negative effects of heat shock on the zygote are not mediated by ROS, 2) previously reported effect of melatonin on fertility of heat-stressed cows might involve actions independent of the antioxidant properties of melatonin, and 3) the deletion mutation in the promoter of *HSPA1L* confers protection to the zygote from heat shock. Perhaps, embryonic survival during heat stress could be improved by selecting for thermotolerant genotypes (Support: BARD US-4719–14).

Key Words: heat shock, melatonin, reactive oxygen species, *HSPA1L*

1123 Transgenerational paternal influence on temperament and growth performance of crossbred beef calves. R. C. Vann[*1], B. P. Littlejohn[2], C. R. Long[3], T. H. Welsh, Jr.[2], and R. D. Randel[4], *[1]MAFES-Brown Loam Experiment Station, Mississippi State University, Raymond, [2]Texas A&M AgriLife Research and Department of Animal Science, College Station, [3]Texas A&M AgriLife Research, Overton, [4]Texas A&M AgriLife Research, Texas A&M University System, Overton.*

The objective was to evaluate the transgenerational paternal influence on temperament characteristics and growth performance in a group of crossbred calves sired by bulls that did or did not experience prenatal stress (PNS). These sires were derived from a purebred Brahman population in which dams were assigned to receive 1 of 2 treatments, control (CTRL; $n = 42$) or PNS ($n = 43$). Cows in the PNS group were subjected to 2 h of transportation at 60, 80, 100, 120, and 140 d of gestation (Littlejohn et al., 2016). From this group, 3 sexually mature control and 3 PNS Brahman bulls were mated with mature cows (20 cows per bull) to produce a second generation of calves. These crossbred calves were evaluated for temperament utilizing pen score (PS; 1 = calm and 5 = excitable), exit velocity (EV; m/sec), and temperament score (TEMP; PS+EV/2) at weaning (d 0; adjusted 205 d), d 28, and d 56. At these same time points body weights were recorded. All data were analyzed using Mixed Models Procedures of SAS. Treatment of sire and sex of calf were included as fixed effects. Male calves had greater birth weights compared to females ($P < 0.001$). Steers had greater adjusted 205 d, d 28, and 56 BW ($P < 0.005$) compared with heifers. Calves from PNS sires had greater ($P < 0.001$) adjusted 205 d BW compared to calves from CTRL sires but this did not carry through d 28 or 56. Male calves from PNS sires had greater ($P < 0.001$) adjusted 205 d BW, male calves from CTRL sires and female calves from PNS sires were intermediate and female calves from CTRL sires had the lowest adjusted 205 d BW. Male and female calves from CTRL sires had the greatest PS ($P < 0.002$), EV ($P < 0.05$) and TEMP ($P < 0.002$) scores at weaning compared to male and female calves from PNS sires. Individual sire influenced ($P < 0.05$) all measures of temperament and BW. Weaning TEMP score was highly ($P < 0.001$) correlated to TEMP scores at d 28 and 56 (0.66 and 0.68, respectively). Calves from CTRL sires had greater TEMP scores at weaning; however, by d 56 these differences had diminished. Calves from PNS sires had greater adjusted 205 d BW; however, these differences in BW at weaning, d 28 or 56 were not apparent where adjustments for age of dam and sex of calf were not included. Temperament measures in PNS were lower than for CTRL calves.

Key Words: beef calves, temperament, transgenerational

1124 DNA methylation is a possible basis of phenotypic alterations observed in suckling Brahman calves. B. P. Littlejohn[*1,2], D. M. Price[1,2], D. A. Neuendorff[2], C. R. Long[2], J. A. Carroll[3], R. C. Vann[4], T. H. Welsh, Jr.[1], and R. D. Randel[2], *[1]Texas A&M AgriLife Research and Department of Animal Science, College Station, [2]Texas A&M AgriLife Research, Texas A&M University System, Overton, [3]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [4]MAFES-Brown Loam Experiment Station, Mississippi State University, Raymond.*

The objective of this experiment was to examine DNA methylation as a potential basis for phenotypic alterations observed in prenatally stressed (PNS) compared to control calves (Littlejohn et al., 2016). Previously, 41 of 85 mature Brahman cows were transported for 2-h periods at 60, 80, 100, 120, and 140 d of gestation, while the remaining cows were controls ($n = 44$). All calves born to control and transported dams (PNS group) were evaluated to determine phenotypic differences in temperament, circulating concentrations of cortisol, immune

Table 1124.

Table 1. Enumeration of strongly hypermethylated and strongly hypomethylated genes in PNS (n=7) compared to control (n=7) bull calves.

	Immune Function	Metabolic Function	Behavior/ Stress/Neural Function	Reproductive Function	Cell Signaling/Gene Function
Strongly Hypermethylated Genes	4	13	3	2	25
Strongly Hypomethylated Genes	14	15	9	2	23

function, and metabolism as suckling calves. At 28 d of age each calf was restrained for collection of jugular blood samples. Buffy coat cells were harvested from whole blood and stored at −80 C. DNA was isolated from buffy coat cells of 7 PNS and 7 control bulls using phenol-chloroform extraction procedures and the samples were analyzed using reduced representation bisulfite sequencing (Zymo Research; Irvine, CA) to determine differential methylation of DNA. Reported genes were differentially methylated ($P < 0.015$) in PNS compared to control calves (Table 1). Genes that were defined as strongly hypermethylated ($n = 41$) were $\geq$ 33% more methylated in PNS than control bulls, while genes that were defined as strongly hypomethylated ($n = 49$) were $\geq$ 33% less methylated than controls. Reported genes were related to immune function, metabolic function, behavior/stress/neural function, reproductive function, and cell signaling/gene function. Several genes were ascribed to multiple functions. Differentially methylated genes related to phenotypic alterations observed in PNS compared to control bull calves suggest epigenetic programming of biological systems in utero.

Key Words: calves, DNA methylation, prenatal stress

1125 Photoperiod manipulations during the dry period significantly impact mammary circadian clock in goats. S. J. Mabjeesh[*1], A. Shamay[2], K. Plaut[3], C. Sabastian[1], and T. M. Casey[3], *[1]Department of Animal Sciences, The Robert H. Smith Faculty of Agriculture, Food and Environment, The Hebrew University, Rehovot, Israel, [2]Institute of Animal Science, The Volcani Center, Bet Dagan, Israel, [3]Department of Animal Sciences, Purdue University, West Lafayette, IN.*

Exposing goats to short day photoperiod (SDPP; 8 h light:16 h dark) during the dry period increases milk production compared to long day photoperiod (LDPP; 16 h light:8 h dark) exposure, due in part to increased mammary cell proliferation rates. Photoperiod information is sent to the master clock in the suprachiasmatic nuclei (SCN) via the retinal nerve. In turn the SCN sends temporal information out to peripheral clocks located in every tissue of the body to synchronize physiological systems to time of day and season. Studies support mammary clock regulates cell proliferation, thus we hypothesized photoperiod effects on milk production are mediated in part by changes in the molecular clock located in mammary gland. The objective of this study was to determine the effect of photoperiod manipulation during the dry period in goats on core clock gene expression in mammary gland. Multiparous Israeli Saanen goats ($n = 6$) were blocked at dry off (?45 d prepartum) into 2 treatments: LDPP ($n = 3$) and SDPP ($n = 3$) based on body weight and previous milk production. All goats were housed in metabolism chambers equipped with two separate but identical environmentally controlled rooms in which photoperiod was adjusted according to the treatment. Goats were fed a total mixed ration in two equal meals at 0800 and 1500 to meet nutritional demands. Serial mammary biopsies were taken over a 24 h period from each goat during 3 wk prepartum at 4 h intervals (0900, 1300, 1700, 2100, 0100, 0500). Tissue was placed in Trizol and immersed in liquid nitrogen. Total RNA was isolated and q-PCR was used to measure expression of two reference genes (BACTIN and GAPDH) and the core clock genes CLOCK and ARNTL. Relative gene expression was calculated using delta-delta CT method with mean of SDPP treatment as normalizer. Exposure to SDPP significantly increased ARNTL ($P < 0.05$) while significantly decreasing CLOCK gene expression. CLOCK and ARNTL heterodimerize to function as a transcription factor, thus changes in their abundance due to photoperiod manipulation will affect expression of target genes, including those that regulate cell proliferation.

Key Words: ARNTL, CLOCK, photoperiod

1126 Management and genetic components of fertility indicators in dairy cattle. T. M. Goncalves[*1], D. Gonzalez-Pena[2], H. Jeong[1], P. J. Pinedo[3], J. E. P. Santos[4], G. M. Schuenemann[5], G. J. M. Rosa[6], R. O. Gilbert[7], R. C. Bicalho[8], R. Chebel[4], K. N. Galvão[9], C. M. Seabury[10], W. W. Thatcher[11], and S. L. Rodriguez Zas[12], *[1]University of Illinois at Urbana-Champaign, Urbana, [2]Zoetis, Kalamazoo, MI, [3]Colorado State University, Fort Collins, [4]University of Florida, Gainesville, [5]Department of Veterinary Preventive Medicine, The Ohio State University, Columbus, [6]University of Wisconsin-Madison, Madison, [7]Cornell University College of Veterinary Medicine, Department of Clinical Sciences, Ithaca, NY, [8]Cornell University, Ithaca, NY, [9]Department of Large Animal Clinical Sciences, University of Florida, Gainesville, [10]Texas A&M University, College Station, [11]Department of Animal Sciences, University of Florida, Gainesville, [12]University of Illinois, Urbana.*

Management and genetic strategies are employed to attain high fertility rates in dairy farms. These high rates in turn enable higher profits from higher milk production, higher replacement rates, higher genetic progress, and lower expenses compared to those in systems with lower fertility efficiency. The goal of this study was to characterize the joint effect of management and genetic variation on fertility indicators that are linked to the cost-effectiveness of diary production systems. Fertility, disease, production, environment, and pedigree records from over 6000 Holstein cows across the U.S Pacific, Southeast, Midwest, and Southwest regions were analyzed. Binary fertility variables included pregnancy at first and second artificial insemination (AI), pregnancy loss after first and second AI, ovarian cyclicity status, and open status +100 d after calving. Explanatory variables included AI method, farm, lactation number, season, body condition

score at 35 d post-calving, milk yield during the first three test-days, retained placenta, twin calving, dystocia, ovarian cyclicity status, open status +100 d after calving, pregnancy at first AI, and pregnancy loss after first AI. Sire of the cow was the random effect in the models. First lactation cows had significantly higher odds of pregnancy at first AI, higher odds of +100 d open status, lower odds of cyclicity than later lactation cows. The odds of pregnancy loss after first and second AI tended to be lower in first lactation cows relative to higher lactation cows. Cyclicity was significant and negatively associated with the odds of pregnancy loss at second AI and was positively correlated with pregnancy loss at first AI, albeit not significant. Calving of twins significantly reduced the odds of cyclicity. Retained placenta and timed AI were associated with significantly higher odds of +100 d open status than estrus-guided AI and not retained placenta, respectively. Higher body condition score was positively and significantly associated with odds of cyclicity. The odds of pregnancy after first and second AI were lower among cows calving during summer relative to winter; likewise, the odds of pregnancy loss after first and second AI were higher during the summer. Heritability estimates for the fertility variables studied ranged from 0.03 (pregnancy at first AI) to 0.12 (pregnancy loss at first AI). These results highlight availability of genetic variation and the major relevance of non-genetic component on fertility indicators. These findings contribute to a long-term multistate project database (USDA-NIFA-AFRI-003542) for direct measures of fertility.

Key Words: milk, pregnancy, reproduction

1127 Effects of OmniGen-AF® on superovulation response and embryo quality in donor beef cows.

A. P. Snider*[1,2], M. R. Gellings[1], S. A. Armstrong[2], D. J. McLean[2], and A. R. Menino[1], *[1]Department of Animal and Rangeland Sciences, Oregon State University, Corvallis, [2]Phibro Animal Health Corporation, Quincy, IL.*

Superovulation is a required yet costly and biologically stressful procedure in cattle embryo transfer. High variation in the number of ova recovered, fertilization rates, and embryo quality result in inconsistent results and prevent full optimization of the procedure for genetic improvement. Inflammation and immune system dysregulation have been suggested to be one cause of this variability. Therefore, the objective of this study was to evaluate OmniGen-AF® (OG) supplementation on superovulatory response, embryo quality, and serum cortisol in beef cattle embryo donors using two doses of follicle stimulating hormone (FSH). Twenty-four cross-bred beef cows were split into four groups and superovulated with 200 or 400 mg FSH and fed OG at 0 or 56 g/hd/day. The feeding period was 49 d. The superovulation protocol was started on Day 28 of feeding and ova were nonsurgically recovered 7 d after estrus and artificial insemination. Good to excellent quality morulae and blastocysts were either fixed for staining or cultured to evaluate in vitro embryo development and plasminogen activator (PA) production. In cows superovulated with 400 mg FSH, feeding OG decreased the percent degenerate embryos recovered ($p = 0.08$). Embryos recovered from cows superovulated with 400 mg FSH and fed OG produced more total PA, with a trend for peak PA production to be higher at 72 h of culture ($p = 0.08$), compared to all other groups. In addition, serum cortisol concentration was significantly lower ($p = 0.049$) in donor cows fed OG at the last breeding of the superovulation protocol compared to controls. In summary, feeding OmniGen-AF may ameliorate negative effects of the higher FSH dose used in superovulation protocols resulting in more transferable and fewer degenerate embryos. Also based on PA production, there is a potential for healthier embryos, with a greater likelihood of developing beyond hatching in an embryo transfer procedure.

Key Words: embryo, OmniGen-AF®, superovulation

1128 OmniGen-AF® reduces basal plasma cortisol as well as cortisol release to adrencocorticotropic hormone or corticotrophin releasing hormone and vasopressin in lactating dairy cows under thermoneutral or acute heat stress conditions.

M. L. McBride[1], N. C. Burdick Sanchez[2], J. A. Carroll[2], P. R. Broadway[3], X. O. Ortiz[1], J. L. Collier[1], D. McLean[4], J. D. Chapman[4], H. G. Kattesh[5], and R. J. Collier*[1], *[1]University of Arizona, Tucson, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [3]Texas Tech University, Wolfforth, [4]Phibro Animal Health Corporation, Quincy, IL, [5]Dep. of Animal Science, University of Tennessee, Knoxville.*

Differences in the adrenal cortisol response of OmniGen-AF® (OG) supplemented and control dairy cows to a corticotrophin releasing hormone (CRH) and vasopressin (VP) or an adrenocorticotropic hormone (ACTH) challenge when housed at different temperature-humidity indices (THI) were studied. Holstein cows ($n = 12$; 162 ± 1 DIM) were balanced for milk yield, BW and DIM and randomly assigned to 1 of 2 trts: 1) OminGen-AF, supplemented with OG at 56 g/hd/day for 70 d; or 2) Control (CON), no supplement. Cows were moved to individual tie stalls in 1 of 2 temperature controlled chambers on d 45 and fitted with indwelling rectal temperature (RT) devices and jugular catheters on d 52. Initially THI was cycling at thermoneutrality (TN; THI < 72 for 24 h/d) for 10d, followed by heat stress (HS, THI > 72 for 12h/d) for 10 d. Cows were challenged with CRH (0.3 μg/kg BW) and VP (1 μg/kg BW) at 1000 h on d 6 of TN (d 53 of study) and d 1 of HS (d 57 of study), and with ACTH (0.1 IU/kg BW) at 1000 h on d 7 of TN and d 2 of HS. Blood samples were collected from −2 to 8 h at 30-min intervals relative to each challenge and serum was analyzed for cortisol and corticoid-binding globulin (CBG). Mean

serum cortisol concentration before challenge was lower in OG fed cows compared to CON (9.24 vs. 15.80 ng/ml, $P < 0.003$). Mean serum cortisol concentration was also lower in OG-fed cows compared to CON challenged with ACTH during both TN (27.2 vs. 43.4 ng/ml, $P < 0.01$) and acute HS (11.2 vs. 47.8 ng/ml, $P < 0.01$). Mean plasma cortisol concentrations tended to be lower in OG-fed animals compared to CON cows infused with CRH-VP during TN (38.2 vs. 44.9 ng/ml, $P < 0.06$) and were lower than CON cows infused with CRH-VP during acute HS (49.8 ng/ml vs. 78.3 ng/ml, $P < 0.01$). Mean serum CBG concentration was lower following ACTH infusion than following CRH-VP (753.2 vs. 913.3 ng/ml, $P < 0.01$). OG supplementation had no effect on serum CBG concentrations under TN or HS conditions in this study. However, serum CBG concentrations were elevated by HS in both CON and OG-fed animals following CRH-VP infusion, (1033 vs. 795 ng/ml, $P < 0.01$). Basal serum cortisol was reduced in cows supplemented with OG. In addition, the cortisol response to ACTH and CRH-VP was reduced in OG-fed cows compared to CON and this difference was enhanced during acute heat stress.

Key Words: ACTH, cortisol, heat stress, OmniGen-AF

1129 Reproductive performance with automated activity monitoring or a timed insemination program for first insemination in dairy cows.

J. Denis-Robichaud*[1], R. L. A. Cerri[2], A. Jones-Bitton[1], and S. J. LeBlanc[1], *[1]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, Canada, [2]Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada.*

The objective of this study was to compare reproductive performance in lactating cows inseminated exclusively with timed artificial insemination (TAI) or with maximal use of an automated activity monitoring (AAM) system for the first insemination postpartum. From April 2014 to December 2015, a total of 998 cows in two herds in Ontario were randomly assigned to be inseminated at 85 ± 3 d in milk (DIM) following a Double Ovsynch protocol (DO), or be inseminated following detection of estrus by the AAM system between 50 and 75 DIM. In the AAM group, if estrus had not been signaled by 75 DIM, cows received the Ovsynch protocol and were inseminated at 85 ± 3 DIM. After first insemination, cows were managed according to routine herd management programs (combination of AAM and timed AI). The odds of pregnancy at first insemination and by 88 DIM were used as the outcome for logistic regression models. Models were adjusted for herd and parity as fixed effects, and interactions between treatment and covariates were tested. Analyses were done on cows that completed the protocol as assigned (completed protocol basis, $n = 719$) and on all cows that were not culled before first insemination (intention to treat basis, $n = 849$). The odds of being pregnant to first insemination were higher for cows in the DO group than in the AAM group in the intention-to-treat analysis (0.56 vs. 0.42, $P = 0.05$), but were not statistically significant (0.58 vs. 0.45, $P = 0.12$) for the completed protocol analysis. The odds of being pregnant by 88 DIM tended to be higher for cows in the AAM group than in the DO group, but was not statistically different for the completed protocol (0.74 vs. 0.59, $P = 0.13$) or the intention–to-treat analyses (0.70 vs. 0.56, $P = 0.11$).There was an interaction of treatment with herd in both models, such that more cows in the AAM group were pregnant by 88 DIM in one herd, but there was no difference in the other. In this study, the exclusive use of Double Ovsynch had a higher probability of pregnancy at first AI than AAM, but earlier insemination in the AAM group and the possibility of re-insemination resulted in no statistical difference in the proportion of cows pregnant by 88 DIM. There were differences in the relative performance of TAI and AAM between herds.

Key Words: automated activity monitoring, Double Ovsynch, reproductive performance

1130 Establishing fertility benchmarks for in-line automated milk progesterone monitoring in postpartum dairy cows.

L. M. Mayo* and M. C. Lucy, *University of Missouri, Columbia.*

Milk progesterone (MP4) concentrations in postpartum dairy cows are indicative of ovarian cyclicity. The adoption of automated in-line MP4 monitoring on farm has created the need for benchmarks to better understand MP4 data across cows, parities, farms, etc. The objective was to establish useful fertility benchmarks for in-line MP4 records. MP4 records ($n = 135,588$) from an automated milk progesterone sampling system (Herd Navigator; DeLaval International, Tumba, Sweden) were used. The records were from 1224 lactations of 1505 lactating cows in 4 European herds from January 2014 to December 2015. Farms started monitoring MP4 by 20 d postpartum. Excluded cows did not have MP4 samples before 30 d postpartum, lacked a defined ovulation (MP4 < 3ng/mL followed consecutively by MP4 > 3ng/mL), or lacked consistent MP4 records. The LIFETEST and GLM procedures of SAS 9.4 (Cary, NC) were used to test for differences among farm, parity, and milk yield for commencement of luteal activity (CLA) and length of postpartum estrous cycle. CLA was defined by MP4 > 3ng/mL on 20 to 22 d for initial samples or by a defined ovulation thereafter. Length of estrous cycle was the difference between the two ovulations. Cows were classified as primiparous, mature (2 to 4 lactations), or aged (> 4 lactations). The UNIVARIATE procedure was used to classify daily milk yield (Q1: < 25 kg/day, Q2: 25 to 33 kg/day, Q3: 34 to 41kg/day, Q4: > 41kg/day). The mean interval to CLA was 28.7 ± 14.6 d for all farms. Farm 4 had more cows (103/308 cows) not achieving CLA by 50 d postpartum than the other farms ($P < 0.001$). Aged cows (28/114, 25%) failed to achieve CLA by 50 d postpartum compared with primiparous cows (13/148; $P < 0.05$). Highest producing cows (Q4) failed to

achieve CLA by 40 d postpartum compared with cows producing less than 33kg/day ($P < 0.001$). Length of estrous cycle was shorter for farms 1 and 2 (21.8 ± 0.4d) compared with 22.7 ± 0.4 and 23.0 ± 0.4d for farms 3 and 4, respectively ($P < 0.05$). Length of estrous cycle differed ($P < 0.001$) for primiparous, mature, and aged cows, 21.3 ± 0.2d, 22.7 ± 0.2d, and 23.0 ± 0.5d, respectively. Strategic sampling of MP4 concentrations using an automated system identified differences between herds, parities, and milk production with respect to ovarian cyclicity. Establishing benchmarks based on these data will enable producers to assess ovarian function and the underlying causes of infertility in their herds.

Key Words: fertility, in-line milk progesterone, ovulation

1131 The effects of aspirin on pregnancy rates and pregnancy specific protein B in lactating dairy cows during the summer. J. A. Spencer*[1], K. G. Carnahan[1], B. Shafii[1], J. Dalton[2], and A. Ahmadzadeh[1], [1]*University of Idaho, Moscow,* [2]*University of Idaho, Caldwell.*

The occurrence of embryonic loss in cattle may be due to a hormonal imbalance and untimely secretion of $PGF_{2\alpha}$ around the time of maternal recognition on Days 14–16 after fertilization. The objective of this study was to examine the effect of aspirin, a non-steroidal anti-inflammatory drug, on pregnancy rates (PR) and blood pregnancy specific protein B (PSPB) in lactating dairy cows bred more than once and during the summer months. On Day 14 after two or more AI, 556 cows, from a commercial drylot herd in the Pacific Northwest, were assigned randomly to aspirin (total of 187.2 g; $n = 277$) or control ($n = 279$) treatment groups. Aspirin was administered orally with a balling gun 24 h apart on Day 14 and 15 (93.6 g/dose) after AI, whereas the control group was subjected to oral stimulation. On Day 25 following AI, blood samples were collected from a subset of cows ($n = 192$) and measured for PSPB concentrations. Pregancy status was determined by palpation per rectum between Day 32 to 40 post-AI. The maximum daily ambient temperature ranged from 27 to 39.4°C during the trial period. To estimate the effect of aspirin on PR/AI, a logistic regression model was used. Concentrations of PSPB were analyzed using the analysis of variance. There were no differences in PR/AI ($P > 0.05$) between aspirin (21.7%) and control (27.6%) groups. There was no effect of parity (primiparious 26.2% vs. multiparous 23.8%) or number of inseminations (TBRD) (second and third 26.2% vs. ≥ 4 21.5%) on PR/AI. There was also no effects of treatment or treatment by pregnancy status on PSPB concentrations ($P > 0.05$). Blood PSPB concentrations were 122.8 ± 8.1 and 127.8 ± 6.4 pg/mL for the aspirin and control groups, respectively. However, PSPB concentrations tended to be greater in multiparous cows compared with primiparous cows (132.7 ± 5.7 vs. 118.1 ± 7.3 pg/mL, $P = 0.07$). In addition, PSPB concentrations tended to be greater ($P = 0.07$) for second and 3rd TBRD (133.1 ± 5.3 pg/mL) than ≥ 4 TBRD (117.6 ± 7.8 pg/mL). These results indicate that aspirin may not have an effect on PR/AI or PSPB concentrations in lactating dairy cows subjected to two or more AI during hot summer months in the Pacific Northwest.

Key Words: aspirin, dairy cow, fertility

1132 Temporarily decreasing progesterone after timed artificial insemination decreased expression of ISG15 in blood leukocytes, serum PSPB concentrations, and embryo size in lactating Holstein cows. P. D. Carvalho, C. E. Consentini, S. R. Weaver, R. V. Barletta, L. L. Hernandez, and P. M. Fricke*, *Department of Dairy Science, University of Wisconsin, Madison.*

Our objective was to evaluate the effect of temporarily decreasing progesterone (P4) after timed artificial insemination (TAI) in dairy cows. Lactating Holstein cows ($n = 80$) were synchronized for first TAI using a Double-Ovsynch protocol, and were randomly assigned to receive 12.5 mg $PGF_{2\alpha}$ (dinoprost tromethamine) 5 d after the last GnRH treatment (LowP4) or serve as untreated controls (HighP4). Blood samples were collected thrice weekly from 5 to 32 d after TAI for all cows and from 32 to 67 d for pregnant cows, and were analyzed for P4 and PSPB concentrations. Expression of interferon-tau stimulated gene 15 (ISG15) was assessed in blood leukocytes 18 and 20 d after TAI. Pregnancy diagnosis was performed weekly using ultrasound from 32 to 67 d after TAI, and embryo size (crown-rump length) was measured 32, 39, and 46 d after TAI. Data were analyzed by ANOVA and logistic regression using the MIXED and GLIMMIX procedures of SAS. LowP4 cows had less ($P < 0.01$) P4 than HighP4 cows from 6 to 11 d after TAI, however, pregnancy outcomes 32 d after TAI [43% (17/40) for both treatments, $P = 0.97$] and pregnancy loss from 32 to 67 d after TAI [6% (1/17) vs. 6% (1/17) for LowP4 and HighP4, $P = 0.84$] did not differ between treatments. HighP4 cows diagnosed pregnant 32 d after TAI had greater ($P < 0.05$) expression of ISG15 20 d after TAI than LowP4 cows diagnosed pregnant 32 d after TAI (7.7 vs. 4.9-fold increase from d 4). Pregnant HighP4 cows had greater ($P < 0.01$) PSPB concentrations from 25 to 67 d after TAI than pregnant LowP4 cows. Embryo crown-rump length did not differ between treatments 32 and 39 d after TAI, but HighP4 cows had larger ($P < 0.05$) embryos 46 d after TAI (26.0 ± 1.0 vs. 23.5 ± 1.0 mm). We conclude that treatment with 12.5 mg of $PGF_{2\alpha}$ 5 d after induction of ovulation temporarily decreased P4 concentrations from 6 to 11 d after TAI without inducing luteal regression. Decreasing P4 after TAI decreased expression of ISG15 in blood leukocytes 20 d after TAI, serum PSPB concentrations 25 to 67 d after TAI, and embryo size 46 d after TAI but did not affect P/AI in lactating Holstein cows. Supported by USDA NIFA Hatch project 1006519.

Key Words: embryo, ISG15, progesterone, PSPB

1133 Effects for fertility of processing steps of a new technology platform for producing sexed sperm. M. A. Faust*, J. Betthauser, A. Storch, and S. Crego, *ABS Global, Inc., De Forest, WI.*

To understand the importance for fertility of key processing steps used in the production of sexed sperm, we conducted a series of field trials in U.S. dairy herds. Steps studied were: staining and processing in the absence of laser excitation (1), excitation laser power (2), and the presence of bisected sperm and debris resulting from laser-based cell destruction (3). For experiment 1, split or coincident collections from 8 dairy bulls were used to produce STAINED-L (2×10^6 motile sperm/straw) and untreated controls (CON-H, 10×10^6 sperm). The STAINED-L comprised sperm stained using Hoechst 33342 and subjected to all steps of the sexing process but with no exposure to laser excitation. Conception rates (CR) in Holstein heifers were 56.1% ± 2.8% (n = 312 pregnancy diagnoses) for STAINED-L and 66.7% ± 2.6% (n = 330) for CON-H. For experiment 2, one collection from each of 4 Holstein bulls was split to create untreated CON-L and stained treatments receiving low, medium, and high laser power during excitation. Post-thaw, these 4 treatments contained similar numbers of progressively motile sperm/straw (0.90 to 1.41 $\times 10^6$). When used in virgin heifers, CR for all laser excited treatments were lower than CON-L ($P < 0.01$), and were 58.7% ± 2.0% (n = 591) for CON-L and 45.2% ± 3.6% (n = 186), 44.9% ± 3.5% (n = 205), and 39.1% ± 3.5% (n = 192) for low, medium, and high laser excitation power, respectively. For experiment 3, TRT-L containing 3×10^6 bisected sperm + 2×10^6 unprocessed sperm was compared to matched untreated controls (CON-L, 2×10^6 sperm), and contemporaneously produced high dosage controls (CON-H, 10×10^6 sperm). The TRT-L was produced by processing an aliquot from each ejaculate through the laser detection + laser-destruction system set to bisect 90% of sperm and after each 1 h of collection, combining equal portions of bisected and unprocessed spermatozoa. Post-thaw, matched low dosage fractions contained similar numbers of progressively motile sperm/straw (1.1 to 1.7 $\times 10^6$ for TRT-L and CON-L), but differed markedly in percentage of bisected sperm (69 to 79% and 32 to 59% non-motile, respectively). For CR in virgin heifers, TRT-L did not differ from CON-L but was lower than CON-H ($P < 0.01$). Conception rates were 43.5% ± 1.9% (n = 666) for TRT-L, 43.7% ± 1.9% (n = 668) for CON-L, and 58.1% ± 1.4% (n = 1334) for CON-H. Staining of sperm, excitation laser power, and sperm dosage have implications for the fertility of sexed sperm produced using this novel technology. Contrary to theory, the presence of significant numbers of non-motile and bisected spermatozoa and their debris did not impact conception rates.

Key Words: conception rate, flow cytometer, sperm sexing

1134 Fertility and sex of calf results from a new commercial scale technology platform for producing sexed sperm. M. A. Faust*, J. Betthauser, S. Crego, and A. Storch, *ABS Global, Inc., De Forest, WI.*

By 2016, sexed sperm constitutes ~8% of AI breedings in dairy and beef cattle. Further growth in the application of sexed sperm is limited by the existing technology. We developed a novel technology for producing sexed sperm at commercial scale to better address current and future needs of genetics companies and their producer customers. For this new technology platform, purpose-built microfluidics and laser based cell destruction components were invented to enable accurate quantification of sperm DNA content and rapid and efficient destruction of unwanted cells while safeguarding sperm of the desired chromosomal content. To assess performance resulting from the sexed sperm, field trials were conducted in dairy herds across the U.S. Experiments compared sexed sperm (SEXED, 2×10^6 motile sperm per straw) and non-sexed controls (CON, 10×10^6 sperm) produced using split or contemporaneous collections from a total of 26 bulls (Holstein and Jersey). All treatments were packaged and cryopreserved in 0.25 mL straws. Quality checks for the new sexed sperm product were developed and included an estimate of numbers of progressively motile sperm per straw and a fluorescence in situ hybridization assay for determining sex chromosome content of live sperm. For experiment 1, post-thaw numbers of progressively motile sperm/straw ranged from 0.75 to 1.5 $\times 10^6$ for SEXED batches, 3.9 to 7.7 $\times 10^6$ for CON-Citrate, and 4.1 to 8.9 $\times 10^6$ for CON-Tris. Conception rates from virgin dairy heifers were 61.4% ± 1.5% (n = 1091 pregnancy diagnoses) for citrate control, 60.7% ± 1.5% (n = 1079) for CON-Tris, and 37.4% ± 1.5% (n = 1082) for SEXED. For experiments 2 and 3, no Tris control was used. Numbers of progressively motile sperm/straw ranged from 4.2 to 8.7 $\times 10^6$ for CON and from 0.74 to 1.6 $\times 10^6$ for SEXED batches. In experiment 2, conception rates in dairy heifers were 65.2% ± 1.5% (n = 1005 pregnancy diagnoses) for CON and 46.2% ± 1.6% (n = 1025) for SEXED. Conception rates for experiment 3 were equally favorable and were 64.1% ± 1.6% (n = 900) for CON and 48.3% ± 1.7% (n = 895) for SEXED. Sex chromosome content for live sperm was 87.2% X-bearing (weighted average) and ranged from 73% to 93% for individual batches of SEXED; as indicated by others, proportion of female calves as reported on-farm was somewhat lower at 84.6% ± 1.3% (n = 775, experiments pooled) for SEXED. Proportion of female calves for CON was 50.5% ± 1.4% (n = 1187, pooled). Our novel sexed sperm technology delivers a new platform enabling preselecting the sex ratio of offspring.

Key Words: conception rate, sexed sperm, sex ratio

1135 A meta-analysis of the impacts of maternal weight and fetal sex on uterine blood flow and maternal heart rate in beef cows from mid- to late-gestation. A. R. Tanner*[1], M. L. Bauer[1], V. C. Kennedy[1], B. Mordhorst[1], L. E. Camacho[2], K. C. Swanson[1], and K. A. Vonnahme[1], [1]*North Dakota State University, Fargo,* [2]*University of Arizona, Tucson.*

Uterine blood flow plays a critical role in the development of the conceptus, allowing for the maternal-fetal exchange of nutrients, hormones, and wastes. The objective was to examine the relationships between maternal BW, fetal sex, uterine blood flow, and maternal heart rate in beef cows during mid- to late-gestation. A total of 4 studies were used in the analyses which included 108 beef cows with blood flow measurements taken via Doppler ultrasonography on 4 d of gestation which resulted in 333 total observations. Fetal sex, BW class (45-kg increments), and body weight class by fetal sex interactions were analyzed with generalized least squares using the mixed procedure of SAS with repeated measures. Day of gestation was included as a covariate and treatment was nested within study. Linear, quadratic, and cubic orthogonal contrasts were tested. Cows carrying bull calves ($n = 82$) had greater ($P = 0.03$) uterine blood flow from d 100 to 250 of gestation compared to cows carrying heifer calves ($n = 26$; 18.46 ± 0.764 vs. 15.56 ± 1.04 L/min). As maternal BW increased, uterine blood flow tended ($P = 0.09$) to increase linearly (14.5 mL per kg). Maternal heart rate also increased linearly ($P = 0.02$) as maternal BW increased (0.03 beats per min per kg). Fetal sex did not impact maternal heart rate ($P = 0.13$). In conclusion, the increase in uterine blood flow for male progeny may be contributing to heavier birth weights when compared to their female counterparts. Also, increasing maternal weight may be associated with increased uterine blood flow and heart rate. Perhaps the reason bull calves are heavier than heifer calves at birth may be due to the male's ability to increase uterine blood flow.

Key Words: fetal sex, maternal body weight, uterine blood flow

1136 Validation of a chemical pregnancy test in dairy cows that uses whole blood, shortened incubation times, and visual readout. L. M. Mayo*[1], S. G. Moore[1], S. E. Poock[1], W. Silvia[2], and M. C. Lucy[1], [1]*University of Missouri, Columbia,* [2]*University of Kentucky, Deceased, Lexington.*

Chemical pregnancy testing is an alternative to traditional methods of pregnancy diagnosis in postpartum dairy cows. The objective was to validate a new chemical pregnancy test that confers the advantages of using whole blood (EDTA), plasma (EDTA), or serum, rapid incubation times, and visual readouts. Blood and milk samples were collected from Holstein cows ($n = 320$) 162 ± 62 d (Mean ± SD) postpartum on a confinement farm in Northeast Missouri at 28 d after timed artificial insemination (TAI). Cows were assayed for pregnancy-associated glycoproteins (PAG) by using a new rapid visual ELISA assay, and plasma and milk-based ELISA assays (IDEXX, Westbrook, ME). Transrectal ultrasonography (TU) diagnosis for pregnancy at 35 d or 38 d after TAI was the reference standard for all PAG tests. The optical density (OD) measured with a microtiter plate reader (plasma, milk, and rapid tests) or visual readout (rapid test) were used to diagnose pregnancy. When the OD was used, the percentage of pregnant cows ($n = 159$; TU diagnosed pregnant) classified correctly (sensitivity) for the plasma, milk, and rapid tests were 97 ± 1%, 96 ± 2%, and 95 ± 1% (± SE), respectively. The sensitivity of the rapid test when assessed visually was 98 ± 1%. The specificity (proportion of non-pregnant cows classified correctly) for the plasma, milk, and rapid was 94 ± 2%, 94 ± 2% and 93 ± 2%, respectively. The lesser specificity for visual readouts (85 ± 3%) was associated with faint visual signals that yielded false positive diagnoses. Primiparous cows had greater (0.35 ± 0.02) rapid OD than multiparous cows (0.30 ± 0.01; $P = 0.03$). First insemination cows had a greater signal than cows with multiple breedings at time of sampling for rapid, milk, and plasma PAG assay OD ($P < 0.001$). In a second experiment, lactating Holstein cows ($n = 291$) from 4 Kentucky commercial confinement dairy farms were tested for pregnancy 25 to 95 d after artificial insemination with the rapid visual test. The OD of the rapid visual test followed the known profile for PAG in circulation (high concentrations during early pregnancy followed by a period of lesser concentrations with increasing concentrations thereafter; $P < 0.05$). Overall, the new rapid visual test has equal sensitivity and accuracy to existing PAG tests.

Key Words: pregnancy-associated glycoprotein, pregnancy diagnosis, whole blood

1137 Effects of parity and mid-gestation nutrient restriction on umbilical blood flow, fetal and placental measurements, and birth weight in sheep. M. A. Vasquez*, K. C. Swanson, and K. A. Vonnahme, *North Dakota State University, Fargo.*

We recently reported that mid-gestation (d 50 to 90) nutrient-restriction decreases umbilical blood flow (UBF) and placentome area (PA), and increases pulsatility index (PI) and resistance index (RI) on Day 80 of gestation in multiparous Dorset ewes. The same nutritional restriction applied in nulliparous ewe lambs decreased UBF by d 70 (Lemley et al. (2012).AJP.302:R454). We hypothesized that multiparous ewes would be more resilient to restriction compared to nulliparous ewes. On d 50 of gestation, adult (15 mo) nulliparous (NUL; $n = 12$) and multiparous (MUL; $n = 16$) Dorset ewes carrying singletons were randomly assigned to receive 100% of NRC recommendations (CON) or 60% of CON (RES). On d 91, RES ewes were realimented to 100% of NRC

recommendations. On d 50, and every 10 d until d 110, fetal and placental measurements and umbilical hemodynamics were obtained via ultrasonography. Lamb birth weights were recorded. The study was conducted as a 2 by 2 factorial arrangement of treatments with repeated measures. Data were analyzed using the MIXED procedure of SAS. By d 60 RES ewes were lighter than CON ewes ($P < 0.01$), and remained lighter throughout the experiment. There were no three way interactions or main effects of treatments on UBF, PI, RI and PA ($P \geq 0.57$). There was a parity by day interaction ($P < 0.05$) for RI, but UBF was not affected by parity or diet. At birth no differences were observed in lamb weight ($P \geq 0.78$). Restriction from d 50 to 90 does not appear to impact umbilical hemodynamics or conceptus growth in adults, regardless of parity. Our laboratory's previous observation that reduced UBF in young ewes (6 mo old) resulting from nutrient restriction may be due to maternal age. Future studies investigating age, parity, and body fat reserves of the dam on umbilical hemodynamics are underway.

Key Words: pregnancy, realimentation, sheep

1138 Comparing two ultrasound devices to determine antral follicle counts in dairy cows.

M. Gobikrushanth*[1] and D. J. Ambrose[1,2], [1]*Department of Agricultural Food and Nutritional Science, University of Alberta, Edmonton, Canada,* [2]*Livestock Research Branch, Alberta Agriculture and Forestry, Edmonton, Canada.*

The determination of antral follicle count (AFC) in dairy cows and its association with fertility is an area of interest to many researchers. Different types of ultrasound scanning (US) devices are available in the market but their comparative efficacy in determining AFC is rarely reported. In this study, we compared the efficacy of EASI-SCAN (BCF Technology Ltd., Rochester, MN; 4.5–8.5 MHz linear array transrectal transducer) and ALOKA (Aloka Co Ltd., Tokyo, Japan; 7.5 MHz linear array transrectal transducer) in the determination of AFC in dairy cows. Eighteen lactating Holstein cows were randomly subjected to transrectal ultrasonography by EASI-SCAN and ALOKA scanners approximately 30 min apart. All scans were performed by the same individual and AFC of each ovary was recorded on separate sheets by a second individual who was blinded to the study. The MEANS procedure of SAS was applied to obtain the mean and standard error of mean for AFC on the left ovary, right ovary and in total. The AFC in left and right ovaries, and total AFC obtained by EASI-SCAN and ALOKA were compared using CORR procedure of SAS and differences determined by TTEST procedure of SAS. The mean (± SEM) AFC determined by EASI-SCAN and ALOKA for the left ovary, right ovary, and total AFC were 6.3 ± 0.7 vs. 9.5 ± 1.0, 7.2 ± 1.4 vs. 11.0 ± 1.8, and 13.6 ± 2.0 vs. 20.5 ± 2.7, respectively. Likewise, the range for the total AFC was lower with EASI-SCAN (4 to 35) than with ALOKA (7 to 46). Although AFC data obtained by EASI-SCAN and ALOKA were significantly correlated ($r = 0.90$; $P < 0.0001$), total AFC was approximately 34% lower ($P < 0.01$) with EASI-SCAN than with ALOKA. Findings indicated that the ALOKA (7.5 MHz transducer) is more precise in determination of AFC than EASI-SCAN (4.5–8.5 MHz transducer).

Key Words: antral follicle count, dairy cows, ultrasound scanner

---

1139 The repeatability of antral follicle count and anti-Müllerian hormone concentration at two different postpartum stages in dairy cattle.

M. Gobikrushanth*[1], P. A. Dutra[1], C. A. Felton[2], A. Ruiz-Sanchez[1], T. C. Bruinjé[1], M. G. Colazo[2], S. Butler[3], and D. J. Ambrose[1,2], [1]*Department of Agricultural Food and Nutritional Science, University of Alberta, Edmonton, Canada,* [2]*Livestock Research Branch, Alberta Agriculture and Forestry, Edmonton, Canada,* [3]*Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Ireland.*

Low antral follicle count (AFC) and low plasma anti-Müllerian hormone (AMH) concentrations are reportedly associated with poor reproductive outcomes in dairy cattle. The primary objective of this study was to evaluate the repeatability of AFC and plasma AMH concentrations at two different postpartum stages. The ovaries of 100 lactating Holstein cows were subjected to transrectal ultrasonography (Aloka Co Ltd., Tokyo, Japan) by a single individual using a 7.5 MHz linear array transducer to determine AFC at 14 ± 1 and 75 ± 1 d postpartum (second exam was approximately 48 h after the second GnRH of an Ovsynch protocol). Blood samples were also collected 14 ± 1 and 75 ± 1 d postpartum to determine plasma AMH concentrations. The MEANS procedure of SAS was used to obtain the mean and standard error of means for the continuous variables, and correlations between continuous variables were tested using the CORR procedure of SAS. The means (± SEM) for AFC determined at 14 and 75 d postpartum were 27 ± 1 and 23 ± 1, respectively. Likewise, the mean (± SEM) AMH concentrations determined at 14 and 75 d postpartum were 190.0 ± 12.8 and 224.8 ± 14.3 pg/mL, respectively. A moderate significant correlation ($r = 0.41$; $P < 0.01$) existed between AFC at 14 and 75 d postpartum. Concentrations of AMH at 14 and 75 d postpartum were strongly correlated ($r = 0.75$; $P < 0.01$). The correlation between AFC and plasma AMH was moderate at both 14 ($r = 0.57$; $P < 0.01$) and 75 d ($r = 0.59$; $P < 0.01$) postpartum. Results indicate that both AFC and AMH concentrations are repeatable at different stages postpartum, although the repeatability is significantly greater for AMH.

Key Words: anti-Müllerian hormone, antral follicle count, repeatability

1140 Dairy cows with shorter ano-genital distance may be more fertile than those with longer ano-genital distance. M. Gobikrushanth*[1], T. C. Bruinjé[1], M. G. Colazo[2], and D. J. Ambrose[1,2], [1]*Department of Agricultural Food and Nutritional Science, University of Alberta, Edmonton, Canada,* [2]*Livestock Research Branch, Alberta Agriculture and Forestry, Edmonton, Canada.*

The ano-genital distance (AGD) is the distance from anus to base of the penis in male, or clitoris in female mammals. The AGD is a reflection of testosterone exposure during in utero development. Thus, AGD in the adult is indicative of prenatal androgen exposure and reportedly associated with several reproductive health outcomes in humans and laboratory animals. The objectives of this preliminary study were: (1) to characterize variations in the measurements of AGD in a population of dairy cows and (2) to determine associations between categories of AGD and traditional reproductive indices. The AGD in 93 lactating Holstein cows (35 primiparous and 58 multiparous) were measured using a digital caliper. To increase precision, the average of three AGD measurements in each animal was used. All cows were subjected to fixed-timed AI at ~75 d postpartum following a Presynch/Ovsynch protocol. The traditional reproductive indices of first service conception rate, number of inseminations and days open were determined for the current lactation. Cows were ranked based on AGD, from shortest to longest, and those in the top and bottom 50th percentiles were classified into SHORT (n = 46) and LONG (n = 47) AGD categories. The continuous variables were analyzed using the MIXED procedure of SAS and first service conception rate was modeled against categories of AGD and parity as interactions between categories of AGD and parity were not significant, and analyzed using LOGISTIC procedure of SAS. The overall AGD ranged from 95.7 to 149.0 mm and mean (± SEM) AGD were 111.3 ± 0.9 and 129.2 ± 1.1 mm for cows categorized as SHORT and LONG AGD groups, respectively. Cows in the SHORT AGD group tended (P = 0.07) to have 2.4 times higher odds of becoming pregnant to the first insemination than cows in LONG AGD. Similarly, cows in the SHORT AGD group tended to have fewer days open (142.5 ± 10.4 vs. 169.5 ± 11.6 d; P = 0.10) and required less number of inseminations (2.3 ± 0.2 vs. 2.8 ± 0.2; P = 0.12) than those in LONG AGD. The AGD ranged from 95.7 to 142.7 mm (mean ± SEM; 119.6 ± 1.2 mm) for primiparous cows and from 100.0 to 149.0 mm (mean ± SEM; 120.8 ± 0.9 mm) for multiparous cows. The first service conception rate, number of inseminations and days open did not differ between primiparous and multiparous cows. In summary, findings of this preliminary study suggest that cows with shorter ano-genital distance tend to have better reproductive performance than cows with longer ano-genital distance.

Key Words: ano-genital distance, dairy cows, fertility

1141 Pregnancy Associated Glycoprotein (PAG) concentrations in early gestation from dairy heifers undergoing embryo transfer. S. Reese[1], M. H. Pereira[2], J. L. M. Vasconcelos[3], and K. G. Pohler*[1], [1]*University of Tennessee, Knoxville,* [2]*UNESP-FMVZ, Botucatu, Brazil,* [3]*Sao Paulo State University, Botucatu, Brazil.*

Diagnosing and identifying successful pregnancies early in gestation has important economic and management implications for dairy producers. The limitation of current ultrasound and chemical based pregnancy diagnosis methods are that they are most effective starting at Day 30 of gestation. Pregnancy associated glycoproteins (PAGs) are produced by the ruminant placenta and can be used to accurately detect pregnancy as early as Day 28 of gestation. More recent data indicate that circulating PAGs may also be a marker of embryonic viability and predictive of embryonic mortality after Day 28 of gestation. The objective of the current study was to determine if early gestation circulating PAG levels could be indicative of pregnancy for an individual heifer following a baseline sample. Our hypothesis was that Day 24 PAG levels could be predictive of pregnancy if there was a significant increase over a Day 17 baseline sample. In vitro produced embryos were transferred into synchronized virgin percentage Holstein dairy heifers (n = 206) using timed embryo transfer (TET). Blood was collected at Day 17 and 24 for PAG analysis as well as Day 31 for confirmation of pregnancy. Serum concentrations of PAG were quantified using an in house PAG ELISA with antibodies raised against PAGs expressed early in gestation (Green et al., 2005, Pohler et al., 2013). Following TET there were 101 heifers identified pregnant on Day 31 of gestation (49%) using ultrasound and PAG testing. Circulating concentrations of PAG were significantly different ($P < 0.05$) at d 24 of gestation between heifers that were pregnant (2.98 ng/mL) and non pregnant (0.69 ng/mL). In addition, when using receiver operating curve (ROC) analysis PAGs were 95% accurate in diagnosing pregnancy at Day 24 of gestation when circulating PAG levels reached 1.39 ng/mL (~50% of pregnant heifers). When determining pregnancy only based on subtracting the Day 17 sample (baseline) from Day 24, we were able to accurately diagnosis 79% of the heifers for pregnancy at d 31 of gestation. Interestingly, about 11% of heifers following TET that ended up being not pregnant at Day 31 of gestation had increased Day 24 circulating PAGs compared to the Day 17 baseline sample. Thus suggesting that pregnancy loss occurred between Day 24 and 31 of gestation in these heifers. In summary, early pregnancy detection may be possible by using PAGs; however more work is needed to refine this area.

Key Words: heifers, PAGs, pregnancy

1142 Protein kinase A directly phosphorylates GSK3β, and regulates β-catenin via phosphorylation in granulosa cells. B. H. Aloqaily*[1], C. A. Gifford[2], B. I. Gomez[1], and J. A. Hernandez Gifford[1], *[1]Oklahoma State University, Stillwater, [2]Department of Animal Science, Oklahoma State University, Stillwater.*

Estradiol serves an important role in female fertility and FSH drives estradiol production. Beta-catenin is a transcriptional co-factor that is required for FSH-induced estradiol production. Beta-catenin is activated via phosphorylation at Ser^{552} and Ser^{675} by protein kinase A (PKA) dependent event. Wingless-type mouse mammary tumor virus (WNT) also regulates the β-catenin pathway. Glycogen Synthase Kinase-3 β (GSK3β) is a component of the β-catenin degradation complex; canonical WNT signaling pathway phosphorylates protein kinase B (AKT) and inhibits GSK3β resulting in β-catenin accumulation in the cytoplasm. Work in our laboratory demonstrated that WNT downregulates steroidogenesis. Furthermore, AKT is required for β-catenin accumulation and FSH-induced estradiol production, suggesting convergence of the WNT and FSH pathways. We hypothesize that WNT inhibition of FSH signaling occurs through modulation of phosphorylation patterns on β-catenin. The objective of these experiments was to evaluate the phosphorylation pattern of β-catenin in response to PKA, AKT, and WNT signaling pathways. Granulosa cells (KGN cell line) were cultured and treated with vehicle control, phosphoinositide 3-kinase (PI3K) inhibitor LY294002 (LY) (30 μM; 30 min), Forskolin (FSK) (10 μM; 1.5 h), WNT (50 ng/mL, 30 min) and the combination of these treatments. Western blot was used to detect total and phosphorylated β-catenin and phosphorylated GSK3β. Protein abundances were analyzed using densitometry software and densitometry values for treatments were analyzed using the GLM procedure of SAS. When significant model interactions were detected, means were separated using PDIFF. Treatment of FSK combined with WNT and LY enhanced GSK3β phosphorylation compared to control ($P < 0.05$). Similarly, FSK alone or in combination with WNT and LY enhanced ($P < 0.05$) phosphorylation of β-catenin at Ser^{675} and Ser^{552}, but WNT did not alter β-catenin phosphorylation after FSK stimulation ($P > 0.10$). However, when the AKT pathway was blocked with LY, FSK, and WNT treatment increased phosphorylation of GSK3β and subsequently β-catenin at Ser^{552} suggesting that PKA can directly phosphorylate GSK3β. Results from these experiments demonstrate that WNT does not alter FSH-stimulated phosphorylation patterns of β-catenin indicating that WNT inhibits FSH signaling via other unknown mechanisms.

Key Words: beta-catenin, FSH, WNT

1143 Plasma anti-Müllerian hormone in dairy heifers and associations with reproductive performance in two reproductive programs for first artificial insemination. T. V. Silva[1], J. E. P. Santos[2], and E. S. Ribeiro*[3], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]University of Florida, Gainesville, [3]Department of Animal Biosciences, University of Guelph, Guelph, Canada.*

The objective was to investigate associations between plasma anti-Müllerian hormone (AMH) and reproductive performance in dairy heifers inseminated after detection of estrus or synchronized ovulation. Heifers ($n = 601$) in three farms were enrolled in the study 6 d before moving to the breeding pens. A randomized complete block design was used to assign one of two reproductive programs (RP) for first artificial insemination (AI): estrous detection (ED, $n = 297$) or timed AI (TAI, $n = 304$). Heifers in the ED group had their tailheads painted with chalk and were evaluated for signs of estrus once daily. Heifers receiving TAI were enrolled in the 5-d TAI protocol. On the day of enrollment, blood was sampled and analyzed for concentrations of AMH using an immune assay (AnshLite Bovine AMH CLIA). Within farm, concentrations of AMH in plasma were ranked and categorized as low (20% lowest values), high (20% highest values), or intermediate (60% intermediate values). Reproductive performance was evaluated for 84 d and the remaining AIs were performed after detection of estrus in both RP groups. Pregnancy was diagnosed on Days 32 and 60 after AI. Binary data were analyzed by logistic regression using the GLIMMIX procedure of SAS, and pregnancy rate was analyzed by the Cox's proportional hazard model using the PHREG procedure of SAS. Statistical models included the effects of AMH, RP, and their interaction, farm and semen. Concentration of AMH in plasma ranged from 2.6 to 566.3 pg/mL, and averaged 12.9, 30.9, and 85.4 pg/mL for low, intermediate and high AMH, respectively. Pregnancy per AI on Days 32 and 60 after first AI were not affected by AMH (d 32: 57.5, 65.9, and 64.2%, $P = 0.21$; d 60: 56.7, 62.6, and 58.3%, $P = 0.38$; for low, intermediate, and high AMH, respectively) or RP (d 32: 62.3, and 65.5%, $P = 0.16$; d 60: 58.2, and 62.8%, $P = 0.11$; for ED and TAI, respectively). Compared with low AMH, rate of pregnancy during the 84 d was similar for intermediate (AHR = 1.19, $P = 0.12$) and high AMH (AHR = 1.11, $P = 0.46$). Nonetheless, TAI had a faster rate of pregnancy (AHR = 1.58; $P < 0.01$) than ED. No interactions between AMH and RP were detected. In conclusion, plasma AMH was not associated with reproductive performance of dairy heifers in neither one of the two RP evaluated.

Key Words: AMH, heifers, timed AI

1144 Wingless-type mouse mammary tumor virus integration site (WNT) regulation of ovarian thec cells of cattle. L. J. Spicer*, *Oklahoma State University, Stillwater.*

During ovarian follicular development, granulosa and theca cell (TC) proliferation and differentiation are influenced by gonadotropins, insulin-like growth factors (IGF), and diverse intraovarian factors. Based on high-density microarray analysis comparing cystic and noncystic bovine follicles, we discovered that secreted frizzled related protein 4 (SFRP4) mRNA is downregulated in granulosa cells of cystic follicles suggesting that the WNT system may be involved in cyst formation. Numerous WNT ligands bind to several cognate Frizzled receptors (FZD), and SFRP4 is a truncated form of FZD capable of blocking the action of WNT ligands. Dickkopf-1 (DKK1) is another WNT antagonist and R-spondin-1 (RSPO1) one of a group of four secreted proteins that enhance Wnt/β-catenin signaling. Our overall hypothesis is that granulosa cells signal TC via SFRP4, DKK1, RSPO1, and WNT secretion to regulate TC differentiation and proliferation during follicular development. Therefore, in vitro experiments were conducted to study the effects of WNT family member 3A (WNT3A), RSPO1, DKK1, IGF1, and fibroblast growth factor-9 (FGF9) on bovine TC proliferation and steroidogenesis. TC of large (8 to 20 mm) follicles were collected from ovaries of beef cattle (n = 20 per replicate) and cultured for 48 h and then treated in serum-free medium for 48 h containing either no additions (control), 30 or 100 ng/mL of recombinant human WNT3A, RSPO1, DKK1, IGF1 and/or ovine LH. At least 7 follicles from 5 or more cattle were used to generate one biological replicate per experiment and this was repeated thrice. Each treatment within a biological replicate was replicated 2 or 3 times. For each set of replicated experiments, ANOVA was conducted using SAS. In experiment 1 using LH-treated TC, both IGF1 and WNT3A increased ($P < 0.05$) cell numbers and androstenedione production, whereas WNT3A inhibited ($P < 0.05$) progesterone production by 30%. In experiment 2 using IGF1 plus LH-treated TC, WNT3A (30 ng/mL) further increased ($P < 0.05$) IGF1-induced androstenedione production from 770 to 930 ± 60 pg/10^5 cells/24 h. Similarly, in experiment 3, 100 ng/mL of RSPO1 further increased ($P < 0.05$) IGF1-induced androstenedione production. In experiment 4, SFRP4 and DKK1 alone had no significant effect on TC proliferation or steroidogenesis. In experiment 5, FGF9 blocked ($P < 0.05$) the WNT3A-induced increase in androstenedione production. We conclude that the ovarian WNT system is functional in cattle, increasing proliferation and androstenedione production of TC.

Key Words: cattle, theca cells, WNT3A

1145 Plasma concentrations of glucagon-like peptide 1 and 2 in calves fed calf starters containing lactose. Y. Inabu*[1], A. Saegusa[2], K. Inouchi[2], M. Oba[3], and T. Sugino[1], *[1]Hiroshima University, Higashi-hiroshima, Japan, [2]ZEN-RAKU-REN, Nishi-shirakawa, Japan, [3]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

The objective of this study was to evaluate the effect of lactose inclusion in calf starters on plasma concentrations of glucagon-like peptide 1 (GLP-1) and 2 (GLP-2). Holstein bull calves (n = 60) were raised on an intensified nursing program using milk replacer containing 28.0% CP and 15.0% fat, and fed the texturized calf starter containing lactose at either 0 (Control), 5.0 (LAC5), or 10.0% (LAC10; n = 20 for each treatment) on a DM basis. All calf starters were formulated for 23.1% CP. Ethanol soluble carbohydrate concentration of Control, LAC5, and LAC10 starters were 7.3, 12.3, and 16.8%, respectively. Starch concentrations of Control, LAC5, and LAC10 were 29.7, 27.0, and 21.4%, respectively. All calves were fed treatment calf starters ad libitum. Blood samples were obtained weekly from 1 wk to 11 wk of age and used to measure plasma GLP-1, GLP-2, insulin, and β-hydroxyl butyric acid (BHB) concentrations. Plasma BHB concentrations were higher ($P < 0.01$) for LAC10 (169 ± 5.1 μmol/L; LSM ± SEM) compared with Control (153 ± 4.8 μmol/L) and LAC5 (148 ± 5.2 μmol/L). Plasma GLP-1 and GLP-2 concentrations were not affected by treatments. However, relative values of plasma GLP-1 concentrations compared with that of the baseline (1 wk of age) were higher ($P < 0.01$) for LAC10 (94.8 ± 5.01%) compared with LAC5 (66.5 ± 5.11%), and for LAC5 compared with Control (42.5 ± 4.73%), and similar tendency was observed for GLP-2 concentrations relative to that of the baseline (80.6 ± 5.42%, 74.7 ± 5.43%, and 73.3 ± 5.3%, respectively, for LAC10, LAC5, and Control, respectively; P = 0.09). Plasma insulin concentrations were lower ($P < 0.01$) for LAC5 (4.69 ± 0.58 ng/mL) and LAC10 (4.60 ± 0.58 ng/mL) compared with Control (5.52 ± 0.58 ng/mL). Lactose intake was positively correlated with plasma BHB concentrations (Spearman's correlation coefficient; $r_s = 0.87$, $P < 0.01$), and tended ($r_s = 0.41$, $P = 0.07$) to be positively correlated to plasma GLP-1 concentrations, but not correlated with plasma GLP-2 concentrations. In addition, plasma GLP-1 concentrations were positively correlated with plasma concentrations of BHB ($r_s = 0.85$, $P < 0.01$). In conclusion, these results indicate that inclusion of lactose in calf starters may contribute to maintaining high plasma concentrations of GLP-1, which was associated with greater plasma BHB concentrations.

Key Words: calf, glucagon-like peptide, lactose

1146 Metabolic profile and inflammatory response in calves with different intake of immunoglobulins.

S. Dander, F. Piccioli-Cappelli, A. Bignami, A. Minuti, and E. Trevisi*, [1]*Università Cattolica del Sacro Cuore, Piacenza, Italy.*

To achieve a successful passive transfer of immunoglobulins in newborn calves, it is recommended to feed the colostrum quickly after birth, paying attention to the quantity and quality of colostrum administered. The quality of colostrum is associated with content of Immunoglobulins G (IgG), which can vary dramatically among cows. The conventional strategy calls for feeding a calf of 45 kg first colostrum with at least 100 g of IgG. The adequate intake should be monitored measuring the concentration of IgG in the colostrum or in the blood of calves after 24–48 h from the first meal. Moreover, besides IgG for which determination is complex, other blood parameters might provide information on amount of IgG intake and eventual consequences on health. The aim was to assess the relationship among IgG intake with average daily gain (ADG), metabolic profile, inflammatory response and oxidative stress using 45 Holstein calves over the first month of life. After colostrum analyses, calves were retrospectively divided in two groups: G1 (n = 24), ingesting less than 100 g of IgG (average intake = 68 g) from first colostrum, and G2 (n = 21), ingesting more than 100 g of IgG (average intake = 133 g), from first colostrum (1.5 L of colostrum). Besides frequent blood samples, daily health status and body weight also were recorded. Our results showed a poor correlation between density and IgG content of colostrum (r = 0.34), while the correlation between blood IgG and gGT was high (r = 0.9 P < 0.001). During the first 4 wk of life, G1 compared with G2 calves had more clinical problems and lower ADG (0.27 vs. 0.40 kg/d, P < 0.01). At 7 d after birth, G1 calves had higher levels of haptoglobin (0.62 vs. 0.43 g/L, P < 0.02), ceruloplasmin (2.39 vs. 1.87 μmol/L, P < 0.01), and reactive oxygen metabolites (14.8 vs. 12.9 mg H_2O_2/100 mL, P < 0.03). These differences indicate that G1 calves (intake of IgG < 100 g with first meal) experienced important inflammatory events after birth, which increased the oxidative stress, impaired liver function, and strongly reduced the ADG. Therefore, to avoid these problems it is insufficient to only check first colostrum quality before feeding. Besides providing a better measure of the IgG intake, an evaluation of targeted blood parameters within 1 wk of life could give more detailed information on calf health and welfare.

Key Words: calves, colostrum, immunoglobulin, inflammation, metabolic profile

1147 Effect of the timing of addition of *trans*-10, *cis*-12 conjuaged linoleic acid and L-carnitine during culture on development and cryotolerance of bovine embryos produced in vitro.

A. M. Zolini*[1], P. J. Hansen[1], C. A. Torres[2], and J. Block[1,3], [1]*Department of Animal Sciences, University of Florida, Gainesville,* [2]*Universidade Federal de Vicosa, Vicosa, Brazil,* [3]*OvaTech LLC, Gainesville, FL.*

The objective was to determine whether embryo development and survival following cryopreservation were affected by the timing of addition of *trans*-10, *cis*-12 conjugated linoleic acid (CLA) and L-carnitine during culture. Bovine embryos were produced in vitro using abattoir-derived cumulus-oocyte complexes. After fertilization, presumptive zygotes (n = 2804) were cultured at 38.5°C in a humidified atmosphere of 5% O_2, 5% CO_2, and 90% N_2 in synthetic oviductal fluid-bovine embryos 1 (SOF-BE1). Presumptive zygotes were randomly assigned to the following treatment groups: vehicle for the entire culture period, 100 μM CLA for the first 88 h, last 72 h, or the entire culture period and 0.75 mM L-carnitine for the first 88 h, last 72 h, or the entire culture period. At 88 h post-insemination, embryos were removed from culture, washed in HEPES-Tyrode's albumin lactate pyruvate, placed into their respective culture treatments and cultured for an additional 72 h. The proportion of oocytes that cleaved was assessed at 88 h (Day 4) after insemination and the proportion of oocytes that developed to the blastocyst and advanced blastocyst (expanded, hatching, and hatched) stages was determined on Day 7. Blastocysts and expanded blastocysts (n = 537) were harvested at Day 7 and subjected to controlled-rate freezing following equilibration in 1.5 M ethylene glycol. After thawing, embryos were cultured for 72 h in SOF-BE1 supplemented with 10% (v/v) fetal bovine serum and 50 mM dithiothreitol at 38.5°C in a humidified atmosphere of 5% O_2, 5% CO_2 and 90% N_2. Post-thaw re-expansion and hatching rates were determined at 24, 48, and 72 h. The experiment was replicated 14 times and data were analyzed by analysis of variance. There was no effect of treatment with CLA or L-carnitine on embryo development or post-thaw survival (Table 1.), regardless of whether treatment occurred during the first 88 h, the last 72 h or the entire culture period. While previous studies have reported beneficial effects of CLA and L-carnitine on embryo cryotolerance, the results of the present study indicate the effects of CLA and L-carnitine are likely not dependent on the timing of their addition during culture.

Key Words: conjugated linoleic acid, cryopreservation, L-carnitine,

1148 An insufficient supply of glucose substrates causes reduced lactose synthesis in lactating dairy cows fed cereal straws instead of alfalfa hay. B. Wang[*1], F. Zhao[1,2], B. X. Zhang[1], and J. X. Liu[1], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]University of Vermont, Burlington.*

The objective of the present study was to investigate the nutrient supply for lactose synthesis in the mammary gland (MG) of lactating cows fed different sources of forage. Thirty Holstein cows were randomly assigned into three groups and fed 3 diets contained 30% corn stover (CS), 30% rice straw (RS), or 23% alfalfa hay plus 7% Chinese wild rye hay (AH) as forage sources, respectively, with identical total concentration and corn silage for 14 wk. Milk lactose, rumen VFA, blood glucose and hormones (n = 10), and mRNA abundance of genes related to glucose metabolism in liver and MG (n = 6) were analyzed in these cows. The data were analyzed using PROC MIXED program of SAS with a randomized complete block design with repeated measures. The percentage of milk lactose was always lower in the RS-fed cows than the cows fed AH or CS during the last 12 wk of feeding trial ($P < 0.01$). The ruminal propionate concentrations were also reduced in the RS group compared to the AH group ($P = 0.03$). The ratio of plasma insulin to glucagon in the mammary vein was greater in the AH group than in the CS or RS group ($P = 0.04$). The abundance of the pyruvate carboxylase mRNA in the liver was reduced in the RS group compared to the AH or CS groups ($P = 0.04$), whereas the mRNA abundance of mitochondrial phosphoenolpyruvate carboxykinase, insulin like growth factor-1 receptor, and phosphofructokinase-liver, -muscle, and -platelet in the liver was reduced in the RS group compared to the AH group ($P < 0.05$). The mammary glucose uptake was greater in the AH-fed cows than in the CS- or RS-fed cows ($P = 0.02$). The mRNA abundance of the glucose transporters in the MG was similar between the 3 treatments. The mRNA abundance of α-lactalbumin in the MG of the cows fed RS tended to increase compared to that of the cows fed AH or CS. The milk potassium concentration was increased in the cows fed RS compared to those fed AH or CS ($P < 0.01$). In summary, the insufficient ruminal propionate levels in the cows fed RS were associated with decreased gluconeogenesis in the liver, resulting in the shortage of the arterial glucose supply for mammary uptake and reduced lactose synthesis.

Key Words: cereal straw diets, glucose substrates, lactose synthesis

1149 Expression of genes involved in the initial steps of steroidogenesis in adipose tissue depots of dairy cows during the dry period and early lactation. A. Alizadeh[1,2,3], H. Sadri[1], J. Rehage[4], S. Dänicke[5], and H. Sauerwein[*1], *[1]Institute of Animal Science, Physiology and Hygiene Unit, University of Bonn, Bonn, Germany, [2]Department of Animal Science, Saveh Branch, Islamic Azad University, Saveh, Iran, [3]Department of Embryology, Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran, [4]University for Veterinary Medicine, Foundation, Hannover, Germany, [5]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Braunschweig, Germany.*

In view of the significant changes in body fat content related to parturition and lactation in dairy cows, together with the role of adipose tissue (AT) not only as a store of steroid hormones but also as a potential site of steroidogenesis, mobilization of body reserves may also alter steroid hormone secretion and eventually reproduction. With this background, our research objectives were (1) to assess the expression of two rate-limiting factors of steroidogenesis, i.e., steroidogenic acute regulatory protein (StAR) and Cytochrome P450scc (CYP11A1) in bovine AT, (2) to characterize the time course of their mRNA abundance during late pregnancy and early lactation, and (3) to compare this time course in a subcutaneous versus a visceral fat depot. StAR triggers cholesterol delivery to the inner mitochondrial membrane (IMM) where CYP11A1 then initiates steroidogenesis by converting cholesterol to pregnenolone, the precursor of all other endogenous steroids. Biopsies were collected from 20 Holstein cows from the subcutaneous (sc) and the retroperitoneal fat depot (rp) on d −42 and d 1, 21, and 100 relative to calving. The mRNA abundance of StAR and CYP11A1 was assessed in the tissue samples by qPCR and normalized using the 4 most stable reference genes. Data were analyzed using the MIXED procedure of SAS. In scAT, the StAR mRNA abundance was lowest on d −42, increased on d 1 ($P < 0.05$) until d 21 to remain at this level at d 100 (~3-fold greater than on d −42; $P < 0.001$). Expression of StAR mRNA in rpAT increased with time of lactation, but differences between sampling days were limited to d −42 versus d 100 (3.3-fold increase; $P = 0.01$). Expression of CYP11A1 mRNA was not detectable in both AT with the protocol used herein (suitability of the protocol was confirmed with ovary as positive control). The increased expression of StAR mRNA abundance after calving in rpAT and scAT indicate an increased capacity for cholesterol uptake to the IMM. Given the apparently absent expression of CYP11A1, de novo synthesis of steroid hormones in bovine AT seems implausible and AT steroid metabolism likely depends on the uptake of preformed steroid precursors. Cholesterol reaching the IMM may thus rather be metabolized

to oxysterols which were suggested to have regulatory functions in adipocytes.

Key Words: adipose tissue, dairy cow, StAR

1150 Effects of a dietary supplementation of rumen-protected B vitamins on reproduction of dairy cows by measuring nutrigenomic parameters.

F. Richard*[1], D. R. Khan[1], C. L. Girard[2], H. Leclerc[3], and E. Evans[4], *[1]Universite Laval, Quebec, Canada, [2]Agriculture & Agri-Food Canada, Sherbrooke, Canada, [3]Jefo Nutrition, St. Hyacinthe, Canada, [4]Technical Advisory Services, Bowmanville, Canada.*

It has been known that supplementary rumen-protected or injected B vitamins can improve dairy cow milk production and reproductive performance. Recently, it has been reported that B vitamins injections were having an impact on granulosa cells of the ovarian follicle when looking at gene expression profiling. Therefore, the aim of the present study was to assess whether rumen-protected B vitamins given as a dietary supplement can have an impact on gene expression in granulosa cells. The experimental design included 30 cows divided in three groups; 1) control, without any B vitamin supplementation, 2) injection, weekly intramuscular injections of 320 mg of folic acid and 10 mg of vitamin B12 starting from −21 to 60 d post calving, and 3) dietary supplementation of rumen-protected B vitamins as 50 g/cow/d of Transition VB™ (Jefo) from −21 to −1 calving, 100 g/cow/d of Transition VB™ from 1 to 21 d post-calving, 3 g/cow/d of Lactation VB™(Jefo) from calving to 60 d post calving. The follicles size was measured by laparoscopic transvaginal ultrasound from 40 d until OPU at 54 d post-calving. The cows were synchronized with two injections of PGF2α 12 d apart with first injection at 40 d. Granulosa cells were collected by OPU 53 h post second injection on the dominant follicle larger than 12 mm in diameter. Hybridization was done in dye swipe on EmbryoGENE microarray slides using three trios of animals. Differently expressed genes were analyzed through Ingenuity Pathway Analysis software. Selected genes were further assessed by RT-qPCR based on their functional significances. Based on estradiol and progesterone levels, the pattern of gene expression is supporting precocious granulosa cell differentiation toward an earlier response to LH (up-regulation of RGS2, NR3C1, OLR1, since significantly different ($p < 0.05$) from the control in both microarray analysis and RT-qPCR validation; downregulation of LHCGR, HSD3B1 and FST, since significantly different ($p < 0.05$) from the control) which may be the result of an increase in LH secretion. While comparing gene expression to superovulation conditions improving oocyte developmental competence, we observed genes commonly expressed with dietary supplementation of protected B vitamins (RGS2 and INHBA). The microarray data of granulosa cells from the dominant follicle are supporting the hypothesis that dietary supplementation of rumen-protected B vitamins is affecting granulosa cells differentiation toward an earlier LH response associated with genes expressed in conditions where oocyte developmental competence is improved.

Key Words: microarray, nutrigenomic, protected B vitamins, reproduction

1151 Impact of dietary protein levels during late pregnancy on the number of binuclear cells in sheep.

H. H. Mansour*[1], A. Reyaz[1], S. T. Dorsam[1], L. A. Lekatz[2], and K. A. Vonnahme[1], *[1]North Dakota State University, Fargo, [2]Illinois State University, Normal.*

Angiogenic and vasoactive factors have been localized to binuclear cells (BNCs) located in the placenta of several species including sheep. During late gestation in the ewe, a low protein diet increased maternal blood pressure and uterine blood flow compared with a high dietary protein level. The objective of this study is to determine the effect of varying protein levels during late pregnancy in ewes on the number of BNCs. We hypothesized that low dietary protein during late gestation would increase the number of BNCs leading to the reported increase in uterine blood flow in ewes. At Day 100 of pregnancy, 18 ewes were randomly divided into three groups (6 each) and provided one of three diets containing different metabolizable protein (MP) levels: low protein level (L; 60% MP), control protein level (C; 100% MP), and high protein level (H; 140% MP). At Day 130 ± 1 of gestation dams were humanly euthanized and placentomes were removed for histology analysis. Histology sections were stained with biotinylated Dolichos biflurus (DBA) lectin, Texas red-avidin, and fluorescein (Fluorescien labeled Griffonia simplifolica lectin). There was no significant effect ($P = 0.90$) of maternal protein level on BNC number (180.0, 166.1, and 165.2 ± 28.41 for L, C, and H, respectively). Furthermore, there was no significant effect of maternal protein level on BNC size, proportion of the placentome occupied by cotyledon, nor number of BNCs per cotyledonary area. While we reject our hypothesis that BNC numbers are increased in protein deficient pregnant ewes, we will continue to evaluate if the ovine BNCs produce angiogenic or vasoactive factors that may influence placental function.

Key Words: binuclear cell, placentome, sheep

1152 Effect of serum concentration of β-carotene at AI on productive and reproductive parameters in lactating Holstein cows. A. M. L. Madureira*[1], T. Guzella Guida[1], R. L. A. Cerri[2], and J. L. M. Vasconcelos[1], [1]*Sao Paulo State University, Botucatu, Brazil,* [2]*Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada.*

The objective of this study was to determine the effect of β-carotene concentration in serum at the moment of artificial insemination (AI) on Holstein cows. A total of 497 lactating dairy cows were enrolled. All animals were assigned to a timed AI protocol (CIDR+ estradiol benzoate+GnRH-7d-PG-F-2d-CIDR-out+PGF+ECP-2d-timed AI). Blood samples and body condition score were collected at the moment of AI. The serum B-carotene was quantified in a single step denaturation and extraction into a solvent, followed by measurement using a portable spectrophotometer (iCheck; BioAnalyt, GmbH, Teltow, Germany). Milk production and herd health records were collected for the entire experimental period, and pregnancy diagnosis performed by ultrasound 31 d post-AI. Data were analyzed using the MIXED and GLIMMIX procedures of SAS. Animals with BCS $\leq$ 2.75 had lower ($P < 0.01$) concentration of B-Carotene compared with cows with BCS $\geq$ 3.0 (3.82 ± 0.09 μg/ml and 4.16 ± 0.06μg/ml, respectively). Multiparous cows had greater concentration of B-Carotene compared with primiparous ($P < 0.01$). The concentration of B-carotene at TAI was greater in cows with at least one disease episode between parturition and timed AI compared with healthy animals (3.95 ± 0.12 μg/ml vs. 5.12 ± 0.46 μg/ml). There was no correlation between milk production and concentration of B-carotene ($r < 0.01$), but a quadratic correlation between pregnancy per AI and concentration of B-carotene ($P = 0.03$) was found. When serum B-carotene was categorized as low (< 3.0 μg/ml), intermediate ($\geq$ 3.0– < 6.0 μg/ml) and high $\geq$ 6.0μg/ml, cows with intermediate concentrations were more fertile than the other two categories (29.0%; 38.9% and 22.6%, respectively; $P = 0.05$). In conclusion, the concentration of β-carotene was affected by BCS, parity, incidence of diseases. Animals with intermediate concentrations in serum had greater pregnancy per AI, suggesting a possible use as a marker for fertility in lactating dairy cows.

Key Words: β-carotene, fertility, pregnancy per AI

1153 Propionic acid decreased hepatic acetyl CoA content compared with glycerol within the timeframe of meals when infused abomasally. L. B. Gualdron-Duarte* and M. S. Allen, *Michigan State University, East Lansing.*

We previously reported that propionic acid (P) reduced dry matter (DMI) and metabolizable energy intake compared with glycerol (G) when administered as isoenergetic infusions to the abomasum of cows in the postpartum (PP) period. Our objective in this experiment was to evaluate short-term effects of P compared with G on hepatic acetyl CoA (AcCoA) content for PP cows. We hypothesized that P compared with G will decrease the AcCoA content in the liver within the time frame of a meal. Six ruminal cannulated cows in the PP period (15.2 ± 7.7 d PP) were used in a crossover design experiment to evaluate the effects of G and P pulse dosed to the abomasum on hepatic AcCoA content and plasma concentrations of metabolites and hormones. Cows were randomly allocated to treatment sequence (G-P and P-G) and each block was completed in 3 d with 2 collection days and a rest day between them. Two moles of P or G (2 mol/500mL, $\geq$ 99.5%) were dosed within 1 min to the abomasum 1 h before feeding. Liver tissue was biopsied and blood was collected immediately before dosing and at 30 and 60 min after dosing. Treatments interacted with time to affect AcCoA content ($P < 0.01$). At 30 min after dosing, P decreased AcCoA content by 34% while G increased AcCoA content by 32%, resulting in differences in AcCoA for P compared to G at 30 min (18.0 vs. 36.9 nM/g, $P < 0.0001$), which persisted at 60 min after dosing (21.9 vs. 32.8 nM/g, $P < 0.01$). Plasma BHBA concentration decreased and glucose concentration increased over time for both treatments ($P < 0.001$). While plasma NEFA concentration tended ($P = 0.059$) to be lower for P compared with G at 30 min, it was numerically higher by 60 min when hepatic AcCoA content was still lower. Therefore, the reduction of hepatic AcCoA content by P compared with G was likely because of oxidation in the tricarboxylic acid cycle. This is consistent with these treatment effects on DMI according to the Hepatic Oxidation Theory.

Key Words: acetyl CoA, hepatic oxidation, postpartum

1154 Feed restriction-induced negative energy balance alters the fatty acid profiles of adipose tissue and milk fat of dairy cows. S. E. Schmidt*, K. M. Thelen, C. L. Preseault, G. A. Contreras, and A. L. Lock, *Michigan State University, East Lansing.*

Negative energy balance (NEB) during early lactation results in extensive adipose tissue lipolysis in dairy cows. However, it is not clear if specific adipose depots or fatty acids (FA) are preferentially mobilized. Our objective was to characterize the FA profile of adipose depots and milk fat following feed restriction-induced NEB. Twelve multiparous late lactation (> 200 DIM) Holstein cows, in two experimental blocks, were subjected to treatments consisting of ad libitum feed intake (ADLIB; $n = 6$) or feed restriction (RESTR; $n = 6$) resulting in an energy balance of −13.3 ± 0.5 Mcal/d over 4 d. Milk samples were analyzed for FA composition and collected on d 4. Following the treatment period, all cows were slaughtered and tissue samples were collected from 6 adipose depots: omental, subcutaneous flank, tailhead, perirenal, inguinal, and sternal. Statistical analysis of adipose and milk FA composition was

performed using linear mixed models. RESTR increased the C14 desaturase index (*cis*-9 C14:1/(*cis*-9 C14:1 + C14:0)) of the sternal and tailhead depots ($P < 0.05$) and the C16 desaturase index (*cis*-9 C16:1/(*cis*-9 C16:1 + C16:0)) of the tailhead depot ($P < 0.01$). RESTR decreased C18:0 content of the tailhead depot (8.7 vs. 12.8 g/100 g FA; $P = 0.01$). Across all depots, RESTR increased the *cis*-9 C14:1 content of adipose tissue ($P = 0.04$). RESTR decreased daily yield of de novo-synthesized FA in milk ($P = 0.02$) but the yields of 16-carbon and preformed FA were not affected by treatment ($P \geq 0.20$). Compared to ADLIB, RESTR increased the C18 desaturase index (*cis*-9 C18:1/(*cis*-9 C18:1 + C18:0)) (0.73 vs. 0.66) and the C16 desaturase index (0.08 vs. 0.05) of milk fat ($P < 0.01$). RESTR increased the daily yields of *cis*-9 C16:1 and *cis*-9 C18:1 in milk fat compared to ADLIB (both $P < 0.05$), while the yields of C16:0 and C18:0 were not affected by treatment ($P \geq 0.24$). RESTR increased total monounsaturated FA yield in milk ($P = 0.03$), but treatment did not alter total saturated FA or polyunsaturated FA yields ($P \geq 0.11$). Alterations in adipose FA composition, suggesting mobilization of saturated FA, occurred only in the subcutaneous adipose depots, and most dramatically in the tailhead. However, increased desaturase activity in the mammary gland most likely prevented a subsequent increase in saturated FA yield of milk.

Key Words: adipose, energy balance, lipolysis

1155 Body condition score and body condition score change: Associations with fertility phenotypes in lactating dairy cows.

M. M. Herlihy*[1], E. Rojas[1,2], J. Kenneally[1], P. Lonergan[2], and S. Butler[1], [1]*Animal & Grassland Research and Innovation Centre, Teagasc Moorepark, Fermoy, Ireland,* [2]*School of Agriculture and Food Science, University College Dublin, Belfield, Dublin, Ireland.*

The objective was to examine the associations between BCS and BCS change and utero-ovarian status in first and second parity dairy cows (n = 910; 22 commercial pasture-based dairy herds). Each cow was examined at wk 3 ± 1 and 7 ± 1 postpartum. Transrectal ultrasound exams were conducted to determine presence/absence of corpora lutea (CL). BCS was measured using a 1 to 5 scale, with increments of 0.25. Vaginal discharge score (VDS) of the contents of the vagina was assessed using the Metricheck device. For VDS, an objective scoring scheme on a 1 to 5 scale with 1 point increments was utilized (1 = no infection; 2 = mild infection; > 2 = severe infection). Binary data were analyzed using the GLIMMIX procedure of SAS. Dependent variables were CL and VDS at 3 and 7 wk postpartum. Independent variables were BCS and BCS change (loss, constant, or gain between 3 and 7 wk postpartum), with farm, parity, and DIM on the day of the exam included as adjustment variables. For CL, VDS score was included as an adjustment variable, whereas for VDS, CL was included as an adjustment variable. Fixed effects were tested and retained where $P \leq 0.1$. For variables with a binary distribution (CL) model-adjusted LSMEAN values are presented, whereas, for variables with a multinomial distribution (VDS), unadjusted raw mean values are presented. The proportion of cows that had a CL at wk 3 was 0.45 and 0.58 when cows had BCS $\leq$ 2.75 and $\geq$ 3.00, respectively ($P = 0.002$), and the corresponding figures at wk 7 were 0.74 and 0.89, respectively ($P < 0.0001$). There was no association between BCS change and CL at wk 3 ($P = 0.7$) or wk 7 ($P = 0.9$). At wk 3, the proportion of cows that were classified as having no infection, mild infection, or severe infection was 0.15, 0.23, and 0.62 for cows with BCS $\leq$ 2.75 and 0.15, 0.32, and 0.53 for cows with BCS $\geq$ 3.00, respectively ($P = 0.01$). At 6–8 wk, the proportion of cows that were classified as having no infection, mild infection, or severe infection was 0.46, 0.32, and 0.23 for cows with BCS $\leq$ 2.75 and 0.52, 0.30, and 0.18 for cows with BCS $\geq$ 3.00, respectively ($P = 0.05$). The findings highlight the importance of BCS during early lactation for restoration of cyclicity and uterine health status in pasture-based systems.

Key Words: BCS, utero-ovarian status

1156 Effects of Omnigen-AF supplementation on body temperature, milk production, and somatic cell count in lactating dairy cows.

T. Leiva*[1], R. F. Cooke[2], A. P. Brandao[1,2], R. L. A. Cerri[3], R. O. Rodrigues[1], and J. L. M. Vasconcelos[4], [1]*UNESP-FMVZ, Botucatu, Brazil,* [2]*Oregon State University-EOARC Burns, Burns,* [3]*Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada,* [4]*Sao Paulo State University, Botucatu, Brazil.*

The objective this study was to evaluate the effects of Omnigen-AF (OMN; Phibro Animal Health, Teaneck, NJ) supplementation on body temperature, and production variables of lactating dairy cows. Thirty-two Holstein × Gir cows (100 ± 10 d in milk) were assigned to either control or OMN treated groups, balanced for previous milk production, parity, and body condition score. Dietary treatments were individually fed to cows once daily after the morning milking, at a rate of 56 g/day of kaolin (rumen-inert substance) or OMN added to 200 g of ground corn used as carrier for 56 d, and separated from the TMR diet that was fed ad libitum and formulated to meet or exceed cow nutritional requirements. Temperature and humidity loggers were used to record environmental data and temperature-humidity index. To assess body temperature, each animal was inserted with a thermometer coupled to an intravaginal device from d 15 to 28, and d 43 to 56 of the experiment. Thermometers were set to measure vaginal temperature every 10 min, and values were averaged hourly. Supplementation with OMN increased ($P < 0.01$) milk yield (21.3 vs. 20.1 kg/d for OMN and control, respectively; SEM = 0.13) and DMI (17.6 vs. 16.6 kg/d for OMN and control, respectively; SEM = 0.19), and decreased ($P = 0.06$) milk somatic

cells count (5.30 vs. 5.48 $\log_{10}$ cells/mL for OMN and control, respectively; SEM = 0.05). Treatment × time interactions were not significant ($P \geq 0.15$) for the production variables analyzed herein. Furthermore, when environmental temperature-humidity index was > 68, cows supplemented with OMN remained less ($P < 0.01$) time with body temperature above 39.1°C (38 vs. 45% for OMN and control, respectively; SEM = 0.05%). In conclusion, supplementing OMN to lactating dairy cows increased milk yield and DMI, decreased milk somatic cells count, and reduced incidence of rectal temperature above 39.1°C under heat stress conditions.

Key Words: dairy cows, dietary supplementation, heat stress

1157 The effects of stage of gestation and maternal nutrient status on binucleate cell numbers in the beef cow.

A. M. Peterson*[1], A. Reyaz[1], S. T. Dorsam[1], L. E. Camacho[2], K. C. Swanson[1], A. Grazul-Bilska[1], and K. A. Vonnahme[1], *[1]North Dakota State University, Fargo, [2]University of Arizona, Tucson.*

Our laboratory has demonstrated that maternal nutrition in beef cows can impact uterine blood flow and vascular function of excised placental arteries. However, there is little evidence to suggest that maternal nutrition is impacting capillary number. There is evidence in other species that multi-nucleated cells (i.e., binucleate cells; BNC) in the placenta may produce vasoactive factors. The objective was to test the hypothesis that maternal nutrient restriction followed by early realimentation would increase BNC numbers in the bovine placentome. On d 30 of pregnancy, multiparous, non-lactating cows (620.5 ± 11.3 kg) were assigned to 1 of 2 dietary treatments: control (C;100% NRC; $n = 18$) and restricted (R; 60% NRC; $n = 30$). On d 85, cows were slaughtered (C, $n = 6$; R, $n = 6$), remained on control (CC; $n = 12$) and restricted (RR; $n = 12$), or were realimented to control (RC; $n = 11$). On d 140, cows were slaughtered (CC, $n = 6$; RR, $n = 6$; RC, $n = 5$), remained on control (CCC, $n = 6$; RCC, $n = 5$), or were realimented to control (RRC, $n = 6$). On d 254, all remaining cows were slaughtered. Placentomes were collected and fixed in formalin. Tissue sections were stained using biotinylated lectin Dolichos Biflorus Agglutinin (DBA), Texas red avidin, and DAPI mounting media to visualize BNC. Using image analysis, BNC number, BNC size, and percentage BNC area per tissue area were determined. While there was no effect of diet ($P > 0.11$) on any measurement, there was a main effect of day ($P < 0.01$) where BNC numbers decreased as gestation advanced (572.5, 504.1, 489.1 ± 31.35 for d 85, 140, and 254, respectively). In addition, the BNC size decreased ($P < 0.01$) from d 85 to 140 of gestation, then increased until d 254 (63.1, 51.8, 65.2 ± 3.0 mm^2, respectively). Similarly, the percent BNC area per tissue area decreased ($P < 0.01$) from d 85 to 140 and then increased by d 254 (3.76, 2.78, 3.39 ± 0.20%, respectively). Thus, stage of pregnancy but not diet affected selected BNC measurements indicating a specific role of BNC as pregnancy progresses. Additional studies are currently underway to investigate expression of vasoactive factors (e.g., endothelial nitric oxide) by the bovine BNC, and if maternal diet can alter the expression of those factors.

Key Words: binucleate cell, cow, placentome

1158 Effects of post-AI supplementation with Ca salts of soybean oil on ovarian and pregnancy development in *Bos indicus* beef cows.

R. S. Cipriano*[1], R. F. Cooke[2], A. D. P. Rodrigues[3], L. G. T. da Silva[2,4], T. F. Schumaher[2], M. V. Biehl[5], L. H. Cruppe[6], D. W. Bohnert[2], A. V. Pires[5], and R. L. A. Cerri[7], *[1]UniSalesiano, Araçatuba, Brazil, [2]Oregon State University-EOARC Burns, Burns, [3]Departamento de Produção Animal-FMVZ-UNESP, Botucatu, Brazil, [4]UNESP-FMVZ, Botucatu, Brazil, [5]ESALQ/University of Sao Paulo, Piracicaba, Brazil, [6]Select Sires, Inc., Plain City, OH,[7]Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada.*

The objective of this experiment was to compare corpus luteum (CL) and pregnancy development in beef cows supplemented or not with Ca salts of soybean oil for 21 d (CSSO) beginning after timed-AI. One hundred lactating multiparous Nelore (*Bos indicus*) cows (BW = 430 ± 5 kg, BCS = 2.87 ± 0.02; age = 8.5 ± 0.2 yr; days post-partum = 152 ± 1 d) were inseminated on d 0 of the experiment, and divided into 20 groups of 5 cows/group. Groups were randomly assigned to receive (as-fed basis) 100 g of protein-mineral mix + 100 g of ground corn per cow/d, in addition to: 1) 100 g/cow daily of CSSO ($n = 10$), or 2) 100 g/cow daily of kaolin (CON; rumen-inert indigestible substance; $n = 10$). Groups were maintained in 4 *Panicum maximum* pastures (5 groups from the same treatment within each pasture) with ad libitum access to forage. However, groups were segregated daily and offered treatments individually during the experimental period (d 0 to 21). Blood samples were collected and transrectal ultrasonography was performed to verify ovulation and corpus luteum (CL) volume immediately before AI (d 0), on d 7, and 15. Immediately after ultrasonography on d 15, 60 cows (30 cows/treatment, 3 cows/group) diagnosed without the presence of a CL on d 0, but with a CL greater than 0.38 cm^3 in volume on d 7 and 15, were assigned to embryo collection via uterine flushing with PBS. On d 30, final pregnancy status was determined via transrectal ultrasonography. No treatment differences ($P = 0.68$) were detected on dominant follicle diameter on d 0. However, mean CL volume on d 7 and 15 was greater ($P = 0.04$) for CSSO vs. CON cows (3.2 vs. 2.7 cm^3, respectively; SEM = 0.2). No treatment differences were detected ($P \geq 0.85$) for the proportion of cows that had an embryo on d 15 (40.0 vs. 39.2% for CSSO and CON cows, respectively; SEM = 8.9) or diagnosed as pregnant on d 30. However, embryos

collected from CSSO cows were longer ($P = 0.04$) compared with embryos collected from CSSO cohorts (2.57 vs. 1.15 cm, respectively; SEM = 0.59). In summary, supplementing beef cows with 100 g of CSSO beginning after AI increased CL and embryo development by d 15 of gestation.

PHYSIOLOGY AND ENDOCRINOLOGY SYMPOSIUM: PRE- AND POST-NATAL IMPACTS ON OFFSPRING PERFORMANCE

1159 Consequences of early nutritional insults on fetal hepatic glucose metabolism and insulin action. S. R. Wesolowski*, *University of Colorado School of Medicine, Aurora.*

Pregnancies complicated by placental insufficiency or reduced maternal nutrient supply produce fetuses with intrauterine growth restriction (IUGR). These in utero insults expose the fetus to a reduced supply of glucose, amino acids, and, in some cases, oxygen. The fetus adapts to these reductions in nutrient supply by reducing insulin secretion, increasing counter-regulatory hormone levels, and developing coordinated tissue-specific adaptations in glucose metabolism. Data from our fetal sheep model of IUGR demonstrate an early activation of hepatic glucose production and increased hepatic gluconeogenic gene expression (*PCK1*, *G6PC*) that are sustained during a hyperinsulinemic-euglycemic clamp, thus demonstrating the development of hepatic insulin resistance. This is liver specific insulin resistance because the IUGR fetus has a robust increase in non-hepatic insulin-stimulated glucose utilization in peripheral tissues. While this early activation of glucose production in utero may be an important adaptive response to produce glucose for other glucose-consuming fetal tissues, uncontrolled and dysregulated hepatic glucose production has adverse consequences postnatally and is a major component to diabetes in humans. The early mechanisms driving dysregulated hepatic glucose production and insulin resistance in the fetal liver are not fully understood. We have found that the AKT protein is robustly phosphorylated in the IUGR liver in response to insulin, yet downstream FOXO1 phosphorylation and nuclear localization is increased. We also find that despite decreased nutrient supply, stress signals like AMPK are not increased in the IUGR fetal liver. In addition to increased glucose production, our recent data also demonstrate decreased mitochondrial oxidation in the IUGR fetal liver and a compensatory increase in hepatic glycolysis, intrahepatic lactate production and utilization, and altered substrate preference for reduced hepatic oxidative metabolism. This combination of metabolic adaptations by the fetal liver may be necessary to activate and sustain GPR. However, decreased hepatic mitochondrial function that persists postnatally may underlie the development of hepatic steatosis in offspring who were IUGR. Overall, understanding the endocrine and molecular pathways responsible for these early metabolic adaptations in the fetus, will allow for development of targeted strategies to improve liver function in the fetus and improve postnatal growth and performance and decrease risk for diabetes and metabolic disease later in life.

Key Words: fetus, metabolic adaptations, nutrition

1160 Alterations in uteroplacental hemodynamics during melatonin supplementation in sheep and cattle. C. O. Lemley*[1] and K. A. Vonnahme[2], [1]*Mississippi State University, Mississippi State,* [2]*North Dakota State University, Fargo.*

Compromised placental function can result in fetal growth restriction which is associated with greater risk of neonatal morbidity and mortality. Large increases in transplacental nutrient and waste exchange, which support the exponential increase in fetal growth during the last half of gestation, are dependent primarily on the rapid growth and vascularization of the uteroplacenta. We are examining maternal nutritional plane along with therapeutic supplements, such as dietary melatonin, which impact placental vascularization, blood flow, and fetal development. Using a mid- to late-gestation ovine model of intrauterine growth restriction ($n = 31$), we examined uteroplacental blood flow and fetal growth during supplementation with 5 mg of dietary melatonin per day. Maternal nutrient restriction decreased uterine artery blood flow, while melatonin supplementation increased umbilical artery blood flow compared to non-supplemented controls. Although melatonin treatment did not rescue fetal weight in nutrient restricted ewes; we did observe disproportionate fetal size and fetal organ development. Moreover, fetal uptake of branched-chain amino acids was partially rescued by dietary melatonin supplementation. Elevated fetal concentrations of melatonin may result in altered blood flow distribution during important time points of development. These specific melatonin responses on umbilical artery hemodynamics and fetal development may be partially mediated through vascular melatonin receptors. Recently, we examined the effects of supplementing Holstein heifers ($n = 20$) with 20 mg of dietary melatonin per day during the last third of gestation. Uterine artery blood flow was increased by 25% and total serum antioxidant capacity was increased by 43% in melatonin supplemented heifers versus non-supplemented controls. In addition, peripheral concentrations of progesterone were decreased in melatonin supplemented heifers vs. non-supplemented controls. Using an in vitro model, melatonin treatment increased the activity of cytochrome P450 2C, a progesterone inactivating enzyme, which was blocked by treatment with the melatonin receptor antagonist, luzindole. Elucidating the consequences of specific therapeutic supplements on the continual plasticity of placental function will allow us to determine the proper timing

and duration for intervention and improvements in offspring growth and development.

Key Words: melatonin, umbilical blood flow, uterine blood flow

1161 Development of the fetus and fetal reproductive tract in gilts subjected to heat stress from week 4 to 8 of gestation. C. J. Bernhard*, T. J. Safranski, M. C. Lucy, W. R. Lamberson, S. G. Moore, L. M. Mayo, and R. Molina-Coto, *University of Missouri, Columbia.*

Gestational heat stress may lead to transgenerational changes in the reproductive capacity of boars and gilts. The objective was to assess fetal and placental development and the development of gonads in conceptuses whose mother was subjected to gestational heat stress (GHS; 28 to 38°C; 65 to 88% relative humidity; $n = 12$) or gestational thermoneutral (GTN; 17 to 22°C; 56 to 65% relative humidity; $n = 11$) conditions during pregnancy. Gilts were housed in the Brody Environmental Chambers from week (wk) 4 to 8 of pregnancy before sacrifice during the eighth wk of gestation for the collection of the reproductive tracts and fetal tissues. During pregnancy, GHS gilts had greater rectal temperature (38.5 ± .04 vs. 38.0 ± .04°C; $P < .001$), skin temperature (35.5 ± .2 vs. 28.7 ± .2°C; $P < .001$), and respiration rate (44.3 ± 2.6 vs. 19.5 ± 2.7 breaths per min; $P < .001$) compared with GTN. Sow was the experimental unit for analyses of fetal development. The weight of the pregnant tract (12.0 ± 1.2 vs. 12.5 ± 1.3 kg), number of viable conceptuses (13.8 ± .8 vs. 15.3 ± .9), the number of non-viable conceptuses (.3 ± .2 vs..1 ± .2), the number of mummies (.2 ± .1 vs..3 ± .1), and the % survival (number of viable conceptuses/number corpora lutea; 89 ± 4 vs. 90 ± 5%) did not differ ($P > .10$) for GHS vs. GTN (respectively). Upon dissection, the weight of the fetus (82.3 ± 3.6 vs. 84.9 ± 3.8 g), placenta (155.5 ± 14.7 vs. 170.1 ± 15.6 g), fetal fluid (80.4 ± 10.0 vs. 90.4 ± 10.6 g), and placental efficiency (fetal weight/placental weight; 0.60 ± .04 vs. 0.55 ± .05) did not differ ($P > .10$) for GHS vs. GTN (respectively). The ratio of male to female fetuses was similar ($P > .10$) for GHS (1.3 ± .3) and GTN (1.6 ± .3). The weight of male fetuses (86.2 ± 3.8 vs. 86.4 ± 4.0 g), combined testis weight (34.2 ± 1.4 vs. 32.8 ± 1.5 mg), and combined testis weight as a % of fetal weight (.040 ± .001 vs. .038 ± .001) did not differ ($P > .10$) for GHS vs. GTN (respectively). The weight of female fetuses (81.2 ± 3.6 vs. 83.5 ± 3.8 g), combined ovarian weight (25.2 ± 1.0 vs. 26.1 ± 1.1 mg), and combined ovarian weight as a % of fetal weight (.031 ± .001 vs..031 ± .001) did not differ ($P > .10$) for GHS vs. GTN (respectively). The conclusion was that heat stress from wk 4 to 8 of gestation in gilts did not change the growth of the fetus, placenta, ovary, or testis at mid-gestation. Research was supported by the National Pork Board.

Key Words: fetal development, gestation, heat stress

1162 The effects of under- and over-feeding ewes during gestation on offspring growth and stem cell function. K. E. Govoni*, S. A. Reed, M. L. Hoffman, S. M. Pillai, and S. A. Zinn, *Department of Animal Science, University of Connecticut, Storrs.*

Poor maternal nutrition during gestation has been linked to poor growth and development, metabolic dysfunction, impaired health, and reduced productivity of offspring in many species. Poor maternal nutrition can be defined as an excess or restriction of overall nutrients or specific macro- or micronutrients in the mother's diet during gestation. Interestingly, there are several reports that both over- and under-feeding during gestation negatively affect offspring postnatal growth with reduced muscle and bone, increased fat, and metabolic dysregulation through reduced leptin and insulin sensitivity. Our laboratory established a model to evaluate both under- and over-feeding during gestation in one population of ewes to evaluate effects on early postnatal growth of offspring. Specifically, ewes were under-fed (60% of NRC for TDN), over-fed (140% of NRC for TDN), or control-fed (100% of NRC for TDN) beginning at d 31 ± 1.3 of gestation. Blood and tissue samples were collected at birth and 3 mo of age. As previously reported, during the first 3 mo of postnatal growth, over-feeding during gestation increased body size, circulating growth factors and metabolic hormones in offspring. Both under- and over-feeding altered muscle growth, increased lipid content in the muscle and caused changes in expression of myogenic factors. Although the negative effects of poor maternal nutrition on offspring growth have been well characterized in recent years, the mechanisms are not well established. Our laboratory has focused on elucidating these mechanisms by evaluating changes in gene and protein expression and stem cell function. Through RNA-Seq analysis, we observed changes in expression of genes involved in protein synthesis, metabolism, cell function, and signal transduction in muscle tissue. We recently reported that satellite cells, muscle stem cells, have altered expression of myogenic factors in offspring from under-fed mothers. Mesenchymal stem cells, multipotent cells that contribute to development and maintenance of several tissues including bone, muscle and adipose, have a 50% reduction in cell proliferation ($P < 0.05$) and altered metabolism in offspring from both under- and over-fed mothers. These findings suggest that poor maternal nutrition may alter offspring postnatal growth by programming the stem cell populations. In conclusion, poor maternal nutrition during gestation negatively affects offspring postnatal growth, potentially through impaired stem cell function. Therefore, determining the mechanisms that contribute to fetal programming are critical to identifying novel methods to manage these offspring and improve efficiency of production.

Key Words: maternal nutrition, sheep, stem cells

1163 Postnatal reproductive development and the lactocrine hypothesis. F. F. Bartol[*1], C. A. Bagnell[2], and A. F. George[2], *[1]Auburn University, Auburn, AL, [2]Rutgers University, New Brunswick, NJ.*

Maternal contributions to development begin at conception. Prenatal conditions that evolve in utero through the course of gestation define the environment in which embryogenesis and fetoplacental development occur. Genotype notwithstanding, maternal effects on development from the time of conception can program cell fate and dictate offspring phenotype as defined by various aspects of performance and health, including fertility and fecundity. Maternal effects on development do not end at birth, but extend into postnatal life through signals communicated from mother to offspring in first milk (colostrum). Transmission of bioactive factors from mother to offspring as a specific consequence of nursing defines a lactocrine mechanism. The female reproductive tract (FRT) is not fully formed at birth. Data for both ungulate species and mice indicate that disruption of the developmental program during critical organizational periods of neonatal life can have lasting effects on the form and function of FRT tissues, including the uterus. Radial patterning of the uterine wall, reflected by differentiation and proliferation of nascent endometrial glands, is a postnatal event in most mammals. Both uterine growth and histogenesis proceed in an ovary-independent manner shortly after birth, suggesting that extra-ovarian inputs are important in this process. Data for the pig indicate that lactocrine signals constitute one source of such uterotrophic support. Disruption of lactocrine signaling by feeding gilts porcine milk replacer instead of colostrum for 2 d from birth (postnatal day = PND 0) retarded uterine gland genesis by PND 14. Differences in endometrial and whole uterine gene expression patterns between colostrum- and replacer-fed gilts were evident by PND 2, when RNA sequencing revealed over 800 differentially expressed, lactocrine-sensitive genes. Organizationally relevant, lactocrine-sensitive processes, pathways, and networks identified through transcriptomic studies included cell adhesion, cell-cell signaling, cytokine-receptor interactions, integrin cell surface interactions, ESR1 and Hedgehog signaling, and the plasminogen activating network. Lactocrine-sensitive expression of nine microRNAs with 115 potential mRNA targets was also identified. Results provide evidence of lactocrine-mediated, epigenetic effects on multiple elements of the uterine developmental program. A single oral dose of colostrum given at birth affects endometrial cell behaviors associated with uterine wall development by 12 h postnatal. Evidence that minimal colostrum consumption at birth is associated with reduced lifetime fecundity in adult sows indicates that lactocrine programming can affect reproductive efficiency. Data support a role for lactocrine signaling in regulation of postnatal reproductive tract development and function.

Key Words: development, lactocrine programming, reproductive tract, uterus

1164 Supplementation of corn-dried distiller's grains plus solubles to gestating beef cows fed low quality forage: neonatal calf performance. V. C. Kennedy[*1], J. J. Gaspers[1], B. Mordhorst[1], G. L. Stokka[2], M. L. Bauer[1], K. C. Swanson[1], and K. A. Vonnahme[1], *[1]North Dakota State University, Fargo, [2]Department of Animal Sciences, North Dakota State University, Fargo.*

We have previously reported that corn-dried distiller's grains plus solubles (DDGS) supplementation to low quality forage during late gestation results in a tendency for heavier calves at birth and larger weaning weights compared to no DDGS (CON). To investigate if birth and weaning weight differences were due to metabolite or hormonal status, calf blood samples were collected during early life. Multiparous beef cows (n = 27; 674 ± 17 kg) were divided randomly into 2 pens equipped with Insentec feeders to monitor individual intake of corn stover and silage. For 10 wk, both treatment groups were fed the basal diet for ad libitum intake while one group was supplemented (SUP; n = 12) with DDGS at 0.3% of BW during the last third of gestation. Following parturition, all cows received the same diet for an additional 8 wk. At calving (0 and 24 h) and weekly for 56 d, blood samples were obtained from calves for analysis of NEFA, urea, glucose, cortisol, thyroxine (T_4) and triiodothyronine (T_3). From 0 to 24 h, NEFA concentrations did not differ between treatment groups, but were greater at 0 h (571 vs. 366 ± 40 μM, $P < 0.01$). Neither urea nor cortisol differed by treatment or hour at 0 and 24 h, however, treatment interacted with time for glucose, where SUP calves had the greatest concentration at 24 h (6.83 ± 0.32 mM). Glucose decreased from birth onward ($P < 0.01$), with treatments beginning to separate near d 56. Both T_3 and T_4 decreased ($P < 0.01$) from birth to d 56. Neither NEFA nor cortisol differed ($P \geq 0.95$, $P \geq 0.35$, respectively) by day or treatment. Urea was influenced by day ($P = 0.06$), but with little overall deviation from concentrations at birth. While there was no impact of diet on dystocia ($P = 0.39$), calves from SUP cows were heavier ($P = 0.01$) at birth than CON calves, which may have impacted their greater glucose concentration at 24 h. It appears that heavier weaning weights observed in calves from SUP cows were not influential on the measured metabolites and hormone profiles at birth and through early life.

Key Words: beef cows, metabolites, neonatal life

1165 The effects of nutritional restriction on endogenous retroviruses and placentation during the first 50 d of gestation in beef heifers.
K. J. McLean[*1], *M. S. Crouse*[1], *M. R. Crosswhite*[2], *N. Negrin Pereira*[1], *A. K. Ward*[1], *C. R. Dahlen*[1], *L. P. Reynolds*[1], *P. P. Borowicz*[1], *B. W. Neville*[3], *and J. S. Caton*[1], *[1]Department of Animal Sciences, North Dakota State University, Fargo, [2]North Dakota State University, Fargo, [3]North Dakota State University, Streeter.*

The objectives of this study were to evaluate the effects of maternal nutrient restriction and day of gestation on mRNA expression of *syncytin-Rum1*, bovine endogenous retrovirus K1 (*BERV-K1*), interferon-tau (*INF-τ*), and pregnancy specific protein B (*PSP-B*). At breeding (0 d), crossbred heifers ($n = 49$; ~15 mo of age; initial BW = 324.9 kg) were assigned to dietary treatments, control (fed to gain 0.45 kg/d BW gain) or restricted (60% of control). Heifers were ovariohysterectomized at d 16, 34, or 50 resulting in a 2 × 3 factorial. Non-bred, non-pregnant heifers ($n = 6$; NP), on the control diet, were ovariohysterectomized as baseline controls on d 16 of the estrous cycle. The tissues collected consisted of pregnant horn caruncle (P-CAR), pregnant horn inter-caruncle (P-ICAR), non-pregnant horn caruncle (NP-CAR), non-pregnant horn inter-caruncle (NP-ICAR), and fetal membrane (chorioallantoic; FM). Relative gene expression was calculated using the delta delta Ct method with β-actin as the reference gene and NP as the control tissue. Data were analyzed using PROC GLM of SAS with the model including d of gestation, nutritional treatment, and their interaction. There was significant d of gestation × nutrition interaction for expression of *BERV-K1* in NP-CAR and *INF-τ* in FM while all other interactions were not significant ($P > 0.08$). Expression of *INF-τ* was influenced by d of gestation and nutritional treatment in FM, with d 16 restricted being greatest (5781 fold; $P < 0.01$) followed by d 16 control FM (3324 fold); the remaining d and treatments were not different. In FM, *BERV-K1* was greatest ($P < 0.01$) on d 34 (2961 fold) compared with d 16 and 50 (5 and 1861 fold, respectively). *Syncytin-Rum1* increased ($P = 0.04$) in FM throughout the first 50 d (375 fold) of gestation. *Syncytin-Rum1* expression in P-ICAR was greatest ($P = 0.01$) at d 16; however, *syncytin-Rum1* expression in P-CAR tended ($P = 0.09$) to be greater at d 50. Expression of *PSP-B* increased ($P < 0.01$) throughout early gestation until d 50 in both NP-CAR (316 fold) and P-CAR (18,215 fold). Although nutritional restriction did not influence endogenous retrovirus expression in maternal or fetal tissues, it did influence *INF-τ* expression. These data suggest that both BERV-K1 and syncytin-Rum1 may interact with PSP-B during the establishment of the feto-maternal interface and syncytial plaques.

Key Words: beef heifers, early gestation, endogenous retroviruses, nutrient restriction

PHYSIOLOGY, ENDOCRINOLOGY, AND EXTENSION SYMPOSIUM: ENHANCING ADOPTION OF REPRODUCTIVE MANAGEMENT TOOLS FOR BEEF AND DAIRY PRODUCERS

1166 History of the development of the Beef Reproduction Task Force (BRTF) and impacts of the BRTF on beef cattle reproductive management.
S. Johnson[*1], R. F. Cooke[2], G. R. Dahlke[3], R. N. Funston[4], J. B. Hall[5], D. J. Kesler[6], G. C. Lamb[7], J. Lauderdale[8], D. J. Patterson[9], G. A. Perry[10], D. R. Strohbehn[3], and A. L. Van Eenennaam[11], *[1]Kansas State University, Colby, [2]Oregon State University-EOARC Burns, Burns, [3]Iowa State University, Ames, [4]University of Nebraska, North Platte, [5]University of Idaho Nancy M. Cummings Research, Extension Education Center, Carmen, [6]University of Illinois at Urbana-Champaign, Urbana, [7]University of Florida, North Florida Research and Education Center, Marianna, [8]Lauderdale Enterprises, Inc., Augusta, MI, [9]University of Missouri, Columbia, [10]Department of Animal Science, South Dakota State University, Brookings, [11]University of California, Davis.*

The Beef Reproduction Task Force (BRTF) was formed during a period of evolving science that resulted in systems to allow producer-acceptable results with a single fixed-timed insemination. The group organized and developed goals to enhance productivity and profitability of U.S. beef herds by integrating research and extension efforts with the intent of more effectively transferring the use of reproductive technologies to the field. A key early step was to coordinate efforts in identifying effective breeding management protocols for beef cattle and to clarify their associated acronyms. A short-list of recommended protocols and their acronyms for synchronization of estrus and ovulation in beef cattle was developed based on results from peer-reviewed, published research and a comprehensive review of data collected from the field. The list of recommended protocols was developed by the BRTF in cooperation with veterinarians and representatives from associated industries. The synergies of this larger industry-centered working group have resulted in ideas for research and broader educational reach. Together the group has planned and hosted 17 in-depth meetings at locations in key cow-calf areas across the country since 2002. These "Applied Reproductive Strategies in Beef Cattle" workshops targeted beef producers, AI industry personnel, veterinarians, allied industry representatives, and academicians. A national media sponsor has provided online coverage of the meetings (www.appliedreprostrategies.com) since 2008. The effectiveness of the team was recognized with the NIFA Partnership Award for

Multistate Efforts in 2013. A 2013 national survey of AI users indicated 97% of respondents (n = 425) were familiar with the BRTF recommended protocol lists. Recommendations from these guidelines were generally used by 65% and sometimes or occasionally used by 20% of respondents. Resources developed by the group include the Estrus Synchronization Planner in a mobile and spreadsheet version, tools to evaluate cost differences of AI and natural service breeding and numerous publications and support materials on a beefrepro.info website. The group has set in place a plan to bring in new members to help address changing industry needs. The multi-state research and extension effort combined with the industry group's insight and support have provided valuable information in a growing beef AI industry.

Key Words: artificial insemination, beef, synchronization of estrus

1167 History of the development of the Dairy Cattle Reproduction Council (DCRC) and impacts of the DCRC on dairy cattle reproductive management.

M. C. Lucy*, *University of Missouri, Columbia.*

The DCRC was founded in 2006 in response to a decline in lactating dairy cow fertility that was occurring worldwide. The initial founders included academicians, allied industry professionals, veterinarians, and producers. The established goals of the organization are to educate and provide support for the development and implementation of new technologies that will sustain and improve reproduction in dairy cows and heifers. The organization is guided by a series of principles that were established by its founding members, the most important of which was to be science-based and non-commercial. The group is inclusive and seeks to involve all individuals with an interest in dairy reproduction. A professional and discounted student membership is offered. Members have full access to past proceedings and newsletters. Officers, directors, and committee members of the DCRC serve on a voluntary basis. There are four primary mechanisms through which the DCRC achieves its stated goals. First, a meeting is held annually that includes invited presentations on relevant topics. An invited poster session is also held during the meeting. The meeting is moved to different locations within the United States to facilitate participation by individuals from different dairy regions. Second, an awards competition is sponsored that identifies and recognizes dairy herds with the best reproduction by using objective criteria. Awardees are invited to participate in the annual meeting and are also recognized in trade magazines. Third, resource materials are prepared that include protocol sheets with diagrams of reproductive protocols for both dairy cows and heifers. The protocols depicted on the sheets are vetted annually by a committee so that the information is current and based on the most-recent scientific findings. The protocol sheets are printed in both English and Spanish languages. Finally an electronic newsletter is published six times each year that includes a president's message, research summaries, technical information, a member profile, and a meeting calendar. The 2015 meeting held in Buffalo, NY was the largest meeting to date. The continued growth of the DCRC and recognized improvements in dairy reproduction in the past 10 yr speak to the success of the organization.

Key Words: cow, dairy, fertility

1168 Physiological and management advances enhancing adoption of applied reproductive management procedures in beef cattle.

*D. J. Patterson[*1], R. F. Cooke[2], G. R. Dahlke[3], R. N. Funston[4], J. B. Hall[5], G. C. Lamb[6], J. Lauderdale[7], G. A. Perry[8], and A. L. Van Eenennaam[9], [1]University of Missouri, Columbia, [2]Oregon State University-EOARC Burns, Burns, [3]Iowa State University, Ames, IA, [4]University of Nebraska, North Platte, [5]Department of Animal & Veterinary Sciences, University of Idaho, Moscow, [6]University of Florida, North Florida Research and Education Center, Marianna, [7]Lauderdale Enterprises, Inc., Augusta, MI, [8]Department of Animal Science, South Dakota State University, Brookings, [9]University of California, Davis.*

Advances in research over the past two decades expanded our understanding of the bovine estrous cycle and led to improvements in methods to more effectively control estrus and ovulation in beef heifers and cows. Precise monitoring of ovarian follicles and corpora lutea over time by transrectal ultrasonography expanded our understanding of the changes that occur during a follicular wave. Consequently, we now know that precise control of estrous cycles requires the manipulation of both follicular waves and luteal lifespan. As a result, breeding management technologies are currently available or emerging that offer the potential to more effectively manage reproduction, expedite genetic progress, enhance efficiencies of production, and add value to beef cattle produced and marketed in the U.S. Until recently, the inability to predict time of estrus for individual cows or heifers in a herd was the primary reason beef producers viewed AI as being impractical to use because of the labor required to detect estrus. However, improvements in methods to control estrus and ovulation in beef heifers and cows provide the opportunity to expand the use of AI by reducing the period of time required to detect estrus or eliminate estrus detection entirely. Protocols for inducing and synchronizing a fertile estrus in which progestins are used strategically with gonadotropin releasing hormone and prostaglandin F2α provide opportunities for beef producers to synchronize estrus and ovulation and facilitate fixed-time AI. Procedures used to control estrous cycles in cattle include synchronization of estrus and ovulation in estrous cycling females, and induction of estrus accompanied by fertile ovulation in heifers that have not yet reached puberty or among cows that have not

returned to estrus after calving. These strategies provide opportunities for producers to utilize sires of elite genetic merit, reduce length of the breeding and calving seasons, produce more uniform calf crops, and improve reproductive rates of replacement beef heifers and the mature cow herd. Collectively, advancements in applied reproductive technologies afford beef producers the flexibility to match specific breeding management protocols to a defined management system, thereby creating the opportunity to significantly expand use of AI in beef herds across the United States and enhance profitability of the beef enterprise.

Key Words: beef, estrus synchronization, fixed-time AI

1169 Physiological and management advances enhancing adoption of applied reproductive management procedures in dairy cattle.

J. S. Stevenson* and L. G. D. Mendonça, *Kansas State University, Manhattan.*

Since the first meeting of the Dairy Cattle Reproduction Council in 2006, several advances occurred to upgrade reproductive management programs in dairy herds. Many advancements are refinements of the currently applied standard 7-d Ovsynch program (GnRH [d 0; G1]; $PGF_{2\alpha}$ [1 dose on d 7]; GnRH [G2; d 9.5]; and AI 16 h after G2). Key advances: (1) including GnRH in presynchronization programs to facilitate ovulation before first or repeat AI to change the proportion of cows with a corpus luteum (CL) and more moderate progesterone concentrations to start Ovsynch, thus increasing G1-induced LH release and subsequent ovulation to G1 and greater pregnancy per AI (P/AI). (2) Clarifying the specific role of progesterone in targeted sub-fertile populations before first or repeat AI of cows without a CL to facilitate greater P/AI compared with non-progesterone treated controls without a CL, but similar P/AI to cows starting Ovsynch in diestrus. (3) Applying increased dosages or additional injections of $PGF_{2\alpha}$ to enhance luteolysis before timed AI to increase P/AI in cows treated with either the 5- or 7-d Ovsynch program. (4) Increasing dosages of GnRH at G1 or G2 to increase ovulation incidence did not always increase P/AI. (5) Diagnosing pregnancy via blood or milk pregnancy-associated glycoprotein (PAG) tests beginning 28 d post-AI to spare veterinarians' time to address other health issues. (6) Field testing the role of a 5- or 7-d Ovsynch program with progesterone inserts to facilitate timed AI in dairy heifers to increase early pregnancy in replacement heifer programs and reduce days on feed before first calving. (7) Incorporating gender-selected semen in AI programs to increase herd size from within, allow for more selective culling, and less outsourced heifer purchases. (8) Applying software tools to project revenues and costs associated with various timed AI and estrus-detection AI programs. (9) Detecting ovarian structures to more accurately diagnose large anovulatory follicles or ovarian cysts, early pregnancy, and subsequent embryo survival via diagnostic transrectal ultrasonography. (10) Applying technologies such as activity monitors to assess increased physical activity associated with estrus, monitor rumination and ear temperature, and RFID for accurate cow identification. (11) Clarifying the role of postpartum health (clinical and subclinical disease) on subsequent P/AI. (12) Applying genomics and fertility-selection traits to enhance fertility. These physiological advances have impacted reproductive management, increased P/AI, and promoted sustainability of dairy herds to provide dairy products to feed a hungry world.

Key Words: dairy, fertility, management

1170 Impacts of temperament on reproductive performance of *Bos indicus* and *B. taurus* beef females.

R. F. Cooke, Oregon State University-EOARC Burns, Burns.*

Temperament is defined as the fear-related behavioral responses of cattle when exposed to human handling. Our group evaluates cattle temperament using: 1) chute score; 1 to 5 scale that increases according to excitable behavior during restraint in a squeeze chute, 2) exit velocity; speed of an animal exiting the squeeze chute, 3) exit score; dividing cattle according to exit velocity into quintiles using a 1 to 5 scale (1 = cattle in the slowest quintile; 5 = cattle in the fastest quintile), and 4) temperament score; average of chute and exit scores. Subsequently, cattle are assigned a temperament type; adequate temperament (ADQ; temperament score ≤ 3) or excitable temperament (EXC; temperament score > 3). To assess the impacts of temperament on reproductive efficiency in beef production systems, our group associated these evaluation criteria with puberty attainment and pregnancy rates in *Bos taurus* and *B. indicus*-influenced females. Cattle classified as EXC had greater plasma cortisol vs. ADQ cattle during handling, independent of breed type (*B. indicus* × *B. taurus*, $P < 0.01$; *B. taurus*, $P < 0.01$; *B. indicus,* $P = 0.04$) or age (cows, $P < 0.01$; heifers, $P < 0.01$). In regards to reproductive variables, *B. taurus* and *B. indicus* × *B. taurus* EXC heifers reached puberty at older ages ($P < 0.05$) compared with ADQ cohorts. Cows classified as EXC had reduced annual pregnancy rates vs. ADQ cows across breed types (*B. taurus*, $P = 0.03$; *B. indicus* × *B. taurus,* $P = 0.04$; *B. indicus*, $P = 0.05$). Moreover, *B. taurus* EXC cows also had decreased calving rate ($P = 0.04$), weaning rate ($P = 0.09$), and kg of calf weaned/cow exposed to breeding ($P = 0.08$) vs. ADQ cohorts. Our group also reported that acclimating *B. indicus* × *B. taurus*or *B. taurus* heifers to human handling improved temperament ($P \leq 0.02$), reduced plasma cortisol ($P < 0.01$), and hastened puberty attainment ($P \leq 0.02$). Hence, strategies to improve herd temperament, including selection for this trait and acclimation of young animals to human handling, are imperative for optimal reproductive efficiency of beef operations based on *B. taurus* and *B. indicus* influenced cattle.

Key Words: beef cattle, reproduction, temperament

1171 Estrus: Association with productive parameters and implications to fertility. R. L. A. Cerri*[1], B. F. Silper[1], T. A. Burnett[1], A. M. L. Madureira[2], J. L. M. Vasconcelos[2], and L. Polsky[1], [1]*Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada,* [2]*Sao Paulo State University, Botucatu, Brazil.*

Comparison between the fertility of timed-AI protocols vs. AI based on spontaneous or induced estrus is often inadequate. Day post-partum at AI and the consequent grouping of animals with different cyclic status, BCS, and overall health status is a confounding factor caused by many experimental designs. Previous studies observing the effect of concentration of progesterone during diestrus, concentration of estradiol and length of proestrus and follicular dominance minimize or neglect the effect of the expression of estrus on parameters such as fertilization rate, embryo quality, and endometrium receptivity. In one study, the likelihood of ovulation was greater for high vs. low relative increase estrus, but a more detailed experiment also showed slight differences in the timing of ovulation. Expression of estrus near AI also modified the expression of genes related with the immune system, adhesion molecules and prostaglandin synthesis in the endometrium (*MX1*, *MX2*, *MYL12A*, *MMP19*, *CXCL10*, *IGLL1*, *SLPI, OTR*, and *COX-2*) and those related with apoptosis, P4 synthesis, and prostaglandin receptor (*CYP11A*, *BAX*, and *FPr*) in the CL. The expression of estrus was associated with increased P/AI for timed-AI (38.9 vs. 25.5%) and embryo transfer (46.2 vs. 32.7%) protocols. Moreover, there was a decrease in pregnancy loss in both programs. Data from other recent studies involving spontaneous and estradiol cypionate induced estrus have shown that greater relative increase and longer duration of estrus, captured by different activity monitors, have a significant impact on P/AI (over 12% points across different studies). Intensity and duration of estrus were correlated with BCS, parity, and secondary behavior signs as expected, but only weakly associated with milk production. Follicle diameter and concentration of estradiol at estrus were also weakly correlated with estrus expression. Collectively, ovulation could partly explain the observed reduction in fertility, but it is clear that the endometrium and the CL play an important role that is independent of parameters such as parity, BCS, and milk production. Quantitative information from estrus events could be used to improve estrus detection quality and develop decision-making strategies at the farm level. Further studies in this field should aim to 1) better understand ovarian, embryo and endometrium mechanisms associated with either the expression or intensity of estrus and, 2) refine the collection of phenotypes related to estrus (i.e., relative increase, absolute increase, baseline levels, duration, and repeatability within cow) to improve estrus detection and possibly genetic selection.

Key Words: dairy cow, estrus expression, fertility

PRODUCTION, MANAGEMENT, AND ENVIRONMENT

1172 Use of evaporative cooling systems and their effects on core body temperature and lying times in lactating dairy cattle. J. R. Johnson*[1], L. G. D. Mendonça[2], J. P. Harner[3], and M. J. Brouk[1], [1]*Department of Animal Sciences and Industry, Kansas State University, Manhattan,* [2]*Kansas State University, Manhattan,* [3]*Department of Biological and Agricultural Engineering, Kansas State University, Manhattan.*

A study was completed to assess the effect of an evaporative cooling system on respiration rates, rear udder skin temperature (T_u), core body temperature (CBT), and resting time in lactating dairy cows. There were two environmental treatments in this study: FAN (Cyclone fans only, no fog); and FANFOG (Cyclone fans and fog on). Cows exposed to these 2 environments were either housed in a bedded pack barn equipped with an evaporative cooling system (Cyclone fans, Chippewa Falls, WI) or a tie-stall barn equipped with cooling cells. Cows were divided into 2 treatment groups with 8 cows/treatment: TIE which spent 50% of the time in the tie-stall barn and 50% of the time in the bedded pack barn, and PACK which also spent 50% of the time in the tie-stall barn and 50% of the time in the bedded pack barn but opposite of TIE. Each cow was fitted with a vaginal temperature logger (HOBO U12, Onset Computer Corporation, Pocasset, MA), a neck collar that contained a sensor (HOBO Pro V2, Onset Computer Corporation, Pocasset, MA) to track temperature and relative humidity of the environment, and an electronic data logger (HOBO Pendant G Acceleration Data Logger, Onset Computer Corporation, Pocasset, MA) to track lying times. Ambient temperature and relative humidity (RH) were also collected and all devices recorded at 1 min intervals. During FANFOG, PACK cows had reduced ($P < 0.05$) respiration rates (breaths per minute) compared with TIE (69 vs. 76 ± 2.4 BPM). Breaths per minute also increased significantly throughout the day for TIE but this was not the case for PACK. No differences were found in T_u between treatments. CBT data were divided into the following categories: < 38.6°C, ≥ 38.6°C, and ≥ 39.0°C. When exposed to the FANFOG environment, cows spent decreased ($P = 0.05$) time above 39°C CBT when compared with FAN (9.2 vs. 14.6 h/d, respectively), while PACK cows during FAN and FANFOG spent fewer hours/day above 39°C CBT vs. TIE ($P < 0.05$). TIE showed numerically greater total daily lying times during FAN and FANFOG compared with PACK ($P > 0.10$). These results confirm that evaporative cooling systems (Cyclone fans and fog) are effective at decreasing respiration rates and CBT thus improving cow comfort, while having no

effect on T_u and lying times in lactating dairy cows.

Key Words: core body temperature, evaporative cooling, heat stress

1173 Relationship between blood parameters, physiological changes, and behavior pattern in Korean native steers under cold stress. W. S. Kim*, U. S. Jung, M. J. Kim, S. W. Jeon, D. Q. Peng, Y. S. Kim, M. H. Bae, J. S. Lee, S. R. Lee, and H. G. Lee, *Department of Animal Science and Technology, College of Animal Bioscience and Technology, Konkuk University, Seoul, Korea.*

The performance, health, and behavior of cattle are strongly affected by climate. The objective of this study was to investigate the relationship between blood parameters, rectal temperature, heart rate, and rumination time in Korean native steers under cold stress. Data were collected from four Korean native steers (331.6 ± 6.46 kg BW and 343.5 ± 3.48 d age), which were kept in three designated temperature levels based on ambient temperature: HCS; high cold stress (−15 to −10°C) period, MCS; medium cold stress (−10 to −5°C) period, and LCS; low cold stress (−5 to 2°C) period. According to the ambient temperature, blood was collected after 3h feeding (at 1100). The blood metabolites and hormone as stress-related indicators were analyzed using biochemical analyzer-T-BA-40FR. Complete Blood Count (CBC) test was conducted to determine the change in blood cells, and rectal temperature (RT) and heart rate (HR) were measured at the same time points. Feed and water intake were recorded daily (at 0900 h), and rumination time (RMT) was monitored through a video monitoring system. Data were analyzed using the JMP 5.0 procedures of SAS. The results showed that the level of serum cortisol ($P = 0.027$) as an indicator of stress steroid hormone was significantly increased in the HCS period compared with the LCS period. Also, RT ($P = 0.003$) and HR ($P = 0.01$) were significantly increased in the HCS period compared with the LCS period. However, RMT ($P = 0.011$) was decreased in the HCS period compared with the LCS period. Feed, water intake, and blood parameters were not associated with RT ($P > 0.10$). In contrast, RMT and HR influenced RT ($P < 0.01$). Serum cortisol, platelet, and RMT were affected in HR ($P < 0.05$). This means that the lower temperature is related to high stress in Korean native steers, and there were close correlations between RT, HR, and cortisol. In conclusion, HR and RT were very important stress indexes in cold season, which has a very close relationship with the concentration of cortisol and RMT. In addition, an increase in cortisol level probably activates the sympathetic nerve system to cause an increase in the heart rate of Korean native steers. This relationship with this physiological action explains that it would be an important factor to reduce stress.

Key Words: blood parameters, cold stress, Korean native steer

1174 Effects of exit-lane water drenching using showers on lactating dairy cow vaginal temperature. A. R. Lee*, S. M. Smith, D. L. Ray, J. D. Clark, and J. M. Bewley, *University of Kentucky, Lexington.*

Dairy producers can help mitigate the negative effects of high temperature and humidity by implementing cow cooling methods. The objective of this study was to quantify the changes in vaginal temperature after drenching cows with water using showers on parlor exit. Forty-five lactating Holstein cows (Parity = 1.89 ± 1.21, days in milk = 244.58 ± 127.58) at the University of Kentucky Coldstream Dairy were enrolled in a 4 wk crossover study from August 31 to September 24, 2013. Vaginal temperature measurements were recorded every 6 min for 7 d using Thermochrom iButtons (Embedded Data Systems, Lawrenceberg, KY) placed in a vaginally inserted blank CIDR (Zoetis, Florham Park, NJ). Vaginal temperature was used as a measure of core body temperature. Cooling Sense showers (Edstrom Industries, Waterford, WI) were installed in 2 parlor exit lanes and automatically activated at morning or afternoon milking when ambient air temperature was ≥ 18.3°C. Showers sensed approaching cows and drenched water for 5 s, as cows walked through each respective exit lane. Showers ran for 5 s, although cows may have received no, some, or all of the drench. Cows were randomly balanced by days in milk and parity into two pens. Cows in pen 1 received 4 d of showers and 3 d of washout during weeks 1 and 3. Cows in pen 2 received 4 d of showers and 3 d of washout during weeks 2 and 4. All other times, cows in pen 1 or pen 2 did not have showers. Shower time was characterized as the time before or after the cow entered the shower. The MIXED procedure of SAS (SAS 9.3, SAS Inst., Inc., Cary NC) was used to analyze the effects of shower time, shower use, and milking sessions on vaginal temperature. Stepwise backward elimination was used to remove nonsignificant interactions ($P \geq 0.05$). Vaginal temperature was lower ($P < 0.01$) 1 h and 2 h after drench than 1h and 2h before drench (LSMean ± SE; 39.1 ± 0.04°C vs. 39.2 ± 0.04°C) and (39.1 ± 0.03°C vs. 39.2 ± 0.04°C), respectively. Morning or afternoon milking had a significant effect on vaginal temperature at 5 min, 10 min, 30 min, 1 h, and 2 h after milking ($P < 0.01$). The use of showers on parlor exit reduced vaginal temperature by 0.1°C for up to 2 h following drenching with showers.

Key Words: cow cooling, shower, vaginal temperature

1175 The effects of zinc amino acid complex on biomarkers of gut integrity and metabolism in heat-stressed steers. M. Abuajamieh*[1], S. K. Kvidera[1], E. A. Horst[1], E. J. Mayorga[1], J. T. Seibert[1], J. S. Johnson[1], J. W. Ross[1], M. A. Al-Qaisi[1], P. J. Gorden[2], J. DeFrain[3], R. P. Rhoads[4], and L. H. Baumgard[1], *[1]Iowa State University, Ames, [2]Veterinary Diagnostic and Production Animal Medicine, Iowa State University, Ames, [3]Zinpro Corporation, Eden Prairie, MN, [4]Virginia Tech, Blacksburg.*

Supplemental Zn improves monogastric intestinal integrity during heat stress (HS), but its ability to improve ruminant gut health is unknown. Forty Holstein steers (173.6 ± 4.9 kg) were used in a replicated, incomplete 2 x 3 factorial design to determine the effect of Zn source ($ZnSO_4$ vs. Zn amino acid complex [CZ; Availa®Zn, Zinpro Corporation]) and environment (thermal neutral [TN] conditions or cyclical HS) on biomarkers of intestinal integrity and villi morphology. Steers were fed ad libitum (AL) one of two diets for 21 d: 1) 75 mg/kg of Zn from $ZnSO_4$ or 2) 35 mg/kg Zn from $ZnSO_4$ and 40 mg/kg Zn from of CZ. Steers remained on assigned diets and were then housed in environmental chambers. The experiment consisted of two periods (P): P1) 5 d of baseline in TN-AL conditions (20.2 ± 1.4°C, 30.4 ± 4.3% RH) and P2) 6 d of environment implementation followed by euthanasia. During P2, steers received one of five diets by environment combinations: 1) TN fed AL 75 mg/kg of Zn from $ZnSO_4$ (Ctrl; n = 8), 2) TN pair-fed (PF) 75 mg/kg of Zn from $ZnSO_4$ (0CZPF, n = 8), 3) HS (27.1 ± 1.5 to 35.0 ± 2.9°C, 19.3 ± 3.5% RH) and fed AL 75 mg/kg of Zn from $ZnSO_4$ (0CZHS; n = 8), 4) TN and PF 35 mg/kg of Zn from $ZnSO_4$ and 40 mg/kg of Zn from CZ (40CZPF, n = 8), and 5) HS and fed AL 35 mg/kg of Zn from $ZnSO_4$ and 40 mg/kg of Zn from CZ (40CZHS; n = 8). The Ctrl, 0CZPF, and 40CZPF steers remained in TN continuously. The 0CZPF and 40CZPF steers were fed to their 0CZHS and 40CZHS counterparts, respectively. Data were analyzed with repeated measures using PROC MIXED in SAS and P1 data used as a covariate. Preplanned contrasts evaluated Zn source and environment. Regardless of environment, 40CZ tended to increase DMI (10%; P = 0.09) relative to 0CZ (P < 0.01). Compared to TN, HS decreased NEFA, serum amyloid A and increased BUN, insulin:DMI, and L-lactate (P < 0.01). 40CZHS calves had reduced rectal temperature compared to 0CZHS (0.24°C; P < 0.01). Compared to PF, HS calves had increased (P < 0.01) goblet cell numbers in the duodenum, jejunum, ileum, and colon. 40CZHS decreased duodenum villi width and increased both jejunum villi height and villi height:crypt depth relative to 0CZHS (P < 0.01). Feeding CZ improved DMI, reduced rectal temperature, and altered intestinal morphology; changes indicative of improved intestinal barrier function during HS.

Key Words: gut health, heat stress, intestine, zinc

1176 Effect of OmniGen-AF® supplementation to heat stressed cows during late gestation on blood parameters and immune cells of their calves. A. L. Skibiel*[1], J. L. Powell[1], T. F. Fabris[1], Y. M. Torres[1], F. N. Corra[1], J. D. Chapman[2], D. J. McLean[2], D. Kirk[2], G. E. Dahl[1], and J. Laporta[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]Phibro Animal Health Corporation, Quincy, IL.*

Exposure to heat (HT) stress during the dry period negatively impacts cow immune status. Feeding OmniGen-AF® (OG) has been shown to improve the immune status of the HT cow, but the effect on the calf is unknown. We evaluated the effect of OG supplementation pre-calving (56 g/d, for approximately 105 d) to cows under HT (shade) or cooled (CL; shade, fans, soakers) environmental conditions during the dry period (~56 d) on the immune and stress response of their calves. The experimental design was a 2 x 2 factorial with four treatments: CL (n = 4), CLOG (n = 6), HT (n = 6), HTOG (n = 7). Data were analyzed with a one- or two-way ANOVA, d as a repeated measure. At birth, heifers were fed maternal colostrum (5.7 L, two meals the first 24h). Blood samples were collected at 0 h, 24 h, d 10, and d 28 to measure cortisol, haptoglobin, (HPT), and serum amyloid-A (SAA). Hematology parameters and immune cell counts were assessed in the circulation of calves at birth and at 24 h (before and after colostrum feeding). Total cortisol concentrations were elevated at birth, but markedly decreased after feeding colostrum and on d 10 (P < 0.01) for all groups. Calves born to OG fed cows tended to have increased circulating cortisol (P = 0.09). Haptoglobin and SAA levels were higher on d 10 for all groups except for the CL calves (P < 0.01). Calves born to OG fed cows, and those born to HT cows, had higher SAA on d 10 (P < 0.03). White blood cell counts were similar at birth, and increased at 24 h after colostrum feeding except in the calves born to CLOG cows. Red blood cell counts (RBC) were elevated at birth and decreased significantly at 24 h for all groups (P < 0.05), except for the CL calves. Calves born to OG fed cows had more RBC (P < 0.02). Neutrophil counts were similar for all groups at birth and increased, after colostrum feeding, only for the HT and CL calves. Calves born to OG fed cows had more lymphocytes at birth compared to those born to cows not fed OG (P < 0.05). Heifers born to HT cows had fewer lymphocytes compared to CL if they weren't fed OG, but if they were born to HTOG cows their lymphocyte count was similar to the CLOG. In summary, in-utero exposure to heat stress during late-gestation negatively affects the immune and stress responses of the calf ex-utero. OmniGen-AF® supplementation to the dam could potentially benefit the offspring.

Key Words: calves, immunity, OmniGen-AF, stress

1177 Effects of cooling and dietary zinc source on the inflammatory responses to an intra-mammary lipopolysaccharide challenge in lactating Holstein cows during summer. A. P. A. Monteiro*[1], X. Weng[1], J. Guo[1], J. K. Bernard[1], J. DeFrain[2], and S. Tao[1], *[1]University of Georgia, Tifton, [2]Zinpro Corporation, Eden Prairie, MN.*

Milk somatic cell count increases during summer and dietary zinc supplementation has been shown to improve mammary health. The objective was to determine the effect of active cooling and dietary zinc source on an intra-mammary lipopolysaccharide challenge during summer. Twenty lactating multiparous Holstein cows were randomly assigned to one of 4 treatments with a 2 × 2 factorial arrangement (n = 5/treatment), including two environments: cooled (CL) or not cooled (NC), and two sources of Zn: 75 ppm ZnCl, or 35 ppm ZnCl+40 ppm Zn-methionine complex. From d 0 to 84 of the trial, all cows were cooled (fans and misters over the freestall and feeding areas, temperature-humidity index = 73). Starting at d 85, NC cows were deprived of cooling (temperature-humidity index = 78). At d 118, cows received infusions of 10 μg of lipopolysaccharide and saline in the left (LQ) and right (control, CQ) rear quarters, respectively. Rectal temperature was assessed. Individual quarter milk samples were collected at −12, −4, 0, 6, 12, 24, 48, 72, 96, 120, 144, and 168 h relative to infusion and analyzed for composition. Plasma was collected at the same time points (with an additional sample at 3 h) for analyses of lactose and Zn, and complete blood count was performed for samples collected within the first 24 h. Treatments did not affect DMI, whereas milk yield tended to be greater for NC at d 6 than CL cows (environment × d, P < 0.10). CL cows tended to have higher somatic cell score at 96, 120, and 144 h in LQ, and at 24 h in CQ than NC cows (environment × h, P < 0.10). Compared with CL, NC cows had higher rectal temperature at 12 h and tended to have higher at 120 and 144 h (environment × h, P = 0.01). CL cows had higher milk protein percentage in CQ, but lower in LQ ($P \leq$ 0.05) than NC. Relative to CL, NC cows had higher milk urea nitrogen in CQ (P = 0.04). Solids-not-fat percent tended to be higher for CL than NC cows in CQ (P = 0.07). Relative to CL, NC cows had higher plasma lactose at 3 h (environment × h, P = 0.02) and lower plasma Zn at 6 and 12 h (environment × h, P < 0.01). NC cows had a greater reduction in blood neutrophils at 3 h (environment × h, P < 0.01) and lymphocytes at 3 and 6 h (P = 0.05) than CL. Active cooling mitigated the inflammatory responses to an intra-mammary lipopolysaccharide challenge; however, dietary Zn source had no impact.

Key Words: cooling, intra-mammary lipopolysaccharide challenge, zinc

1178 Survey of facility design and heat abatement strategies in progressive Central California dairies. A. H. Souza*[1], E. O. S. Batista[2], B. Gonzales[3], and F. Doricci[4], *[1]Ceva Animal Health, Libourne, France, [2]University of Sao Paulo, Pirassununga, Brazil, [3]Large Animal Veterinary Practitioner-Campestre Dairy, Sao Pedro, Brazil, [4]University of Sao Paulo, Sao Paulo, Brazil.*

An on-farm survey was performed to assess type of facilities and common practices used to mitigate heat stress in progressive Central California dairies. A total of 18 dairies (10 drylot, 8 free-stall herds) classified as in the top quartile in terms of milk production and reproduction performance according to DHIA benchmarking for herds in Central California agreed to participate in the on-farm data collection procedure, which consisted of ~1 h walk through on all facilities in the dairy plus a 20 min interview with herd managers. Data collection and recording were performed by the same trained technician and all herd visits were performed in the morning hours from June to October of 2014. Complete sanitization of clothes and rubber boots used during the visit occurred after all visits and an interval of at least 72 h between visits was respected for biosecurity reasons. All participating dairies purposely chosen to avoid breed-related facility variations milked predominantly (≥ 90% of the cows in the herd) Holstein cows with an average herd size of 1959 lactating cows (range 703 to 5987). In terms of heat abatement strategies, all herds had shade, soakers, and fans in their pre-milking holding areas. Most herds (15) had fans in the holding area positioned to the opposite side of the milking parlor, but 3 of them had fans positioned toward the milking parlor. In addition, 11 herds had functioning under-wash systems in their holding areas. However, only 6 herds had showers, 13 had water troughs, and 7 had rubber-mattress in the return alleys after milking time. Interestingly, only 1 herd had shade provided in the return alleys from milking parlor to all milking pens. Thirteen herds used dry-manure beddings, 3 had compost-manure beddings, and 2 used sand-based bedding systems. Out of the herds that used stalls in the bedding area (9), stall front width averaged 121.3 cm. All herds used head-locks instead of neck-rails in the feeding lane, all had shaded areas for resting in the yard, all had soakers, and only 12 herds had shaded feed-bunks. Interestingly, only 3 herds had fairly clean water troughs in their barns, and most herds should implement more frequent routines to improve water trough cleanness. In conclusion, top performing dairy herds in CA use several strategies to mitigate detrimental effects of heat stress and keep cows comfortable while housed in confined systems.

Key Words: dairy cow, facility design, heat stress

1179 The effect of vaginal temperature on expressed physical activity of lactating Holstein cows following induced estrus. L. Polsky*[1], A. M. L. Madureira[2], E. L. Drago Filho[2], J. L. M. Vasconcelos[2], and R. L. A. Cerri[1], *[1]Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada, [2]Departamento de Produção Animal-FMVZ-UNESP, Botucatu, Brazil.*

The objective of this study was to determine the effect of vaginal temperature on levels of physical activity expressed by lactating Holstein cows following induced estrus. Lactating Holstein cows (n = 641; 41.5 ± 9.4 kg milk/d) were fitted with a leg-mounted pedometer (AfiActII, Afimilk, Israel) resulting in 843 evaluated activity episodes of estrus. Vaginal temperature was monitored using thermometers (Thermochron iButton −40°C thru +85°C), attached to an intravaginal device (CIDR) as part of a timed-AI protocol (CIDR+estradiol benzoate+GnRH-7d-PGF-2d-CIDR out+PGF+ECP-2d-timed AI), which recorded vaginal temperature every 10 min for 3 d. Ambient temperature and relative humidity were monitored using an external thermometer placed in the center of each pen. Milk production and BCS were collected at time of thermometer insertion. All statistical analysis was performed in R and R Studio using GLM and ARM packages. Heat stress was calculated based on the percentage of time the cow spent with a vaginal temperature greater than 39.1°C (HS). The mean HS was 36.8 ± 24.5%, whereas the mean maximum (MaxVT) and minimum (MinVT) vaginal temperatures were 39.7 ± 0.5°C and 38.0 ± 0.8°C, respectively, with an average amplitude (AMP) 1.71 ± 0.9°C. Mean peak activity (PA) at estrus was 237.0 ± 160.0% relative increase. Increasing MaxVT negatively affected mean PA (ODDS = 0.67, $P < 0.01$). PA was significantly affected by parity as multiparous cows expressed lower PA compared to primiparous cows (ODDS = 0.76, $P < 0.01$). MinVT, AMP, and HS had no significant effects on mean PA, but cows displaying greater PA at estrus had greater P/AI compared with lower PA (28% vs. 18%$P < 0.003$). The P/AI at 32 d was significantly reduced by increasing MaxVT (ODDS = 0.67 $P < 0.05$); however HS, MinVT, and AMP did not significantly affect P/AI. Future research should aim to refine variables related to hyperthermia as well as further effects of body temperature on physical activity behaviors such as lying time, bout, rumination, and subsequent effects on estrous expression and pregnancy rates.

Key Words: estrus, heat stress, physical activity

1180 Partial carbon footprint of milk and interaction between enteric methane and nitrous oxide emissions in grazing dairy farms: The case of Costa Rica. M. A. Wattiaux*[1], J. P. Iñamagua-Uyaguari[2], F. Casasola-Coto[3], L. Guerra-Alarcón[4], and A. Jenet[3], *[1]University of Wisconsin-Madison, Madison, [2]Universidad de Cuenca, Cuenca, Ecuador, [3]Centro Agronómico Tropical de Investigación y Enseñanza (CATIE), Turrialba, Costa Rica, [4]Université Laval, Québec, Canada.*

Pasture-based dairy production systems in Costa Rica vary considerably from the tropical coastal areas to the temperate highlands (1600 to 2400 m above sea level). The objective of this study was to identify indicators of on-farm partial carbon footprint (PCFP) of milk among 31 variables describing farm conditions (e.g., altitude, rainfall, temperature), farm structure (e.g., stocking rate, breed), feeding and housing management practices (e.g., concentrate fed, intake from pasture), and pasture management (e.g., fertilization rate, hours in pasture). A second objective was to explore the correlation between methane (CH_4) and nitrous oxide (N_2O) emissions. Farm records and face-to-face survey data from 104 farms of the Dos Pinos cooperative were collected to estimate PCFP based on enteric CH_4 of lactating cows and N_2O from commercial fertilizers applied to grazed pastures (Fertilizer-A), cut-and-carry pastures (Fertilizer-B), and estimated manure N deposited during grazing. The PCFP ranged from 0.378 to 1.054 with CH_4 ranging from 0.310 to 0.692, and N_2O ranging from 0.056 to 0.609 kg CO_2eq./kg of fat-and-protein corrected milk (FPCM). Contribution of enteric CH_4, Fertilizer-A, Fertilizer-B and manure N to PCFP averaged 69.5, 9.2, 0.7 and 20.7%, respectively. Forward regression analysis indicated that the three most important variables explaining the PCFP were (all $P < 0.001$) feed efficiency (FPCM (kg/d)/dry matter intake (kg/d)), which ranged from 0.49 to 1.36 (partial r^2 = 0.52), Fertilizer-A, which ranged from 0 to 1058 kg/ha per year (partial r^2 = 0.16), and estimated dry matter intake from pasture, which ranged from 0 to 15.6 kg/d (partial r^2 = 0.08). Pearson correlation between CH_4 and N_2O emissions was 0.41 ($P < 0.001$). The contribution of CH_4 to PCFP was determined primarily by feed efficiency and estimated dietary dry matter digestibility, whereas the contribution of N_2O to PCFP was determined primarily by Fertilizer-A, feed efficiency, stocking rate (lactating cows per ha), hours of the day that cows were in pasture, and cow N use efficiency (milk N (g/d)/intake N (g/d)). Thus feeding practices had a substantial impact on both CH_4 and N_2O emissions. The relationship between CH_4 and N_2O emission was mediated in part through hours of the day that cows are in pasture, estimates of pasture consumption and pasture digestibility. In some farms PCFP of milk could be reduced readily simply by reducing excess fertilizer application. However, the adoption of management practices aimed at reducing enteric CH_4 may substantially alter pasture

N_2O emission and possibly vice-versa.

Key Words: climate change, greenhouse gases, LCA

1181 WS Effects of dry and wet conditions during the pre-weaning phase on subsequent feedlot performance and carcass composition of beef cattle. G. A. Gatson[*1], B. L. Vander Ley[2], W. D. Busby[3], P. J. Gunn[4], and A. M. Meyer[1], *[1]Division of Animal Sciences, University of Missouri, Columbia, [2]College of Veterinary Medicine, University of Missouri, Columbia, [3]Tri-County Steer Carcass Futurity, Lewis, IA, [4]Department of Animal Science, Iowa State University, Ames.*

The objective of this study was to determine the effects of dry and wet conditions during the pre-weaning phase of beef cattle production on subsequent feedlot performance and carcass characteristics. Steers (n = 7439) and heifers (n = 2380) finished in 16 feedlots in southwestern Iowa through the Tri-County Steer Carcass Futurity Cooperative (Lewis, IA) were used for a retrospective analysis. Cattle originated in the Midwest, were born in February, March, or April, and were slaughtered between 2003 and 2014. Feedlot performance and carcass composition data were obtained for each animal. Palmer Drought Severity Index (PDSI) values were obtained for each animal for the pre-weaning forage growing season on a monthly basis. These values were used to classify conditions as dry (mean PDSI value ≤ -2.00), normal (mean PDSI value > -2.00 and < 2.00), or wet (mean PDSI value ≥ 2.00) for the cool season, warm season, and combined seasons. Mixed models were used to evaluate the effects of dry and wet conditions on subsequent performance. Birth year, feedlot, and sex were included as fixed effects. Average daily gain was greater ($P < 0.03$) for cattle from the dry class than those from the wet class during the cool season and the combined seasons. Cattle from the dry and normal classes for both the cool season and combined seasons had greater ($P < 0.02$) final BW than those from the wet class. During the cool season, HCW was greater ($P < 0.0001$) for the normal class than wet class, although HCW was greater ($P < 0.04$) for the dry class compared with normal and wet during the combined seasons. Calculated yield grade was improved ($P < 0.01$) for the normal class during the cool season compared with the dry and wet classes. For both the warm and combined seasons, the dry class had improved ($P < 0.02$) calculated yield grade compared with normal and wet classes. For the cool season, the dry and normal classes had greater ($P < 0.03$) marbling scores than the wet class. For marbling score in the warm season, the normal and wet classes were greater ($P < 0.02$) than the dry class. In conclusion, this study indicates that both dry and wet conditions during the pre-weaning phase may impact ultimate feedlot performance and carcass composition.

Key Words: carcass, drought, feedlot

1182 Predicting manure volatile solid output of lactating dairy cows. R. Appuhamy[*1], L. Moraes[1], C. Wagner-Riddle[2], D. P. Casper[3], and E. Kebreab[1], *[1]University of California, Davis, Davis, [2]University of Guelph, Guelph, Canada, [3]Dairy Science Department, South Dakota State University, Brookings.*

Organic matter (OM) in livestock manure consisting of biodegradable and non-biodegradable fractions are known as volatile solids (VS). According to Intergovernmental Panel on Climate Change Tier 2 (IPCC-Tier 2) guidelines, methane emissions from manure is determined based on VS. However, only biodegradable OM generates methane. So methane emissions should be based on biodegradable VS (dVS, dVS = VS – lignin). The objective of the study was to develop mathematical models for estimating VS and dVS outputs by lactating dairy cows. Dry matter intake, dietary nutrient contents, milk yield and composition, body weight, and days in milk were used as potential predictor variables. Multicollinearity, model simplicity, and random study effects were taken into account during model development that used 588 VS and dVS measurements (kg/cow/d) from 43 studies. New models and the IPCC-Tier 2 model [VS = {fecal energy (MJ/d) + urinary energy (MJ/d)} × fecal OM/18.45] were evaluated with an independent set of VS and dVS measurements (n = 244) made on Holstein cows in the United States. Dry matter intake (kg/d) and dietary CP and NDF contents (% of DM) were significantly associated ($P < 0.001$) with VS. A model including these variables [VS = 0.364 ± 0.007 × DMI + 0.026 ± 0.004 × NDF– 0.078 ± 0.008 × CP] fitted best to data. When evaluated with independent data, the new model had a root mean square prediction error, as a percentage of average observed value (RMSPE%), of 14.0%. More than 93% of the error was due to random variability of data. Under the assumptions that feed digestibility = 66%, energy intake partitioning to urine = 0.04, and fecal OM = 0.92, the IPCC-Tier 2 model also performed well on independent data and had a RMSPE of 14.5%. A model including DMI, and dietary CP and hemicellulose (HC, HC = NDF– ADF in % of DM) contents as predictor variables fitted best to dVS data [dVS = 0.334 ± 0.007 × DMI + 0.029 ± 0.006 × HC– 0.058 ± 0.008 × CP] and performed well, when evaluated with independent data (RMSPE = 13.9%). The majority of the error (95.7%) was due to random variability of data. The study offers empirical models that can predict VS. and dVS of lactating dairy cows accurately and thereby, could assist in determining methane emissions from manure successfully.

Key Words: dairy cow, manure, prediction model, volatile solid

1183 The effects of vermifiltration on gaseous emissions from dairy lagoon water. *E. Lai*, Y. Zhao, Y. Pan, and F. M. Mitloehner, University of California, Davis, Davis.*

Dairy lagoon water contains high concentrations of nitrogen (N), which has the potential to pollute groundwater and the atmosphere. To reduce N loading of an anaerobic lagoon at a commercial dairy, a pilot project vermifilter was installed, which used earthworms embedded in woodchips to enhance removal of solids and contaminants. The objective was to mitigate nitrogenous gases, greenhouse gases (GHGs), volatile organic compounds (VOCs), and criteria pollutants from lagoon water using this new technology. Specifically, emissions of ammonia (NH_3), nitrous oxide (N_2O), carbon dioxide (CO_2), methane (CH_4), hydrogen sulfide (H_2S), and ethanol (EtOH) were measured using Thermo analyzers (Franklin, MA) that were housed inside a Mobile Agricultural Air Quality Lab. To assess whole filter system performance, emissions were measured from the untreated dairy lagoon water (LAG), as well as from the vermifilter's influent (INF), effluent (EFF), the top (TOP), and bottom (BOT) of the filter. Gases were measured using a flux chamber approach for LAG, INF, and EFF, a triangle wind tunnel for the TOP, and an inlet threaded to the bottom of the filter for BOT. Results for EFF vs. INF showed a 90.2% reduction of NH_3 emissions without increasing emission of N_2O, CO_2, CH_4, H_2S, and EtOH from the rest of the vermifilter's system. The vermifilter's ability to reduce nutrient loading and subsequent NH_3 emissions without producing other detrimental gaseous emissions needs to be replicated across more dairy operations. However, this new technology has the potential to be a viable candidate for nitrogen removal particularly in regions like the San Joaquin Valley of California, where dairy air and water quality issues are most sensitive.

Key Words: dairy wastewater, emissions, nitrogen

1184 Trends in milk urea nitrogen, milk composition, and milk yield in dairy farms in the Northeast U.S. A. N. Hristov[*1], M. T. Harper[1], J. Oh[1], F. Giallongo[1], J. C. Lopes[1], G. Cudoc[2], J. Clay[3], and L. E. Chase[4], *[1]The Pennsylvania State University, University Park, [2]Dairy One Coop., Inc., Ithaca, NY, [3]Dairy Records Management Systems, Raleigh, NC, [4]Cornell University, Ithaca, NY.*

The main objective of this survey was to examine trends in milk urea nitrogen (MUN) in DHI herds (all dairy cattle breeds were included) in the Northeast U.S. Data for milk fat and true protein concentrations, milk yield, days in milk (DIM) on test day, and lactation number of the cows were also collected. Close to 11 million historical (2004 to 2015) records from the Dairy Records Management Systems (Raleigh, NC) for 14 states (CT, DE, MA, MD, ME, NC, NH, NJ, NY, PA, RI, VA, VT, and WV) were included in the analysis. Average (across states and years) MUN, milk fat, milk true protein, milk yield, DIM, and lactation number were (mean and SD): 13.3 (0.65) mg/dL, 3.85 (0.07)%, 3.13 (0.04)%, 31.6 (0.86) kg/d, 178 (19.2) d, and 2.3 (0.04) lactations. MUN was 13.3 mg/dL in 2004, decreased to 12.4–12.6 mg/dL in 2009–10, steadily increased to 14.6 mg/dL by 2013, and then decreased to 13.0 and 12.4 mg/dL in 2014 and 2015, respectively. Milk fat concentration steadily increased from 3.69 in 2004 to 3.92–3.93% in 2013–14 and decreased to 3.87% in 2015. Milk true protein was 3.01% in 2004, increased to 3.15–3.16% in 2008–09 and declined to 3.13–3.11% thereafter. Except for 2004 (33.5 kg/d), milk yield steadily increased from 30.7 in 2005 to 32.3–32.8 kg/d in 2014–15. The likely explanation for the higher average milk yield in 2004 was the lower average test day DIM (119 d) in that year vs. all other years (184 d, SD = 4.3). In an effort to explain the observed trends in MUN, we investigated variability in dairy feed cost in PA and the U.S. (Northeast data were not available). Average dairy feed cost in PA (for a cow producing 29.5 kg milk/d) increased from $3.08 in 2005 to $5.22 in 2008, declined to $4.01 by 2010, increased again to $6.03 in 2012, and then declined to $5.07/d in 2015. Dairy feed cost for the U.S. followed similar trends. It was apparent that high MUN coincided with high feed cost and vice versa. Therefore, our conclusion from this survey was that MUN in Northeast dairy herds fluctuated following trends in feed cost; however, ration data are not available to better define the reasons for the variations in MUN levels.

Key Words: dairy cow, milk composition, milk urea nitrogen, northeast U.S.

1185 Effect of time and storage conditions on cow urine pH. M. C. Lewis*, S. A. Armstrong, J. P. Jarrett, and D. J. McLean, *Phibro Animal Health Corporation, Quincy, IL.*

Analysis of bovine urine pH is a common practice for dairy professionals wishing to evaluate the efficacy of a negative dietary cation anion difference (DCAD) diet in pre-fresh transitional dairy cows. However, immediate measurement of urine pH on collection is not always possible in an on-farm setting, and information regarding how storage conditions and time impact changes in urine pH is not available. The objective of this study was to analyze the effect of various storage conditions over time on the urine pH of dairy cows fed a fully-acidified and non-acidified diet. This information will be used to advise professionals on the best method of urine storage to consistently obtain accurate urine pH values. Urine from three randomly selected Jersey cows was collected and an initial time zero pH reading was taken with a pre-calibrated Milwaukee portable pH meter, model MW101. Samples were aliquoted and assigned for either 2, 4, 6, and 24 h of storage in triplicate, then placed at 4°C, 20°C, 37°C, and field conditions at temperatures ranging from 0.5°C to 7°C and 81% to 100%

humidity. Urine pH was measured at the indicated storage time intervals. Study one (S1) measured sampled urine from cows on a fully acidified diet, while study two (S2) measured sampled urine from cows without diet acidification. Data were analyzed as change in pH units from the pH value at initial collection (time = 0), using two way ANOVA procedure in graph pad Prism 6.03 with storage method and time as fixed effects. Significance was declared at $P < 0.05$. The urine pH values from the fully-acidified cows had a significant storage effect ($P < 0.0001$) as well as a significant time effect ($P < 0.0001$) while the interaction of storage and time was not significant. Urine pH values were not different across time when collected from non-acidified cows, however storage temperature conditions did significantly change sample pH values ($P < 0.0001$), and the interaction between time and storage was significant ($P < 0.0001$). Diet acidification influenced urine pH values for all storage methods ($P < 0.05$). In cows fed both fully-acidified and non-acidified diets, urine stored at a temperature closest to the animal's normal internal temperature of 38.5°C had the least amount of change in pH units from initial collection, indicating that keeping samples at 37°C or 20°C produces significantly less pH variation than at cooler temperatures.

Key Words: dairy cows, dietary cation anion difference, urine pH

1186 Farm gate environmental impacts of beef production in the Northern Plains and Midwest regions of the U.S. S. Asem-Hiablie, C. A. Rotz*, and R. C. Stout, *USDA-ARS Pasture Systems and Watershed Management Research Unit, University Park, PA.*

Cradle-to-farm gate environmental impacts of beef production in two cattle producing regions were assessed as part of an ongoing national sustainability study of the U.S. beef value chain launched by the Beef Checkoff. Region-specific data on common ranch and feedlot management practices were characterized from producer surveys and site visits in each of the 10 states within the Midwest and Northern Plains regions. This management information was used along with appropriate climate and soil data to simulate representative operations and predict environmental impacts with the Integrated Farm System Model (IFSM). The representative ranch and feedlot operations were then linked to form full production systems in each region. Weighted averages of the environmental footprints for the regions were determined using animal distribution data from both the producer survey and the National Agricultural Statistics Service. Preliminary results gave footprints of total carbon emission, reactive nitrogen loss, and energy and non-precipitation water use for the two regions as 19.7 ± 1.5 kg CO_{2e}, 158 ± 12.9 g N, 48 ± 4.3 MJ, and 1106 ± 154 L per kilogram of carcass weight produced, respectively. The carbon and reactive nitrogen footprints were greater in the Midwest than the Northern Plains, but water use was greater in the Northern Plains. These farm-gate results will be linked with post-farm gate impacts for each of seven study regions to provide the basis for a full national life cycle assessment of beef production and consumption.

Key Words: beef production, environmental footprint, sustainability

118 Effect of temperature on ammonia emissions from feedlot cattle manure. K. M. Koenig* and S. M. McGinn*, Agriculture and Agri-Food Canada, Lethbridge Research and Development Centre, Lethbridge, Canada.*

Livestock feeding operations are the largest contributor to anthropogenic ammonia emissions affecting air quality and terrestrial and aquatic ecosystems. Ammonia emissions are highly temperature dependent and can be expected to vary through the production cycle from the major cattle producing regions of Western Canada that experience environmental extremes of cold winters and hot, dry summers. A study was conducted to simulate and quantify the effects of temperature on ammonia emissions from manure of feedlot cattle. Fresh feces and urine were collected separately for 24 h from eight beef heifers fed high concentrate, barley grain-based diets (14.8% CP). Urine was collected using bladder catheters into collection vessels submerged in an ice-slurry. Feces and urine were each pooled, sampled for chemical composition, divided into subsamples, and frozen. Feces and urine were thawed, equilibrated to treatment temperatures, combined to constitute manure (1:1 wt/wt wet basis), and ~2.25 kg of the manure were incubated in each of four open flow-through chambers. Chambers were housed within a walk-in controlled environment room with a fresh air exchange rate to prevent build-up of gases. Air flow through the chambers was 1.5 m/s and was subsampled by pumping 200 mL/min through sorbent tubes fitted on the inlet and exhaust ports at 24, 48, 72, and 96 h at temperatures of 5, 10, 15, 20, and 25°C. Flux and cumulative NH_3–N emissions were analyzed with a mixed model with experimental temperature as a fixed effect and chamber as a random effect and the experimental unit. Orthogonal contrasts were applied to determine linear and quadratic effects of temperature on emissions. Manure contained 17.6% DM and 1.12% N (as-is basis) of which 54.2% was urea-N. Increasing the temperature from 5 to 25°C increased the NH_3–N flux (g N/m^2) and cumulative emissions (g N/96 h, % of total N, and % of urea-N; linear and quadratic, $P < 0.001$). Cumulative NH_3–N emissions expressed as a percentage of total manure N for the 96-h incubations were 6.3, 21.2, and 30.8% at temperatures of 5, 15, and 25°C, respectively. Cumulative NH_3–N emissions expressed as a percentage of manure urea-N were 20.3, 38.3, and 58.7% for 5, 15, and 25°C, respectively. Temperature had a marked effect on volatilization of NH_3–N from feedlot manure and was reduced by 75% as temperature decreased from 15 to 5°C and increased

by 50% as temperature increased from 15 to 25°C.

Key Words: ammonia emissions, feedlot cattle, temperature

1188 A novel method for collecting gas produced from the in vitro ANKOM gas production system.

P. S. Alvarez Hess*[1], P. Giraldo[1], R. O. Williams[2], P. J. Moate[2], K. A. Beauchemin[3], and R. J. Eckard[1,2], *[1]The University of Melbourne, Faculty of Veterinary and Agricultural Sciences, Melbourne, Australia, [2]The Department of Economic Development, Jobs, Transport and Resources Ellinbank Research Centre, Ellinbank, Australia, [3]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, Canada.*

Enteric methane produced by ruminants is a source of greenhouse gas emissions. One method for investigating methane production from ruminants is the in vitro method which when compared with in vivo methods is faster and less expensive. The ANKOM™ system is an in vitro system that periodically releases excess gas during the incubation to prevent it from diffusing into the medium. For this reason, a gas sample taken from the module's headspace at the conclusion of the incubation period may not be representative of the gas produced during the entire fermentation period. This study tested two methods that enable the collection of released gases. Yeast and sugar were incubated for 24 h in 310 mL ANKOM™ bottles equipped with an ANKOM module to regulate headspace pressure through ventilation. Incubations were made with three different methods: vented gas not collected (NC); vented gas collected in gas bags through a 304 cm gas sample line with an internal diameter (ID) of 1.0 mm (C304); and vented gas collected in gas bags through a 22 cm extension tube with an ID of 4.0 mm (C22). Each method was conducted using four different venting pressures (0.4, 0.6, 0.8, and 1.0 psi). When total gas production was calculated from absolute pressure measurements made by the pressure transducer in the ANKOM module, the mean of total gas production (ml) for the C304 method was significantly ($P < 0.05$) greater (125.3 ± 1.9) than either the C22 method (114 ± 1.9) or the NC method (115 ± 1.7), while the C22 method was not different from the NC method. There was no effect of venting pressure across treatments on estimated total gas production. It is concluded that the C22 method for collecting gas can be used in gas production studies with the ANKOM system as it does not interfere with measurement of gas production.

Key Words: enteric methane, gas collection technique, in vitro gas production

1189 Effect of forage source of dairy cow diets on methane emission from enteric fermentation and manure storage.

F. Hassanat* and C. Benchaar, *Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, Canada.*

The aim of this study was to determine the effect of corn silage (CS), barley silage (BS), alfalfa silage (AS), and timothy silage (TS) on CH_4 emissions from enteric fermentation and manure storage of dairy cows. For this purpose, 3 experiments (9 cows; replicated 3 × 3 Latin square design; 32-d periods) were conducted. Forages included at 60% of diet DM were, in study 1: 100% CS (0% AS), 100% AS (0% CS), and 50:50 mix CS:AS; in study 2: 100% CS (0% BS), 100% BS (0% CS), and 50:50 mix CS:BS; and study 3: 100% AS (0% TS), 100% TS (0% AS), and 50:50 mix AS:TS. Cows were fed for ad libitum intake and enteric CH_4 emission was determined (3 d) using respiration chambers. Manure excretion was measured over 5 d. Manure CH_4 emissions were estimated using the Eq. [10].23 of the IPCC (2006). Total CH_4 emissions are the sum of enteric and manure CH_4 emissions. Data were analyzed using the MIXED procedure (SAS) and differences between treatments were declared significant at $P \leq 0.05$ using the Tukey multiple comparison test. Overall, 72% of total CH_4 emission was from enteric source and 28% was from manure storage. In study 1, enteric CH_4 emissions (17.7 vs. 20.5 g/kg DMI) and manure CH_4 emissions (6.78 vs. 7.50 g/kg DMI) were lower in cows fed 100% CS compared to cows fed 100% AS or 50:50 mix CS:AS. Consequently, total CH_4 emissions were also lower in cows fed 100% CS compared to cows fed 100% AS or 50:50 mix CS:AS (24.4 vs. 28.0 g/kg DMI). Similarly, in study 2, enteric (19.1 vs. 22.1 g/kg DMI), manure (7.59 vs. 9.04 g/kg DMI) and total (26.7 vs. 31.1 g/kg DMI) CH_4 emissions decreased in cows fed 100% CS compared to cows fed 100% BS or 50:50 mix CS:BS. In study 3, no treatment effect was observed on enteric CH_4 (19.8 g/kg DMI), manure CH_4 (7.16 g/kg DMI), and total (27.0 g/kg DMI) emissions. Results of this study show that replacing AS or BS with CS in dairy cow diets is expected to lower total CH_4 emissions (g/kg DMI) because of reduced enteric and manure CH_4 emissions. However, no effect on CH_4 emissions (enteric, manure, and total) can be expected by replacing TS with AS in dairy cow diets.

Key Words: enteric/manure, forage, methane

1190 Intake, milk production, and methane emission of dairy cows fed diets that differ in ruminal in vitro NDF digestibility. *M. J. Aguerre*[*1], M. J. Powell[2], A. R. Pelletier[1], and M. A. Wattiaux[1], [1]University of Wisconsin-Madison, Madison, [2]USDA-ARS, US Dairy Forage Research Center, Madison, WI.*

The objective of this study was to determine how feeding diets that differed in dietary ruminal in vitro NDF digestibility (IVNDFD) affected DMI, milk production, and CH_4 emission from lactating dairy cows. Twenty four multiparous Holstein cows (mean ± SD; 717 ± 67 kg of BW; 160 ± 49 d in milk) were randomly assigned to four dietary treatments in a randomized complete block design study. Four levels of dietary IVNDFD (digestibility determine after 30 h of incubation) were achieved by substituting corn stover (15% of dietary DM) with alkaline-treated corn stover (at 7.0% $Ca(OH)_2$ of stover DM; stover DM was 50%) in stepwise increments (0, 5, 10, and 15% of dietary DM). Following a 2-wk covariate adjustment period, cows were assigned to dietary treatments for 6 wk. Cows were fed a total mixed ration with (DM basis) 55% forage, 45% concentrate, 16.6% crude protein, 28.7% NDF, and 23.7% starch once daily. Replacing untreated corn stover with 5, 10, and 15% treated corn stover increased dietary IVNDFD by 2.2, 4.3, and 6.2% units, respectively. Performance and CH_4 emission measurements were conducted in four tie-stall emission chambers during three consecutive days the last week of the covariate and experimental periods. Treatment effects are presented as covariate-adjusted least squares means (± SEM). Increasing IVNDFD in the diet had no effect on DMI (21.3 ± 1.3 kg/d), milk yield (32.1 ± 2.2 kg/d), fat-and-protein corrected milk yield (FPCM; 29.9 ± 2.3 kg/d), FPCM/DMI (1.42 ± 0.1), CH_4 emission (524 ± 35 kg/d), and CH_4/FPCM (18.4 g/kg ± 1.7). However, with increasing levels of IVNDFD in the diet there was a linear decrease ($P = 0.02$) in CH_4/DMI from 26.4 to 23.3 (g/kg) and a tendency ($P = 0.06$) to reduce CH_4/milk from 18.8 to 14.4 (g/kg). Also, a tendency ($P = 0.08$) for a quadratic response was observed for CH_4/milk; increasing dietary IVNDFD by 2.2 and 6.2% units decreased CH_4/milk to 17.7 and 14.4 g/kg respectively, compared with 15% untreated corn stover diet (18.8 g/kg), but a 4.4% increase on IVNDFD resulted in the highest yield of CH_4/milk (20.0 g/kg). Under the conditions of this study increasing IVNDFD in the diet by as much as 6.2% units had little impact on performance or emission of CH_4 (g/d), but decrease CH_4 emission per unit of DMI by 12% and decreased CH_4 emission per unit milk by 23%.

Key Words: dairy, forage, greenhouse

1191 Life cycle energy and greenhouse gas comparison of co-located organic and conventional dairy systems. B. J. Heins*, M. Reese, J. Tallaksen, and E. Buchanan, *University of Minnesota West Central Research and Outreach Center, Morris.*

The objective of this study was to directly compare life cycle fossil energy use and greenhouse gas (GHG) emissions in an organic and conventional dairy system at a site that utilizes both systems. The study was conducted at the University of Minnesota's West Central Research and Outreach Center, Morris, MN with SimaPro software. Conveniently, the on-site conventional and organic cropping systems provide comparable feed sourcing data. The life cycle assessment (LCA) is a cradle to gate study, with a functional unit of 1 kg of energy and fat corrected milk (EFCM). In terms of GHG, as measured by equivalents of CO_2, the organic system is greater (1.36 kg CO_2 equivalent per kg EFCM) compared to the conventional system (0.975 kg CO_2 equivalent). The organic dairy had higher emissions (1.3 and 0.0596 kg CO_2 equivalent) for animal maintenance/feeding and milk harvesting compared to the conventional herd (0.94 and 0.0351 kg CO_2 equivalent), respectively. In terms of fossil energy use, the organic system required more of fossil energy (3.47 MJ/kg EFCM) than the conventional system (2.72 MJ/kg EFCM). Fossil energy use for animal/maintenance and milk harvesting was similar for greenhouse gases for the organic system (1.87 and 1.6 MJ) compared to the conventional system (1.78 and 0.941 MJ), respectively. The largest factor influencing these results is the relative productivity of the organic and conventional herd. The organic herd is a pasture based low maintenance system, whereas the conventional herd is a more confinement based system. The conventional herd (20.9 kg/d) had greater milk production compared to the organic herd (12.3 kg/d). Another key difference between these systems is the feed use, which is higher per kg of milk produced in the organic system because of the greater use of pasture and high forage diets. The conventional system is able to use co-products such as DDGS and beet pulp to fulfill dietary requirements. With co-products, GHG and fossil energy impacts are spread between the main product (i.e., ethanol or sugar), resulting in a lower impact feed. It is important to note that this is an ongoing study and that additional data analysis may likely change the findings as the study progresses.

Key Words: greenhouse gas emissions, LCA, organic

1192 Effects of canola meal and soybean meal as protein sources on methane and ammonia emissions of high producing dairy cows.

S. A. E. Moore*[1], K. F. Kalscheur[2], M. J. Aguerre[1], and M. J. Powell[2], [1]*University of Wisconsin-Madison, Madison,* [2]*USDA-ARS, US Dairy Forage Research Center, Madison, WI.*

Manipulating dietary ingredients may effect greenhouse gas emissions by dairy cows. The objective was to determine CH_4 and NH_3 emissions of lactating cows fed canola meal (CM) or soybean meal (SBM) as the main protein source at either a high (HI; 17.6%) or low (LO; 15.4%) CP concentration. Twenty-four multiparous Holstein cows (mean ± SD; 120.5 ± 3.24 DIM; 2.71 ± 0.81 parity) were assigned 1 of 4 treatment diets at calving in a randomized complete block design with a 2 x 2 factorial arrangement of treatments. After wk 16 of lactation, cows were randomly assigned to 1 of 4 air-flow controlled chambers. Cows remained in the chamber for 6 d. Performance and emission data were measured on the last 3 d of each block. Diets were formulated to contain 55.0% forage (39.6% corn silage, 15.4% alfalfa silage) and 45% concentrate on DM basis. CM was included at 19.4% and 11.9% DM and SBM was included at 14.5% and 8.9% DM for the HI and LO diets, respectively. Soyhulls were included to balance nutrients and alter CP concentration. All other ingredients were the same across diets. Data were analyzed using the MIXED procedure of SAS. Cows fed either source or CP concentration of protein did not differ in DMI (mean ± SEM; 26.67 ± 0.75) or 4% fat-corrected milk (FCM; 53.89 ± 2.04 kg/d). Milk yield (59.1 vs. 53.3 ± 2.48 kg/d; $P = 0.095$) and feed efficiency (FCM/DMI; 2.11 vs. 1.95 ± 0.09; $P = 0.082$) tended to be greater for cows consuming HI protein compared to LO protein diets. Milk urea N (MUN) was lower for cows fed LO protein compared to HI protein (9.14 vs. 12.93 mg/dL; $P < 0.001$). There was a source x CP concentration interaction for CH_4 emission. Cows fed HICM produced less CH_4 than those consuming HISBM and LOCM (465.7 vs. 528.5 and 537.9 ± 28.7 g/d; $P = 0.036$). CH_4 expressed per unit of DMI (19.3 ± 1.24) or FCM (9.23 ± 0.71) did not differ among treatments. NH_3 tended to be higher for cows fed HI protein compared to LO protein (29.5 vs. 24.6 ± 2.31 g/d; $P = 0.062$). Milk N (g/d) and NH_3 emission expressed per unit of milk N was not affected by diet. NH_3 tends to increase with added protein inclusion in the diet and CM may reduce methane under specific feeding strategies.

Key Words: canola meal, greenhouse gas, methane

1193 Optimizing nitrogen efficiency on commercial dairy farms: Impact on production performance and herd profitability.

L. Fadul-Pacheco*[1], D. Pellerin[1], P. Y. Chouinard[1], M. A. Wattiaux[2], and E. Charbonneau[2], [1]*Département des sciences animales, Université Laval, Québec, Canada,* [2]*University of Wisconsin-Madison, Madison.*

Nitrogen efficiency (milk N/dietary N; NE) can be used as a tool for the environmental management of dairy herds. The aim of this study was to identify factors affecting NE and assess its impact on herd profitability. One hundred dairy herds comprising 17 to 117 lactating cows and located in the province of Québec, Canada were visited from October 2015 to June 2016. Feed intake was measured over 24 h. Samples of each feedstuff were taken and sent to a commercial laboratory for analysis of chemical composition. Particle size distribution of silages and total mixed ration was determined using the Penn State Particle Separator. Feeding management and feed prices were recorded. Milk yield was recorded and milk samples were collected over two consecutive milkings. Fat, protein, lactose, and milk urea nitrogen (MUN) were analyzed. Farms were divided according to their NE as low NE (L-NE) and high NE (H-NE) by the 25th and 75th percentiles, respectively. Differences between these groups were analyzed with the GLIMMIX procedure of SAS. Metabolizable protein (MP supply–MP requirements) and rumen degradable N (RDP supply–RDP requirement) balances were calculated according to NRC (2001). Income over feed cost was also calculated. Milk production was higher for H-NE than for L-NE (32.5 vs. 29.4 kg/d; $P < 0.001$) whereas MUN was lower for H-NE (11.1 vs. 12.8 mg/dL; $P < 0.01$). Herds with H-NE received diets with higher non-fiber carbohydrate (NFC; 41.1 vs. 37.3; $P < 0.01$), physically effective NDF (6.9 vs. 3.7; $P < 0.05$) and TDN (74.0 vs. 71.0; $P < 0.01$), and lower CP (11.1 vs. 12.8; $P < 0.01$), NDF (36.5 vs. 40.0; $P < 0.001$), lignin (3.0 vs. 4.0; $P < 0.001$) and soluble protein (4.6 vs. 5.3; $P < 0.05$) than herds with L-NE. Metabolizable protein and RDP balances were lower for H-NE than L-NE (−320 vs. 206 g/d; $P < 0.001$ and 314 vs. 525 g/d; $P < 0.001$, respectively). Furthermore, the negative MP balance for H-NE herds indicates that NRC (2001) may have overestimated the MP requirements for this group. Finally, income over feed cost was higher for H-NE (0.56 vs. 0.50 $/kg; $P < 0.001$). In conclusion, herds with H-NE had lower MUN and less CP, but higher NFC contents in the diet, which suggest a greater energy availability allowing a better efficiency of N utilization. This strategy was shown to be economically profitable.

Key Words: lactating dairy cows, milk urea nitrogen, nitrogen efficiency

1194 Including corn in crop rotations is profitable for dairy farms and does not result in greater greenhouse gas emissions at the whole-farm level. V. Ouellet*[1], D. Pellerin[1], M. Chantigny[2], and E. Charbonneau[1], [1]*Département des sciences animales, Université Laval, Quebec, Canada,* [2]*Soils and Crops Research and Development Centre, Agriculture and Agri-Food Canada, Quebec, Canada,*

Corn silage is recognized as a palatable and digestible source of energy for dairy cows. On the other hand, corn silage production is widely criticized as it may carry more environmental risks than perennial forages. Our objective was to use the whole-farm model N-CyCLES to assess the effect of different crop rotations with varied levels of environmental risks on dairy farm profits, N and P balance, and greenhouse gas emissions, while optimizing the management practices required to achieve maximum profits. Adaptations made to the model included modification to rotations, adjustment in the optimization constraints, evaluation of crop production cost, evaluation of forage nutritive value, and update in fertilization requirements. Data representative of an average dairy farm from Centre-du-Quebec region in Quebec, Canada were used. Four crop rotation scenarios considered to have different environmental impact were built in the model, and compared: corn grain-soybean-corn silage-alfalfa-alfalfa (very high negative impact, +++); corn grain-soybean-corn silage-alfalfa/timothy-alfalfa/timothy-alfalfa/timothy (moderate negative impact, ++); cereal-alfalfa/timothy-alfalfa/timothy-alfalfa/timothy-naked oats (low negative, +); cereal-alfalfa/timothy-alfalfa/timothy-alfalfa/timothy-alfalfa/timothy-mixed grains (positive impact,-). Results showed that the highest dairy farm profits (0.12 $/kg of FPCM) were associated with the (++) rotation, whereas the lowest profits (0.05 $/kg of FPCM) were associated with the (-) rotation. The lowest farm-gate to farm-gate greenhouse gas emission allocated to milk production (0.98 CO_2 eq./kg of FPCM) was predicted for the (+++) rotation, whereas the highest value (1.03 CO_2 eq./kg of FPCM) was predicted for the (-) rotation. This result is mainly explained by the lack of cash crop sold and the lower NFC and higher N content in cow's diet for the farm with (-) rotation. The highest N and P balances (20.1 g/kg of FPCM and 1.185 g/kg of FPCM, respectively) were predicted for the (-) rotation since more corn grain was bought (156.5 t/yr) to compensate for the absence of corn grain and corn silage produced on the farm. Moreover, the lowest N and P balances (12.8 g/kg of FPCM, 0.465 g/kg of FPCM) were predicted for the (++) rotation. These results suggested that including corn silage in the crop rotation do not carry a greater environmental risk on the considered output than crop rotations without corn and that growing corn silage is profitable when the whole farm is considered as a single unit of decision. Sound practices still need to be developed to improve other environmental considerations such as soil structure and erosion.

Key Words: corn silage, crop rotation, whole-farm model

1195 Effect of baling or grazing of corn residue on the subsequent crop yields. K. M. Ulmer*[1], J. L. Cox[1], M. K. Rakkar[1], R. G. Bondurant[1], M. E. Drewnoski[1], J. C. MacDonald[1], H. Blanco-Canqui[2], and R. J. Rasby[1], [1]*University of Nebraska, Lincoln,* [2]*Department of Agronomy and Horticulture, University of Nebraska, Lincoln.*

The amount of corn residue in the Midwest has increased with the increased corn production. Producers have utilized this resource as a feedstuff for cattle for grazing in the fall and winter and as a baled feed resource for future feeding. The objective of this 2 yr study was to determine how grazing or baling of corn residue affects subsequent grain yield and harvest index in multiple regions across Nebraska. In year 1, there were three locations and in year 2, an additional two locations were added. At each location, there were 3 treatments: grazed (GZD), baled (BLD), and no graze-no bale (NGNB) with 2–3 reps per treatment per location. Hand harvest yield estimates were collected once the corn reached black layer stage of maturity. Corn plants were cut from 5.33 m rows (3 rows per rep), corn grain was removed, then the grain and remaining plant material were weighed separately and subsequently subsampled for dry matter analysis (60°C). Dry matter measurements from the grain and stover were used to calculate corn yield and stover (total biomass minus the grain) per ha. Harvest index was calculated based on the percentage of dry grain out of total biomass (grain plus stover). Data were analyzed using the MIXED procedure of SAS with yield, location (nested within year), and treatment as fixed effects. There were no interactions ($P \geq 0.15$) between location and treatment for all analyses, but location was significant ($P \leq 0.01$). No differences were observed among treatments for grain yield ($P = 0.137$) with BLD having yields of 14,918 kg grain DM/ha, GZD with 14,689 kg grain DM/ha and NGNB with 13,682 kg grain DM/ha (SEM = 306). Across location, grain yields ranged from 11,981 to 17,085 kg DM/ha across locations. There was no difference ($P = 0.87$) in stover yield among treatments (8974, 9137, and 8743 ± 237 kg/ha stover DM for BLD, GZD, and NGNB, respectively). Stover yield ranged from 7649 to 11,562 kg DM/ha across locations. There was no difference ($P > 0.40$) in harvest index among treatments (62.2, 61.5 and 61.0 ± 0.57% for BLD, GZD, and NGNB, respectively). Harvest index ranged from 55.1 to 63.0% across locations. Results indicate that in the short term, removing corn residue provides a potential feed resource with no negative impact on grain yield or harvest index.

Key Words: baling, corn residue, crop yields, grazing

1196 Use of a novel continuous culture fermentor system for in vitro determination of enteric methane output from ruminants. A. I. Roca-Fernandez*, S. L. Dillard, M. D. Rubano, R. J. Tillmann, and K. J. Soder, *USDA-Agricultural Research Service, University Park, PA.*

Continuous culture fermentor systems (CCFS) serve to evaluate the effect of diet on in vitro nutrient digestibility, fermentation, and microbial protein synthesis. Limitations of CCFS are: maintaining protozoa populations, and avoiding accumulation of undigested material in the vessels. Therefore, a 4-unit, 3-L bioreactor CCFS (Applikon Biotechnology Inc., Foster City, CA) was adapted to determine pH, DM, protozoa numbers, and enteric CH_4 output of a forage diet. Each unit was fed 82 g DM/d of 50% orchardgrass (*Dactylis glomerata*) + 50% alfalfa (*Medicago sativa*) in equal portions, 4 times daily (07:30, 10:30, 14:00, and 19:00 h) throughout 10-d periods ($n = 4$, 7 d adaptation and 3 d collection). The CCFS was programmed to maintain temperature = 39°C, stirrer = 255 rpm, and CO_2 flux = 1 mL/min. Temperature and pH were recorded every 2 min. On d 1 of each period, 1500 mL of rumen fluid + 32 g of digesta were collected from a fistulated cow and added to each fermentor. Vat volume was maintained at 1500 ± 200 mL during the 10 d. Solid mean retention time, solid dilution rate, and liquid dilution rate were adjusted daily to 24 h, 4%/h, and 11%/h, respectively, by regulation of buffer input and effluent removal. Effluent and fermentation vats were sampled daily to determine protozoa numbers and DM. Gas samples for CH_4 analysis were collected 6 times daily (07:25, 09:00, 10:00, 13:55, 15:30, 16:30 h) during the 3-d collection periods and analyzed by GC (Varian CP 3800, Agilent Technologies, Santa Clara, CA). Data were analyzed using PROC GLIMMIX (SAS Inst. Inc., Cary, NC). There were no differences ($P \geq 0.067$) in total buffer and effluent volume, effluent DM, and CH_4 output between periods or among days within a collection period. There were no differences in pH or vat DM ($P \geq 0.445$) between periods. However, pH was greater ($P < 0.001$) on d 10 than d 8 or d 9 (6.51, 6.43, and 6.45, respectively). Preliminary results show fewer ($P < 0.001$) protozoa during the adaptation vs. collection period ($11.5 \pm 2.82 \times 10^4$ and $34.0 \pm 3.95 \times 10^4$ cells/ml, respectively). There was no difference ($P = 0.786$) in protozoa during the 3 d of the collection period ($34.0 \pm 2.25 \times 10^4$cells/ml). This CCFS not only provides a stable fermentation environment, but also preserves protozoal populations, which better simulates in vivo ruminal fermentation conditions compared with previous CCFS methods.

Key Words: continuous culture fermentor, methane, ruminants

1197 Effect of introducing legumes containing condensed tannins in an orchardgrass diet on forage nutritive value and enteric methane output in continuous culture. A. I. Roca-Fernandez*, S. L. Dillard, M. D. Rubano, C. J. Dell, and K. J. Soder, *USDA-Agricultural Research Service, University Park, PA.*

Legumes containing condensed tannins (CT) have been shown to reduce enteric CH_4 in ruminants; however, research is lacking on how increased CT levels affect forage nutritive value and CH_4 output. A 4-unit, dual-flow continuous culture fermentor system was used to assess CH_4 output of CT legumes in an orchardgrass diet (*Dactylis glomerata*). Treatments included: alfalfa (ALF, *Medicago sativa*) used as control, birdsfoot trefoil (BFT, *Lotus corniculatus*) as a low CT legume (7% CT, DM basis), crown vetch (CV, *Coronilla varia*) as an intermediate CT legume (12% CT, DM basis), and sericea lespedeza (SL, *Lespedeza cuneata*) as a high CT legume (31% CT, DM basis). Treatments were randomly assigned to fermentors in a 4 × 4 Latin square design using 7 d for adaptation and 3 d for collection. Feedings (82 g DM/d) occurred 4 times daily (07:30, 10:30, 14:00, and 19:00 h) throughout 4, 10-d periods. Treatments consisted of 50% orchardgrass and 50% legume. Forage samples were analyzed for DM, OM, CP, soluble and degradable protein, fiber, lignin, and NE_L. Gas samples for CH_4 analysis were collected 6 times daily (07:25, 09:00, 10:00, 13:55, 15:30, 16:30 h) during the last 3 d of each period and analyzed by GC (Varian CP 3800, Agilent Technologies, Santa Clara, CA). Methane data were analyzed using the GLIMMIX procedure of SAS (SAS Inst. Inc., Cary, NC) with treatment and period as fixed effects and fermentor as random effect. Pearson correlation coefficients between CH_4 output and forage characteristics were determined using PROC CORR, and stepwise linear regression analysis was conducted according to PROC REG to detect predictive statistical associations between CH_4 output and forage characteristics. Methane output of SL was 60, 68, and 73% less ($P < 0.012$) compared to CV, BFT, and ALF, respectively. Crown vetch reduced ($P < 0.025$) CH_4 output by 33% compared to ALF. There were no differences ($P > 0.200$) in CH_4 output between BFT and ALF or BFT and CV. Correlation analysis revealed a positive relationship between CH_4 output and degradable protein ($r = 0.630$, $P = 0.009$). An inverse relationship was found between CH_4 output and OM ($r = -0.520$, $P = 0.039$). Stepwise regression analysis revealed that degradable protein explained 40% of the variation in CH_4 output across all CT legumes. In summary, inclusion of legumes containing CT reduces CH_4 output and was affected by nutrient content of the forage.

Key Words: condensed tannins, enteric methane, legumes

1198 Effect of summer annuals on ruminal fermentation and methane output in continuous culture. *S. L. Dillard*[*1], *A. I. Roca-Fernandez*[1], *A. N. Hafla*[1], *M. D. Rubano*[1], *A. F. Brito*[2], *and K. J. Soder*[1], [1]*USDA-Agricultural Research Service, University Park, PA,* [2]*University of New Hampshire, Durham.*

Summer annuals (SA) provide forage during the summer "forage slump", yet research on ruminal fermentation and CH_4 output of SA is lacking. A 4-unit, dual-flow continuous culture fermentor system was used to assess nutrient digestibility, VFA production, bacterial protein synthesis, and CH_4 output of SA. Treatments were randomly assigned to fermentors in a 4 × 4 Latin square design using 7 d for adaptation and 3 d for collection. Treatments were: 1) 100% orchardgrass (*Dactylis glomerata*) herbage (HERB), 2) 50% herbage + 50% Japanese millet (*Echinochloa esculenta*; MIL), 3) 50% herbage + 50% sorghum × sudangrass (*Sorghum bicolor* × *S. bicolor var. sudanense*; SSG), and 4) 50% herbage + 25% MIL + 25% SSG (MIX). Feedings (60 g DM/d) occurred 4 times throughout four, 10-d periods; fermentors were fed orchardgrass herbage at 730 and 1030 h. At 1400 and 1900 h, SA treatments received SA supplements while HERB received orchardgrass. Samples for CH_4 were collected 6 times daily (725, 0900, 1000, 1355, 1530, 1630 h) during d 8, 9, and 10; samples for NH_3–N, VFA, and pH were taken on d 8, 9, and 10. Samples were also analyzed for DM, OM, CP, and fiber fractions for determination of nutrient digestibility, and estimation of bacterial protein synthesis. Data were analyzed using MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). Apparent DM, NDF, and ADF, and true DM digestibilities were not different ($P > 0.062$) among treatments. True OM and CP digestibilities, and apparent OM digestibility, were not different ($P > 0.084$; 76 ± 2.3, 93 ± 2.4, and 66 ± 2.6%, respectively) among treatments. Total N intake was not different ($P = 0.389$) among treatments (2.3 ± 0.01 g N/d), but bacterial N was greater ($P = 0.013$) in MIL and MIX than HERB (0.33, 0.34, and 0.25 ± 0.020 g N/d). There was no difference ($P = 0.296$) in total VFA concentration among treatments (57.5 ± 1.16 mmol/L). There was no difference ($P > 0.178$) in daily CH_4 output (6.7 ± 2.14 mmol/d) or CH_4 per gram OM fed (1.9 ± 0.62 mg CH_4/g of OM fed). Addition of SA to an herbage-based diet provided similar nutrient digestibility, VFA production, and CH_4 output as HERB, suggesting SA would produce similar animal performance to that of HERB.

Key Words: methane, pasture, summer annuals

1199 Analysis and review of publicly available GreenFeed results. S. Zimmerman* and P. R. Zimmerman, *C-lock, Inc., Rapid City, SD.*

The GreenFeed is a novel tool for measurement of enteric methane (CH_4) from ruminant animals. The GreenFeed method uses repeated short-term measurement of CH_4 emitted from the animal in a feed trough while animals are receiving a feed reward. To date, over 50 papers, conference proceeding, and reports are available that have used GreenFeed. The research covers a wide range of applications including method comparisons, animal genetics and dietary studies, and on-farm use. In many studies, variability and repeatability of the GreenFeed data are reported. The objective of this study was to aggregate the public data, analyze the results for overall accuracy compared to reference methods, summarize variability and repeatability of CH_4 emissions across applications, and to determine the strength of individual animal ranking relationships. Overall, 22 method comparison trails ranging in herd averaged emission from 150–485 g/d have been completed comparing GreenFeed to either the Sulfur Hexafluoride tracer method (SF_6, 11 trials), respiration chambers (9 trials), or model predictions (2 trials). The herd averaged results for the reference method compared to GreenFeed showed no significant slope bias (Reference = 0.99 × *g*reenFeed, $R^2 = 0.99$) and the average absolute mean error for all trails was 6.4%. For individual animal CH_4 emissions, GreenFeed measured CH_4 emissions were positively and moderately-to highly correlated with respiration chamber, SF_6, or modeled CH_4 in all but 4 trials. In the 4 trials with less agreement for individual animals, the number of GreenFeed samples per animal was very low for some animals (4–10 samples) or there was no chamber replication. GreenFeed measured CH_4 for individual animals also showed moderate correlations with DMI in three studies ($r^2 = 0.73$, $r^2 = 0.61$, $r = 0.77$), and in other studies was found to be higher ($r^2 = 0.42$ and $r^2 = 0.47$) than for SF_6 ($r^2 = 0.17$, $r^2 = 0.08$). Between animal variation in GreenFeed CH_4 emissions were found to be the same, or lower than between animal variation in DMI, BW, or Respiration Chambers, or SF_6 in all but one trail. Long term repeatability (R) of GreenFeed CH_4 emissions on forage based diets was $R = 0.70$- 0.88 in 7 different trials. Overall, the GreenFeed method produced similar absolute CH_4emissions estimates to reference methods, demonstrated the ability to rank animals, produced low but accurate between animal variability, and was highly repeatable on forage diets.

Key Words: emissions, GreenFeed, methane

1200 Evaluation of an enteric methane emissions measurement system for cattle. E. M. Andreini*[1,2], M. S. Calvo-Lorenzo[1,3], C. J. Richards[1], J. E. White[1], and S. E. Place[1], [1]*Oklahoma State University, Stillwater,* [2]*University of California, Davis,* [3]*Elanco Animal Health, Fayetteville, AR.*

Growing concern about climate change and sustainability has increased societal pressures toward livestock production to quantify and reduce its environmental impact. Through enteric fermentation, ruminants produce the greenhouse gas methane (CH_4), and to improve emission inventories and evaluate mitigation techniques, several methods (i.e., whole animal and head chambers, SF_6 tracer technique) of measuring emissions have been developed. The objectives of this study were to evaluate a ventilated head box system capable of measuring CH_4 and carbon dioxide (CO_2) emissions, and oxygen (O_2) consumption from cattle and to compare emissions across ad libitum and restricted intake periods. An additional objective was to provide insight to animal comfort while housed in the head box system. Six Holstein heifers (n = 6), initial live weight between 364 and 430 kg, were used to measure CH_4 and CO_2 emissions and O_2 consumption from two ad libitum intake periods (ADAPT and ADLIB) and one period (RESTRICT) with intake restricted to 2% of body weight on a dry matter basis. In the head box system, ambient air was circulated around the animal's head, and expired air was collected. Emissions were determined by calculating the difference in gas concentrations between ambient and expired air. As a measure of comfort in the head box system, all cattle were assessed for lying time, and respiration rates and THI were evaluated for thermal comfort. During ADAPT and ADLIB, DMI in individual pens (10.40 ± 0.41 kg and 11.00 ± 0.41 kg, respectively) was higher ($P < 0.0001$) than DMI during gas measurement (9.20 ± 0.45 kg and 9.80 ± 0.45 kg, respectively). During RESTRICT, DMI in individual pens (8.40 ± 0.44 kg) did not differ ($P > 0.05$) from DMI during gas measurement (8.40 ± 0.45 kg). Methane and CO_2 emissions were lower ($P < 0.05$) during RESTRICT as compared to ADAPT and ADLIB (Table 1, next page). Oxygen consumption rates differed for each period (Table 1). Lying time while in the head box system was similar to lying behaviors of dairy

Table 1200.

Table 1. Least-squares means (n = 6) of heifer emissions and lying time[v] by period for periods ADAPT, ADLIB, and RESTRICT[+].

	Period					
	ADAPT		ADLIB		RESTRICT	
Item	LS mean	SE	LS Mean	SE	LS Mean	SE
CH_4 Production (L/day)	235.00[a]	6.19	228.26[a]	6.18	193.19[b]	8.88
CO_2 Production (L/day)	3627.47[a]	90.72	3632.35[a]	90.47	3183.95[b]	104.79
O_2 Consumption (L/day)	3390.59[a]	99.77	3453.90[b]	99.57	3001.81[c]	111.36
Lying Time (Min/day)	779.17[a]	31.19	768.79[a]	31.19	842.78[a]	31.19

[a, b, c] Least-squares means within row without common superscript letters differ ($P < 0.05$).

[+] For periods ADAPT and ADLIB heifers were fed *ad libitum* feed intake. For period RESTRICT, feed was restricted to 2% of body weight on a dry matter basis 4 days prior to and for the duration of the 3-day gas measurement.

[v] Lying time measurement refers to average time spent lying during the 3-day gas measurement at the end of each period.

heifers reported in previous literature. There was no difference ($P > 0.05$) in THI and respiration rate across all periods, and THI and respiration rate were positively correlated ($R^2 = 0.381$; $P < 0.0001$). The head box system evaluated will be useful in examining the effects of emissions mitigation strategies, and variation in emissions caused by different feeds and throughout the 24-hour cycle of a day.

Key Words: cattle, enteric methane, measurement

1201 Impact of corn or soybean in crops and lactating cow diets on estimated greenhouse gas emission from Wisconsin certified organic dairy farms.

D. Liang*, F. Sun, M. A. Wattiaux, V. Cabrera, and E. M. Silva, *University of Wisconsin-Madison, Madison.*

This study used a partial life cycle assessment approach to estimate the impact of feeding strategies and associated cropping systems on greenhouse gases emission intensity (GHG-EI, kg CO_2–eq/t energy corrected milk, ECM) from Wisconsin certified organic dairy farms. Gases and sources of emissions included in the study were: nitrous oxide (N_2O) from fields (row crop and pasture), enteric methane (CH_4), and manure management (N_2O and CH_4). An earlier study had identified four clusters from a survey dataset of 69 organic dairy farms. In cluster 1, 2, 3, and 4 daily DMI of lactating dairy cows was 22.1, 15.2, 20.9, and 18.1 kg/d, amount of concentrate fed was 8.0, 2.0, 6.0, and 6.0 kg/d, time grazing on pasture was 39.2, 53.5, 38.6, and 47.7% of the year, and ECM was 6657, 3857, 7666, and 5495 kg/yr per cow, respectively. Three combinations of corn grain (CG) and soybean (SB) as concentrate (100%CG, 75%CG+25%SB, and 50%CG+50%SB) were assigned to each cluster to study the substitution effect of protein vs. energy supplementation. Overall, GHG-EI was 1273 ± 235 kg CO2-eq/t ECM with contributions of 57.4, 34.1, and 8.5%, for enteric fermentation, manure management, and field emissions, respectively. There was a strong inverse relationship between level of production and GHG-EI, which averaged 1209, 1622, 996, and 1264 kg CO2-eq/t ECM for cluster 1, 2, 3, and 4, respectively. Grazing time was positively related with GHG-EI in part because longer grazing time was associated with lower ECM production and increased N_2O emission from manure deposited on pasture during grazing. The GHG-EI was the greatest in Cluster 2 with 50%CG+50%SB and the lowest in Cluster 3 with 100%CG (1635 vs. 983 kg CO_2–eq/t ECM). The GHG-EI was predicted to increase with increasing SB in all four clusters and on average GHG-EI was 1260, 1273, and 1285 kg CO_2–eq/t ECM for 100%CG, 75%CG+25%SB, and 50%CG+50%SB, respectively. Planting soybean decreased N_2O emission from cropland due to lower intensity of N fertilization and greater reliance on biological N-fixation compared with planting corn. Lowering CG for more SB in the diet reduced enteric CH_4 emission (because of greater fat content in the latter) but increased N_2O emission from manure (because of greater CP content of the latter). This study suggested that growing and feeding CG or SB might explain only a small fraction of the large differences in emission observed among clusters.

Key Words: carbon footprint, LCA, organic dairy farms

1202 Winter feeding systems and farm greenhouse gas emissions.

A. W. Alemu*[1], R. R. Doce[2], A. C. Dick[2], J. Basarab[3], R. Kröbel[1], K. Haugen-Kozyra[4], and V. Baron[2], *[1]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, Canada, [2]Lacombe Research and Development Centre, Agriculture and Agri-Food Canada, Lacombe, Canada, [3]Lacombe Research Centre, Alberta Agriculture and Forestry, Lacombe, Canada, [4]Viresco Solutions, Calgary, Canada.*

Overwintering beef cows is a major cost in Canadian cow-calf production systems and swath grazing is a potential alternative to reduce winter feeding cost relative to the traditional drylot feeding systems. The objective was to estimate and compare greenhouse gas (GHG) emissions from winter feeding systems: i) swath grazing on triticale, ii) swath grazing on corn, and iii) conventional drylot feeding systems (control). Data were obtained from a study conducted over three production cycles (2008/2009, 2009/2010, 2010/2011) at the Lacombe Research Center in western Canada. Greenhouse gas emissions were estimated by calculating methane (CH_4), nitrous oxide (N_2O) and carbon dioxide (CO_2) emissions from different sources using Intergovernmental Panel on Climate Change (IPCC) Tier 2 approach. Methane emissions were estimated from enteric fermentation and manure, N_2O emissions from fertilization and manure, and CO_2 emissions from energy use for farm activities related to feed production and processing, feed and bedding delivery and manure removal. Total emission expressed per kg of feed produced and fed were significantly ($P < 0.001$) lower for both the swath grazing treatments relative to the control treatment. Emissions per cow varied among treatments ($P < 0.001$), higher for control (12.3 kg CO_2e cow-d^{-1}) than corn (9.4 kg CO_2e cow-d^{-1}), with triticale (11.0 kg CO_2e cow-d^{-1}) intermediate. In all the treatments, the largest fraction of emissions was enteric CH_4 (69–76%), followed by N_2O (14–24%). The contribution of energy-derived CO_2 emissions for total GHG emissions was lower in swath grazing treatments (5–7%) compared to a traditional feeding system (11%) due to their minimal energy use. Farm activity related energy use was 9.4, 11.5, and 21.4 MJ cow-d^{-1} for triticale, corn, and conventional drylot feeding, respectively. This study indicated that swath grazing on triticale or corn can be an effective alternative winter feeding systems to reduce GHG emissions and increase energy use efficiency of Canadian beef cattle industry.

Key Words: greenhouse gas, swath grazing, winter feeding

1203 Grazing management and farm greenhouse gas emission intensity of beef production systems.
A. W. Alemu*[1], H. Janzen[1], S. Little[1], X. Hao[1], D. Thompson[1], V. Baron[2], A. D. Iwaasa[3], K. A. Beauchemin[1], and R. Kröbel[1], *[1]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, Canada, [2]Lacombe Research and Development Centre, Agriculture and Agri-Food Canada, Lacombe, Canada, [3]Agriculture and Agri-Food Canada, Swift Current, Canada.*

The objective of the study was to evaluate the impact of grazing management on greenhouse gas (GHG) emission intensity at the farm-gate for beef production systems in western Canada using life cycle analysis. A life cycle analysis over an 8-yr period was conducted on a beef farm that managed 120 cows, 4 bulls, and their progeny. Calves were stocked on pasture and market cattle were finished on grain for 136 d. Four grazing management systems were evaluated: i) light continuous grazing (LC), ii) heavy continuous grazing (HC), iii) light continuous grazing for the cow-calf pairs and moderate deferred-rotational grazing for the stocker cattle (LCDR), and iv) heavy continuous grazing for the cow-calf pairs and moderate deferred-rotational grazing for the stocker cattle (HCDR). Primary data for pasture quality, animal performance and soil were from short- and long-term grazing studies. GHG emissions from different sources within the farm were estimated using the whole-farm model, Holos. Soil carbon change related to the different grazing managements was estimated using the Introductory Carbon Balance Model. Emissions intensity of beef varied among grazing management strategies and ranged between 14.4–15.9 kg CO_2e kg^{-1} live weight. Emissions intensity decreased with increasing stocking rate where the LC management had 9% greater GHG emission intensity than the HC treatment (14.4 kg CO_2e kg^{-1} live weight). There was no difference in emission intensity estimates between LC and LCDR or between HC and HCDR, indicating that the use of moderate deferred-rotational grazing for the stocker operation in LCDR and HCDR has no effect on emission intensity. However, the LCDR management had 7% greater emission intensity than HCDR (14.5 kg CO_2e kg^{-1} live weight). Regardless of the grazing management, methane emission from enteric fermentation was the major contributor (67–68%) followed by nitrous oxide from manure management (14–16%). Similarly, in all the grazing managements, emissions from the cow-calf herd were the major contributor (68–70%) for the total farm GHG emissions. When soil carbon sequestration was included into the total farm emissions, intensity estimate was reduced by 25–30% and were similar among the grazing management scenarios. Overall, the outcome from our study emphasizes the impact of grazing management on farm emissions as well as the importance of accounting for all the emission sources and sinks within the beef production system while estimating its environmental footprint.

Key Words: grazing management, life cycle analysis, soil carbon

1204 A life cycle assessment of a beef feedlot finishing ration supply chain in California.
S. J. Werth*, J. W. Oltjen, E. Kebreab, and F. M. Mitloehner, *University of California, Davis.*

A life cycle assessment (LCA) was conducted for the feed supply chain (FSC) of a total mixed ration (TMR) typical of finishing feedlot cattle produced in California, USA. The goal was to determine the global warming potential (kg CO_2e kg^{-1} TMR) associated with the FSC along with the associated impacts of the FSC on the total life cycle of feedlot cattle produced in California. The methodology used followed the Livestock Environmental Assessment and Performance (LEAP) Partnership guidelines for FSC. System boundaries included feed production (crops and feed additives), transportation (from field or factory to feedmill), and TMR compound feed production (i.e., at the feedmill). Life cycle inventory data for a typical finishing TMR was collected. Given the scope of the study, primary data were limited. In accordance with LEAP guidelines, secondary data were sourced from national databases and Ecoinvent™ unit process data. Three scenarios were assessed as a result of allocation at the transportation step. Scenario A, B, and C assumed that once a feed ingredient was transported to the feedmill, 100%, 50%, and 0% of the empty return load would be allocated to TMR production, respectively. Additionally, the impacts of feed production in relation to the entire feedlot cattle production life cycle, for Scenario A, was determined. Total GHG emissions were determined to be 0.630 kg CO_2e/kg TMR for Scenario A, 0.576 kg CO_2e/kg TMR for Scenario B, and 0.521 kg CO_2e/kg TMR for Scenario C. Corn production, feed transportation, and liquid premix production were the main contributors to the life cycle impacts of the TMR. When assessing the entire feedlot life cycle for Scenario A, total GHG emissions were determined to be 0.824 CO_2e/kg TMR. Additionally, for scenario A, feed production in the Angus and Holstein feedlot scenarios was found to contribute approximately 76% and 58% of total feedlot emissions, respectively. The FSC is a major contributor of emissions to the total life cycle of feedlot cattle production and knowledge thereof is a first step in improving efficiencies and reducing emissions.

Key Words: feedmill, greenhouse gas, sustainability

1205 Estimating farm-gate ammonia emissions from Canadian beef production in 1981 as compared with 2011.

G. Legesse[*1], R. Kroebel[2], A. Alemu[2], K. H. Ominski[1], E. J. McGeough[1], K. A. Beauchemin[2], and T. A. McAllister[2], *[1]Department of Animal Science, University of Manitoba, Winnipeg, Canada, [2]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, Canada.*

The quantity of beef produced per animal in Canada over the past three decades has increased significantly as a result of improvements in production efficiency and increases in carcass weights. This resulted in a decline in greenhouse gas emissions per kilogram beef. As NH_3 volatilization from beef cattle manure is also a major environmental concern, the present study compared the NH_3 emissions of Canadian beef production in 1981 and 2011. A nation-wide mass balance approach based on total ammoniacal nitrogen (TAN) content in animal manure was used to estimate NH_3losses from housing, grazing, manure storage, and land spreading. Temporal and regional differences in cattle categories, feed types, and management systems, average daily gains and carcass weights were considered. On average, 21% to 22% of the total nitrogen (N) consumed by Canadian beef cattle was lost as NH_3–N in both years. Highest losses were observed in finished cattle where approximately 43% of the N consumed was lost as NH_3–N. Contribution of NH_3 from the various cattle classes differed between years and was mainly due to differences in the type of feeds used, and proportions of breeding stock and cattle finished in feedlots. Emission sources were generally consistent in both years, with average values of 12%, 40%, 28%, and 21% associated with animal housing, animal grazing, manure storage and land spreading, respectively. Total NH_3 emissions from the production of Canadian beef cattle (standardized on the basis of the size of the breeding herd within the reference year) was 27% higher in 2011 than they were 1981. The average emissions per animal in 1981 and 2011 were 14.2 and 15.7 kg NH_3/animal/yr, respectively. On an intensity basis, however, kilogram of NH_3 emitted per kilogram of beef decreased by 20%, from 0.17 in 1981 to 0.14 in 2011. The reduction in NH_3 intensity is mainly attributed to increase in reproductive efficiency, average daily gain and slaughter weights, and the resulting improvement in productivity per breeding herd over the study period. Differences in intensity may also be attributed to increased use of extended grazing (*e.g.*, swath, stockpiled and bale grazing) in 2011 compared to 1981. As management practices are altered in response to changes in profitability and policy, further studies are necessary to assess the impact of the beef industry on NH_3 emissions and air quality at the local, regional and national scale.

Key Words: ammonia emission intensity, beef, Canada.

1206 The effect of reduced crude protein, synthetic amino acid supplemented diets on nutrient excretion in wean to finish swine.

C. E. Vonderohe[*1], K. M. Mills[1], M. D. Asmus[1], E. R. Otto-Tice[1], J. Ni[1], C. V. Maxwell[2], B. T. Richert[1], and J. S. Radcliffe[1], *[1]Purdue University, West Lafayette, IN, [2]Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville.*

Seven hundred twenty mixed-sex pigs were placed in 12 rooms at the Purdue University Swine Environmental Research Building to study the effect of reduced crude protein diets supplemented with synthetic amino acids on nutrient excretion from wean-finish. Pigs were blocked by BW and gender, and randomly assigned to a room and pen (10 pigs/pen). There were two deep pits per room and three pens over each pit. Each room was fed one of three diets: 1) control diet (Control) balanced to the first limiting amino acid with no synthetic amino acids, 2) a low crude protein (2X), high synthetic amino acid diet that balanced to the seventh limiting amino acid, and 3) an intermediate CP diet (1X) formulated to have a CP concentration intermediate to the Control and 2X diets, with a moderate level of synthetic amino acid inclusion. This resulted in approximately a 3 and 5%-unit reduction in CP, respectively for 1X and 2X diets. Pig BW, feed intake, and manure pit depths were determined at each diet phase change. Pit vacuum samples were collected at the end of each growth phase and frozen at −20°C for subsequent analyses. Data were analyzed using the GLM procedure in SAS. Reductions in dietary crude protein resulted in a linear reduction in ammoniated N excretion per kg of BW gain in both Nursery (Control = 8.6 g/kg gain, 1X = 7.2 g/kg gain, 2X = 5.5 g/kg gain; $P < 0.0001$) and Grow-Finish (Control = 18.0 g/kg gain, 1X = 14.3 kg/kg gain, 2X = 10.1 g/kg gain; $P < 0.0001$) phases. Reductions in dietary CP, with synthetic amino acid supplementation also resulted in a linear reduction in total N excreted per kg gain in the Grow-Finish phase (Control = 18.5 g/kg gain, 1X = 14.9 g/kg gain, 2X = 13.1 g/kg gain; $P < 0.0001$) and overall (Control = 17.4 g/kg gain, 1X = 15.4 g/kg gain, 2X = 13.1 g/kg gain; $P = 0.0009$). Total mineral excretion (Ash) per kg gain was reduced in the 1X and 2X diets compared to the control (Control = 39.6 g/kg gain, 1X = 36.0 g/kg gain, 2X = 33.4 g/kg gain; $P = 0.0046$). There was no effect of diet on total manure volume or P excreted per kg gain. These results indicate that reductions in dietary crude protein of ~3 and 5%-units from wean-finish result in reductions of total N excretion of 11.7 and 24.4%, respectively.

Key Words: crude protein, excretion, swine

1207 Oxalic acid production by *Aspergillus niger* when using whey permeate lactose as a carbon source.
K. M. Hilt[*1], J. H. Harrison[2], and K. Bowers[3], [1]*Washington State University, Pullman,* [2]*Washington State University, Puyallup,* [3]*Multiform Harvest Inc., Seattle, WA.*

When manure is applied to crops on a nitrogen basis, it often creates a buildup of phosphorus (P) in the soil. Phosphorus recovery by struvite precipitation is one strategy to capture excess P before land application. However, daily operating costs are expensive due to chemical inputs. Dairy cow manure contains larger concentrations of calcium compared to other livestock manure, which requires an acid addition to break the calcium phosphate bonds. Oxalic acid is desirable because, in addition to breaking bonds, its anion (oxalate) binds the calcium. This study investigated the production of a dilute oxalic acid solution by the fungus *Aspergillus niger* (*A. niger*) using whey permeate as a substrate. This study was based on the work by Strasser et al., which found that *A. niger* exclusively produces oxalic acid when fermenting a lactose carbon source. Whey permeate is a desired substrate due to its high lactose content, and because it can be viewed as a by-product of the dairy industry. Oxalic acid production was evaluated by independently incubating two strains of *A. niger*, ATCC 9029 and ATCC 6275, at two concentrations: 11% lactose whey permeate (no lactose added) or a 20% lactose whey permeate (lactose added), to see if either strain could produce the 1–1.5% oxalic acid solution necessary for struvite formation. Fungi were grown in two-liter vessels for 6 d at 30°C and a pH of 6. Samples were collected each day and analyzed for oxalic acid content. The first study compared oxalic production between the two strains when fermenting a 20% lactose whey permeate solution, and found that *A. niger* 9029 produced a 125mM oxalic acid solution and *A. niger* 6275 produced a 200mM oxalic acid solution over a period of 6 d. The production data were fitted with polynomial regression lines of $y = -5.0x^2+41.17x+37.95$ ($R^2 = 0.72$) and $y = -2.80x^2+36.88x+68.98$ ($R^2 = 0.89$), respectively. The second study compared oxalic production between the two strains when fermenting an 11% lactose whey permeate solution (no added lactose), and found that *A. niger* 9029 produced a 350mM oxalic acid solution and *A. niger* 6275 produced a 150mM oxalic acid solution over a period of 6 d. The data were fitted with polynomial regression lines of $y = -17.4x^2+147.7x+57.26$ ($R^2 = 0.85$) and $y = -6.85x^2+58.23x+28.81$ ($R^2 = 0.75$), respectively. These data indicate that *A. niger* can produce the necessary concentration of oxalic acid for struvite production when fermenting whey permeate with no added lactose.

Key Words: *Aspergillus niger*, oxalic acid, whey permeate

1208 Effects of pre- and postpartum supplementation of ruminally protected polyunsaturated fatty acids on reproductive performance of suckled beef cows.
P. L. P. Fontes[*1], N. Oosthuizen[1], F. M. Ciriaco[1], D. D. Henry[1], M. E. Garcia-Ascolani[1], V. R. G. Mercadante[2], N. DiLorenzo[3], and G. C. Lamb[1], [1]*University of Florida, North Florida Research and Education Center, Marianna,* [2]*Virginia Tech, Blacksburg,* [3]*University of Florida, Marianna.*

To evaluate the effects of a ruminally protected PUFA supplement (M-R, Church & Dwight Co., Princeton, NJ) on reproductive performance of suckled beef cows, 66 multiparous cows (621 ± 70 kg of BW) were used in a completely randomized design. Cows were stratified by breed, BCS and the previous year's calving date and assigned to 1 of 2 treatments: Control (CTRL; 0.91 kg·d^{-1} of corn gluten feed (CGF) + 0.23 kg·d^{-1} of Megalac-E) and treatment (MEGR; 0.91 kg·d^{-1} of CGF + 0.23 kg·d^{-1} of Megalac-R). The experiment was designed for cows to receive treatments from 30 d prepartum to 30 d postpartum (mean d fed prepartum = 29.66; mean days fed postpartum = 29.34). Treatments were provided individually 5 d per wk. All cows had ad libitum access to bermudagrass hay (*Cynodon dactylon*), water and mineral supplement during supplementation period. After completion of supplementation, all cows grazed a mixed winter forage pasture of rye (*Secale cereale*) and ryegrass (*Lolium multiflorum*) during for the remainder of the study. Cow and calf BW and cow BCS were assessed weekly. Postpartum concentrations of progesterone were determined on a weekly basis to access resumption of postpartum estrous cycles. Cows were exposed to a 7-d CO-Synch+CIDR estrus synchronization protocol and fixed timed artificial insemination (TAI) was performed 60 ± 6 h after $PGF_{2\alpha}$. Cows where then exposed to fertile cleanup bulls for 70 d. Ultrasonography was performed 35 d after AI when pregnancy status and embryo size was assessed. Pregnant cows were monitored until calving and calf birth weight and calving distribution were determined. Data were analyzed using the Mixed procedure of SAS with cow as the experimental unit and treatment as fixed effects. There was no difference between treatments for mean cow BW ($P = 0.97$) or BCS ($P = 0.20$). In addition, weaning weights of calves among treatments did not differ ($P = 0.16$) and the percentage of cows resuming estrous cycles by initiation of the breeding season did not differ ($P = 84$). There was no effect of treatment on pregnancy percentage at d 35 ($P = 0.13$) and at the end of the breading season ($P = 0.56$). At d 35 postbreeding, there were no differences ($P = 0.26$) between treatments on fetus crown-rump length and no effect of treatment on birth weight ($P = 0.31$) and calving distribution ($P = 0.91$). We conclude that Megalac-R supplementation failed to improve reproductive performance of suckled beef cows when compared with Megalac-E.

Key Words: Beef cows, polyunsaturated fatty acids, reproduction

1209 The effect of straw bedding on dry matter intake and residual feed intake ranking in yearling bulls. J. B. Hall[1,2], M. C. Roberts Lew[*3], and W. K. Smith[3], *[1]University of Idaho Nancy M. Cummings Research, Extension Education Center, Carmen, [2]Department of Animal & Veterinary Sciences, University of Idaho, Moscow, [3]UI Nancy M. Cummings Research, Extension & Education Center, Carmen, ID.*

The objective of this study was to examine the effect of straw bedding on dry matter intake (DMI) and residual feed intake (RFI) ranking in bulls. For animal care purposes, cattle are commonly bedded with straw when being housed in pens where snow and rain are frequent. Over 2 yr, residual feed intake (RFI) was analyzed on Angus and Shorthorn bulls (n = 188) using the GrowSafe® system. The bulls were fed a total mixed ration (TMR) with 14.2% protein and 68.7% TDN. These bulls were divided into four pens based on bull owner. Daily feed intake was measured for 80 d and 47 d in 2014 and 2015, respectively. Straw bedding was added twice a week. Dry matter intake (DMI, kg), average daily gain (ADG, kg/d), feed to gain ratio (F:G) and residual feed intake (RFI) were calculated. For F:G and RFI, bulls were ranked numerically then DMI was excluded from days where straw bedding was included and the bulls were ranked again. The individual bull DMI decreased ($P < 0.001$) on days were straw bedding was added (Bedding = 11.3 ± 0.1 kg, No bedding = 11.6 ± 0.1 kg). The pen DMI decreased ($P < 0.02$) when straw bedding was added as well (Bedding = 267.1 ± 2.2 kg, No bedding = 273.1 ± 1.4 kg). Year was not significant for both individual and pen DMI. The majority of the bulls did not maintain the previous ranking. 86.4% (159/184) and 77.7% (146/188) of the bulls changed rank for RFI and F:G, respectively. Of those bulls that changed rank, 76.7% (122/159) of the RFI and 56.9% (83/146) of the F:G changed by more than 2 rankings. The average change in rank for RFI and F:G was 4.63 and 1.86, respectively. It can be concluded that adding straw bedding to pens with cattle decreases DMI in a GrowSafe® system. Reduced intake due to bedding caused a change in RFI and F:G rankings within bulls. Bulls on a RFI test should be given minimal straw bedding and those days bedding is added should be left out of the RFI calculation.

Key Words: Bulls, feed efficiency, residual feed intake, bedding

1210 Management of dairy bull calves on U.S. dairy operations. C. B. Shivley[*1,2], N. Urie[1,2], and J. E. Lombard[1], *[1]USDA:APHIS:VS:Center for Epidemiology and Animal Health, National Animal Health Monitoring System, Fort Collins, CO, [2]Colorado State University, Fort Collins.*

The objective of this study was to evaluate management practices of dairy bull calves and compare these practices to those used for dairy heifer calves in the United States. This study was conducted as part of the National Animal Health Monitoring System's Dairy 2014 study, and included 36 operations in 8 states. Overall, 7.9% (SE 0.7) of bull calves were stillborn. Stillbirth percentage for all calves on the 36 operations was 6.0% (SE 0.6). Regarding colostrum management, 95.6% (SE 2.8) of bull calves received colostrum; 94.9% (SE 2.1) received colostrum by hand feeding only, 3.3% (SE 1.5) received colostrum by hand feeding and suckling, and 1.8% (SE 1.0) received colostrum by suckling only. No heifer calves received colostrum by suckling only. Bull calves received colostrum 4.6 h (SE 0.5) after birth, compared with 3.0 h (SE 0.5) after birth for heifer calves. At the first feeding, bull calves received 3.3 L (SE 0.1) of colostrum, plus 1.7 L (SE 0.3) in all subsequent feedings for a total of 5.0 L (SE 0.3) of colostrum in the first 24 h, compared with a total of 5.4 L (SE 0.4) of colostrum in the first 24 h for heifer calves. On average, 2.3% (SE 0.5) of bull calves died before leaving the operation. Most operations did not dehorn bull calves (77.8%). Of the 22.2% of operations that did dehorn bull calves, 62.5% of operations dehorned using hot irons at an average age of 21.0 d (SE 7.6). Only 12.5% of operations used analgesics/anesthetics when dehorning bull calves. Heifer calves were dehorned on 91.4% of operations, with hot iron being the most commonly used method. Anesthetics/analgesics were used when dehorning heifer calves on 28.0% of operations. Most operations did not castrate bull calves (71.4%). Of the 28.6% of operations that did castrate bull calves, 30.0% used a knife, with an average age of 14.7 d (SE 4.8); no operations used analgesics/anesthetics. Bands were used by 70.0% of operations at an average age of 6.3 d (SE 0.9 d); 9.8% of operations (n = 1) used analgesics/anesthetics. Bull calves on these operations were managed differently from heifer calves. These results highlight the need to administer the appropriate volume of quality colostrum in a timely manner, and the value of using analgesics or anesthetics for painful procedures in bull calves.

Key Words: dairy bull calves; colostrum quality; dehorning practices

1211 Assessment of different bedding systems for lactating cows in freestall housing. H. Su[*1], N. M. Esser[2], W. K. Coblentz[3], M. A. Borchardt[3], W. Jokela[3], and M. Akins[1], *[1]University of Wisconsin, Madison, [2]University of Wisconsin, Marshfield, [3]US Dairy Forage Research Center, Marshfield, WI.*

The objective of this study was to compare different bedding systems for lactating cows in freestall housing. Bedding systems included new sand (NS), recycled byproducts of manure separation (organic solids [OS] and recycled sand [RS]), and foam-core mattresses with a shallow layer of OS (MS). The experimental barn contained 128 freestalls that were divided into 4 equal quadrants with 1 bedding system for each quadrant. All animals included in this study were first lactation cows, randomly assigned to different quadrants as cows calved. This experiment was conducted between January 2014 and December 2015 with 2 periods (1 calendar year for each period). Bedding systems were changed the last week of the first period. Milk yield data was recorded daily and milk samples were collected monthly for milk composition and somatic cell count (SCC). Cow's behavior, hygiene, and hock score were collected monthly. Clinical mastitis and hoof trimming cases were summarized based on veterinary records. Quadrant (pen) was considered the experimental unit with all data averaged by quadrant before analysis. Results represent 2 yr of data collection, and are presented as means ± SD (Table 1); Therefore, yearly comparisons of means are numerical only, and do not imply statistical significance. The OS and NS groups had greater milk yield compared with RS and MS groups, and the same responses were observed for energy-corrected (ECM) and fat-corrected milk (FCM). The SCC and somatic cell score (SCS) were greatest for the OS group. Cows housed in NS stalls had the greatest cow comfort and stall usage indexes. Cows in OS, NS and RS stalls were cleaner (lower flank score) than cows in MS stall. Cows in MS stalls had the most severe hock lesions (greater hock score). Greater incidence (total cases over 2 yr) of clinical mastitis was observed for cows with OS freestalls. Cows housed in NS and RS stalls needed fewer hoof trimmings than cows housed in OS and MS stalls. Based on the data thus far, NS seems to be the best bedding material for lactating cows based on milk performance, behavior, hygiene, and health data.

Key Words: lactating cow, bedding, freestall housing

1212 Management practices related to the welfare of dairy heifer calves on U.S. dairy operations. C. B. Shivley[*1,2], N. Urie[1,2], and J. E. Lombard[1], *[1]USDA:APHIS:VS:Center for Epidemiology and Animal Health, National Animal Health Monitoring System, Fort Collins, CO, [2]Colorado State University, Fort Collins.*

Animal welfare is a growing concern among the general public. The objective of this study was to evaluate dairy heifer welfare based on the results of the calf component of the National Animal Health Monitoring System's Dairy 2014 study. The 18-mo longitudinal calf study focused on dairy heifer calves from birth to weaning, and included 104 dairy operations in 13 states. Data were collected on 2,545 calves. Major risk factors for poor calf welfare were identified. Regarding calving management, 43.7% of births were unattended and 21.2% of calves did not have their navels disinfected. Concerning colostrum management, 22.7% of calves received poor quality colostrum (IgG < 50 g/L), and 13.0% of calves had failure of passive transfer with serum IgG < 10 g/L. Colostrum was primarily obtained via sucking for 22.1% of calves, with no control over quantity or quality. While the average timing after birth to colostrum feeding was within the recommended 4 h at 2.8 h (SE 0.05), 14.9% of calves received colostrum after 4 h, with the maximum 20 h after birth. An inadequate volume of colostrum (< 5.7 L) was administered to 67.5% of calves within the first 24 h. Of the 52.3% of all calves that were dehorned during the preweaning period, only 27.8% received any anesthetics or analgesics. Regarding milk feeding, restrictive feeding practices were common, with 29.6% of calves receiving less than 4.7 L of milk per day, and the average volume of milk per day fed was 5.7 L (SE 0.03). This restriction was reflected in the average daily gain of calves, with 35.5% of calves gaining less than 0.63 kg/day. The average age at weaning was 9.4 wk (SE 0.05), which was slightly higher than the recommended 6 to 8 wk of age. The most commonly used weaning criterion was age; only 4.6% of calves were weaned based on starter intake. Only 13.4% of calves were housed in groups, which has been shown to increase cognitive development but has increased disease risk. Bedding is important for calves to remain clean and comfortable but 12.6% of calves were bedded with sand or no bedding. Overall, 5.0% of calves died during the preweaning period, and most of these deaths had no reported cause, identifying an area for further investigation. Identifying risk factors for calf welfare is the first step toward finding solutions.

Key Words: dairy heifer calves; animal welfare; colostrum management

1213 Performance and health of calves pre- and post-weaning when fed pasteurized whole milk and whole milk supplemented with differing milk replacer protein sources. D. Ziegler[*1], H. Chester-Jones[1], D. L. Cook[2], J. L. Olson[2], and S. M. McCusker[2], *[1]University of Minnesota Southern Research and Outreach Center, Waseca, [2]Milk Products, Chilton, WI.*

The objectives of this study were to compare calf pre- (d 1 to 49) and postweaning performance (d 50 to 56) when fed pasteurized waste milk (PWM) or a combination of 67% PWM with 33% milk replacers (MR) formulated with similar crude protein (CP) to PWM with varying protein sources. One hundred-eight (2 to 5 d old) individually fed Holstein heifer calves (38.4 ± 0.64 kg) were randomly assigned to 1 of 4 milk treatments. Milk treatments included 1) PWM fed at 0.34 kg DM 2× daily from d 1 to 42 and 1× daily from d 43 to weaning at d 49 **(**WM); 2) PWM (67%) fed with 33% all-milk protein MR as in treatment 1 **(**AM); 3) PWM (67%) fed with 33% MR containing 50% all-milk and 50% blend of soy protein concentrate/wheat protein as in treatments 1 and 2 (SWP); 4) PWM (67%) with 33% MR containing 50% all-milk and 50% blend of hydrolyzed vegetable proteins and autolyzed yeast fed as in treatments 1, 2, and 3 (PP). Calf starter (CS;18%CP) and water were fed free choice d 1 to 56. Waste milk was collected 2× wk and pasteurized before each feeding. Total milk DMI was similar for all calf groups, averaging 29.9 kg. Pre-weaning ADG tended to be greater ($P = 0.09$) for WM (0.76 kg/d) and AM (0.73 kg/d) calves vs. those fed SWP (0.69 kg/d) and PP (0.70 kg/d). There were no postweaning ADG differences ($P > 0.05$) in the nursery. Pre- and postweaning CS DMI, were similar ($P > 0.05$) across treatments, averaging 21.8 and 15.5 kg, respectively. Hip height gain d 1 to 56 averaged 12.7 cm. Preweaning and overall d 1 to 56 gain/feed was highest for WM calves ($P < 0.05$). There were no differences ($P > 0.05$) in number of scouring days and treatment costs. From d 57 to d 84 there were no differences in ADG ($P > 0.05$) across calf groups when all calves were on a common diet in group pens. Under conditions of this study calves fed WM tended to have better pre-weaning performance parameters vs. those fed 2/3 WM and 1/3 MR containing varying protein sources.

Key Words: calf performance, pasteurized waste milk, milk replacers.

1214 Performance and health of calves pre- and post-weaning when fed milk replacers formulated with alternative protein sources. H. Chester-Jones[*1], D. Ziegler[1], R. Blome[2], and D. Wood[2], *[1]University of Minnesota Southern Research and Outreach Center, Waseca, MN, [2]Animix, Juneau, WI.*

The objectives of this study were to compare pre- (d 1 to 42) and postweaning performances of calves (d 43 to 56) when fed milk replacers (MR) with differing protein sources. One-hundred thirty (2 to 5 d old) individually fed Holstein heifer calves (38.4 ± 0.71 kg) were randomly assigned to 1 of 5 non-medicated 24% CP: 20% fat MR treatments (trt): 1) MR containing all-milk protein fed at 0.34 kg DM with 2.39 L water 2× daily for 35 d and once daily from d 36 to weaning at d 42 **(**AM), 2) MR fed as in trt 1 with 16% of the CP replaced by Manildra GemPro 7700 wheat (MG)**,** 3) MR fed as in trt 1 and 2 with 16% of the CP replaced by MG and 16.8% by plasma (Nutrapro B; MGNB), 4) MR fed as in trt 1, 2, and 3 with 17.1% of the CP replaced by Chamtour Nutrior wheat (CN), and 5) MR fed as in trt 1, 2, 3, and 4 with 16.8% of the CP replaced by NB. All diets were formulated to contain standardized 2.4% lysine, 0.8% methionine and 1.6% threonine. Calf starter (CS;18% CP as-fed) and water were fed free choice d 1 to 56. There were no differences in pre- and postweaning ADG ($P > 0.05$) which averaged 0.68 and 1.07 kg, respectively. Overall d 1 to 56 ADG averaged 0.78 kg. All calf groups doubled their initial BW by 56 d with 12.24 cm of HH gain average. Total MR was 24.9 kg across calf groups. There were no differences ($P > 0.05$) in pre- and postweaning CS intake which averaged 48.9 kg for the 56 d. Pre- (0.67 kg), postweaning (0.48 kg), and overall (0.63 kg) gain/feed were similar ($P > 0.05$) across calf groups. Serum protein averaged 5.9 mg/dl. There were no trt differences in scouring d and trt costs. Under the conditions of this study replacing milk protein in milk replacers with 2 different sources of wheat (approx.17%) with or without plasma (16.8%) resulted in very acceptable calf performances. Calf performance was not compromised by inclusion of wheat proteins in the milk replacers fed for 42 d.

Key Words: calf performance, milk replacers, protein sources.

1215 Performance and health of calves pre- and post-weaning when fed milk replacer supplemented with algae. D. Schimek*[1], B. Ziegler[1], D. Ziegler[2], and H. Chester-Jones[2], *[1]Hubbard Feeds Inc., Mankato, MN, [2]University of Minnesota Southern Research and Outreach Center, Waseca.*

The objectives of this study were to compare calf pre- (d 1 to 42) and postweaning performance (d 43 to 56) when fed milk replacer (MR) supplemented with microalgae meal *(All-G Rich™ Schizochytrium limacinum* CCAP 4087/2; Alltech, Inc.) in a dose titration study from August through November, 2015. One hundred-eight (2 to 5 d old) individually fed Holstein heifer calves (38.6 ± 0.61 kg) were randomly assigned to 1 of 4 treatments (trt); 1) Milk replacer, 24% CP:20% fat fed at 0.34 kg in 2.39 L water ×2 daily for 35 d and ×1 daily from d 36 to weaning at d 42 (CON); 2) Milk replacer as in trt 1 plus 2 g algae/calf daily (2 gA); 3) Milk replacer as in trt 1 with 4 g algae/calf daily (4 gA); 4) Milk replacer fed as in trt 1 supplemented with 6 g algae/calf daily (6 gA).Texturized calf starter (CS; 18% CP) and water were fed free choice d 1 to 56.There were no differences in pre- and postweaning total BW and daily gain ($P > 0.05$). Calves fed 6 g algae tended to have numerically higher preweaning gain (linear effect, $P = 0.11$). Average BW and HH after 56 d for all calf groups, met the suggested guidelines of double their initial BW and at least 10.2 cm of HH gain. Total MR intake was similar ($P > 0.05$) among all calf groups, averaging 24.7 kg. There were no CS intake differences among calf groups ($P > 0.05$). There was a trend for a linear increase in gain/feed preweaning ($P = 0.08$) with increasing levels of algae in the MR compared to CON. This numerical trend was also observed from d 1 to 56. There were no differences in scouring d (fecal score ≥ 3). There was a linear decrease ($P = 0.06$) in the number of scouring d when the fecal scores = 4 from calves fed CON compared to those fed increasing MR algae levels. There were no differences in treatment costs. Under conditions of this study, supplementing algae in MR from 2 to 6 g/calf daily was not detrimental to pre- and postweaning calf performance. There was an indication of a positive trend for supplementing 6 g algae for feed efficiency especially preweaning.

Key Words: calf performance, milk replacers, algae

1216 Evaluation of the efficacy of a copper sodium hypochlorite footbath and a 5% copper sulfate footbath on the control of digital dermatitis lesions. B. A. Wadsworth*, J. D. Clark, and J. M. Bewley, *University of Kentucky, Lexington.*

Digital dermatitis (DD) may be prevented using a 5% copper sulfate footbath. One alternative solution is a copper sodium hypochlorite solution (treatment; 2.5% copper sulfate footbath with 1.4 L of sodium hypochlorite solution added; GEA Farm Technologies, Naperville, IL). The objective of this study was to compare the copper sodium hypochlorite solution to a 5% copper sulfate footbath (positive control) on the frequency and severity of DD. This study was conducted at the University of Kentucky Coldstream Dairy from May 11, 2015 to June 26, 2015. Holstein cows ($n = 66$) were housed in 2 freestall barns (A and B) and cows were balanced for parity and days in milk. Footbath solutions were administered through 2 poly footbaths (J&D Manufacturing, Eau Claire, WI) in separate locations, measuring 15.24 cm × 81.28 cm × 198.12 cm and holding 94.64 L of solution each. Cows in barn A passed through the positive control footbath 5 d a week, 2 times per day. Cows in barn B passed through the treatment footbath 5 d a week, 2 times per day. The positive control footbath was refreshed every other day and the treatment footbath was refreshed every day. Rear feet DD lesions were scored weekly using a M0 to M4 scoring system: M0 indicates no lesion (non-active lesion); M1 represents an early growth < 2 cm in size (active lesion); M2 indicates an ulcerative lesion > 2 cm in size (active lesion); M3 represents a healing growth (non-active lesion); and M4 designates a chronic growth (non -active lesion). The DD lesions were further separated into active lesions or non-active lesions for statistical analysis. The GENMOD procedure of SAS (SAS Institute, Inc., Cary, NC) was used to analyze the probability of having an active lesion with each treatment. The probability of having left rear active lesions was 1.53 times greater ($P = 0.28$) than non-active lesions for the positive control compared to the treatment. The probability of having right rear active lesions was 1.87 ($P = 0.10$) times greater than non-active lesions for the positive control compared to the treatment. In conclusion, no significant differences were observed between the two footbaths, highlighting that copper sodium hypochlorite solution might be a viable alternative footbathing solution.

Key Words: digital dermatitis, footbath, copper sulfate, sodium hypochlorite

1217 Comparison of DX613 copper sulfate acidifier to a 5% copper sulfate footbath for prevention of digital dermatitis lesions in dairy cattle. H. B. Reichenbach*, B. A. Wadsworth, J. D. Clark, and J. M. Bewley, *University of Kentucky, Lexington.*

Digital dermatitis (DD) is an infectious disease seriously plaguing the dairy industry. The gold standard for prevention is a copper sulfate footbath. Although this method is effective, the large quantities of product required and the negative environmental impacts of bath waste necessitates a search for alternatives. The objective of this study was to compare a 2.2% copper sulfate footbath with 325.31 mL of DX613 Acidifier (treatment; GEA Farm Technologies, Naperville, IL) to a 5% copper sulfate footbath (positive control) on the frequency and severity of DD. Footbaths were delivered via a split footbath (Intra Care Foot Bath, Diamond Hoof Care LTD Alberta, Canada), measuring 32.5 cm wide by 233 cm

long, allowing for 80 L of solution per side. A metal coil separated the 2 footbaths to prevent cross contamination of solutions and decrease organic matter contamination. The left side of the bath served as the positive control and the right side served as the treatment. Baths were refreshed every 2 to 3 milkings, twice weekly. The study was conducted at the University of Kentucky Coldstream Dairy from November 11, 2015 to January 20, 2016. Holstein (n = 59) cows were housed in 2 freestall barns and balanced for parity and days in milk. The cows were exposed to the solutions on leaving the parlor after morning and afternoon milkings, 5 times per week. The DD lesions were scored biweekly using a M0 to M4 scoring system. A M0 score indicated no lesion (non-active lesions); M1 indicated small lesions (active lesions); M2 indicated large and potentially severe lesions (active lesions); M3 represented healing lesions (non-active lesions); and M4 represented chronic lesions (non-active lesions). The DD lesions were further separated into active lesions or non-active lesions for statistical analysis. A Chi-Square test calculated using the FREQUENCY procedure of SAS (SAS Institute, Inc., Cary, NC) indicated no-significant difference between the two solutions (chi-square = 1.18, P = 0.56). Eleven percent of treatment cows had active lesions and 9% of positive control cows had active lesions. A McNemar's test indicated significant differences in the prevalence of lesions from the beginning to end of the study (treatment: $P < 0.05$, positive control: $P < 0.01$; Table 1). This concludes a comparable effectiveness of both solutions. Given the potential for reduced environmental impact, the DX613 Acidifier may be a viable alternative for dairy producers.

Key Words: digital dermatitis, footbath, copper sulfate, acidifier, hoof care

Table 1217.

Table 1: Prevalence of lesions from beginning to end of study

Item	Positive Control	Treatment
No lesion at baseline and no lesion at end	46	42
No lesion at baseline and lesion at end	1	13
Lesion at baseline and no lesion at end	11	4
Lesion at baseline and lesion at end	1	0

1218 ortheast dairy herd characteristics: transition cow management strategies, performance, culling, and health. A. B. Lawton*[1], W. S. Burhans[1], D. V. Nydam[2], M. Tetreault[3], and T. R. Overton[1], *[1]Cornell University, Department of Animal Science and PRO-DAIRY, Ithaca, NY, [2]Cornell University, Department of Population Medicine and Diagnostic Sciences, Ithaca, NY, [3]Poulin Grain Inc., Newport, VT.*

A cross-sectional field study was conducted to describe transition cow management strategies and herd performance characteristics in high-producing dairies. A convenience sample of commercial Holstein herds (n = 72) in New York and Vermont were enrolled between November 2012 and August 2015. Data reported represent annual data at herd enrollment. Herd size range was 345 to 2,900 milk cows (mean ± SD; 935 ± 486) with a Dairy Herd Improvement herd milk average of 12,283 ± 1,051 kg (n = 50) and herd average milk yield/cow of 37.8 ± 3.8 kg/d (n = 69). Within the 40% of herds using recombinant bovine somatotropin (rbST) an average of 78% of eligible cows received rbST. Primiparous and multiparous animals had similar average days dry (56.5 ± 5.6) and herd reported voluntary waiting period (58.3 ± 9.4). All farms moved cows as parturition approached; 28% of herds moved animals to a maternity pen 0 to 3 d before calving; the other 72% used a calving pen, defined as animals moving to a pen when showing signs of calving. Eighteen percent of herds used separate calving locations for nulliparous and parous animals. Farms used a 1-group (9.7%) or 2-group (90.3%) dry cow system and 1-group (6.9%) or 2-group (93.1%) early lactation system for parous animals. Far-off and prefresh pens were either freestall (92.7%, 82.5%, respectively) or bedded packs (7.3%, 17.5%, respectively). Pens housing prefresh animals had animals moving in 1×/wk (71.6%) whereas 23.2% had animals moving in multiple times per week. From dry off until calving, number of pen moves for parous animals was either 2× (19.4%), 3× (69.4%), or 4× (11.1%) (n = 72 herds). From 60 d before due date until calving, nulliparous animals were moved 1× (4.2%), 2× (50.7%), 3× (40.3%), or 4× (4.2%) (n = 72 herds). Herd mean cull and death rate for animals $\leq$ 60 d in milk (DIM) was 5.9 ± 4.5% for primiparous animals and 8.4 ± 4.3% for multiparous animals (n = 71). Herd mean (SD) cull and death rate for animals overall was 20.6% (7.8%) for primiparous animals and 35.7% (7.2%) for multiparous animals (n = 71). Incidence of herd identified post-partum health

events (n = 71) were as follows; stillborn heifers: 5.9 ± 1.8%, twinning: 4.1 ± 1.4% (n = 72), RP: 6.5 ± 3.8%, metritis ≤ 30 DIM: 6.4 ± 8.5%, DA ≤ 60 DIM: 2.0 ± 1.6%, and ketosis ≤ 30 DIM: 6.6 ± 8.9%. These results demonstrate the variability in current practices and health related outcomes in large, progressive dairies in the Northeast.

Key Words: Transition cow, management, health outcomes

1219 Facilities, management, and animal factors associated with heifer culls in New York State dairy farms. B. D. Scott* and J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Objectives were to evaluate the rate of heifers leaving herds from 151 to 600 d of age relative to facilities, management practices, and individual animal factors. A survey was conducted on 55 commercial dairy farms in 2014 to assess and define herd factors for the prior and subsequent year. Dairy records from the on farm herd management software were collected approximately 1 yr later to analyze data for calves born in 2013 and 2014. Cull rates (P[mortality, dairy sales, or slaughter]) were established for a 151 to 360 (EXIT360) and 361 to 600 (EXIT600) days of age risk period. Risk ratios of EXIT360 and EXIT600 were analyzed using Poisson regression with PROC GENMOD of SAS. The heifer was the experimental unit within farm, utilizing an exchangeable correlation matrix. Variables of interest for both EXIT360 and EXIT600 were birth season (BIRTHSSN; cold = September through February and warm = March to August) and year, pneumonia or diarrhea events for the first 150 (ILLNESS150), 151 to 360 (ILLNESS360), and 361 to 600 (ILLNESS600) days of age, colostrum and milk feeding factors (quantity and duration), wean transition (methodology, age, and duration), number of pen moves, bunk space access, relative stocking density (heifers per stall), number of feedings and pushups per day, bedding amount and type, herd growth mode, culling style of herd manager (forgiving, moderate, aggressive), and number of lactating cows in the herd. Mortality and dairy sales were reported as 50% and 26% of all EXIT360 (6.2% of 33,168 heifers). Mortality and dairy sales were reported as 31% and 11% of all EXIT600 (10.6% of 9465 heifers). Birth season, birth year, ILLNESS150, and ILLNESS360, were all associated with EXIT360 (Table 1). Birth season and ILLNESS600 were associated with EXIT600 (Table 1). When ILLNESS and BIRTHSSN are considered, no facility or management factors were associated (P > 0.10) with EXIT360 or EXIT600 across these herds and their diversity of facilities and management in 2013 to 2014. We conclude that birth season and year as well as pneumonia and diarrhea events are associated with the probability of dairy heifers leaving herds between 151 and 600 d of age.

Key Words: replacements, mortality, illness

1220 Facilities, management, and animal factors associated with primiparous cows postpartum herd exit risk in New York state dairy farms. B. D. Scott* and J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Objectives were to evaluate the rate of primiparous cows leaving herds in the first 60 DIM relative to facilities, management practices, and individual animal factors. A survey was conducted on 55 commercial dairy farms in 2014 to assess and define herd factors for the prior and subsequent year. Dairy records from the on farm herd management software were collected approximately 1 yr later to analyze data for cows entering first lactation in 2013 and 2014. Cull rates (P[mortality, dairy sales, or slaughter]) were established for a 60 d eligible risk period (EXIT60). Risk ratios of EXIT60 were analyzed using Poisson regression with PROC GENMOD of SAS. The cow was the experimental unit within farm, utilizing an exchangeable correlation matrix. Cow level variables of interest for EXIT60 were calving season, age at first calving (AFC), maximum energy corrected milk produced in the first 60 DIM (MECM60), and maximum somatic cell linear score in the first 60 DIM (LSFresh). Peripartum facility and management variables analyzed were bunk space access, relative stocking density (animals per stall), bedding depth, bedding type, commingling with multiparous cows, herd growth mode, culling style of the herd manager (forgiving, moderate, aggressive), years of experience of the herd manager, lactating cow herd size, and whether heifers were all raised on-farm or some purchased. Final EXIT60 included 54 farms with

Table 1219.

Table 1. Estimates of relative risk (RR) for EXIT360 and EXIT600 within 52 farms, 2013-2014

LSFresh (Moderate[a] vs. Low)	1.20	1.03	1.41	0.022
LSFresh (High[a] vs. Low)	1.82	1.52	2.17	<0.001

[a]Low<4.0, 4.0≤Moderate≤6.0, High>6.0

adequate records for analysis and 30,145 cows. Mortality and dairy sales were reported to be 20% and 16% of all EXIT60, respectively, which totaled 6.6% of all cows at-risk. Table 1 summarizes differences and parameter estimates. Calving season, AFC, MECM60, LSFresh, and purchasing cows were associated with EXIT60. Conversely, no facilities or management factors were associated ($P > 0.10$) with EXIT60 across these herds and their diversity of facilities and management. We conclude that in years 2013 and 2014 calving season, age at first calving, milk production, and linear score were associated with the probability of a primiparous exiting the herd in the first 60 DIM across these 54 dairies in New York.

Key Words: culling, primiparous cow, dairy

1221 Facilities, management, and animal factors associated with calf losses in New York state dairy farms. B. D. Scott* and J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Objectives were to evaluate the rate of calves leaving herds in the first 150 d of age relative to facilities, management practices, and individual animal factors. A survey was conducted on 55 commercial dairy farms in 2014 to assess and define herd factors for the prior and subsequent year. Dairy records from the on-farm dairy management software were collected approximately 1 yr later to analyze data for calves born in 2013 and 2014. Cull rates (P[mortality, dairy sales, or slaughter]) were established for calves with a 150 d of age eligible risk period (EXIT150). Risk ratios of EXIT150 were analyzed using Poisson regression with PROC GENMOD of SAS. The calf was the experimental unit within farm, utilizing an exchangeable correlation matrix. Variables of interest were birth season (BIRTHSSN) and year, first colostrum administration (liters, type, and timeline), liters of colostrum (total) on the day of birth, number of milk feedings in a day, type of milk solution fed and quantity, weaning approach, weaning age and duration of process, pre-wean housing type, growth mode of the dairy, reported culling style of manager, experience level of calving supervisor, hours of calving area supervision, post wean ration, age at first exposure to fermented feeds, recorded pneumonia and/or diarrhea (ILLNESS) events, and relative scale of the dairy operation. The final regression model for EXIT150 retained 53 herds (n = 55,108 calves) after losses for inadequate records. Overall, mean EXIT150 was 4.91% (range = 0.53 to 22.0%). Reported mortality and dairy sales represented 59.9 and 16.3% of all EXIT150, respectively. Birth year of 2014 had higher ($P < 0.01$) EXIT150 (7.68%, n = 26,807) than 2013 (2.29%, n = 28,301). Colder BIRTHSSN (September through February) was associated with increased ($P < 0.01$) EXIT150 (RR = 1.58, 95%CI = 1.33–1.88) relative to other seasons. Reported ILLNESS data were available from 38 herds with 11.2% of the total calves having reported ILLNESS. Calves with reported ILLNESS had higher ($P < 0.01$) EXIT150 (RR = 1.43, 95%CI = 1.16–1.76). All other factors tested had no association with EXIT150 ($P > 0.10$) across the dairies included in the study and within their diversity of facility and management practices. We conclude that events of pneumonia and diarrhea, birth season, and birth year were associated with heifers leaving the herd and mortality within the dairies surveyed in 2013 and 2014.

Key Words: culling, survey, risk ratio, mortality

1222 Seasonal effects on milk yield and somatic cell score in organic dairy farms from the Northeast United States. J. G. B. Galvão Jr.*[1], A. F. Brito[2], A. H. N. Rangel[3], and J. B. A. Silva[4], *[1]Federal Institute of Science, Education,and Technology of Rio Grande do Norte, Ipanguaçu, Brazil, [2]University of New Hampshire, Durham, NH, [3]Federal University of Rio Grande do Norte, Natal, Brazil, [4]Universidade Federal do Semiarido, Mossoro, Brazil.*

The objective of this study was to evaluate the seasonal milk performance of organically-certified dairy farms in the Northeast region of the United States. Dairy Herd Improvement (DHI) records from May 2012 to May 2015 were obtained monthly from 7 herds in the states of New Hampshire (n = 2), Maine (n = 3), Vermont (n = 1), and New York (n = 1).

Table 1222.

Table 1. Least square means and SEM for the effects of season on milk yield and composition, and somatic cell score in Northeastern organic dairy farms

Season	Milk yield, kg/d	Protein, %	Fat, %	SCS	n
Fall	20.7 ± 0.34[b]	3.43 ± 0.01[a]	4.41 ± 0.02[ab]	2.47 ± 0.03[ab]	2,725
Spring	22.0 ± 0.34[a]	3.22 ± 0.01[c]	4.24 ± 0.02[c]	2.46 ± 0.03[b]	2,894
Summer	21.7 ± 0.32[a]	3.24 ± 0.01[c]	3.97 ± 0.02[d]	2.58 ± 0.03[a]	2,988
Winter	21.5 ± 0.35[a]	3.34 ± 0.01[b]	4.46 ± 0.02[a]	2.51 ± 0.03[ab]	2,837

[a,b,c]Values in the same column with different superscripts are significantly different at $P < 0.05$.

A total of 11,444 observations including milk yield, concentrations of milk fat and protein, and somatic cell score (SCS) were obtained and tested against the effects of season using the PROC GLM procedure of SAS. The herds averaged (mean ± SD) 166 ± 107 DIM, 21.5 ± 8.21 kg/d milk yield, 3.31 ± 0.52% milk protein, 4.27 ± 0.98% milk fat, and 2.51 ± 1.71 SCS. The seasonal effects on selected milk variables are shown in Table 1. All milk variables analyzed herein were affected by season. Milk yield was lower ($P < 0.05$) in the fall (mean = 20.7 ± 8.03 kg/d) compared with spring (mean = 22.0 ± 8.35 kg/d), summer (mean = 21.7 ± 7.88 kg/d), and winter (mean = 21.5 ± 8.48 kg/d), which did not differ from each other. The observed decrease in milk yield during the fall may be explained by limited pasture biomass production and changing of diets as cows transition from pasture- to winter-based rations. Milk protein and fat concentrations showed an inverse relationship with milk yield, thus suggesting a dilution effect caused by increased or decreased milk volume. The SCS was greatest during the summer (2.58 ± 1.74), intermediate during the fall and winter, and lowest during the spring (2.46 ± 1.71). Cows are susceptible to heat stress and nuisance flies during the summer, which can depress their immune system and increase intramammary infections. Somatic cell score is positively correlated with poor udder heath and a SCS over 4.0 possibly indicates the presence of intramammary infections and associated reduction in milk yield. However, the SCS across the 7 organic dairies used in our study ranged from 2.46 to 2.58, suggesting adequate milking procedures and preventative mastitis program. The use of annual forage crops can extend the grazing season potentially helping farmers mitigate milk yield losses during late fall, while management tools to reduce fly pressure and heat stress are likely needed to reduce SCS during the summer.

Key Words: milk composition, organic dairies, somatic cell score

1223 Argentina Veterinarian preferences to devise a mastitis control plan: A conjoint analysis approach.

C. Vissio[1,2], M. Richardet[1,2], C. Bonetto[3], P. Turiello[*1], and A. Larriestra[1], *[1]Facultad de Agronomia y Veterinaria, UNRC, Rio Cuarto, Argentina, [2]CONICET, Rio Cuarto, Argentina, [3]IAP Ciencias Basicas y Aplicadas, UNVM, Villa Maria, Argentina.*

The rationale applied for veterinarians to propose the most suitable udder health plan to farmers is not well understood in Argentina. Objective: to quantify the preference of different technical and economic criteria considered by veterinarians when a mastitis control plan (MCP) is being devised to apply on farm. Methodology: During an annual meeting of the Argentinian Milk Quality Association, 45 veterinarians with at least 5 yr of experience working on milk quality participated in a choice experiment (CE). Six interventions were considered in the design of MCP: milking machine maintenance, milking routine, clinical mastitis management, dry cow therapy, culling of cows with persistent infection, and environmental hygiene. Four attributes were defined for MCP: operational costs, efficacy over bulk milk somatic cell count (BMSCC) reduction, efficacy on clinical mastitis (CM) reduction, and specific level of technical support needed to implement the MCP. The cost attribute had 3 levels (50, 40, and 30 US$ /day), the efficacy on BMSCC reduction had two levels (300,000 to 500,000 cells/mL or < 300,000 cells/mL), the efficacy in reducing CM cases had 3 levels (10 to 20%, 5 to 10% and < 5%) and technical support had three levels (3, 6, and 16 US$/day). The CE was framed using a fractional factorial design combining MCP attributes ($n = 4$) and their level ($n = 12$) in an orthogonal matrix (IBM SPSS Conjoint 20). Ten cards were randomly chosen from the matrix (48 combinations) to perform the CE. Each card contained a MCP (A to I) with its attributes and its specific

Table 1223.

Table 1: Relative importance (%) of the mastitis control plan attributes for two choice scenarios

	Cost	Efficacy on BMSCC reduction	Efficacy in reducing CM cases	Technical support
Completely confined dairy herd	22.5	23.2	42.2	12.1
Confined plus grazing dairy herd	26	24.4	38.3	11.3

level. The CE was conducted considering that the MCP would be applied in a 100 milking cows herd with a BMSCC around 500,000 to 600,000 cells/mL, during the last 12 mo. The veterinarians had to evaluate two scenarios; a completely confined and a confined plus grazing dairy herd. Participants ranked the MCP list from the best to the worst, for both herd scenarios. Such arrange was used to estimate the average utility (U) taking into account the preferences of the participants. The model was as follows, U = u(a1)+u(a2)+…+u(a4), where, U = total utility of MCP; a = attribute; $u(a_i)$ = unit of change of U for u. Results: The model showed that efficacy criteria prevailed over economic criteria; while the technical support had marginal influence in the decision (Table 1). An inverse relationship between cost and utility was found, which means that less costly intervention is preferred. In contrast, we found a direct relationship between efficacy and utility.

Key Words: conjoint analysis, mastitis control, choice experiment

1224 A model to estimate losses due to bovine mastitis for Argentinian dairy herds. M. Richardet[1,2], H. Solari[3,4], C. Vissio[*1,2], J. Bartolome[5], G. Bo[6], P. Turiello[2], C. Bogni[7], and A. Larriestra[2], *[1]CONICET, Rio Cuarto, Argentina, [2]Facultad de Agronomia y Veterinaria, UNRC, Rio Cuarto, Argentina, [3]CONICET, Buenos Aires, Argentina, [4]Facultad de Ciencias Exactas, Fisicas y Naturales, UBA, Buenos Aires, Argentina, [5]Facultad de Ciencias Veterinarias, UNLPam, General Pico, Argentina, [6]IAP Ciencias Basicas y Aplicadas, UNVM, Villa Maria, Argentina, [7]Facultad de Ciencias Exactas, Físico-Químicas y Naturales, UNRC, Rio Cuarto, Argentina.*

A comprehensive economic evaluation of disease control implies developing models to capture the complexity and dynamics of the production system, especially for diseases like mastitis, which has multiples effects such as milk losses, increased risk of culling or a higher likelihood of reproductive failure. Objective: to describe preliminary results of estimated clinical (CM) and subclinical mastitis (SCM) frequency caused by *S. aureus* and their milk associated losses by a stochastic simulation model. Methodology: The model simulates discrete events overtime mimicking a real Holstein herd in terms of production and reproduction. The system has been divided into compartments involving reproduction, production, disease, feeding and culling/mortality events and their respective costs overtime. The model has been written in C language and its parameters have been gathered through a literature review. The model starts with a user defined herd in terms of demography and health status. From that point, the system projects the whole dynamics of the herd for a specific time horizon (e.g., 12 mo). The model focuses on *S. aureus* infections and drives the infection within the herd considering transition probabilities among different cows (uninfected or subclinically or clinically infected). The system updates the whole herd and disease information every 2 wk. As an example, the model has been run 100 times in a 200-cow herd. Results: The annual projection showed a median gross CM prevalence of 3% (q1 = 2%; q3 = 4%) and a median gross SCM prevalence of 21% (q1 = 17%; q3 = 25%). Estimated milk losses due to CM and SCM were 2.87 and 1.40 l/cow/day, respectively. All results are consistent with observational data recently published in Argentina. The model evaluation and verification on relevant assumptions need to be done. The model runs satisfactorily and it can be customized for the user. Further development will involve the inclusion of multiples contagious and environmental microorganisms.

Key Words: stochastic model, milk loss, mastitis

1225 Effects of oral calcium formate supplementation in peripartum dairy cows. E. W. Carneiro[1], E. E. Ichikawa[2], D. M. V. F. Carneiro[3], and R. D. Almeida[*1], *[1]Universidade Federal do Paraná, Curitiba, Brazil, [2]Bayer HealthCare, São Paulo, Brazil, [3]Instituto Federal Catarinense, Araquari, Brazil.*

The objective of the study was to evaluate the effects of oral calcium formate supplementation on serum total calcium (tCa), ionic calcium (iCa), β-hydroxybutyrate (BHBA), total cholesterol, and cortisol in early-lactation dairy cows. In 2 commercial dairy farms in Castro county, Paraná State, Southern Brazil, 242 Holstein cows (150 multiparous and 92 primiparous) were blocked by herd, parity, and tCa status 6 h after calving. Blood samples were analyzed for group allocation (normal and hypocalcemia groups) using 8.9 mg/dL as the cutpoint (IDEXX VetTest® Chemistry Analyzer, Inc., Westbrook, ME). Within each block, fresh cows were randomly allocated to treatment (T) and control (C) groups, with treated -cows being supplemented twice, 6 and 31 h after parturition, with 350 mL of 14.3% (w/w) calcium as a 48.6% aqueous suspension of calcium formate (Calfon Oral®, Bayer HealthCare). Six blood samples from each animal were collected (6, 12, 31, 54, 78, and 102 h after calving) for determination of tCa and iCa. Blood samples for cortisol and cholesterol analysis were collected 6 h and 5 d after calving, while for BHBA analysis, blood samples were collected on Days 3, 5, and 7. Data was analyzed using MIXED procedure of SAS with a model containing the effects of block, treatment, time, and treatment*time interaction as fixed effects and cow within treatment as a random effect. Hypocalcemia incidence rates were 43% using on-farm tCa from VetTest ($\leq$ 8.9 mg/dL), 78% using tCa ($\leq$ 8.0 mg/dL) and 76% using iCa (concentration $\leq$ 4.0 mg/dL), with the lowest iCa values being observed at 12 h postpartum. Serum iCa values were higher (P = 0.04) in oral Ca formate-treated cows; 3.62 vs. 3.55 ± 0.02 mg/dL for the controls. Subclinical ketosis (serum BHBA $\geq$ 1.2 mmol/L) incidence rate was 21.5% (52/242). Estimates

of BHBA on Day 5 were lower ($P = 0.03$) for treated cows; 0.70 vs. 0.87 ± 0.06 mmol/L for the non-treated ones. No differences were detected ($P > 0.05$) for tCa, cholesterol, and cortisol concentrations between T and C animals. During the experimental period, both farms had shown very high levels of subclinical hypocalcemia. The oral calcium formate supplementation had shown modest, but beneficial effects in early-lactation dairy cows, increasing ionic Ca and reducing BHBA concentrations, important goals to control metabolic disorders in dairy farms.

Key Words: milk fever; ketosis; subclinical hypocalcemia

1226 Effect of prenatal and lactating cow trace mineral source on Angus and Brangus calf acute phase protein response to a weaning stressor.

D. M. Price*[1], K. G. Arriola[2], K. K. Arellano[3], M. M. O'Neil[1], W. B. Watson III[1], D. M. Irsik[3], D. O. Rae[3], M. J. Hersom[1], J. V. Yelich[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [3]College of Veterinary Medicine, University of Florida, Gainesville.*

Trace mineral (TM) source provided to gestating and lactating Angus and Brangus cows and its subsequent effect on acute phase protein (APP) response in like breeds of calves at weaning was examined during 2 yr. Treatments were inorganic (salt sulfates) or organic (Se-yeast and proteinates) TM supplementation of Co, Cu, Fe, I, Mn, Mo, Se and Zn (3 d/wk, 0.4 kg·$^{-1}$454 kg BW·$^{-1}$d·cow^{-1}·d^{-1}). Delivery of TM to cows was initiated 88 ± 2 d pre-calving in year 1 and from conception to weaning of year 2. In both years, calves (year 1, $n = 28$/sex, 7/treatment×breed of bulls, heifers, steers; year 2, $n = 48$/sex, 24/treatment×breed of heifers, steers) were physically separated from dams at weaning (d 0) and maintained in dry-lot pens from d 0– 7, and on bahiagrass pastures from d 7–14. Calf blood samples were collected for analysis of APP including acid soluble protein (ASP), ceruloplasmin and haptoglobin on d 0, 1, 3, 7, and 14 relative to weaning. Calf was the experimental unit with PROC MIXED repeated measures within each year for analysis. Models included fixed effects of TM treatment, breed, calf sex, day relative to weaning, and interactions. Treatment did not affect any APP in year 1 ($P > 0.05$) or year 2 ($P > 0.05$). Day affected ($P \leq 0.05$) all APP values within a year. In year 1, peak concentrations of all APP occurred on d 3. In year 2, peak concentrations of ASP and haptoglobin occurred on d 3, while ceruloplasmin concentrations peaked on d 7. Within a year, ASP concentrations were greater ($P \leq 0.01$) in Brangus (year 1 = 83.4 ± 3.5; year 2 = 84.9 ± 2.6 mg/dL) than Angus (year 1 = 68.0 ± 3.5; year 2 = 61.7 ± 2.6 mg/dL) calves. Haptoglobin concentrations were greater ($P \leq 0.05$) in year 1 and year 2 in Angus (1.8 ± 0.1 units) than Brangus (1.5 ± 0.1 units) calves within each year. For ceruloplasmin, heifers had greater ($P \leq 0.05$) concentrations (15.2 ± 0.5 mg/dL) than steers (13.6 ± 0.5 mg/dL) and bulls (12.9 ± 0.5 mg/dL) in year 1; whereas in year 2, heifers (16.7 ± 0.4 mg/dL) had greater ($P \leq 0.05$) ceruloplasmin concentrations than steers (15.5 ± 0.4 mg/dL). In conclusion, calf breed and sex had greater effects on APP response to weaning than TM source.

Key Words: trace minerals, weaning, acute phase response

1227 Factors associated with average daily gain in dairy heifer calves on U.S. dairy operations.

C. B. Shivley*[1,2], N. J. Urie[1,2], and J. E. Lombard[2], *[1]Colorado State University, Fort Collins, [2]USDA:APHIS:VS:Center for Epidemiology and Animal Health, National Animal Health Monitoring System, Fort Collins, CO.*

The objective of this study was to evaluate average daily gain (ADG) in U.S. dairy heifer calves based on different health, feeding, and management practices, as well as environmental factors. This study was conducted as part of the calf component of the National Animal Health Monitoring System's Dairy 2014 study, which included 104 dairy operations in 13 states. The calf component was an 18-mo longitudinal study focused on dairy heifer calves from birth to weaning. This analysis included data from 1,331 Holstein calves. The mean ADG was 0.75 kg/day (SE = 0.007), and calves were fed liquid diets an average of 63.8 d (SE = 0.4). Backward elimination model selection in Proc Mixed of SAS® was used after univariate screening ($P < 0.2$) to determine which environmental factors, diet, and management practices significantly impacted ADG. The final model included disease Y/N ($P < 0.001$), kg protein fed in the liquid diet per day ($P < 0.001$), the average temperature and humidity index for the preweaning period ($P < 0.001$), dam lactation number ($P < 0.001$), bedding type ($P < 0.001$), and singleton vs. twin birth ($P = 0.006$). After controlling for other independent variables in the model, calves with no disease events gained on average 0.05 kg/d more than calves with one or more disease events. Every 1 kg of protein fed per day equated to 0.1 kg/day of gain. Each 10-unit decrease in THI equated to 0.02 kg/day of gain. Calves from third or higher lactation dams had the highest gains (0.68 kg/d), followed by second lactation dams, and last first lactation dams (0.63 kg/d). Calves bedded with a combination of bedding materials gained the most (0.72 kg/d), followed by those bedded with shavings, then straw or hay, and lastly no bedding or sand (0.52 kg/d). Single calves gained 0.08 kg/day more than twins. These results highlight the importance of feeding an appropriate quantity and quality of a liquid diet, keeping calves healthy, and mitigating the effects of temperature and humidity on ADG.

Key Words: dairy heifers, average daily gain, calf nutrition

1228 Factors associated with morbidity in dairy heifer calves on U.S. dairy operations.

N. Urie*, C. B. Shivley, and J. E. Lombard, *USDA:APHIS:VS:Center for Epidemiology and Animal Health, National Animal Health Monitoring System, Fort Collins, CO.*

The objective of this study was to evaluate morbidity in U.S. dairy heifer calves based on different health, feeding, and management practices, as well as environmental factors. This study was conducted as part of the calf component of the National Animal Health Monitoring System's Dairy 2014 study, which included 104 dairy operations in 13 states. The calf component was an 18-mo longitudinal study focused on dairy heifer calves from birth to weaning; data were collected on 2,545 calves. The morbidity rate for all calves enrolled in the study was 34%, with 7% of calves experiencing more than one disease event. It is likely that some sick calves were neither identified nor recorded and morbidity is underreported. The majority of clinical signs reported were digestive (56%) and respiratory (34%). Almost all sick calves (90%) received treatment, with 81% of treated calves receiving antimicrobials. Of calves treated with antimicrobials, the most commonly used classes were fluoroquinolones (28% of calves) and sulfonamides (25% of calves). The mortality rate for the study was 5.2%. The primary causes of death were reported as unknown (35% of calves), digestive (31%), and respiratory (16%). Backward elimination model selection in Proc Genmod of SAS® was used after univariate screening ($P < 0.2$) to determine which environmental factors and management practices significantly impacted morbidity. The final model included serum IgG ($P = 0.024$), gender of the primary caretaker ($P = 0.031$), and number of calves housed together ($P = 0.049$). Calves with an increased serum IgG were less likely to have a reported a disease event. Calves that had a female or male as the primary caretaker were 1.2 times more likely to have a reported disease event compared with calves that had a male and female as the primary caretaker. As group size increased, the risk of reported disease also increased. Practices that weren't significant in the final model included the use of vaccines, the addition of antibiotics, coccidiostats, or direct fed microbials to milk, and pasteurization of milk. These results highlight the continued importance of ensuring a high level of passive transfer of immunoglobulins in calves via colostrum, the importance of vigilant caretakers, and the possible morbidity risks of group housing.

Key Words: dairy heifers, morbidity, mortality

1229 Factors associated with *Cryptosporidium* and *Giardia* infection in preweaned dairy heifer calves.

N. Urie[*1,2], C. B. Shivley[1,2], and J. E. Lombard[2], [1]*Colorado State University, Fort Collins,* [2]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, National Animal Health Monitoring System, Fort Collins, CO.*

The objective of this study was to evaluate the presence of *Cryptosporidium* (*Crypto*) and *Giardia* in U.S. dairy heifer calves based on different management practices and environmental factors. This study was conducted as part of the calf component of the National Animal Health Monitoring System's Dairy 2014 study, which included 104 dairy operations in 13 states. The calf component was an 18-mo longitudinal study focused on dairy heifer calves from birth to weaning. Fecal samples were collected from 2,009 calves: 1,258 calves in the East region (IA, MI, MN, MO, NY, OH, PA, VT, VA, WI) and 751 calves in the West region (CA, CO, WA). Calves were sampled from 3 to 66 d of age, with a mean of 22 d (SE = 0.13). Calves were evenly sampled throughout the spring ($n = 491$), summer ($n = 539$), fall ($n = 536$), and winter ($n = 443$) seasons. Overall, 43.6% of calves were infected with *Crypto* and 30.0% of calves were infected with *Giardia*. Backward elimination model selection in Proc Genmod of SAS® was used after univariate screening ($P < 0.2$) to determine which environmental factors and management practices significantly impacted the presence of *Crypto* or *Giardia*. The final *Crypto* model included days of age at fecal collection ($P < 0.001$), herd size ($P = 0.03$), and season ($P = 0.04$). Calves £28 d of age were 1.24 times more likely to be infected with *Crypto* compared with calves > 28 d of age. Large herds (500+ cows) were 1.12 times more likely to be infected with *Crypto* compared with small herds (30 to 99 cows). Calves sampled in the fall were 1.1 times more likely to be to be infected with *Crypto* than calves sampled in the spring. The final *Giardia* model included season ($P < 0.001$), region ($P = 0.001$), liquid diet additives ($P = 0.002$), and average daily gain (ADG; $P = 0.003$). Calves sampled in spring, summer, or fall were 1.14 times more likely to be infected with *Giardia* than calves sampled in the winter. Calves in the East region were 1.15 times more likely to be positive for *Giardia* than calves in the West region. Calves fed additives other than antibiotics and direct fed microbials, such as larvicides and coccidiostats, in their liquid diet were 1.12 times more likely to be infected with *Giardia.* Additionally, ADG had a negative association with *Giardia*. These results highlight the factors associated with the presence of *Crypto* and *Giardia* in preweaned dairy heifer calves.

Key Words: dairy heifers, *Cryptosporidium*, *Giardia*

1230 Factors associated with colostrum quality and passive transfer status of dairy heifer calves on U.S. dairy operations. J. E. Lombard[*1], C. B. Shivley[1,2], and N. Urie[1,2], *[1]USDA:APHIS:VS:Center for Epidemiology and Animal Health, National Animal Health Monitoring System, Fort Collins, CO, [2]Colorado State University, Fort Collins.*

Passive transfer of immunity is essential for the short- and long-term health of dairy calves. The objective of this study was to evaluate colostrum quality and passive transfer status of U.S. dairy heifer calves. This study was conducted as part of the calf component of the National Animal Health Monitoring System's Dairy 2014 study, which included 104 dairy operations in 13 states. This longitudinal study focused on dairy heifer calves from birth to weaning and was conducted over an 18-mo period. Data analysis included 1,972 Holstein calves. The mean colostrum IgG was 74.4 g/L (SE 0.72), with 77.4% of samples having colostrum IgG levels above 50 g/L. The mean serum IgG was 21.6 g/L (SE 0.25), and 73.3% of calves had serum IgG levels above 15 g/L. Backward elimination model selection in Proc Mixed of SAS® was used to determine which factors were most important ($P < 0.05$) for determining colostrum IgG levels. The final model for colostrum IgG included the source of the colostrum ($P < 0.001$) and the temperature and humidity index (THI) for the month before calving ($P < 0.001$). Colostrum IgG was highest for third or higher lactation dams (84.2 g/L) and lowest for commercial colostrum replacers (39.5 g/L). For every 10-unit increase in THI, the colostrum IgG increased 1.4 g/L. Factors most important for predicting serum IgG levels were also evaluated using a backward elimination model selection in Proc Mixed after univariate screening ($P < 0.2$). The final model for serum IgG included source of the colostrum ($P < 0.001$), timing to the first feeding ($P < 0.001$), total amount of colostrum fed in 24 h ($P = 0.010$), the age of the calf at blood sampling ($P < 0.001$), colostrum IgG ($P < 0.001$), and THI for birth month ($P = 0.026$). Serum IgG was highest for calves from first lactation dams (23.4 g/L) and lowest for commercial colostrum replacer (14.5 g/L). For every hour following birth that colostrum was administered, serum IgG decreased 0.37 g/L. For every 1 L of colostrum administered in the first 24 h after birth, the serum IgG increased 0.56 g/L. For every 10 g/L increase in colostrum IgG, serum IgG increased 1.1 g/L. For every 10-unit increase in birth month THI, the serum IgG increased 0.32 g/L. These results indicate that prompt feeding of high-quality colostrum in appropriate amounts following birth and THI are crucial to the passive transfer status of dairy calves.

Key Words: dairy heifer calves; colostrum quality; passive transfer

1231 Risk factors for calf mortality on farms using automated feeders in the Midwest USA. M. Jorgensen* and M. I. Endres, *University of Minnesota, St. Paul.*

Use of automated calf feeding systems is increasing across the USA, yet information regarding health and mortality outcomes is limited. The objective of this study was to investigate the association of various farm management practices, housing, and environmental factors with mortality in preweaned dairy calves. Twenty-three Midwestern dairy farms were included in this mortality analysis. Farms were visited approximately every 60 d for 18 mo. Housing and environmental factors were measured at the time of each visit. Management practices were collected using a questionnaire and mortality events were gathered from producer-kept records. Relationships between categorical factors of interest and mortality rate were calculated using the mixed procedure of SAS. Pearson's correlation was used for continuous variables. Average mortality of calves on farms using automated feeders was 3.85 ± 3.70%/yr and 57% of farms (13/23) reported mortality rates below 3%/yr. The maximum recorded mortality rate was 13.41%/yr and the minimum was 0.24%/yr. Farm average serum total protein concentration of calves < 5 d old was negatively associated with farm annual mortality rate ($R = -0.50$, $P = 0.02$; mean sTP = 5.4 g/dL ± 0.74). Farms that disinfect the navels of newborn calves had a lower ($P = 0.03$) mortality rate (mean ± SE, 2.97 ± 0.80%; 78% of farms) than farms that do not disinfect (7.32 ± 1.59%; 22% of farms). Farms that use the drinking speed of calves as an alarm had a lower ($P < 0.001$) annual mortality rate (2.37 ± 0.83%; 74% of farms) than those that do not (6.57 ± 1.13%; 36% of farms). Farms that disinfect the calf pens between groups had a lower ($P = 0.04$) annual mortality rate (2.55 ± 0.94; 59% of farms) than those that do not disinfect (5.78 ± 2.55%, 41% of farms). Trends were detected in the correlations between mortality rate and bacteria counts (standard plate count) of milk collected from the feeder hose ($R = 0.37$, $P = 0.08$; median = 435,000 cfu/mL, IQR = 3764,375 cfu/mL), size of the dairy (number of calves on site; $R = -0.41$, $P = 0.08$; mean = 82.18 ± 84.26 calves) and age difference in calf groups ($R = 0.41$, $P = 0.06$; mean = 3.07 ± 2.03 wk). Basic calf-care practices remain vital to ensuring calf survival in automated feeding systems. These data indicate that farms using automated feeders are able to achieve a very low rate of death loss in preweaned calves, but a high variability in mortality among farms indicates continued room for improvement in calf death losses.

Key Words: automated calf feeding, mortality, management

1232 Impact of milk-feeding programs on fecal bacteria population and antimicrobial resistance genes in *Escherichia coli* isolated from feces in preweaned calves. G. Maynou[*1], L. Migura-Garcia[2], J. Subirats[3], H. Chester-Jones[4], D. Ziegler[4], A. Bach[1,5], and M. Terré[1], *[1]IRTA, Caldes de Montbui, Spain, [2]CRESA, Cerdanyola del Vallès, Spain, [3]ICRA, Girona, Spain, [4]University of Minnesota Southern Research and Outreach Center, Waseca, MN, [5]ICREA, Barcelona, Spain.*

The objectives of this study were to characterize fecal bacteria communities and evaluate the presence of antimicrobial resistance genes isolated from fecal *Escherichia coli* of dairy calves fed two different milk feeding programs. Fifteen Holstein newborn female calves (38.4 ± 3.21 kg BW) were fed pasteurized waste milk (pWM) with β-lactam antimicrobials residues, and 10 calves (39.2 ± 4.89 kg BW) were fed milk replacer (MR) with similar nutrient composition (27.5% CP, 32.1% fat) to waste milk (28.6% CP, 30.0% fat) from birth to weaning at 49 d of age. Fecal samples of 8 calves fed MR and 11 calves fed pWM were obtained on d 42 to profile fecal bacteria populations. The DNA was extracted and amplified for Eubacteria sequencing using Illumina Miseq platforms. Samples were filtered and assigned to a reference taxonomy using the SILVA reference database. A first analysis was made to assess differences in α and β diversity between the 2 milk-feeding sources using QIIME. An ANOVA was used to identify differences at order level between feeding practices. Furthermore, 25 *E. coli* isolates from fecal swabs of all calves at 35 d of age were used to identify resistance genes. A total of 10 resistance genes corresponding to aminoglycosides (*aadA*, *strA/strB* and *aac(3)IV*), β-lactam (*bla*CMY-2), tetracyclines (*tetA*, *tetB* and *tetC*) and sulfonamides (*sul1*, *sul2* and *sul3*) were examined by PCR and analyzed using a binary logistic regression to assess differences between feeding practices. Chao1 and Shannon α diversity indexes were similar in calves regardless of the feeding program followed. The prevalence of Clostridiales order was greater ($P < 0.05$) whereas Bacteroidales tended ($P = 0.07$) to be lower in pWM calves (0.58 ± 0.029 and 0.33 ± 0.032, respectively) than in those fed MR (0.44 ± 0.034 and 0.46 ± 0.038, respectively). A high prevalence of *sul1*, *sul2*, *tetA*, *aadA*, *strA/strB* and *aac(3)IV* were found in both treatments (0.43 ± 0.142, 0.62 ± 0.137, 0.50 ± 0.141, 043 ± 0.142, 0.63 ± 0.138, 0.43 ± 0.149, respectively) whereas the prevalence of CMY-2 in pWM calves (0.67 ± 0.122) was greater ($P < 0.05$) than in MR fed calves (0.10 ± 0.095). In conclusion, milk feeding practices can cause shifts in calf gut bacteria populations. High prevalence of extended spectrum β-lactamase resistance genes has been found in fecal *E. coli* isolates from pWM fed calf.

Key Words: calf feeding programs, fecal bacteria population, resistance genes.

1233 A survey of management practices and producers' perceptions regarding manual and automated milk feeding systems for dairy calves. C. Medrano-Galarza[*1,2], J. Rushen[3], A. M. de Passillé[3], A. Jones-Bitton[1], T. J. DeVries[4,5], S. J. LeBlanc[1], and D. B. Haley[1,2], *[1]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, [2]Campbell Centre for the Study of Animal Welfare, University of Guelph, Guelph, ON, Canada, [3]Faculty of Land & Food Systems, University of British Columbia, Agassiz, BC, Canada, [4]Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada, [5]University of Guelph, Guelph, ON, Canada.*

Dairy calves are commonly housed individually and fed by manual milk feeding (MMF) methods, with buckets or bottles. Automated milk feeders (AMF) allow for more natural milk feeding frequency and volume, with calves usually housed in groups. A national online survey was developed to determine management practices for the care of milk-fed calves in Canada, and factors that influence use of MMF or the switch to AMF. A total of 670 responses were received (5.7% of all dairy farms in Canada). Of respondents, 16% used AMF and 84% used MMF. Seventy percent of farms using AMF had free-stall barns compared to only 48% for those using MMF. Interestingly, 30% of AMF farms also had automatic milking systems (AMS), compared to 8% for MMF farms. Having a herd size > 80 milking cows (OR = 5.1; $P = 0.003$) and automated feed pushers (OR: 5.0; $P = 0.03$) were associated with having an AMF among tie-stall farms. For loose-housing farms (i.e., free-stall and bedded-pack), herd size > 80 milking cows (OR = 2.7; $P = 0.004$), having an AMS (OR = 2.4; $P = 0.01$), and use of cow-brushes (OR = 4.5; $P = 0.002$) were associated with having an AMF. Automated milk-fed calves were typically housed in groups of 10 to 15, while nearly 75% of the farms with MMF housed calves individually. Having group housing for milk-fed calves was associated with larger farms (> 80 milking cows; OR = 2.2; $P < 0.001$), having an AMS (OR = 1.8; $P = 0.03$), and having fewer personnel looking after the calves (1 vs. 2 people: OR = 1.8; $P = 0.009$; and 1 vs. ≥ 3 people: OR = 2.0: $P = 0.007$). Although both AMF and MMF farms fed similar amounts of milk the first week of life (a median of 6 L/d), the cumulative volume fed in the first 4 wk differed significantly ($P < 0.001$), with a median of 231 vs. 182 L, respectively. Median milk allowance for AMF also peaked higher than for MMF (10 vs. 8 L/d, respectively). The 4 most important producer-identified factors that motivated producers to switch to automation were to raise better calves, offer more milk to calves, reduce labor, and improve working conditions. For MMF farms, the investment in equipment and in group housing facilities, and farm size were the primary reasons given for maintaining manual feeding methods. To conclude, AMF farms were larger, provided more milk to calves, and use

more automation. These data provide insights into calf rearing practices across Canada, resulting in improved understanding of producers' uptake, and application of technology.

Key Words: calves, feeding practices, automation.

1234 Investigating the within-herd prevalence and risk factors of hyperketonemia of dairy cattle in Ontario as diagnosed by the test-day concentration of milk β-hydroxybutyrate.

E. H. Tatone*[1], T. F. Duffield[1], S. J. LeBlanc[1], T. J. DeVries[2], and J. L. Gordon[1], *[1]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada, [2]Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada.*

A large-scale observational study was conducted to estimate the within-herd prevalence and cow-level risk factors of hyperketonemia (HK) in dairy herds in Ontario that participate in a dairy herd improvement association (DHIA) program. Hyperketonemia was diagnosed as milk β-hydroxybutyrate ≥ 0.15 mmol/L (Ketoscreen test, MilkoScan FT600, Foss Analytical A/S, Hillerød, Denmark) at first DHIA test within the first 30 d in milk (DIM). Eight hundred and thirteen herds providing at least 61 first milk tests from June 2014 to December 2015 and were used to estimate the provincial within-herd prevalence with 95% confidence, 80% power and precision of 10%. All herds on DHIA in Ontario (n = 3,042) were used to construct multi-level logistic regression models to investigate the association of commonly measured variables with the odds of HK at first DHIA milk test at the cow-level. The overall HK prevalence in Ontario was 22% of cows at first test, with an average within-herd prevalence of 21% (SD = 10.6). The prevalence of HK had a distinct seasonality with the lowest prevalence occurring from July to November. Herds with automatic milking systems (AMS) (11%, n = 92) had higher within-herd prevalence than all other herds, as well as increased odds of HK in multiparous animals at first test (OR: 1.46; CI_{95}: 1.30 to 1.63). This association requires further study of causal factors. Both primiparous and multiparous Jersey cattle had 1.4 times higher odds of HK than Holstein cattle. After controlling for breed, a milk yield > 26 kg and milk fat > 4.8% at the last milk test of the previous lactation were associated with decreased odds of HK in the current lactation (OR_{yield}: 0.55; $OR_{fat\%}$: 0.83). Increased days dry and longer calving intervals, for multiparous animals, and older age at first calving for primiparous animals increased the odds of hyperketonemia at first test. This is the first report of associations of AMS, and milk yield and components late in the previous lactation with increased HK.

Key Words: prevalence hyperketonemia β-hydroxybutyrate

Table 1235.

Table 1. Effect of 8 wk milk replacer (kg) and calf starter (kg) intake on first-lactation 305-d milk, fat, and protein yield (kg) in all cows (n=2880).

Item	R^2	Variable	Estimate	SE	P-value
305-d milk	0.10	Milk Replacer	9.89	12.42	0.4261
		Calf Starter	8.21	2.53	0.0012
305-d fat	0.28	Milk Replacer	0.52	0.53	0.3332
		Calf Starter	0.36	0.10	0.0002
305-d protein	0.17	Milk Replacer	0.29	0.35	0.4115
		Calf Starter	0.33	0.07	<0.0001

1235 Relationships between early life milk replacer and starter intake and first lactation performance of Holstein dairy cows.

H. Chester-Jones*[1], B. J. Heins[2], D. Ziegler[1], D. Schimek[3], S. E. Schuling[3], B. Ziegler[3], M. B. De Ondarza[4], C. J. Sniffen[5], and N. Broadwater[6], *[1]University of Minnesota Southern Research and Outreach Center, Waseca, [2]University of Minnesota West Central Research and Outreach Center, Morris, [3]Hubbard Feeds Inc., Mankato, MN, [4]Paradox Nutrition, West Chazy, NY, [5]Fencrest, LLC, Holderness, NH, [6]University of Minnesota Extension, Rochester.*

The objective was to determine relationships between early life milk replacer and starter intake and first lactation performance of Holstein cows. Data were collected from birth yr of 2004 to 2012 for 2,880 Holstein animals. Calves were received from 3 commercial dairy farms and enrolled in 37 different calf research trials at SROC from 3 to 195 d. Upon trial completion, calves were returned to their respective farms. Milk replacer options included varying protein level and amounts fed but in the majority of studies calves were fed a 20% CP: 20% fat MR at 0.57 kg/calf daily. Most calves (93%) were weaned at 6 wk. Milk replacer DM intake, starter intake, ADG, and BW at 8 wk were (mean ± SD): 21.7 ± 2.5, 44.4 ± 12.0 kg, 0.63 ± 0.12 kg/d, and 75.8 ± 8.4 kg, respectively. Average age at first calving and first lactation 305-d milk yield were: 715 ± 46.5 d and 10,959 ± 1,527 kg, respectively. Mixed model analysis was conducted using the REML model fitting protocol of JMP (SAS) to determine the effect of 8 wk milk replacer and 8 wk calf starter intake on first-lactation 305-d milk, milk fat, and true protein yield. Birth season, calving season, calving yr, and calving yr nested within herd were included in the models with calf trial as a random effect. Eight-wk intake of calf starter had a significant positive effect on first lactation 305-d yield of milk and milk components (P < 0.01; Table 1). However, these improvements were modest and variation was high suggesting additional factors not accounted for in this analysis impact first lactation performance. Milk replacer intake, which varied very little in this dataset, had no effect on first

lactation 305-d yield of milk and milk components.

Key Words: calves, milk replacer, calf starter, first lactation.

1236 Feeding management strategies on large and smaller freestall dairy herds in Minnesota. L. Kloeckner* and M. I. Endres, *University of Minnesota, St. Paul.*

The objectives of this study were to evaluate feeding management practices on freestall dairy farms in Minnesota and compare practices between two dairy farm sizes. Eighty-two farms were randomly selected from a list provided by the Minnesota Department of Agriculture that included all dairies in the state. Farms were visited once between May and November to collect on farm measurements and observations and to inquire about management practices. Farms were blocked by size: large farms ($\geq$ 400 cows; n = 45) and smaller farms (> 150 and < 400 cows; n = 37). Data were analyzed using the MEANS, TTEST and FREQ procedures of SAS. Mean farm size for the large and smaller farms was 886 and 278 cows, respectively. Large farms had more separate lactating rations (mean ± SE, 2.98 ± 0.20) and non-lactating rations (1.71 ± 0.07) than smaller farms (1.81 ± 0.15 and 1.35 ± 0.08, respectively). Large farms had more frequent feed pushups (8.91 ± 0.63) and milkings (2.95 ± 0.05) per day than smaller farms (4.94 ± 0.45 and 2.36 ± 0.08, respectively). Bovine somatotropin was used on 75.6% of large farms vs. 43.2% of smaller farms (P = 0.004). The use of a feeding management software (57.8% vs. 2.7%, P < 0.001) and the use of other technologies (84.4% vs. 62.2%, P = 0.03) was greater on large farms compared to smaller farms. Large farms were more likely to use an on farm master mix (37.8% vs. 16.2%, P = 0.047) and less likely to use uprights silos (20.0% vs. 43.2%, P = 0.03) and Ag bags (17.8% vs. 43.2%, P = 0.02) than smaller farms. There were no differences in the usage of bulk bins, commodity bays, bunker silos, and forage piles between each farm size. There were no differences in the type of plastic used to cover forages. Other management practices where no differences were observed included number of feedings per day, target percent refusals, processing method of corn silage, own or hired chopping, corn silage hybrids, TMR mixer type, and an estimate of feed shrink. Results of the study indicate that some feeding management practices are influenced by farm size.

Key Words: feeding, herd size, management practices

1237 Evaluation of the CowVac for controlling flies on Minnesota organic dairy farms. M. A. Kienitz[1] and B. J. Heins*[2], [1]*University of Minnesota, Lakeville,* [2]*University of Minnesota West Central Research and Outreach Center, Morris.*

The objective of this study was to evaluate the efficacy of the CowVac (Spalding Laboratories, Reno, NV) in on-farm organic dairy production systems to control horn flies, stable flies, and face flies. The CowVac utilizes a chute apparatus and powerful vacuums to suction flies off the cows as they walk through the system. The study utilized eight organic dairy farms during the summer of 2015 in Minnesota, and herds ranged from 30 to 350 cows. The farms were divided into pairs by location and during the first period of the summer (June to July) the CowVac was set up on one farm and during the second period of the summer (August to September) the CowVac was sent to its paired farm. Farms were visited once per week to collect flies (or collect and count flies) from the CowVac, as well as count and record flies on cows. Bulk tank milk, fat, and protein production and SCC were collected on farms during the entire study period. Data were analyzed using the GLM procedure of SAS. Independent variables for analyses were the fixed effects of farm, CowVac presence, housing scenario, and period. Horn fly numbers on cows were reduced (P < 0.05) by 44% on farm in the presence of a CowVac (11.4 vs. 20.5 flies/side) compared to the absence of a CowVac. Stable fly (5.4 vs. 7.1 fly/leg) and face fly (1.0 vs. 1.0 fly/cow) numbers were similar (P > 0.05) on farm whether the CowVac was present or absent on farms, respectively. Milk production was similar (P > 0.05) for farms with the CowVac (15.5 kg/d) compared to without (15.3 kg/d) the CowVac. The presence of a CowVac on farm reduced (P < 0.05) horn fly population growth rates (−0.008 vs. 0.002 flies/d) compared to the absence of a CowVac. Cows on farms with no housing (100% pasture) tended (P = 0.07) to have reduced horn fly numbers (11.7 vs. 28.3 flies/side) in the presence of a CowVac compared to the absence of a CowVac on farm. Cows on farms with housing had similar (P > 0.60) horn fly numbers (11.2 vs. 14.8 flies/side) in the presence of a CowVac compared to the absence of a CowVac on farm. In summary, these results indicate the CowVac was effective in reducing horn fly numbers on cows and reduced horn fly growth rates during the pasture season in organic dairy production systems.

Key Words: organic, CowVac, fly control

1238 Prediction of daily concentration of milk and milk components from single-milking values.
M. Duplessis[*1], L. Fadul-Pacheco[2], R. Lacroix[1], D. M. Lefebvre[1], D. E. Santschi[1], and D. Pellerin[3], *[1]Valacta, Ste-Anne-de-Bellevue, QC, Canada, [2]Département des sciences animales, Université Laval, Québec, QC, Canada, [3]Universite Laval, Quebec, QC, Canada.*

Alternate a.m.-p.m. milk testing has been introduced in many countries and is often used instead of collecting milk for 2 consecutive milkings. Models taking into account milking interval have been developed to predict 24-h yield and concentration from milk yield and fat concentration single-milking values. However, there is still a gap between the prediction and the reality. It has been hypothesized that feeding factors could help better estimating 24-h prediction. The purpose of this study was to evaluate feed-related management factors affecting a.m. and p.m. milk yield and milk fat, protein, lactose, urea, somatic cell count (SCC), and β-hydroxybutyrate (BHBA) concentrations as a single predictor of 24-h concentrations. Separate milk samples from a.m. and p.m. milkings were taken for each cow on 98 tiestall and 2 freestall barns. Milk samples were analyzed using Fourier transform infrared spectroscopy. Milk production weighted averages were calculated to obtain daily concentrations. Milking intervals, number of concentrate meals offered, feeding systems (conventional, individual concentrate feeding [ICF] and total mixed ration [TMR]), interval between milking and last concentrate meal were recorded and used as independent variables in the multiple regression analysis. Milk yield and component concentrations from a.m. or p.m. samples to calculated daily concentrations ratios were computed and considered as dependant variables. For analysis purposes, individual ratios were averaged by herd. Multiple regressions were performed with Proc GLMSELECT of SAS using stepwise selection and $P = 0.05$ as the cut-off point. Highest R-squares were obtained while predicting milk yield (a.m.: $r^2 = 0.63$; p.m.: $r^2 = 0.51$), followed by fat concentration (a.m.: $r^2 = 0.30$; p.m.: $r^2 = 0.26$), SCC (a.m.: $r^2 = 0.29$; p.m.: $r^2 = 0.26$), BHBA (a.m.: $r^2 = 0.15$; p.m.: $r^2 = 0.16$), protein (a.m.: $r^2 = 0.14$; p.m.: $r^2 = 0.10$), urea (a.m.: $r^2 = 0.13$; p.m.: $r^2 = 0.08$), and lactose (a.m.: $r^2 = 0.03$; p.m.: $r^2 = 0.00$). Milking interval affected daily prediction of a.m. and p.m. milk yield and a.m. and p.m. fat, SCC, and BHBA contents. Interval between milking and last concentrate meal affected 24-h prediction in all a.m. models except for BHBA. Feeding system had an impact on 24-h prediction of a.m. and p.m. protein and urea concentrations. Regarding lactose, results confirm that a.m. or p.m. concentrations without adjustment could predict 24-h lactose concentration as this component is relatively constant. In summary, feed-related management factors slightly improved 24-h prediction as compared with models adjusting only for milking interval as suggested by the low R-Square increment.

Key Words: single milking, milk yield, component

1239 Sources of variation in dry matter content and particle size distribution in total mixed rations in dairy farms in Argentina.
P. Turiello[*1], M. Ruiz de Huidobro[1], F. Bargo[2], A. Larriestra[1], and A. Relling[3], *[1]Facultad de Agronomia y Veterinaria, UNRC, Rio Cuarto, Argentina, [2]Facultad de Agronomia, UBA, Buenos Aires, Argentina, [3]Department of Animal Sciences, OSU, Wooster.*

Total mixed rations (TMR) composition variation has been associated with lower milk yield and higher health problems at herd level. Our objectives were to describe TMR DM percentage and particle size distribution, and to partition that variance into different sources of variation. Ten dairy farms in Southern Cordoba province, Argentina, were visited for 3 consecutive days during the summer. Fresh TMR offered in the morning to each lactating pen was sampled within 5 min after delivery, to assess DM percentage and particle size distribution with a

Penn State Particle Separator. Duplicate samples were taken at the beginning and at the end of the feed bunk (feed bunk site) in each pen. Number of pens ranged from 1 to 4. To estimate variances in physical and DM composition of TMR and to partition that variance into measurements components, random effects models including farm, pen within-farm, day within-pen and farm, place, and residual error, were fitted to the data (n = 318) using mixed procedures of InfoStat. Particles were assumed to be logarithmically normally distributed. Results are shown in Table 1. Mean DM content of TMR was 45.2% and it ranged from 22.8 to 56.9%. Particle retention on the top sieve (>19.0 mm) was higher than recommended (2 to 8%) for high producing cows. Because cows are expected to sort against large particles and that would change NDF and starch intake, it is important to follow the recommended proportion on the top sieve. Although mean particle percentage on the 19.0 to 8.0-mm sieve was according to the recommendation (30 to 50%), there is a wide range of values. More than 72% of the variation in particle size distribution and DM content was explained by farm and pen within-farm. Within-pen, daily variation accounted for half of the variation for particle size distribution (46 to 61%), which is demonstrating that procedures involved in ration preparation (including adjusting forage inclusion for moisture content) were not always the same. The rest of this variation was explained by sampling and analytical variance. For DM content, 73% of the within-pen variation was explained by day-to-day variation. Our data shows that day-to-day ration variation is an important source of variation within pen in a farm, particularly when DM content is determined, although attention should be paid to sampling and analytical effects to make appropriate decisions.

Key Words: variation, TMR, particle size distribution

1240 Growth measurements of crossbred dairy steers compared to Holstein dairy steers raised in an organic production system. H. N. Phillips* and B. J. Heins, *University of Minnesota West Central Research and Outreach Center, Morris.*

Bull calves (n = 30) were used to compare growth measurements of crossbred and Holstein dairy steers raised in an organic production system. Calves were born at the University of Minnesota West Central Research and Outreach Center organic dairy from March to May 2015 and assigned to 1 of 3 replicated breed groups at birth. Breed groups were: crossbreds comprised of Montbéliarde, Holstein, and Viking Red (MVH; n = 10), crossbreds comprised of Jersey, Normande, and Viking Red (NJV; n = 10), and purebred Holstein (HO; n = 10). Calves were group-housed by breed group (n = 5) and group-fed 6 L/d of 13% total solids organic milk once daily and were weaned when the group consumed an average of 0.91 kg of organic starter per calf per day for 3 consecutive days. Body measurements were recorded at birth, weekly during the pre-weaning period, at weaning, and monthly thereafter. After weaning, steer groups were fed a diet of organic corn, corn silage, alfalfa haylage and minerals. Diets were recorded daily with herd management software. Analysis was performed using PROC MIXED of SAS, independent variables for statistical analysis were the fixed effects of breed group, and replicate was a random effect. Analysis of variables was on a pen basis. Birth weight for calves was: HO: 40.2 kg, MVH: 46.4 kg, and NJV: 39.3 kg ($P > 0.05$). Weaning age was: HO: 69.1 d, MVH: 68.4 d, and NJV: 78.8 d; weaning weight was: HO: 91.7 kg, MVH: 106.0 kg, and NJV: 100.6 kg; and gain per day was: HO: 0.74 kg/d, MVH: 0.86 kg/d, NJV: 0.77 kg/d. Breed groups were not different ($P > 0.05$) for weaning age and weaning weight. However, the MVH calves tended ($P < 0.10$) to have greater gain per day than the HO calves. For the first 9 mo of age, gain per day for steers was: HO: 1.07 kg/d, MVH: 1.01 kg/d, and NJV: 0.98 kg/d ($P > 0.05$). Hip height (cm) (HO: 95.9; MVH: 97.8, and NJV: 94.9) and heart girth (cm) (HO: 107.7, MVH: 112.4, and NJV: 112.1) at weaning was not different ($P > 0.05$) for breed groups. In summary, no significant differences in growth measurements were found between breed groups for dairy steers in this organic production system.

Key Words: organic; dairy steers; growth; breeds

1241 Accuracy and precision of diets for high-producing dairy cows and their impacts on production and milk composition. J. H. Carneiro[1,2], J. F. Santos[2], P. Schmidt[1], T. J. DeVries[3], and R. D. Almeida*[1], *[1]Universidade Federal do Paraná, Curitiba, Brazil, [2]Castrolanda Cooperativa Agroindustrial, Castro, Brazil, [3]Department of Animal Biosciences, University of Guelph, Guelph, ON, Canada.*

The goal of this study was evaluate associated feeding management and nutritional accuracy with milk production and composition on commercial herds. Twenty high-producing dairy farms from Campos Gerais county, Paraná State, Southern Brazil, were visited for 3 consecutive days in the 2015 fall season. Feeding management and TMR preparation related variables, and the physical and chemical characteristics of the offered diets and orts were collected. Production performance and milk composition from the high-production group of cows were obtained from regular milk testing, performed on average 1 ± 5d before or after the data collection period. Pearson correlations were estimated among the management and diet variables with production, milk composition, and feed sorting estimates. Using the Penn State Particle Separator, the offered diets had on average 14.9, 41.8, 32.8, and 10.5% (DM) of long, medium, short, and fine particles, respectively. Long particles showed a daily refusal rate of 9.0%, whereas short and medium particles were preferentially consumed at 1.1 and 1.7%, respectively. A high proportion of long particles in the forage (78.2% of haylage and hay) was

associated with reduction in milk fat % (%MF) ($r = -0.50$; $P < 0.05$), and an increased proportion of cows with fat:protein ratio lower than 1 (FPR < 1) ($r = 0.50$; $P < 0.05$). Errors associated with loading an excess of concentrate ingredients in the TMR wagon were negatively associated with %MF ($r = -0.52$; $P = 0.05$) and milk production ($r = -0.47$; $P < 0.05$). By comparing the formulated diet with the one delivered to the cows, we noted, on a DM basis, a decrease in CP (−3.1%), fat (−7.0%), and ash contents (−10.5%), and an increase in NDF (+10.3%). The accuracy observed between formulated and delivered diets was not associated with the performance of the cows. However, daily variation of the DM content of the diet was associated with a greater proportion of cows with FPR < 1, and reduced FPR ($r = 0.40$; $P = 0.09$ and $r = -0.43$; $P = 0.07$, respectively). Low homogeneity (across 3 d) of the % of long particles in the diet was associated with greater selection against these particles ($r = -0.64$; $P < 0.05$), which showed a curvilinear association with %MF. These results demonstrated that the addition of more concentrate ingredients than expected, as well as the inconsistent intake of different particle sizes throughout the day, had a negative impact on milk production and composition of the studied herds.

Key Words: feed management, feed sorting, total mixed ration

1242 Health treatment costs of pure Holsteins in 8 high-performance Minnesota dairies. M. R. Donnelly*[1], A. R. Hazel[1], B. J. Heins[2], and L. B. Hansen[1], *[1]University of Minnesota, St. Paul, [2]University of Minnesota West Central Research and Outreach Center, Morris.*

Health treatment costs of pure Holstein cows (n = 4,997) were evaluated in 8 high-performance dairy herds in Minnesota. Cows calved from March 2008 to September 2015, and 17 types of health treatments were defined uniformly across herds. The cost for treatment of retained placenta, metritis, cystic ovary, miscellaneous reproduction, ketosis, displaced abomasum, milk fever, lameness, mastitis, digestive, respiratory, injury, California Mastitis Test/milk culture, and other treatments were summed within 6 stages of lactation for parities 1 to 5. Excluded from analysis were hoof trimming, palpation, and reproductive aid. The 6 stages of lactation were defined based on days in milk. The first 4 stages were 60 d each, stage 5 started on Day 241 and was variable in length and continued until the dry date, and stage 6 included the dry period only. Treatment costs were the mean cost of treatment protocols defined by the veterinarians used by the herds in addition to a fixed labor cost of $18/h reported by producers. Labor costs were applied based on time per treatment from a producer survey. Cows were grouped into 2 year-blocks of calving and year-blocks were defined as 2008 to 2010 and 2011 to 2015. Statistical analyses were conducted separately for each parity, and independent variables were the fixed effects of herd, year-block of calving, interaction of herd and year-block, stage of lactation, and interaction of stage of lactation and year-block. Year-blocks were combined for parities 3 to 5 because cows left the herds as they aged. For this reason, only the fixed effects of herd and stage of lactation were considered for parities 3 to 5. For all 5 parities, herd and stage of lactation were highly significant ($P < 0.01$). For parities 1 and 2, year-block and its interactions were highly significant ($P < 0.01$). As expected, treatment costs were largest during the first 60 d in milk, which is usually when cows experience high treatment costs for transition disorders. Least squares means of treatment costs (Table 1) for parities 1 and 2 decreased as year-block increased for most stages of lactation. The most dramatic decrease in treatment cost by year-block occurred within the first 60 d in milk, perhaps indicating an improvement in transition cow management among the herds during the years of the study.

Key Words: treatment costs, management, health

1243 Relationships between early life growth and first lactation performance of Holstein dairy cows. B. J. Heins*[1], H. Chester-Jones[2], D. Ziegler[2], M. B. De Ondarza[3], S. E. Schuling[4], B. Ziegler[4], D. Schimek[4], N. Broadwater[5], and C. J. Sniffen[6], *[1]University of Minnesota West Central Research and Outreach Center, Morris, [2]University of Minnesota Southern Research and Outreach Center, Waseca, [3]Paradox Nutrition, West Chazy, NY, [4]Hubbard Feeds Inc., Mankato, MN, [5]University of Minnesota Extension, Rochester, [6]Fencrest, LLC, Holderness, NH.*

The objective was to determine relationships between early life ADG and BW and first lactation performance of Holstein

Table 1243.

Table 1. Effect of 6 wk BW (kg) and ADG (kg/d on first-lactation 305-d milk, fat, and protein yield (kg; n=2,880).

Item	Variable	R^2	Estimate	SE	P-value
305-d milk	6 wk BW	0.11	20.11	4.41	< 0.0001
	6 wk ADG	0.10	543.71	248.80	0.0290
305-d fat	6 wk BW	0.28	0.84	0.17	< 0.0001
	6 wk ADG	0.28	21.04	9.46	0.0262
305-d protein	6 wk BW	0.17	0.70	0.12	< 0.0001
	6 wk ADG	0.16	22.98	6.70	0.0006

cows. Data were collected from birth yr of 2004 to 2012 for 2,880 Holstein animals. Calves were received from 3 commercial dairy farms and enrolled in 37 different calf research trials at SROC from 3 to 195 d. Upon trial completion, calves were returned to their respective farms. Milk replacer options included varying protein level and amounts fed but in the majority of studies calves were fed a 20% CP: 20% fat MR at 0.57 kg/calf daily. Most calves (93%) were weaned at 6 wk. Milk replacer DM intake, starter intake, ADG, and BW at 6 wk were: 21.5 ± 2.2 kg, 17.3 ± 7.3 kg, 0.53 ± 0.13 kg/d, and 62.4 ± 6.8 kg, respectively. Average age at first calving and first lactation 305-d milk yield were: 715 ± 46.5 d and 10959 ± 1527 kg, respectively. Separate mixed model analyses were conducted using the REML model fitting protocol of JMP (SAS) to determine the effect of 6 wk BW or ADG on first-lactation 305-d milk, fat, and true protein yield. Birth season and calving season, yr, and yr nested within herd were included in the models with calf trial as a random effect. Early life BW and ADG positively affected first-lactation 305-d yield of milk and components ($P < 0.03$; Table 1). Six-week ADG class (< 0.23, 0.23 to 0.33, 0.34 to 0.44, 0.45 to 0.56, 0.57 to 0.67, 0.68 to 0.80, and > 0.80 kg/d) also affected 305-d yield of milk and components ($P < 0.02$). Greater BW and ADG at 6 wk resulted in increased first lactation milk and milk component yields. However, these improvements were modest and variation was high suggesting additional factors not accounted for in this analysis impact first lactation performance.

Key Words: calves, early life, growth, first lactation

1244 Relationships between birth season versus early life starter intake and growth and first lactation performance of Holstein dairy cows.

B. J. Heins*[1], D. Ziegler[2], D. Schimek[3], S. E. Schuling[3], B. Ziegler[3], H. Chester-Jones[2], M. B. De Ondarza[4], C. J. Sniffen[5], and N. Broadwater[6], *[1]University of Minnesota West Central Research and Outreach Center, Morris, [2]University of Minnesota Southern Research and Outreach Center, Waseca, [3]Hubbard Feeds Inc., Mankato, MN, [4]Paradox Nutrition, West Chazy, NY, [5]Fencrest, LLC, Holderness, NH, [6]University of Minnesota Extension, Rochester.*

The objective was to determine the effect of birth season on early life starter intake, growth, and on first lactation performance of Holstein cows. Data was collected from birth yr of 2004 to 2012 for 2,880 Holstein cattle. Calves were received from 3 commercial dairy farms and enrolled in 37 different calf research trials at SROC from 3 to 195 d. Upon trial completion, calves were returned to their respective farms. Milk replacer options included varying protein level and amounts fed but in the majority of studies calves were fed a 20% CP: 20% fat MR at 0.57 kg/calf daily. Most calves (93%) were weaned at 6 wk. Milk replacer DM intake, starter DM intake, ADG, and BW at 8 wk were: 21.7 ± 2.5, 44.4 ± 12.0 kg, 0.63 ± 0.12 kg/d, and 75.8 ± 8.4 kg, respectively. Average age at first calving and first lactation 305-d milk yield were: 715 ± 46.5 d and 10,959 ± 1,527 kg, respectively. Separate mixed model analyses were conducted using the REML model fitting protocol of JMP (SAS) to determine the effect of birth season on 8 wk starter intake, BW, and ADG, and on first-lactation 305-d milk, milk fat, and true protein yield. Birth season, calving season, calving yr, and calving yr nested within herd were included in the models with calf trial as a random effect. Eight wk ADG and 8 wk ADG x birth season were also included when evaluating first-lactation performance. Calves born in fall and winter had greater ($P < 0.05$) starter intake (48.3 vs. 42.8 kg), BW (77.5 vs. 75.1 kg), and ADG (0.66 vs. 0.63 kg/d) at 8 wk. However, calves born in summer produced more 305-d milk during their first lactation than those born in the fall and winter ($P < 0.05$). There was no interaction between birth season and 8 wk ADG on first lactation performance.

Key Words: birth season, early life growth, first lactation

1245 ADSA®-EAAP Speaker Exchange Presentation: Comparing milk yield between cows with different dry period lengths over multiple lactations.

A. Kok*[1], C. van Middelaar[1], A. van Knegsel[2], B. Engel[3], H. Hogeveen[4], B. Kemp[2], and I. de Boer[1], *[1]Animal Production Systems group, Wageningen University, Wageningen, Netherlands, [2]Adaptation Physiology Group, Wageningen University, Wageningen, Netherlands, [3]Biometris, Wageningen University, Wageningen, Netherlands, [4]Business Economics group, Wageningen University, Wageningen, Netherlands.*

To assess economic and environmental consequences of shortening the dry period (DP), we need to be able to compare milk yields of cows with different DP lengths, and to estimate effects on yield over multiple lactations. Milk yield is generally

Table 1244.

Table 1. Effect of birth season on first-lactation 305-d milk, fat, and protein yield.

Item	Birth season P-value	Spring	Summer	Fall	Winter
305-d milk (kg)	0.0206	11,033[ab]	11,145[a]	10,875[b]	10,863[b]
305-d fat (kg)	0.0508	401[ab]	409[a]	401[ab]	397[b]
305-d protein (kg)	0.0343	336[ab]	340[a]	333[ab]	332[b]

[ab]Values in the same row with different superscripts are different ($P < 0.05$)

compared using 305-d yields. This measure, however, does not account for additional yield before calving and potentially shorter calving intervals in case the DP is shortened. First, we aimed to develop a measure to compare milk yields between cows with different DP lengths. We defined an 'effective lactation yield' as kg of fat-and-protein-corrected milk (FPCM) per cow per day from 60 d before calving to 60 d before next calving. We applied this measure to 817 cows with a standard (49d to 90d), short (20d to 40d), or no DP before second calving, using first parity 305-d yield as a covariate. Compared with cows with a standard DP, 305-d yields were reduced by 2.3 kg FPCM d^{-1} for cows with a short DP ($P < 0.05$) and by 7.0 kg FPCM d^{-1} for cows with no DP ($P < 0.05$). Compared with cows with a standard DP, effective lactation yields were similar for cows with a short DP and reduced by 3.1 kg FPCM d^{-1} for cows with no DP ($P < 0.05$). Second, we aimed to assess the impact of shortening the DP over multiple lactations on effective lactation yield. Lactation data (2007 to 2015) of cows of 16 Dutch dairy farms that apply no or short DP were selected if effective lactation yield, current DP, and previous DP were known. Dry period categories were: no (0 to 2 wk), short (3 to 5 wk), standard (6 to 8 wk), and long (9 to 12 wk). A long, short, or no current DP reduced effective lactation yield, compared with a standard DP. Previous DP, however, did not affect effective lactation yield over multiple lactations. In conclusion, the effective yield enables comparison of yield when DP length and calving interval vary. Moreover, cows can be managed with short or no DP over multiple lactations without increasing yield losses.

Key Words: dairy cow, dry period length, long-term effects

1246 Economic impact of introducing automatic milking system on Canadian dairy farms.

J. Ferland[1], E. Vasseur[2], M. Duplessis[*3], E. A. Pajor[4], and D. Pellerin[5], *[1]Université Laval, Québec, QC, Canada, [2]McGill University, Ste-Anne-de-Bellevue, QC, Canada, [3]Valacta, Ste-Anne-de-Bellevue, QC, Canada, [4]University of Calgary, Calgary, AB, Canada, [5]Universite Laval, Quebec, QC, Canada.*

Adoption of automatic milking system (AMS) increased exponentially over the last years around the world. In 2014, 5% of Canadian dairy farms owned an AMS. The objective of this study was to evaluate the economic impact following AMS introduction in Canadian dairy herds. Data were first collected during a phone interview on 213 Canadian dairy farms having shifted to AMS (British-Colombia, $n = 8$; Alberta, $n = 42$; Saskatchewan, $n = 6$; Manitoba, $n = 12$; Ontario, $n = 73$; Québec, $n = 65$; and Atlantic provinces [New-Brunswick, Nova-Scotia, Prince-Edward-Island], $n = 7$). Second, 151 farms out of 213 have answered a more detailed online survey. After AMS adoption, herd size, milk production, and number of robots per herd averaged 100.2 ± 64.3 cows, 10,764 ± 1,663 kg, and 1.94 ± 1.36 robots, respectively. Milk production, reproduction, and culling data were provided by Valacta and CanWest DHI. Partial budgets were computed using an Excel spreadsheet; surveyed data were completed with literature data. Results of the partial budgets were divided by the respective number of cows after the AMS introduction to allow comparison regardless of herd size. Average parameter values were calculated for herds below percentile 25 and above percentile 75 for the net margin per cow and were compared with either a *t* test or a Wilcoxon signed-rank test. On average, after AMS introduction, herd size, milk production and culling rate were increased by 7.3 cows, 741.6 kg/cow/yr and 1.5%, respectively, and calving interval and labor requirement were decreased by 6.8 d and 15.1 h/cow/yr, respectively. Net margin per cow following AMS adoption was negative and averaged CAN $-1,204.41 ± 1,080.06. Introducing AMS resulted in increased costs of CAN $2,277.45 ± 1,362.21/cow mainly due to robot, barn construction or modifications and cow purchase amortizations (41.9% of total increased costs) and interest (27.8%). Increase in income averaging CAN $1,073.04 ± 1,739.10/cow was explained by milk production increase (55.1% of total increased income) and labor requirement decrease (29.8%). Highest net margin herds (P75) were characterized by having higher increased income (P75, CAN $2,331.76 and P25, CAN $-315.81; $P < 0.0001$) as compared with P25 herds. No difference was noted for increased costs ($P = 0.82$) between P25 and P75 herds. Difference in profitability between P75 and P25 herds was mainly due to milk production increase (CAN $524.47/cow; $P = 0.0004$). In summary, only 6% of dairy producers shifting to AMS have an expected payback less than 12 yr, which is the theoretical milking robot useful life.

Key Words: milking robot, partial budget, dairy

1247 Potential economic returns associated with weekly body condition scoring.

C. M. Truman* and J. M. Bewley, *University of Kentucky, Lexington.*

The objective of this study was to estimate the potential economic returns from weekly recordings of body condition score (BCS) using a farm-level decision support tool. The feasibility of weekly BCS increases with the availability of automated BCS systems. To fully benefit from frequent BCS, the information must be used to make BCS-related cow, group, or herd management changes. These decisions may alter BCS distributions which can positively impact disease incidence, reproduction parameters, and feed efficiency. User inputs for the decision support tool included farm-specific herd demographics, financial data, disease incidences, and herd BCS distribution at calving. Differences between the current and goal BCS distributions were used to evaluate the economic returns from a potential improvement. The reported current disease incidences of metritis, milk fever, and ketosis were compared with the newly predicted disease incidences estimated from published odds ratios for effects of BCS on the

disease occurrence. Reproductive improvements were evaluated from a change in days open estimated from odd ratios describing BCS effects on conception rate. The lactation BCS curve was estimated using average herd BCS at calving and a sixth order polynomial regression equation. The average herd BCS before and after implementing regular scoring were used to compare differences in net energy costs across each lactation to compare the effects of BCS on feed efficiency. In an example scenario, input assumptions were sourced from 2015 DairyMetrics (DRMS, Raleigh, NC), USDA National Agriculture Statistics Service, and peer-reviewed literature. The inputs for current and herd BCS distributions are shown in Table 1. The increased revenue from improvements in disease incidence, reproduction, and feed efficiency estimated from this investment were $1,961.95/yr for a herd size of 183 cows. When the herd size was increased to 500 cows, with all other inputs held constant, financial improvements resulted in $3,692.12. Results from improvements in BCS are highly dependent on herd size, prior herd BCS, disease occurrence, and reproduction. This model can be used as a decision support tool to estimate farm-specific economic returns from improving BCS, potentially resulting from an investment in an automated BCS technology.

Key Words: body condition score, economics

1248 The influence of genetic potential on lactation curve and survival response of commercial dairy cattle to early lactation non-steroidal antiinflammatory (NSAID) drug administration.

A. J. Carpenter*[1],J. Ehrlich[2], L. G. D. Mendonça[1], M. J. Brouk[1], and B. J. Bradford[1], *[1]Kansas State University, Manhattan, [2]DairySight LLC, Argyle, NY.*

Previous research has indicated that the attenuation of inflammation in early lactation through the use of NSAID has a beneficial effect on whole-lactation milk production. Multiparous dairy cattle were blocked by breed, dystocia, and twin births, and assigned to 1 of 3 treatments at 12 to 36 h post-parturition (n = 153). Treatments were 1 placebo bolus on the first day of treatment and 3 consecutive daily drenches of sodium salicylate (125 g/cow/d; SAL); 1 bolus of meloxicam (675 mg/cow) and 3 drenches of an equal volume of water (MEL); and 1 placebo bolus and 3 daily drenches of water (CON). Daily milk production was averaged by week of lactation for statistical analysis. As reported previously, there was a significant increase in daily milk production and whole-lactation milk yield following NSAID administration, and a tendency for fewer cows receiving MEL to leave the herd up to 300 d in milk compared to CON. For all cows with at least 8 weekly milk observations reported (n = 130), lactation curves were fit to the MilkBot® model (DairySight LLC, Argyle, NY) to estimate decay, persistence, ramp, and scale. In brief, "decay" describes the rate of decline in daily milk production following peak, and it is used to mathematically derive persistence; "ramp" describes the rate of incline in daily milk production up to peak; and "scale" is a factor that is used to adjust the magnitude of the lactation curve without altering its shape. As a main effect, NSAID did not influence any of these parameters ($P \geq 0.15$); however, there was a significant interaction between the predicted transmitting ability for milk production (milk PTA) and NSAID treatment for decay of the lactation curve (P = 0.02; n = 121). A significant milk PTA and NSAID interaction was also detected for survival ($P < 0.01$). While milk PTA itself had a significant effect on risk of leaving the herd, such that lower milk PTA was associated with increased risk of leaving (P = 0.02), there was no evidence of this relationship in cows who had received either NSAID treatment. In conclusion, NSAID administration protected cattle with lower genetic potential from removal from the herd, possibly through an interaction with persistency of milk production in later lactation.

Key Words: lactation, persistence, inflammation, risk

Table 1247.

Table 1. Body condition score distributions in the before and after example scenario

BCS Score	Before	After
1.00 to 1.75	2.10%	1.20%
2.00 to 2.25	7.40%	4.80%

1249 Management practices and dietary physically effective fiber are related to bulk tank milk de novo fatty acid concentration on Holstein dairy farms. M. E. Woolpert*[1,2], H. M. Dann[1], K. W. Cotanch[1], C. Melilli[3], L. E. Chase[3], R. J. Grant[1], and D. M. Barbano[4], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]University of Vermont, Burlington, [3]Cornell University, Ithaca, NY, [4]Cornell University, Department of Food Science, Northeast Dairy Foods Research Center, Ithaca, NY.*

This study investigated the relationship of management and diet with de novo fatty acid (FA) concentration in bulk tank milk from commercial Holstein dairy farms. De novo FA are synthesized primarily from rumen fermentation products acetate and butyrate. It was hypothesized that farms with higher de novo FA concentrations would prioritize management that optimizes rumen conditions and cow comfort. Farms (n = 39) located in Vermont and northern New York were selected based on high (HDN; 24.5 ± 0.8 g/100 g FA; mean ± SD) or low (LDN; 22.9 ± 0.9 g/100 g FA) bulk tank de novo FA from the previous 6 mo. Milk FA were analyzed using mid infrared spectroscopy chemometric prediction models. Management was assessed during one visit per farm (February to April 2015). Total mixed ration samples were collected and analyzed for chemical composition using near infrared spectroscopy and for particle size distribution using a Penn State Particle Separator modified to include a 4-mm screen. Data were analyzed using the GLIMMIX procedure of SAS with de novo group as the fixed effect and farm as the random effect. In addition, data were categorized as above or below a defined threshold and odds ratios (OR) were calculated using a binary distribution with GLIMMIX. Milk fat (4.0 vs. 3.8%, SE < 0.1, P < 0.01), true protein (3.2 vs. 3.1%, SE < 0.1, P < 0.01), de novo FA concentration (26.0 vs. 23.8 g/100 g FA, SE = 0.2, P < 0.01) and de novo FA yield (315.6 vs. 276.2 g/d, SE = 9.5, P < 0.01) were greater for HDN than LDN farms. Milk (31.9 ± 4.1 kg/d; mean ± SD), fat (1.2 ± 0.2 kg/d), and true protein (1.0 ± 0.1 kg/d) yields and days in milk (173 ± 30 d) were not different (P > 0.25). Bunkspace (50.0 vs. 39.8 cm/cow; SE = 3.7, P = 0.06) tended to be greater for HDN than LDN freestalls. High de novo freestalls tended to be more likely to feed twice per day (OR = 5.0, 95% CL = 0.9 to 28.0, P = 0.07), have a stocking density ≤ 1.1 cows/stall (OR = 4.7, 95% CL = 0.8 to 27.2), P = 0.08) and ≥ 46 cm bunkspace per cow (OR = 10.1, 95% CL = 0.9 to 112.4, P = 0.06). Dry matter (42.6 ± 4.8%), crude protein (15.8 ± 1.5%), neutral detergent fiber (36.4 ± 4.0%), and starch (23.4 ± 4.5%) were not different (P > 0.20) between groups. Ether extract was lower (3.7 vs. 4.0%, SE = 0.1, P < 0.01) and physically effective neutral detergent fiber was higher (26.8 vs. 21.4%, SE = 1.1, P < 0.01) for HDN diets. Overcrowded freestalls, reduced feeding frequency, greater dietary ether extract and lower physically effective fiber were associated with lower milk fat, protein, and de novo FA content on commercial Holstein dairy farms.

Key Words: feed management, milk fat composition, stocking density

1250 Estimating the benefit:cost ratio of monensin supplementation. K. A. Dolecheck* and J. M. Bewley, *University of Kentucky, Lexington.*

The economic benefits of monensin supplementation have not been well documented. The objective of this study was to estimate the benefit:cost ratio of monensin supplementation. A deterministic, partial-budget model was used to estimate the effect of monensin supplementation in the lactating and dry cow rations of a dairy herd. Feed costs for lactating, far-off dry, and close-up dry rations were set at $227 per ton dry matter, $2.50 per cow per day, and $3.50 per cow per day, respectively. The non-supplemented herd level incidence rate of clinical mastitis, displaced abomasum, and clinical ketosis were set at 19.7%, 3.6%, and 6.3%, respectively. Milk price was determined using 5-yr (2011 to 2015) means of Federal Milk Marking Order product prices for butterfat ($4.50/kg), protein ($6.76/kg), and other solids ($0.73/kg). Monensin supplementation costs per cow per day were set at $0.050 and $0.035 in lactating and dry rations, respectively. The average response to monensin supplementation across lactation was established by a 2008 meta-analysis (2% decrease in dry matter intake, 2% increase in milk yield, 3% decrease in milk fat percentage, 1% decrease in milk protein percentage, decreased risk of ketosis [risk ratio = 0.75], decreased risk of displaced abomasum [risk ratio = 0.75], and decreased risk of mastitis [risk ratio = 0.91]). The model was run under 3 scenarios to estimate the sensitivity of monensin supplementation to pre-supplemented herd milk yield, milk fat percentage, and milk protein percentage. In scenario 1, milk yield was 31.8 kg/cow/d with 4.1% milk fat and 3.2% milk protein. In scenario 2, milk yield was 36.3 kg/cow/d with 3.8% milk fat and 3.1% milk protein. In scenario 3, milk yield was 40.8 kg/cow/d with 3.5% milk fat and 3.0% milk protein. All scenarios increased income over feed cost per cow per day ($0.29, $0.35, and $0.42, respectively) and resulted in a positive benefit:cost ratio (5.6:1, 6.8:1, and 8.0:1, respectively). The biggest factor influencing returns from monensin supplementation in all scenarios was increased income from milk sales ($5.63, $7.11, and $8.69 per cow per month, respectively). Other factors contributing to the positive benefit:cost ratio of monensin supplementation were reduced total feed costs (-$1.53,-$1.70, and-$1.85 per cow per month, respectively) and reduced losses from disease (-$0.95,-$0.99, and-$1.02 per cow per month, respectively). Future stochastic models should consider how variation in other factors affect the monensin supplementation benefit:cost ratio.

Key Words: monensin, benefit:cost, economic model

1251 TMR versus grazing supplemented with TMR out or into the grazing plot: Productive response. D. A. Mattiauda*[1], J. P. Marchelli[2], and P. Chilibroste[1], [1]*Facultad de Agronomia, Universidad de la Republica, Paysandu, Uruguay,* [2]*Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay.*

An experiment was performed to study the effect of three contrasting feeding strategies involving TMR and grazing, during the first 60 d in milk of Holstein dairy cows. Thirty six multiparous dairy cows were blocked according to parity, expected calving date, body condition score (BCS; 2.9 ± 0.37) and BW (641 ± 49.2 kg) before calving, and were randomly allocated to follow one of three feeding treatments: TMR = total mix ratio (corn silage/concentrate mix 40/60; respectively), GR-one = one grazing session (AM: 0800 to 1400 h) supplemented with 50% of TMR out of the grazing plot and GR-two = two grazing sessions (AM: 0800 to 1400 h; PM: 1800 to 0400 h) supplemented with 50% of the TMR into the grazing plot. The three treatments were based on the same offer of energy (50 Mcal ENL/cow/d), differing in the source of feed (TMR vs. grazing plus TMR) and the synchrony or not between the access to pasture and to TMR (GR-one vs. GR-two). The cows were milked twice a day (04:30 and 15:00 h). Milk production was registered daily, milk composition weekly (samples from two consecutive milking) and BCS every 2 wk (scale 1 to 5). A fresh daily strip of a fescue based pasture (3,270 ± 758 kgDM/ha) was open to each grazing treatment with an herbage allowance (above 4 cm) enough to reach 25 Mcal ENL per cow/d. A mix model was used (Glimmix procedure, SAS 9.2, 2010) to analyze the results with treatment, week and their interaction as fix effects and block as a random effect. A first order autoregressive heterogeneous (AR1) covariance structure was selected. TMR cows produced more milk, energy, protein and lactose (Table 1) than grazing cows. Daily fat production was not different between treatments, since TMR cows produced milk with less ($P < 0.05$) or tendency for less ($P < 0.1$) fat content than GR-two and GR-one treatments, respectively. Grazing treatments did not differ except on the tendency ($P < 0.1$) for a higher milk fat content in GR-two than GR-one cows (Table 1). A reverse trend ($P < 0.1$) was observed for BCS (2.9 vs. 2.7 for GR-one and GR-two, respectively). The potential of GR-two cows to select a better mix of TMR and herbage than GR-one cows was not expressed in this trial. The long distance to the grazing plots (1.7 km) might have masked the potential benefits of GR-two feeding strategy.

Key Words: grazing, TMR, early lactation dairy cows, synchronizing

1252 Shearing during milking increases milk yield in dairy ewes. A. Elhadi[1], G. Caja*[2], A. A. K. Salama[1,3], X. Such[1], and E. Albanell[1], [1]*Universitat Autonoma de Barcelona, Bellaterra, Spain,* [2]*Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Spain,* [3]*Animal Production Research Institut, Giza, Egypt.*

The effect of shearing during lactation was investigated in 48 dairy ewes of 2 breeds (Manchega, MN; Lacaune, LC); 32 were multiparous (MN, n = 16, 69.5 ± 1.7 kg BW; LC, n = 16, 69.1 ± 1.9 kg BW) and 16 were primiparous (MN, n = 8, 59.4 ± 2.0 kg BW; LC, n = 8, 57.4 ± 2.4 kg BW). Ewes were permanently sheltered indoors and allocated in 4 groups by breed to which treatments were randomly applied in duplicate. Treatments were: US (unshorn) and SH (shorn) during mid lactation at mild winter conditions. Diets consisted of alfalfa hay ad-libitum and concentrate rationed individually at milking according to breed and requirements (MN, 0.45 kg/d; LC, 0.65 kg/d). Ewes were in straw-wood chips bedded pens and the ambient temperatures were mild before (12.6 ± 0.9°C) and after (13.0 ± 0.3°C) shearing. Fleece weight was greater in shorn MN than LC (1.04 ± 0.10 vs. 0.75 ± 0.09 kg/ewe). As a result of shearing, rectal temperature decreased in the MN-SH ewes, when compared to the MN-US (38.51 ± 0.11 vs. 38.88 ± 0.12°C, respectively), but did no vary in the LC ewes (38.57 ± 0.08°C). No differences were detected in the fill value of

Table 1251.

Mean within a row with different superscript differ (Tukey; $p < 0,05$)
TMR= No grazing; GR-one= one grazing session; GR-two= two grazing sessions; SED= SE of the difference; T= treatment; W= week; T*W= interaction T*W.
Energy= energy in milk: (0.0929*Fat (kg/d) + 0.0547*Protein (kg/d) + 0.0395*Lactose (kg/d)) * 100.

the alfalfa hay, expressed as French sheep fill units (SFU), between sheep breeds (0.97 ± 0.03 SFU/kg DM). Lactational responses to shearing during milking varied according to breed, the results in LC being more marked than in MN ewes. Feed intake increased 5% in the LC-SH, when compared to LC-US, but did not vary in the MN ewes. Moreover, the LC-SH ewes yielded 10% more milk than LC-US ewes, but no differences were detected in the MN ewes. There were no differences in milk composition between US and SH ewes in both breeds. The milk protein and lactose yields were higher for LC-SH than LC-US ewes (20% and 17%, respectively) agreeing with the milk yield increase. No effects of shearing were detected on metabolic (glucose, NEFA) and hormonal (cortisol, insulin) plasma values, as well as on BW and BCS changes. In conclusion, shearing lactating ewes during winter, under moderate cold conditions, is a suitable management option for improving feed intake and milk production of high-yielding dairy ewes, without deleterious effects neither on physiological indicators nor milk composition regardless their production level.

Key Words: dairy sheep, shearing, lactation, milk yield, milk composition

1253 Evaluation of different synchronization and early pregnancy diagnosis methods in postpartum Holstein cows. A. H. Shahzad*[1], A. Sattar[2], I. Ahmad[3], A. Y. Qamar[3], and N. Ahmad[3], *[1]University of Veterinary and Animal Sciences, Lahore, LAHORE, Pakistan, [2]Department of Theriogenology, University of Veterinary and Animal Sciences, Lahore, Pakistan, [3]University of Veterinary and Animal Sciences, LAHORE, Pakistan.*

Objectives were to appraise the pregnancy rate (PR) after G7G-Ovsynch and Ovsynch protocol as well as accuracy of Pregnancy Associated Glycoproteins (PAGs) in milk, plasma, and plasma P4 in comparison with ultrasonography as gold standard pregnancy diagnosis (PD) method. In experiment 1, Holstein cows (n = 37) were bred by G7G-Ovsynch protocol (n = 19) or MG7G-Ovsynch (PG-8h-PG in Ovsynch). Pregnancy was evaluated by ultrasonography (US) at Days 31, 59, and 87 after breeding. Blood plasma and Milk samples were collected on Day 3 after insemination and at weekly intervals either 1) through Day 59 PTAI in open cows on d31 or 2) through Day 87 if the cow was found pregnant. The PAGs were measured by using ELISA and P4 by RIA. These PAGs classified samples either open or pregnant. In experiment 2, Lactating cows (n = 212) were bred by TAI following G7G-Ovsynch protocol (n = 110) or standard Ovsynch. Cows were subjected to PD on Day 30, 60, and 90 PTAI. Subset (n = 15 in each group) was subjected to blood plasma and milk samples on Day 30, 45, 60, 75, and 90 for PAGs and P4 profile. Pregnancy rate was compared by chi square. Effect of treatment on BCS, Plasma PAGs and P4 profiles were calculated by GLM procedures of SAS. Association of P4 with Plasma Milk PAGs was calculated using REG procedures of SAS (P < 0.05). In experiment 1, PR was 47% compared with 53% for G7G-Ovsynch versus MG7G-Ovsynch, respectively on d 31 post-TAI. On d 59 and 87, PR was recorded as 37% in G7G-Ovsynch group in comparison with MG7G-Ovsynch group (33%). In experiment 2, PR was 52% versus 42% (P = 0.159) on d 30,45% versus 37% (P = 0.226) on d 60, and 44% versus 36% on d 90 with overall pregnancy loss of 16% and 14% in G7G-Ovsynch and Ovsynch, respectively. In milk PAGs method sensitivity was 100%. Positive predictive value (PPV) was 92%. Negative predictive value (NPV) was 100% (P < 0.05). Sensitivity of plasma PAGs was recorded as 98% with 92% PPV and 83% NPV. Sensitivity of plasma P4 was 98% with 98% PPV and 89% NPV. There was positive correlation among P4 profile and PAGs concentration in both milk and plasma.Other parameters including BCS, cyclicity, and parity did not show any impact on pregnancy neither independently nor in interaction with treatment. In conclusion, although non-significant, increase in PR in G7G-Ovsynch makes it a protocol of choice in postpartum cows and PAGs as PD tool either in milk or plasma is as feasible as ultrasonography.

Key Words: G7G-Ovsynch, Pregnancy Associated Glycoproteins, milk sample, blood plasma, ultrasonography, pregnancy rate

1254 WS Effects of octacosanol on non-seasonal spermatogenesis in ovine. J. W. Dickison*, *Angelo State University, San Angelo, TX.*

This study was conducted to understand the benefits of utilizing octacosanol as an additive to increase fertility of rams during the non-seasonal time of the year. Rams of Suffolk and Rambouillet influence were placed on a 60-d trial to determine the value of octocasanol as a feed supplement to promote semen production through the summer months. Rams were randomly divided into 2 groups of mixed breeds. Treatment group was fed a balanced ration containing 0.25% octocasanol per ton, while control rams were fed identical ration with no added octocasanol. Rams were fed at the rate of 6 lbs a day with alfalfa hay supplementation 3 times a week. Final collection was June 27 when ambient stress is generally at its highest point. Semen characteristics such as scrotal circumference, volume, concentration, and motility were used in the evaluation of the success of the product. Scrotal circumference (SC) measurements taken at onset of project to final showed no significant differences among control or treatment (P = 0.21) respectively although, the treatment group saw a larger increase in SC when compared to control (0.81 ± .01, 0.31 ± .01), respectively. Volume of ejaculate of both treatment and control also showed no significant difference from initial to final collection (P = 0.13) although as SC in the middle of summer the treatment group did show some increase when compared to control (0.32 ± .01, −0.60 ± .01 respectively). The same progressions were observed with concentration and motility of ejaculates

from beginning to final collection although again there was no significance ($P = 0.51$, $P = 0.34$ respectively). Concentration of ejaculate from treatment, again showed some increase from the control rams (2.32×10^9, -1.28×10^9 respectively). Like the previous measurements, motility also showed an increase from the treatment group when compared to the control rams (0.31×10^9, -0.27×10^9 respectively). Rams fed octacosanol for 60 d tended to have larger scrotal circumference, produced larger ejaculates with greater volume and sperm concentrations than control rams during the harshest period of the year for these parameters.

Key Words: Octacosanol, spermatogenesis, ovine

1255 WS Winter grazing or confinement feeding heifer development strategies differ in energetics as measured by 24 h heart rate and activity.

M. K. Petersen*[1], J. M. Muscha[2], and A. J. Roberts[1], *[1]USDA-ARS Fort Keogh Livestock and Range Research Laboratory, Miles City, MT, [2]Fort Keogh Livestock & Range Research Laboratory, Miles City, MT.*

The ability of a heifer to thrive is partially due to traits including behavioral/metabolic adaption and genetic background. Type of weaning and development program implemented creates an environment replacement heifers must adapt to flourish. This study was designed to determine if heifers developed in confinement or grazing native range use different adaption and coping processes by measuring activity such as distance traveled and percent resting time in 24 h along with resting heart rate and average heart rate per day. Spring-born, crossbred heifers were stratified to 1 of 2 treatments at weaning (start of Period 1): (1) fence-line weaning on native range (NR) with self-fed salt-mineral protein supplement ($n = 118$) and after weaning received a hand fed daily energy supplement or a self fed protein supplement, or (2) weaned into a dry lot (DL) and fed a corn silage diet formulated to gain 0.68 kg/d ($n = 53$). Ad libitum grass hay was made available in mid-December due to snow coverage resulting in range forage inaccessibility. Heifer BW were taken every 28 d from initiation of weaning. Each month (except February and June) a cohort of 7 heifers from each treatment were fitted with equine heart rate monitors (Polar Equine RS800CX) and QSTARZ CR-Q1100P GPS tracking recorder. Data were recorded for 48 h. On April 9, 2014 (Period 2) the two supplement groups grazing NR and DL heifers were combined into a common pasture. Heifers receiving DL had greater ($P < 0.01$) BW throughout the entire study. Resting heart rate was influenced ($P < 0.01$) by an interaction of period and weaning/development management. The rankings of resting heart rate were reversed from period 1 to period 2. Resting heart rate was also shown to influence BW. Resting heart rate relationship with BW was negative suggesting that lower resting heart rate is related greater BW. The analysis suggests that for every 2.2 decline in resting HR there is an additional 0.45 kg of BW. This study indicates that resting heart is negatively related to BW implying that animals with lower resting heart rate may have a production advantage.

Key Words: beef heifers, heart rate, heifer development

1256 WS Effects of dietary phytoestrogens on testicular growth and semen quality characteristics in developing Angus bulls.

S. C. Yurrita*, *Angelo State University, San Angelo, TX.*

This study investigated the impact of scrotal growth and semen quality parameters of bulls consuming dietary phytoestrogens versus bulls that are not exposed to phytoestrogen-containing diet ingredients. Angus bulls born in consecutive years were used in 2 independent trials. Bulls born in the spring of 2014 ($n = 39$) and 2015 ($n = 24$) were stratified by weaning weight, age of dam (AOD), and sire into a soybean meal diet group (SBMTRT) or a cottonseed meal diet group (CSMCON). At weaning (d −42), bulls were assigned to treatment and adapted to concentrate diets. At d 0, 21, 54, and 86 scrotal circumference measures were collected with semen collection and assessment also being conducted at d 86. Differences in scrotal circumference were detected due to the diet × day (year) interaction. On d 54 and 86, SBMTRT in 2014 exhibited larger scrotal measures than SBMTRT in 2015 ($P \leq 0.05$). At d 54, SBMTRT scrotal measures were also greater than the CSMCON scrotal measures in 2015 ($P = 0.05$). Scrotal growth from d 0 to 21 was greater for SBMTRT across both years ($P < 0.0001$). This pattern of larger teste growth was also observed from d 54 to d 86 ($P = 0.05$), and from d 0 through d 86 ($P < 0.0001$). Variation in semen concentration was due to the diet × AOD (year) interaction. The SBMTRT, produced from 2-yr old females, expelled higher concentrated semen samples in 2014 ($P = 0.026$) and 2015 ($P = 0.0006$), and this was inconsistent with the 2015 CSMCON out of 5+ year old cows who were higher for semen concentration ($P < 0.0001$). The diet × AOD (year) interaction was also a source of variation for motility. The 2014 bulls from 2 and 5+ year old cows ranked higher than the CSMCON cohorts of like aged cows ($P < .0001$). This trend was not evident in 2015 however, as the CSMCON mean was greater than the SBMTRT from 3 yr old cows only ($P = 0.0129$). Variation from the effect of diet for motility was also observed as well, as SBMTRT scored higher than CSMCON ($P = 0.0308$). These data suggest that dietary phytoestrogens at 10% soybean meal diet inclusion improves scrotal growth and semen quality and this is particularly evident in bulls produced by 2-yr old, first calf females.

Key Words: bull development, phytoestrogen, semen quality

1257 Reproductive performance of lactating dairy cows managed for first service with the Double-Ovsynch or Presynch-Ovsynch protocol and different duration of the voluntary waiting period.
M. L. Stangaferro*, R. Wijma, M. Masello, and J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Our objective was to investigate time to pregnancy of dairy cows during lactation after submission for first AI service with three different treatments. Holstein cows (522 primiparous and 870 multiparous) from a commercial farm were stratified by parity and total milk production in their previous lactation (multiparous only) and randomly allocated to receive timed AI (TAI) after the Double-Ovsynch protocol (DO; GnRH-7d-P-GF-3d-GnRH-7d-GnRH-7d-PGF-56h-GnRH-16h-TAI) at 60 ± 3 DIM (DO60 = 476), TAI after DO at 88 ± 3 DIM (DO88 = 431), or a combination of insemination after detected estrus and TAI with the Presynch-Ovsynch protocol (PGF-14d-P-GF-12d-GnRH-7d-PGF-56h-GnRH-16h-TAI; PSOv = 485). Cows in the PSOv group received AI to estrus (AIE) after the second PGF treatment given at 50 ± 3 DIM or TAI at 72 ± 3 DIM. Subsequent AI services occurred through AIE or TAI after the Ovsynch protocol (32 ± 3 d after AI-GnRH-7d-PGF-56h-GnRH-16h-TAI). Pregnancy outcomes were determined using transrectal ultrasonography at 35 ± 3 and 94 ± 3 d after AI. Time to pregnancy up to 350 DIM was analyzed using Cox's regression whereas pregnancies per AI, pregnancy loss, and cows nonpregnant at 350 DIM were analyzed by logistic regression. Hazard of pregnancy was greater ($P < 0.01$) for DO60 [HR = 1.50 (95%CI = 1.29 to 1.74)] and PSOv [HR = 1.37 (95%CI = 1.18 to 1.59)] than for DO88 but it was similar ($P > 0.10$) for DO60 and PSOv [HR = 1.10 (95%CI = 0.95 to 1.26)]. Median days to pregnancy were 97, 117, and 98 for DO60, DO88, and PSOv, respectively. Hazard of pregnancy was greater ($P < 0.01$) for primiparous than multiparous cows [HR = 1.44 (95%CI = 1.27 to 1.62)]. The percentage of cows nonpregnant at 350 DIM was similar ($P = 0.16$) for the 3 groups (9.9, 13.8, and 12.6% for DO60, DO88, and PSOv). First service pregnancies per AI were similar ($P = 0.24$) for the 3 groups (DO60 = 41.4% [$n = 454$], DO88 = 44.1% [$n = 397$], PSOv = 38.2%; [$n = 461$]) but greater ($P < 0.01$) for cows that received TAI (45.2% [$n = 188$]) than AIE (33.3% [$n = 273$]) in the PSOv group. Pregnancy loss was similar ($P = 0.80$) among groups (DO60 = 5.9%, DO88 = 7.4%, and PSOv = 7.4%). We conclude that time to pregnancy was reduced when cows received TAI at 60 DIM after the Double-Ovsynch protocol or a combination of AIE after 50 DIM and TAI at 72 DIM with the Presynch-Ovsynch protocol than when cows received TAI at 88 DIM after the Double-Ovsynch protocol. Despite differences in time to pregnancy, the percentage of cows nonpregnant at 350 DIM was similar for the 3 groups. Supported by New York Farm Viability Institute project AOR13006.

Key Words: Double-Ovsynch, Presynch-Ovsynch, dairy cow

1258 Estrus detection intensity and accuracy, and optimal timing of insemination with automated activity monitors for dairy cows.
C. S. Leroy[1], J. S. Walton[1], and S. J. LeBlanc*[2], *[1]University of Guelph, Guelph, ON, Canada, [2]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

The objectives were to assess: the ability of automated activity monitoring (AAM) to detect estrus for first insemination; the accuracy of detection; and the optimum interval from the onset of estrus to insemination. Four commercial farms were studied over 1 yr; 2 employed the AfiAct (Afikim) system and 2 the Heatime HR (SCR Inc.) system. Cows were inseminated between 55 and 80 DIM based on AAM only, then supplemented with timed AI (TAI). Blood progesterone was measured in 1,014 cows at weeks 5, 7, and 9 postpartum; purulent vaginal discharge (PVD) was assessed at week 5 and lameness and BCS at week 7. Overall, AAM detected 83% of cows in estrus by 80 DIM. Cows that had 3 serum P4 < 1 ng/mL, had PVD, or were both lame and had BCS $\leq$ 2.5 were less likely to be detected in estrus by 80 DIM (62, 68, 53%, respectively). Blood samples were collected on the day of 445 AI based on AAM and 323 TAI. The proportion of cows not in estrus (P4 > 1 ng/ml) on the day of AI was similar ($P = 0.35$) between AAM (4 ± 1.8%) and TAI (3 ± 1.2%). Activity data were extracted from AAM software for 1454 AI. Onset of estrus was calculated using the same (AfiAct) or similar (for the proprietary SCR algorithm) criteria as the AAM system. Producers recorded the time of AI. The interval from onset of estrus to AI was categorized as 0 to 8, 8 to 16, or > 16 h. There was no effect of AAM system on the probability of pregnancy per AI, but there was an interaction of interval with parity. For multiparous cows, the probability of pregnancy per AI was 31%, which did not differ ($P = 0.7$) with the interval to AI. For primiparous cows, the odds of pregnancy were greater if AI occurred 0 to 8 h (49%) than 8 to 16 h (36%) or > 16 h (31%) after the onset of estrus. AAM can detect estrus for first AI in just over the length of 1 estrus cycle for over 80% of cows, but the remainder would likely require intervention. For multiparous cows, performing AI based on AAM once per day would not affect pregnancy per AI, but for primiparous cows AI within 8 h of the onset of estrus may be advantageous.

Key Words: reproduction, management

1259 Beta-hydroxybutyrate concentration influences conception date in young beef cows in Tennessee.

J. D. Hobbs*[1], E. R. Cope[1], S. R. Edwards[1], Z. D. Mcfarlane[1], and J. T. Mulliniks[2], [1]*University of Tennessee, Knoxville,* [2]*University of Tennessee, Crossville.*

Selection for increased maternal traits like milk production in beef cattle may decrease reproductive efficiency due to increased metabolic load of lactation resulting in metabolic dysfunction. Therefore, our objective was to analyze the association of milk production, serum metabolites, cow BW change, and calf performance with time of conception in 183 spring-calving beef cows. Cows were classified by conception date as cows conceiving by timed-AI (TAI) or natural breeding (NAT). In addition, cows were grouped by age to represent young (3-and 4-yr-old), mature (5- and 6-yr-old), and old (7- to 9-yr-old) cows. Starting approximately d 30 postpartum, cow BW and BCS were recorded and blood samples were collected weekly through the end of breeding. Serum samples were aliquoted into pre-breeding and breeding composites then analyzed for metabolites. Cow BW and BCS did not influence ($P > 0.40$) conception date. Similarly, calf performance did not influence ($P > 0.30$) conception date. An age group × treatment interaction ($P < 0.01$) occurred for serum β-hydroxybutyrate (BHB). Serum BHB concentrations for mature and old cows were similar ($P > 0.05$) regardless of conception date. However, serum BHB concentrations for young NAT cows were greater ($P < 0.01$) than young cows conceiving at timed-AI. Serum non-esterified fatty acids (NEFA) exhibited ($P < 0.05$) a conception date × sampling period interaction. Pre-breeding serum NEFA concentrations were greater ($P < 0.05$) for NAT cows than TAI cows. Contrarily, serum NEFA concentrations during breeding were similar ($P > 0.05$) regardless of conception date. Serum glucose and urea N concentrations were not different ($P > 0.23$) between cows conceiving by timed-AI or natural service. Results from this study indicate that only the young, postpartum beef cows during early lactation were susceptible to metabolic dysfunctions and elevated blood BHB concentrations causing a delayed time to conception.

Key Words: beef cattle, β-hydroxybutyrate, conception time

1260 Heifer development using stockpiled, dormant native forages delays gain without altering reproductive performance.

Z. D. McFarlane*[1], J. D. Hobbs[1], E. R. Cope[1], R. L. Nave[2], and J. T. Mulliniks[2], [1]*University of Tennessee, Knoxville,* [2]*University of Tennessee, Crossville.*

Winter grazing utilizing stockpiled forages is an economical alternative to feeding harvested feedstuffs during heifer development. However, development on stockpiled forages may have a negative impact on productivity due to restricted growth during a key physiological period. Therefore, our objective was to determine growth rate, nutritional status and reproductive performance of yearling heifers grazing differing stockpiled forages. Spring-born, crossbred heifers ($n = 155$) were stratified by BW at weaning to 1 of 3 stockpiled forage types: 1) endophyte-infected tall fescue (TF; 7.51% CP and 65.82% NDF, DM basis) 2) big bluestem and indiangrass combination (BI; 4.54% CP and 69.74% NDF, DM basis), or 3) switchgrass (SG; 4.23% CP and 75.77% NDF, DM basis). Each year, grazing began in January and was terminated in April at the onset of a 60-d breeding season. Heifers were fed twice per week at a rate of 0.18 kg·heifer^{-1}·d^{-1} of CP and were managed together before and after the grazing period. Heifer BW was obtained monthly from initiation of grazing until breeding and again at overall pregnancy diagnosis in September. Blood samples were collected 10 d prior and the day of timed-AI for serum metabolite analysis. Initial BW was not different ($P = 0.72$) among forage types. However, ADG from January to March was lower ($P < 0.01$) in heifers grazing BI and SG pastures. From March to April, ADG was not different ($P = 0.56$) among forage types. However, from April until September, heifers grazing both BI and SG pastures compensated and outgained ($P < 0.01$) heifers developed on stockpiled tall fescue pastures. Overall, heifers developed on TF pastures did have greater ($P < 0.01$) BW at final pregnancy detection. Circulating serum glucose concentration did not differ ($P = 0.19$) irrespective of forage type. Forage type × year interactions ($P < 0.05$) were exhibited for circulating NEFA and serum urea N concentrations. Serum β-hydroxybutyrate concentrations did not differ ($P = 0.15$) among forage types. Although BI and SG heifers exhibited restricted growth early in development, timed-AI pregnancy rates were 66, 51, and 59% for TF, BI, and SG heifers ($P = 0.40$), respectively. In addition, final pregnancy rates were 93, 92, and 87% for TF, BI, and SG heifers ($P = 0.56$), respectively. These results indicate that stockpiling native warm-season forages for winter grazing during heifer development delayed gain without reducing reproductive competence.

Key Words: beef heifers, heifer development, stockpiled forages

1261 Effect of pre- and postnatal trace mineral (TM) source on Angus and Brangus heifer growth and body composition. D. M. Price*[1], M. M. O'Neil[1], W. B. Watson III[1], R. West[2], D. O. Rae[2], D. M. Irsik[2], M. J. Hersom[1], and J. V. Yelich[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]College of Veterinary Medicine, University of Florida, Gainesville.*

A 2 by 2 factorial design evaluated growth and body composition in Angus (n = 40) and Brangus (n = 40) heifers born to cows supplemented with either inorganic (n = 40, 20/breed) or organic (n = 40, 20/breed) TM sources. The TM was initiated 82 ± 2 d pre-calving and resultant calves were weaned, and blocked by maternal TM source, age, sire, and weaning BW, and randomly assigned to 10 pens (5 pens/TM) for a 168 d development period. The TM supplement was pen fed 3 d/wk at 0.4 kg·454 kg BW-^{1}·heifer-^{1}·d-^{1}. Heifer BW and BCS (scale 1 to 9) were collected every 28 d. Ultrasound LM area (LMA), 12th rib back fat thickness (FAT), and LM intramuscular fat percentage (IMF) were recorded every 84 d. Statistical analysis used heifer as the experimental unit and repeated measures PROC MIXED to analyze BW, BCS, and ultrasound measurements. Fixed effects included TM, breed, day, and interactions. Results are presented as LSM ± pooled SE. At trial start, BW did not differ (P > 0.05) by TM or breed in inorganic, organic, Angus or Brangus (217, 224, 218, 223 ± 3 kg, respectively) heifers; however, organic and Brangus heifers had greater ($P \leq 0.01$; 4.6 ± 0.04) BCS than inorganic and Angus (4.4 ± 0.04). On d 84, organic (276 ± 4 kg) had greater ($P \leq 0.05$) BW than inorganic (261 ± 4 kg) heifers, while Angus and Brangus BW did not differ (P > 0.05). The BCS did not differ (P > 0.05) by TM or breed on d 84 (4.9 ± 0.04) and d 168 (5.4 ± 0.1). On d 168, BW did not differ (P > 0.05) by TM or breed in inorganic, organic, Angus, or Brangus (328, 338, 329, 337 ± 5 kg, respectively) heifers. No TM, breed, or interaction affected (P > 0.05) the 168 d ADG. The TM had no effect (P > 0.05) on IMF, FAT, or LMA. Breed did not affect (P > 0.05) FAT. Angus had greater ($P \leq 0.05$) IMF, but lesser LMA ($P \leq 0.01$) than Brangus (4.80 vs. 3.44 ± 0.12% and 43.99 vs. 49.67 ± 0.89 cm^2, respectively) when pooled across days. The TM source administered to cows during the last 1/3 of gestation did not affect heifer BW, BCS, or body composition over a 168 d post-weaning development period.

Key Words: heifers, trace minerals, performance, ultrasound

1262 Effect of pre- and postnatal trace mineral (TM) source on Angus and Brangus heifer growth and reproductive performance. D. M. Price*[1], M. M. O'Neil[1], W. B. Watson III[1], R. West[2], D. O. Rae[2], D. M. Irsik[2], M. J. Hersom[1], and J. V. Yelich[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]College of Veterinary Medicine, University of Florida, Gainesville.*

A 2 by 2 factorial design evaluated reproductive performance in Angus (n = 40) and Brangus (n = 40) heifers born to cows supplemented with either inorganic (n = 40, 20/breed) or organic (n = 40, 20/breed) TM sources. The TM was initiated 82 ± 2 d pre-calving and resultant calves were weaned, and blocked by maternal TM source, age, sire, and weaning BW, and randomly assigned to 10 pens (5 pens/TM) for a 168 d development period. On d 161 and 168, blood samples were collected to determine pubertal status (puberty = progesterone $\geq$ 1.5 ng/mL at one of two samples). A BW, BCS (Scale 1 to 9), and reproductive tract score (RTS, 1 to 5) were recorded and heifers were sorted by breed and TM source into 4 pastures (1 pasture/TM × breed) on d 168 for a 72 d natural service breeding season. Pregnancy was determined by ultrasound on d 51 of breeding season and 28 d after bull removal. The TM supplement was pen fed 3 d/wk at 0.4 kg·454 kg BW^{-1}·heifer^{-1}·d^{-1} as a pellet during development and as loose mineral during breeding (88.8 g·heifer^{-1}·d^{-1}). Heifer was the experimental unit and analysis utilized PROC MIXED for BW, BCS, and RTS data and PROC GLIMMIX for pregnancy and pubertal status. Fixed effects included TM, breed, and interaction. On d 168, inorganic (328 ± 5 kg) and organic (339 ± 5 kg) did not differ (P > 0.05) in BW or BCS (5.4 ± 0.1). Heifer RTS tended (P = 0.10) to be greater for organic (3.3 ± 0.1) than inorganic (3.0 ± 0.1) and greater ($P \leq 0.01$) in Brangus (3.4 ± 0.1) than Angus (2.9 ± 0.1) on d 168. Pubertal status did not differ (P > 0.05) on d 168 for TM (Inorganic, 20% = 4/20; Organic, 20% = 4/20) and breed (Angus, 20% = 4/20; Brangus, 20% = 4/20). On d 51 of breeding, pregnancy rates did not differ (P > 0.05) between inorganic (45% = 18/40) and organic (63% = 25/40) but were greater ($P \leq 0.05$) in Brangus (65% = 26/40) than Angus (43% = 17/40). Final breeding season pregnancy rates did not differ (P > 0.05) between inorganic (87.5% = 35/40) and organic (95% = 38/40), or between Angus (93% = 37/40) and Brangus (90% = 36/40). The TM source affected RTS but not pubertal status at the start of breeding season in yearling Angus and Brangus heifers. Additionally, TM source did not influence pregnancy rates to a natural breeding.

Key Words: trace minerals, heifers, pregnancy rate

1263 Impacts of zinc, manganese, and copper source on mature bull trace mineral status and spermatozoa characteristics. A. L. Zezeski*[1], M. Van Emon[2], R. C. Waterman[3], B. Eik[1], J. S. Heldt[4], and T. W. Geary[5], *[1]USDA-ARS Fort Keogh LARRL, Miles City, MT, [2]Montana State University, Bozeman, MT, [3]USDA-ARS Fort Keogh Livestock and Range Research Laboratory, Miles City, MT, [4]Micronutrients, Indianapolis, IN, [5]USDA ARS Fort Keogh, Miles City, MT.*

Our objective was to measure impacts of trace mineral source on liver mineral status and spermatozoa characteristics in mature bulls. Thirty-seven bulls (682 ± 147 kg) of mixed breeds, 2 to 4 yr of age were used in a 71 d trial. Bulls were blocked by length of time without trace mineral supplementation and stratified by initial liver Cu status to one of three dietary treatments (4 pens/treatment): 1) Supplement without Cu, Zn, and Mn; 2) Supplement with Cu, Zn, and Mn sulfate (sulfate); and 3) Supplement with basic Cu chloride, Zn and Mn hydroxychloride (hydroxy). Liver biopsies were collected on d −73, −24, and 71 to determine trace mineral status. Supplements containing Cu, Zn, and Mn were fed at 75% of NRC requirements as top dressing to a feedlot (corn silage) diet. Semen collection and scrotal circumference measurements were collected on d 0, 36, and 70. Ejaculates were evaluated for spermatozoa concentration, motility, and morphology as part of a standard breeding soundness examination. Acrosome integrity, sperm viability, and mitochondrial membrane potential were evaluated via flow cytometry counting at least 5,000 sperm per ejaculate. The mixed procedure of SAS was used for statistical analysis. On d 71, liver Cu concentrations of bulls receiving hydroxy minerals were greater ($P = 0.008$) than bulls receiving no mineral supplement or sulfate minerals. Liver Zn concentrations tended to be greater ($P = 0.08$) in bulls receiving hydroxy minerals compared to sulfate minerals. All other trace minerals (Co, Mn, Mo, and Fe) were not different ($P \geq 0.16$) due to dietary treatments. Liver concentration of Cu increased ($P = 0.04$) from the d −24 to 71 biopsy in bulls receiving hydroxy mineral. No differences ($P \geq 0.17$) were observed in any other trace mineral concentrations between treatments from the d −24 to 71 liver biopsies. Bulls with greater liver Zn concentrations on d 71 were correlated ($r = -0.39$, $P = 0.02$) with less acrosome damaged spermatozoa and tended to be correlated with greater spermatozoa concentrations ($r = 0.31$, $P = 0.06$). We conclude that basic Cu chloride and Zn hydroxychloride is more bioavailable and more readily stored in the liver compared with Cu and Zn sulfate. Increased liver Zn concentrations may also improve acrosome integrity of bull spermatozoa. However, diets deficient in trace mineral for > 170 d had no other detrimental effects on semen quality of mature bulls.

Key Words: trace mineral, bull, spermatozoa

1264 WS Effects of early or conventional weaning on beef cow and calf performance in pasture and drylot environments. G. W. Preedy*[1], J. R. Jaeger[2], J. W. Waggoner[3], and K. C. Olson[1], *[1]Kansas State University, Manhattan, [2]Western Kansas Agricultural Research Center, Kansas State University, Hays, [3]Western Kansas Agricultural Research Center, Kansas State University, Garden City.*

Spring-calving beef cows (initial BW = 599 ± 54.5 kg; initial BCS = 5.5 ± 0.54) and calves (initial BW = 204 ± 26.7 kg; 153 ± 15 d of age) were assigned randomly to 1 of 4 weaning treatments: weaning at 153 d of age followed by 56 d of limit feeding in confinement (E-D), confinement of cow and calf together for a 56-d period of limit feeding followed by weaning at 209 d of age (C-D), weaning at 153 d of age followed by a 56-d grazing period (E-P), and a 56-d grazing period with cow and calf together followed by weaning at 209 d of age (C-P). Calves assigned to E-D and C-D were fed a concentrate-based diet at 2.5% of BW, whereas cows assigned to E-D were fed a forage-based diet at 1.6% of BW. Cows assigned to C-D were offered the diet fed to E-D cows at 2.0% of BW. All cows and calves were limit fed common diets for 7 d at the end of our study to equalize gut fill. Calves ADG were influenced by diet and weaning treatments ($P \leq 0.03$). In general, calves managed in confinement and fed concentrate-based diets (i.e., E-D and C-D) had greater ADG than unsupplemented calves maintained on pasture (i.e., E-P and C-P). Cow BW and BCS change (d 0 to 63) were influenced by diet and weaning status ($P \leq 0.05$). Non-lactating cows maintained on pasture had lesser BW loss than other treatments, whereas non-lactating cows fed in confinement had lesser BCS on d 63 and greater BCS loss from d 0 to 63 than other treatments. Conversely, rump-fat depth on d 63 was greater ($P < 0.01$) for non-lactating cows maintained on pasture than for lactating cows in either pasture or drylot environments. Similarly, change in rump-fat depth was greatest ($P < 0.01$) for non-lactating cows on pasture and least for lactating cows in both pasture and drylot environments. Results were interpreted to indicate that weaning at 153 d of calf age spared cow BW and rump fat compared to weaning at 209 d of calf age. Performance of cows appeared to be similar when either limit-fed under drylot conditions or pastured without supplement. Conversely, calf performance was greater in confinement than on pasture.

Key Words: beef cows, concentrate, early weaning, pasture

1265 Association between management practices and reproductive performance of lactating dairy cows.
G. M. Schuenemann*[1], J. M. Piñeiro[1], and P. Turiello[2], [1]*Department of Veterinary Preventive Medicine, The Ohio State University, Columbus,* [2]*Facultad de Agronomia y Veterinaria, UNRC, Rio Cuarto, Cordoba, Argentina.*

It is common to observe great variation in reproductive performance among dairy herds; which ultimately impacts profitability. The objective was to assess the association of pre- and post-partum management practices with the annual average 21-d pregnancy rate (PR) in lactating dairy cows. A survey instrument was developed to collect information on herd demographics (e.g., breed, size, facilities), management practices for replacements and cows (e.g., housing, feeding, criteria to initiate breeding), reproductive program and performance (e.g., PR), health management (e.g., written protocols), and personnel (e.g., training, frequency, turnover). Multivariable regression and CORR models were performed using SAS. Information was collected from approximately 17,008 lactating dairy cows distributed in 41 herds in Argentina. The most predominant breed of cows was Holstein (> 85%) with an average herd size of 414 cows (ranged from 78 to 2,300). The average PR was 17% (ranged from 5 to 31.5%) and the voluntary waiting period (VWP) was 54 d (ranged from 40 to 70 d). The reproductive programs utilized (estrus detection, timed-AI, or bull) were not significantly associated with PR. The 21-d PR was positively correlated with prevention of hypocalcemia in prepartum cows (r = 0.36, P = 0.03), personnel training (primarily on reproductive program and AI technique; r = 0.57, P = 0.0006), an established VWP $\geq$ 50 d (r = 0.59, P = 0.0001), defined criteria (body weight, age, and reproductive tract score) to initiate breeding in replacement heifers (r = 0.47, P = 0.002), and availability of written protocols at the farm (yes vs. no; r = 0.37, P = 0.01). These management practices accounted for more than 52% of the observed variation in PR. There was considerable variation in PR (about 26.5% points) that could be attributed, at least in part, to pre- and post-partum management practices among herds. The most important reasons for increased annual PR were associated with a program for replacement heifers (4.6% points increase), prevention of metabolic diseases early in lactation (4.2% points increase), and training of dairy personnel responsible for breeding cows (5.6% points increase).

Key Words: dairy, management, reproduction

1266 Association between management practices and dairy herd performance.
P. Turiello*[1], J. M. Piñeiro[2], and G. M. Schuenemann[2], [1]*Facultad de Agronomia y Veterinaria, UNRC, Rio Cuarto, Cordoba, Argentina,* [2]*Department of Veterinary Preventive Medicine, The Ohio State University, Columbus.*

It is common to observe large variation in milk yield among herds; which ultimately impacts profitability. The objective was to assess the association of pre- and post-partum management practices with average milk yield (kg/cow/d) of 41 dairy herds in Argentina. A survey instrument was developed to collect information on herd demographics (e.g., breed, size, facilities), management practices for replacements and lactating cows (e.g., housing, feeding, milking frequency), reproductive management of replacements and lactating cows (e.g., breeding methods, criteria to initiate breeding), herd performance (e.g., milk yield) and health management (e.g., written protocols), and personnel (e.g., training, turnover). Multivariable regression and CORR models were performed using SAS. Information from approximately 17,008 lactating dairy cows distributed in 41 herds was collected. The most predominant breed of cows was Holstein (> 85%) with an average herd size of 414 cows (ranged from 78 to 2,300). The average milk yield per cow was 29.5 kg/d (ranged from 12.6 to 33.8 kg/d). The average daily milk yield was positively correlated with housing (confinement vs. grazing) for lactating cows (r = 0.46, P = 0.02), milking frequency (2 vs. 3 times per d; r = 0.67, P = 0.0003), availability of written protocols at the farm (yes vs. no; r = 0.52, P = 0.008), personnel training (yes vs. no; r = 0.54, P = 0.006), water analysis (yes vs. no; r = 0.68, P = 0.0002), and defined criteria (body weight, age, and reproductive tract score) to initiate breeding in replacement heifers (r = 0.50, P = 0.01). These management practices accounted for more than 54% of the observed variation in the average daily milk yield of lactating cows. There was a considerable variation in milk yield (about 21.2 kg/cow/d) that could be attributed to different diets and management practices among herds. The most important reasons for increased milk production were associated with training of dairy personnel (primarily on TMR and feed bunk management; ~5.5 kg/cow/d) and defined criteria (~5.4 kg/cow/d) to initiate breeding in replacement heifers.

Key Words: dairy, management, milk yield

1267 Impacts of early lactation hyperketonemia on reproduction and 305-d milk production.
D. E. Santschi*[1], R. Lacroix[1], R. K. Moore[1], F. Miglior[2], and D. M. Lefebvre[1], *[1]Valacta, Ste-Anne-de-Bellevue, QC, Canada, [2]Candian Dairy Network, Guelph, ON, Canada.*

Hyperketonemia is a common early lactation disorder. Analysis of β-hydroxybutyrate (BHBA) by Fourier transform infrared spectroscopy in DHI milk samples provides a rapid and low-cost herd-level monitoring tool to evaluate the prevalence of hyperketonemia. The objective of this study was to evaluate the impact of elevated BHBA concentrations in early lactation DHI samples on reproduction and 305-d milk and component yields. Test-day and lactation records from 220,939 Holstein cows (114,267 primiparous and 106,672 multiparous) were used. All cows in the dataset had BHBA concentration on first test-day between 5 and 35 DIM. The following thresholds were used to classify cows based on milk BHBA concentration in early lactation: < 0.15 mmol/L = Negative (NEG); 0.15 to 0.19 mmol/L = Suspect (SUSP); and ≥ 0.20 mmol/L = Positive (POS), based on a previously published trial comparing milk and blood BHB concentrations. The MIXED procedure of SAS was used to evaluate the impact of BHBA classification on reproduction and production outcome. Cows with high BHBA concentration in early lactation had longer calving to first service and first service to conception intervals, increased days open, more services per conception, and lower 56d nonreturn rate. Cows with high BHBA concentration in early lactation produced higher 305-d milk and fat yields, but lower 305-d protein yields. Overall, trends were similar for primiparous and multiparous cows. Results indicate that hyperketonemia negatively impacts reproduction, but suggest higher producing cows are more affected. Monitoring and prevention strategies to reduce the prevalence of hyperketonemia in early lactation could result in improved reproduction and potential benefits on lactation milk yield.

Key Words: BHB, DHI, Reproduction

1268 Reproductive performance and culling dynamics of lactating dairy cows with detected pregnancy loss.
R. Wijma*, M. L. Stangaferro, and J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Our objective was to evaluate the reproductive performance and culling dynamics of dairy cows that lose their pregnancy after an initial pregnancy examination. Individual cow records (AI dates, AI outcomes, and date of sale or death) were collected from five commercial farms. In all farms cows received AI after detected estrus and timed AI. Pregnancy outcomes after AI were determined using transrectal ultrasonography or rectal palpation at 32 ± 3 (*n* = 3 farms) or 39 ± 3 d (*n* = 2 farms) after AI. Pregnancy reconfirmation was conducted at 63 ± 3 (*n* = 1 farm), 90 ± 3 (*n* = 3 farms), or 100 ± 3 d (*n* = 1 farm) after AI. Cows with at least one pregnancy loss (PL) event were included in the PL group (PLG; *n* = 893) and cows with no PL recorded were included in the no PL group (NoPLG; *n* = 7856). Pregnancies per AI (P/AI) and PL were determined for inseminations preceded (*n* = 627) or not (*n* = 14,619) by a PL event for cows in the PLG and NoPLG combined. Dichotomous and time to event outcomes were analyzed using logistic regression and Cox's regression, respectively. Only cows that reached 150 d of gestation were considered pregnant for the analysis of time to pregnancy and P/AI. Hazard of pregnancy until 400 DIM was greater ($P < 0.001$) for NoPLG than PLG (HR = 4.2; 95%CI = 3.8 to 4.6). Median time to pregnancy was 114 and 324 d for NoPLG and PLG, respectively. Hazard of pregnancy was also greater ($P < 0.001$) for primiparous than multiparous cows (HR = 1.3; 95%CI = 1.2 to 1.4). The percentage of cows pregnant by 400 DIM was greater ($P < 0.001$) for the NoPLG (72.3%) than PLG (47.6%) and for primiparous (79.5%) than multiparous (64.3%) cows ($P < 0.001$). Pregnancies per AI were greater ($P < 0.001$) for AI services preceded (35.6%) than not preceded by PL (29.1%). Nevertheless, more cows ($P < 0.001$) underwent PL for AI services preceded (21.9%) than not preceded by PL (11.6%). Hazard of leaving the herd tended to be greater ($P = 0.08$) for the PLG than NoPLG (HR = 1.1; 95%CI = 0.9 to 1.2). More cows left the herd ($P < 0.001$) by 400 DIM for the PLG (39.5%) than NoPLG (30.9%) and the multiparous (46.7%) than the primiparous (20.5%) group ($P < 0.001$). We conclude that cows that underwent PL had delayed time to pregnancy and were more likely to leave the herd. Also, P/AI and PL for AI services preceded by PL were greater than for AI services not preceded by PL. Supported by USDA NIFA Multistate project NYC-127813.

Key Words: Pregnancy loss, reproductive performance, culling dynamics

1269 Profitability of dairy cows receiving first service timed artificial insemination after the Double-Ovsynch protocol with a voluntary waiting period of 60 or 88 d.
M. L. Stangaferro*, R. Wijma, M. Masello, G. E. Granados, and J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Our objective was to evaluate the profitability of dairy cows receiving first service timed artificial insemination (TAI) after a voluntary waiting period (VWP) of 60 or 88 d. Holstein cows from 3 commercial farms received TAI after the Double-Ovsynch protocol (GnRH-7d-PGF-3d-GnRH-7d-GnRH-7d-PGF-56h-GnRH-16h-TAI) at 60 ± 3 (SVWP = 1,365) or 88 ± 3 DIM (LVWP = 1275). Subsequent AI services were conducted after detected estrus or TAI (32 ± 3 d after AI-GnRH-7d-PGF-56h-GnRH-16h-TAI). Individual cow production and reproduction data was collected for an 18 mo period

(18MP) after calving. Only cows that calved ≥ 18 mo before the day of data collection for the current analysis were included in the 18MP evaluation (SVWP = 523 and LVWP = 520). Total profitability (TPROF; $/cow) for the experimental lactation (EL) and the 18MP was the aggregation of: income over feed cost (IOFC), reproductive cost (RPRC; EL only), replacement cost (REPLC), calf value (CF; 18MP only), and fixed cost (FXC). Time to pregnancy was analyzed using Cox's regression, whereas continuous and binomial outcomes were analyzed by linear or logistic regression, respectively. Hazard of pregnancy up to 350 DIM for the EL was greater ($P < 0.01$) for SVWP than for LVWP [HR = 1.35 (95%CI = 1.24 to 1.48)] with median days to pregnancy of 102 and 128 for SVWP and LVWP, respectively. During the EL, lactation length was greater ($P < 0.01$) for LVWP (308 ± 3 d) than for SVWP (297 ± 2 d) and the same proportion ($P = 0.14$) of cows were culled (SWVP = 29% vs. LVWP = 32%). During the EL, similar TPROF (SVWP = $1,982 ± 36 vs. LVWP = $2,051 ± 38; $P = 0.12$) and profitability per day of lactation (SVWP = $5.5 ± 0.2 vs. LVWP = $5.3 ± 0.2; $P = 0.71$) was observed. Specifically, IOFC was greater ($P = 0.01$) for LVWP ($3,146 ± 37) than SVWP ($3,033 ± 35), FXC was greater ($P < 0.01$) for LVWP ($770 ± 7) than SVWP ($743 ± 6). Conversely, RPRC was greater ($P < 0.01$) for SVWP ($66.1 ± 0.9) than LVWP ($61.6 ± 0.9) and REPLC was similar ($P = 0.25$) for SVWP ($242 ± 12) and LVWP ($270 ± 13). For the 18MP, similar TPROF (SVWP = $2,885 ± 77 vs. LVWP = $2,764 ± 78; $P = 0.31$) and profitability per day (SVWP = $5.4 ± 0.2 vs. LVWP = $5.1 ± 0.3; $P = 0.45$) was observed. Specifically, no differences were observed for IOFC ($4,353 ± 76 vs. $4,227 ± 79; $P = 0.26$), REPLC ($373 ± 23 vs. $408 ± 24; $P = 0.45$), CF ($81.6 ± 2.8 vs. $80.8 ± 2.8; $P = 0.96$), and FXC ($1,112 ± 16 vs. $1,073 ± 17; $P = 0.16$). Percentage of cows culled during the 18MP was similar ($P = 0.57$) for SVWP (48%) and LVWP (50%). We conclude that despite differences in reproductive performance and individual factors that affect profitability, there were no differences in profitability during the EL or an 18 mo period after calving for cows that received TAI after a VWP of 60 or 88 d.

Key Words: Profitability, Double-Ovsynch, dairy cow

1270 Profitability of dairy cows managed for first service with the Double-Ovsynch or Presynch-Ovsynch protocol and different duration of the voluntary waiting period. M. L. Stangaferro*, R. Wijma, M. Masello, G. E. Granados, and J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Our objective was to evaluate the profitability of dairy cows managed with 3 different strategies for first service. Holstein cows from a commercial farm were randomly allocated to receive timed AI (TAI) after the Double-Ovsynch protocol (DO; GnRH-7d-PGF-3d-GnRH-7d-GnRH-7d-PGF-56h-GnRH-16h-TAI) at 60 ± 3 DIM (DO60 = 476), TAI after DO at 88 ± 3 DIM (DO88 = 431), or a combination of insemination after detected estrus (starting at 50 DIM) and TAI with the Presynch-Ovsynch protocol (PGF-14d-PGF-12d-GnRH-7d-PGF-56h-GnRH-16h-TAI;PSOv = 485). Subsequent AI services were conducted after detected estrus or TAI (32 ± 3 d after AI-GnRH-7d-PGF-56h-GnRH-16h-TAI). Data was collected for an 18 mo period (18MP) after calving. Only cows that calved ≥ 18 mo before the day of data collection for the current data analysis were included for the 18MP evaluation (DO60 = 218, DO88 = 208 and PSOv = 217). Total profitability (TPROF; $/cow) for the experimental lactation (EL; all cows included) and the 18MP was the aggregation of: income over feed cost (IOFC), reproductive cost (RPRC; EL only), replacement cost (REPLC), calf value (CF; 18MP only), and fixed cost (FXC). Time to pregnancy was analyzed using Cox's regression, whereas continuous and binomial outcomes were analyzed by linear or logistic regression, respectively. Hazard of pregnancy up to 350 DIM was greater ($P < 0.01$) for DO60 [HR = 1.50 (95%CI = 1.29 to 1.74)] and PSOv [HR = 1.37 (95%CI = 1.18 to 1.59)] than for DO88. Median days to pregnancy were 97, 117, and 98 for DO60, DO88, and PSOv, respectively. During the EL, lactation length was greater ($P = 0.03$) for DO88 (302 ± 4 d) than for DO60 (293 ± 5 d) and PSOv (289 ± 4 d). During the EL, similar TPROF (DO60 = $1,884 ± 55, DO88 = $1,893 ± 59 and PSOv = $1,860 ± 56; $P = 0.78$) and profitability per day (DO60 = $5.5 ± 0.3, DO88 = $5.1 ± 0.3 and PSOv = $5.5 ± 0.2; $P = 0.58$) was observed. Specifically, RPRC was greater ($P < 0.01$) for DO60 ($64.2 ± 1.4) and DO88 ($61.4 ± 1.5) than for PSOv ($55.3 ± 1.3), whereas FXC was greater ($P = 0.03$) for DO88 ($756 ± 11) than for DO60 ($733 ± 9) and PSOv ($723 ± 10). No differences were observed for IOFC (DO60 = $2,905 ± 53, DO88 = $2,989 ± 59 and PSOv = $2,926 ± 52; $P = 0.31$) and REPLC cost (DO60 = $225 ± 18, DO88 = $279 ± 20 and PSOv = $288 ± 22; $P = 0.11$). For the 18MP, similar TPROF (DO60 = $2,925 ± 119, DO88 = $2,627 ± 123 and PSOv = $2,708 ± 125; $P = 0.28$) and profitability per day (DO60 = $5.3 ± 0.4, DO88 = $6.1 ± 0.4 and PSOv = $5.1 ± 0.3; $P = 0.49$) was observed. Specifically, no differences were observed for IOFC (DO60 = $4,363 ± 117, DO88 = $4,073 ± 126 and PSOv = $4,175 ± 122; $P = 0.31$), REPLC (DO60 = $373 ± 31, DO88 = $408 ± 35 and PSOv = $417 ± 38; $P = 0.18$), CF (DO60 = $88.1 ± 4.3, DO88 = $81.3 ± 4.8 PSOv = $83.4 ± 4.8; $P = 0.69$), and FXC (DO60 = $1,136 ± 24 DO88 = $1,062 ± 27 and PSOv = 1078 ± 26; $P = 0.17$). We conclude that despite differences in reproductive performance and individual factors that affect profitability, there were no differences in profitability during the experimental lactation or an 18 mo period after calving.

Key Words: Profitability, Double-Ovsynch, Presynch-Ovsynch, dairy cow

1271 Economic evaluation of a milk test for pregnancy confirmation in dairy cows. E. M. Wynands[*1], M. von Massow[2], S. J. LeBlanc[1], and D. F. Kelton[1], [1]*Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada,* [2]*School of Hospitality, Food & Tourism Management, University of Guelph, Guelph, ON, Canada.*

Timely diagnosis of pregnancy and pregnancy loss is economically important. A commercially available pregnancy-associated glycoprotein milk assay is offered through routine Dairy Herd Improvement (DHI) testing for diagnosis of pregnancy. The objective was to complete a cost-benefit analysis of the milk pregnancy test for confirmation of pregnancy. The test can be used to complement, or as an alternative to, veterinary diagnosis by palpation or ultrasound. CanWest DHI currently recommends using the test for confirmation of pregnancy $\geq$ 60 d in gestation. Therefore, for this analysis it was assumed cows had been previously diagnosed pregnant. The model included 4 simulated pregnancy confirmation strategies: 1) no confirmatory testing, 2) confirmation by milk PAG test, 3) confirmatory examination by a veterinarian, and 4) confirmation using a combination of the milk test and veterinary exam. The analysis was done by simulations of economic outcomes using a cow-level stochastic model (with @Risk for Excel) with uniform distributions for additional days open due to testing frequency. Model assumptions were that cows became eligible for testing at 60 d in gestation, the herd had biweekly veterinary visits, and was enrolled in DHI milk recording with a milk test every 5 wk. Data from the current literature were used to model input variables associated with losses due to days open (for cows eligible to be re-inseminated after pregnancy loss) and culling after pregnancy loss for cows too late in lactation to re-inseminate. The base cost of veterinary exam was $2 and the milk test was $6. For each scenario, 1,000 simulations were run generating a minimum, maximum, and mean value. The most costly option was no confirmatory testing. The benefit of confirmatory testing compared to no confirmatory testing was between $11.80 and $17.90 per cow. On average, the milk test was $6.10 more costly per cow tested than veterinary confirmation. Under the assumed inputs, milk testing would have to cost < $1.00 or occur weekly to have a lower cost than veterinary confirmation. Sensitivity analysis indicated that the models were most sensitive to the proportion of cows found open and the proportion of open cows eligible to re-inseminate. Models were found to be less sensitive to the cost of a day open, additional days open due to testing frequency, and the cost of the test. Pregnancy loss is a costly event but the cost can be limited by pregnancy confirmation testing.

Key Words: pregnancy confirmation, economics

1272 Effect of synchronizing, access to supplement, and grazing session on grazing behavior of early lactating dairy cows. P. Chilibroste[1], J. P. Marchelli[2], and D. A. Mattiauda[*1], [1]*Facultad de Agronomia, Universidad de la Republica, Paysandu, Uruguay,* [2]*Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay.*

An experiment was performed to study the effect of two contrasting feeding strategies involving TMR and grazing, during the first 60 d in milk of Holstein dairy cows. Twenty four multiparous dairy cows were blocked according to parity, expected calving date, body condition score (BCS; 3.2 ± 0.35) and BW (688 ± 60.7 kg) before calving, and were randomly allocated to follow 1 of 2 feeding strategies: GR-one = 1 grazing session (AM: 800 to 1400 h) supplemented with a total mixed ratio (TMR corn silage/concentrate mix 40/60; respectively) out of the grazing plot orGR-two = 2 grazing sessions (AM: 0800 to 1400 h; PM: 1800 to 400 h) supplemented with TMR into the grazing plot. The 2 treatments were based on the same offer of energy (50 Mcal ENL/cow/d), differing in the synchrony or not between the access to pasture and to TMR (50% each of the total energy on offer). In both treatments TMR supplementation was offered once a day at 1700 h on feed troughs (0.6 m lineal access per cow). On Days 10, 13, 30, and 33 of the experiment the number of cows grazing or idling were determined every 15 min during the first 4 h of the AM and 3 h of the PM grazing session. The PROC GLIMMIX of SAS (SAS 9.2, 2010) with a binomial response distribution and with Logit as a link function was used to determine the probability of the different events. A first order autoregressive heterogeneous (AR1) covariance structure was selected. The probability of cows grazing (approximately 0.5) during the AM grazing session was not different between treatments. There was a significant effect of time with higher probability of grazing during the first hour than in the following ones (0.84^{a}, 0.32^{b}, 0.36^{b} and 0.41^{b} for the first, second, third and fourth h, respectively; $p < 0.01$). A significant interaction between treatment and time was detected: GR-one cows grazed longer than GR-two cows during the first h (0.89 vs. 0.75; $p < 0.05$) but shorter during the third hour (0.26 vs. 0.47; $p < 0.05$) of the grazing session. During the PM grazing session the GR-two cows expended a large proportion of time either around the feed troughs (0.83, 0.57 and 0.50) or idling (0.10, 0.19 and 0.17) during the first, second and 3rdh, respectively. The changes observed on grazing behavior were no reflected on productive performance (companion abstract).

Key Words: early lactation dairy cows, grazing behavior, grazing, TMR

1273 Profitability of reproductive management strategies for second and greater artificial insemination service in dairy cows.

W. C. Chandler*, M. L. Stangaferro, and J. O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Our objective was to evaluate the profitability of dairy cows managed with two different resynchronization protocols. Individual cow production and reproduction data was collected for an 18 mo period after calving for cows that completed a study aimed at evaluating two management strategies for second and greater AI services (Giordano et al., 2015; J Dairy Sci. 98:2488–2501). Briefly, cows enrolled in the control group (CON; n = 634) received insemination based on increased physical activity (AIACT) any time after a previous AI and timed AI (TAI) after the Ovsynch protocol (GnRH-7d-PGF2α-56h-GnRH-16h-TAI) initiated 32 ± 3 d after AI. Cows enrolled in the treatment group (TRT; n = 616) diagnosed non-pregnant 32 ± 3 d after AI with a corpus luteum (CL) ≥ 20 mm received a PGF2α treatment to induce estrus. Cows not AIACT within 9 d of the PGF2α received TAI after a 5d-CIDR-Ovsynch protocol (GnRH+CIDR-5d-PGF2α+CIDR-removal-24h-PGF2α-32h-GnRH-16h-TAI). Cows in TRT with no CL received a GnRH treatment for presynchronization and if not AIACT within 7 d were enrolled in the 5d-CIDR-Ovsynch protocol to receive TAI. Total profitability (TPROF; $/cow) during the 18 mo period of evaluation was the aggregation of: income over feed cost (IOFC) during lactation and the dry period, reproductive program cost (RPRC), replacement cost (REPLC), calf value (CF), and fixed cost per day (FXC). Time to pregnancy was analyzed using Cox's regression whereas, continuous and binomial outcomes were analyzed by linear or logistic regression, respectively. The hazard of pregnancy up to 270 DIM was similar for cows in the CON and TRT group (HR = 1.07; 95%CI = 0.95 to 1.21) with median days to pregnancy of 111 and 110 d for the CON and TRT group, respectively. Total days in lactation were similar (P = 0.57) for CON (417 ± 5 d) and TRT (420 ± 6 d) and the same proportion (P = 0.79) of cows were culled for both groups (CON = 57% vs. TRT = 55%). Similar TPROF (CON = $3,563 ± 71 vs. TRT = $3,498 ± 69; P = 0.71) and profitability per day of lactation (CON = $8.2 ± 0.2 vs. TRT = $8.1 ± 0.2; P = 0.89) was observed. Among individual factors used to calculate profitability, there were no differences between groups for IOFC (CON = $4,771 ± 68 vs. TRT = $4,724 ± 66; P = 0.80), FXC (CON = $1,041 ± 14 vs. TRT = 1049 ± 14; P = 0.57), REPLC (CON = $468 ± 19 vs. TRT = $449 ± 18; P = 0.82), and CF (CON = 86.2 ± 2.6 vs. TRT = 85.2 ± 2.7). Conversely, RPRC was greater (P < 0.01) for TRT ($68.8 ± 2.1) than for CON ($59.4 ± 1.7). We conclude that despite a greater reproductive program cost for TRT than CON, overall profitability for an 18 mo period after calving was similar for both strategies.

Key Words: profitability, resynchronization, dairy cow

1274 Pre-weaning injections of bovine somatotropin enhanced puberty attainment of bos indicus-influenced beef heifers.

G. M. Silva*, P. Moriel, J. M. B. Vendramini, and J. D. Arthington, *UF/IFAS, Range Cattle Research and Education Center, Ona, FL.*

A 2-yr study evaluated the effects of three pre-weaning 14-d apart injections of bovine somatotropin (bST) on growth and puberty of beef heifers. On d 0 of each yr, Angus × Brangus heifers (n = 15 heifers/treatment/yr; BW = 153 ± 21 kg; age = 135 ± 12 d) were stratified by BW and age, and randomly assigned to receive s.c. injections of saline (SAL; 5 mL; 0.9% saline) or half-dose of bST (250 mg of sometribove zinc; Posilac, Elanco, Greenfield, IN) on d 0, 14, and 28. Cow-calf pairs were allocated to 4 bahiagrass (*Paspalum notatum*) pastures (7 to 8 pairs/pasture/yr) from d 0 until weaning (d 127). Unshrunk BW and blood samples were collected on d 0, 14, 28, and 127. From d 127 to 346, heifers were pooled by treatment and allocated to bahiagrass pastures (1 pasture/treatment/yr) and fed blackstrap molasses-based concentrate at 1.1% BW (DM basis). Unshrunk post-weaning BW was obtained every 28 d, and blood samples every 9 to 10 d to determine plasma progesterone (P4) concentrations. Heifers were considered pubertal when 2 consecutive plasma samples had P4 ≥ 1.5 ng/mL. Each group of heifers was placed with 1 Brangus bull from d 282 to 346. Effects of treatment × yr and treatment × yr × time were not detected for any variable measured in the study (P ≥ 0.11). During pre-weaning phase, bST heifers had greater mean plasma IGF-1 concentrations (115 vs. 102 ± 3.8 ng/mL; P = 0.02) and ADG from d 0 to 42 (1.17 vs. 1.06 ± 0.035 kg/d; P = 0.01), but tended to have less ADG from d 42 to 127 than SAL heifers (0.77 vs. 0.84 ± 0.029 kg/d; P ≥ 0.06). Hence, BW at weaning did not differ between bST and SAL heifers (267 vs. 270 ± 1.70 kg, respectively; P = 0.58). During post-weaning phase, bST heifers had similar ADG from d 127 to 347 (0.17 vs. 0.12 ± 0.07 kg/d; P = 0.11), BW and age at puberty (290 vs. 291 ± 6.9 kg and 395 vs. 419 ± 14 d, respectively; P ≥ 0.15), but greater puberty achievement at start of breeding season (63 vs. 44 ± 7.9%; P = 0.02) than SAL heifers. Hence, three half-dose injections of bST administered to suckling beef heifers at 14-d intervals may be a feasible management practice to enhance puberty attainment at the start of the breeding season.

Key Words: somatotropin, heifers, puberty

1275 Effects of temperament on physiological and reproductive responses of Bos Indicus beef cows.

R. F. Cooke*[1], K. M. Schubach[1], R. F. G. Peres[2], R. S. Cipriano[3], R. Marques[1], R. Carvalho[2], D. W. Bohnert[1], M. V. Biehl[4], A. V. Pires[4], and J. L. M. Vasconcelos[5], *[1]Oregon State University-EOARC Burns, Burns, OR, [2]Departamento de Produção Animal- FMVZ- UNESP, Botucatu, Brazil, [3]UniSalesiano, Araçatuba, Brazil, [4]ESALQ/ University of Sao Paulo, Piracicaba, Brazil, [5]Sao Paulo State University, Botucatu, Brazil.*

This experiment evaluated the effects of temperament on physiological and reproductive responses of *Bos indicus* cows. A total of 954 lactating, multiparous, non-pregnant Nelore cows (age = 99 ± 1.6 mo; days post-partum = 51.4 ± 0.3 d; BCS = 5.34 ± 0.04; BW = 430 ± 2 kg), allocated into 8 groups of approximately 120 cows each, were utilized. Groups were assigned to an estrus synchronization + timed-AI protocol from d 0 to 11. On 11, cows were inseminated, blood samples were collected, and cow temperament was evaluated via chute score and exit velocity. Individual exit score was calculated by dividing exit velocity results into quintiles and assigning cows with a score from 1 to 5 (exit score: 1 = slowest; 5 = fastest cow). Temperament scores were calculated by averaging cow chute score and exit score, and cow temperament type was defined according to temperament score (≤ 3 = adequate temperament, ADQ, > 3 = excitable temperament, EXC). Pregnancy status was verified 30 d after timed-AI via transrectal ultrasonography. Cows not pregnant to AI were assigned to a second timed-AI protocol. Cows that still remained non-pregnant were exposed to natural breeding for 60 d. Cow age, BW, BCS, and days post-partum on d 0 were similar ($P \geq 0.27$) between ADQ and EXC cows. On d 11, EXC had greater ($P < 0.01$) plasma cortisol but similar ($P = 0.89$) plasma haptoglobin concentrations compared with ADQ cows (48.9 vs. 38.4 ng/mL of cortisol, SEM = 1.0). Pregnancy rate to the first timed-AI tended ($P = 0.10$) to be less in EXC vs. ADQ cows (41.0 vs. 47.2%; SEM = 3.5), whereas pregnancy rates to the second timed-AI, natural breeding, and final pregnancy rates (AI + natural breeding) were similar ($P \geq 0.23$) between ADQ and EXC cows. However, calving rate was less ($P = 0.02$) in EXC vs. ADQ cows (66.9 vs. 74.9%; SEM = 2.5), which can be associated with the greater ($P = 0.04$) pregnancy loss (based on final pregnancy status and actual calving) detected in EXC vs. ADQ cows (11.3 vs. 6.4%; SEM = 1.6). Results from this experiment indicate that *B. indicus* cows with excitable temperament have impaired reproductive performance during a breeding season based on timed-AI + natural breeding compared to cohorts with adequate temperament.

Key Words: beef cows, reproduction, temperament

1276 Carcass quality of primiparous cows managed under a single-calf heifer model combined with use of sexed semen and early weaning.

J. A. Arce-Cordero*[1], J. K. Ahola[1], D. R. Woerner[2], G. E. Seidel[3], and S. L. Archibeque[1], *[1]Department of Animal Sciences, Colorado State University, Fort Collins, [2]Colorado State University, Fort Collins, [3]Department of Biomedical Sciences, Colorado State University, Fort Collins.*

The single-calf heifer model (SCHM) harvests females after early-weaning their first calf, reducing average age and maintenance requirements of the herd, hence increasing biological efficiency of beef production. However, pregnancy estrogens accelerate bone ossification, which might affect carcass value of SCHM females. This study evaluated: overall maturity (OM), bone maturity (BM), lean maturity (LE), marbling (MA), Warner-Bratzler (WBSF) and slice shear force (SSF), and cooking loss (CL) of carcasses of SCHM females. Fifty-three Angus-based yearling heifers (BW = 353 ± 38.8 kg) and a second set of 58 (BW = 307 ± 29.9 kg), were synchronized and inseminated with sexed semen during first and second year of the project, respectively, to calve at approximately 24 mo of age. At weaning, average age of calves was 106 ± 22 and 120 ± 21 d, and first-calf heifers (43 each year) were fed for 88 and 90 d at a feedlot, for years 1 and 2, respectively. At harvest, carcasses were scored for LE, BM, and MA (slight = 300, small = 400, and modest = 500); OM was estimated from BM and LE (A^{00}, $B^{00}$and C^{00} maturities corresponded to scores of 100, 200, and 300, respectively). One LM sample was removed for SSF, WBSF and CL measurements. Carcasses were sorted by OM as < 300 or $\geq$ 300, and the resulting means for carcass traits were compared with a *t* test. Data were combined across years, since same significant differences ($P < 0.05$) between OM groups were obtained for both years. Means ± SD for the 66% of the carcasses classified as < 300 OM were: 192 ± 39.3 OM, 211 ± 53 BM, 165 ± 29 LE, 446 ± 84 MA, 25.4 ± 8.6 kg SSF, 4.94 ± 1.19 kg WBSF, and 25.4 ± 4.1% CL. Remaining carcasses ($\geq$ 300 OM) were 305 ± 18 OM, 346 ± 46 BM, 167 ± 27 LE, 462 ± 78 MA, 27.6 ± 9.1 kg SSF, 4.96 ± 0.84 kg WBSF, and 26.1 ± 4.2% CL. Significant differences between the 2 OM groups were found for BM ($P < 0.001$). However, no differences were detected for LE ($P = 0.81$), MA ($P = 0.39$), WBSF ($P = 0.96$), SSF ($P = 0.29$) or CL ($P = 0.47$). Therefore, differences in OM and BM did not affect palatability characteristics of carcasses of primiparous SCHM females approximately 30 mo of age.

Key Words: bone ossification, shear force

1277 Milk metabolomics of dairy goats with mammary inflammation under heat stress conditions.
S. Love[1], A. Salama[*1,2], N. Mehaba[1], and G. Caja[1], [1]*Group of Ruminant Research (G2R), Universitat Autonoma de Barcelona, Bellaterra, Spain,* [2]*Animal Production Research Institute, Dokki, Giza, Egypt.*

The objective was to test whether mammary gland response to bacterial endotoxin could be conditioned by heat stress, and to detect biomarkers for heat stress and inflammation in milk. Eight multiparous Murciano-Granadina dairy (2.2 ± 0.1 L/d; 100 ± 5 DIM, 42 ± 2 kg BW) goats were maintained under 2 environmental conditions varying in temperature, relative humidity (RH) and temperature humidity index (THI): 1) 4 goats under thermoneutral (TN; 15 to 20°C, RH = 50 ± 5%, THI = 59 to 65), and 2) 4 goats under heat stress conditions (HS; 35°C from 0900 to 2100 and 28°C from 2100 to 0900, RH = 45 ± 5%, THI = 75 to 83). Adaptation of 11 d to the experimental treatments was allowed. On d 12 each animal had 1 udder half infused with 10 µg *E. Coli* lipopolysaccharide (LPS) and the other udder half as the control with 0.9% saline (CON). This resulted in 4 treatment combination: TN-CON, TN-LPS, HS-CON, and HS-LPS. Milk samples (0, 4, 6, 12, and 24 h) were collected and analyzed by ^{1}H NMR spectroscopy operating at 600 MHz. Data were processed by the ChemoSpec package of R program and further analyzed by the web-based MetaboAnalyst program. Principal component analysis and partial least square–discriminant analysis were used to identify possible metabolite markers in milk. Citrate, glucose-1-phosphate, pyruvate and malonic acid increased in milk of HS goats. The increment in milk citrate might explain the previously observed deteriorated coagulation properties during the cheese making from the milk of heat-stressed animals. On the other hand, the LPS challenge resulted in an increment in milk lactate, acetate, butyrate, and capric acid. In conclusion, the metabolomic profile of milk was dramatically affected by environmental temperature and udder health status. Milk citrate and lactate were detected as good markers for heat stress and udder inflammation, respectively. Acknowledgment: Project AGL-2013–44061-R (Plan Nacional, MINECO, Spain).

Key Words: metabolomics, mastitis, heat stress, dairy goats

1278 Winter climate variables and their effect on feed intake in *Bos taurus* bulls.
R. C. Pauling*, S. E. Speidel, M. G. Thomas, M. M. Culbertson, R. K. Peel, and R. M. Enns, *Department of Animal Sciences, Colorado State University, Fort Collins.*

In beef cattle, there are numerous factors that influence feed intake such as breed composition, ration formulation, and body size. Additionally, an animal's intake could be influenced by many different environmental factors such as weather and climate factors. It is hypothesized that animal intake is influenced by weather events, specifically daily temperature difference (TDIFF) and average daily wind speed (WSPD), experienced prior and up to a feeding event, however there is limited research on the affects of these variables on feed intake. Therefore the objective of this study was to determine if average daily pen DMI (ADMI) were significantly influenced by changes in weather during winter months. Feed intake observations were collected from a total of 158 *Bos taurus* bulls from 3 different sources that were separated into pens ($n = 5$), with pen allocation based on source and BW. Feed intake observations were collected for approximately 70 d from December through February. Climate and feed intake data were obtained from the Colorado State University Agricultural Research, Development and Education Center. The distance between the weather station and the feed intake unit was approximately 5 km. The independent variable TDIFF was defined as the difference between the daily maximum temperature and minimum temperature. The effects of pen, WSPD, and TDIFF were evaluated for their influence on ADMI using a generalized linear model. This regression was performed for the intake observation day (d0), as well as every day up to 4 d before d0. Pen was included in the model to account for differences in cattle's breed, size and pen location. The model results suggested that TDIFF was significant ($P < 0.0001$) on d0, as well as 1, 2, and 3 d before d0. WSPD was shown to be significant 2 ($P < 0.0003$) and 4 ($P < 0.0001$) days before d0. Model R2 was shown to be the greatest 2 d before d0 (0.55). These results suggest that differences in a bull's DMI are influenced by weather changes occurring 2 d before the intake day during winter months. Better understanding of climate variables effect on feed intake in beef cattle could potentially lead to more accurate evaluations of differences of feed efficiency in beef cattle in the future.

Key Words: beef cattle, feed intake, winter climate

1279 Maternal heat stress reduces body and organ growth in calves: relationship to immune tissue development.
B. M. S. Ahmed[*1], U. Younas[1], T. O. Asar[1], A. P. A. Monteiro[2], J. Hayen[1], S. Tao[2], and G. E. Dahl[3], [1]*University of Florida, Gainesville,* [2]*University of Georgia, Tifton,* [3]*Department of Animal Sciences, University of Florida, Gainesville.*

Maternal heat stress (HT) not only reduces fetal growth but also influences postnatal performance and immune function of the offspring. The objective was to evaluate the effect of in utero HT on overall fetal growth and organ development, particularly those associated with immune function. Dams were dried off 45 d before expected calving and randomly assigned to one of two treatments: HT or cooling (CL). During the dry period, all cows were housed under shade in a freestall barn, where the pen for CL cows was equipped with active cooling including water soakers and fans whereas the pen for HT cows had no soakers and fans. Based on rectal temperature (RT) and

respiration rate (RR), heat stress was severe. Average RT in HT cows was 39.3°C compared with 38.9°C for CL cows, and HT cows had 66.7 breath/min respiration rate and 43.2 for CL cows. After birth all bull calves were immediately separated from their dams and weighed. Bull calves (n = 30) were sacrificed at birth without colostrum feeding (5/trt) and 1 and 2 d of age (DOA, following colostrum feeding, 5/trt). Pooled colostrum (3.8 L) was fed within 4 h after birth to bulls slaughtered on 1 and 2 DOA. After slaughter, the small intestine was removed, weighed (1.0 to 1.4 kg), and dissected into duodenal, jejunal and ileal segments, and tissue samples from each section were fixed in 4% neutral formalin and then transferred to 70% ethanol for immunohistochemistry. Bull birth weight from HT dams was lower than bulls from CL dams (HT: 39.3; CL: 43.8 SEM = 1.1 kg; $P < 0.01$). The thymus, spleen, and heart weight of HT bulls was lower compared with the CL bulls (Thymus, HT: 107.7; CL: 138.0, SEM = 14.4 g; $P = 0.02$; Spleen, HT: 75.5; CL: 93.7, SEM = 6.9 g; $P < 0.01$; Heart, HT: 292.4; CL: 329.4, SEM = 19.6 g; $P = 0.03$). The liver weight of HT bulls tended to be lower compared with the CL bulls (HT: 811.4; CL: 914.0, SEM = 70.4 g; $P = 0.09$). We conclude that the acute difference in heat strain on HT and CL cows during the dry period has significant impact on general fetal growth and on immune tissue development, which may be associated with reduced immune function in early life.

Key Words: heat stress, bull, immune tissue

1280 Liver proteomic analysis of cows exposed to heat stress or cooling conditions during the dry period.

A. L. Skibiel[*1], M. Zachut[2], Y. Levin[3], B. C. do Amaral[4], and G. E. Dahl[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, [2]Institute of Animal Science, Volcani Center, Bet Dagan, Israel, [3]The Nancy and Stephen Grand Israel National Center for Personalized Medicine, Weizmann Institute of Science, Rehovot, Israel, [4]PMI Nutritional Additives, Shoreview, MN.*

Heat stress negatively impacts cow performance, compromises immune function and increases susceptibility to metabolic disorders, particularly during the transition period. Metabolic adaptations of the liver are critical for successful transition from gestation to lactation, yet it is unclear how heat stress impacts metabolic pathways within the liver at the molecular level. The objective of this study was to investigate the liver proteome of cooled and heat stressed dry cows to gain insight into how molecular pathways are altered by heat stress and may contribute to poor performance and transition-related disorders. The experiment was conducted at the University of Florida Dairy Unit. During the dry period, cows were either housed in shaded barns with fans and soakers (cooled group [CL]; n = 5) or in shaded barns lacking these cooling devices (heat stressed group [HT]; n = 5). Liver biopsies were collected +2 d relative to calving. Proteins were analyzed by quantitative shotgun proteomics at the Weizmann Institute of Science (Rehovot, Israel). Proteins were extracted and subjected to in-solution tryptic digestion followed by nanoflow liquid chromatography coupled to high-resolution tandem mass spectrometry. Quantitative data was extracted using the Genedata Expressionist data analysis package and proteins identified using the Mascot search engine. Proteomics data, after logarithmic transformation, were analyzed by t test to examine effect of treatment (CL vs. HT). Proteins were regarded as differential at $P \leq 0.05$ and fold change ± 1.2. Differentially expressed proteins were analyzed by Ingenuity Pathway Analysis. A total of 3270 proteins were identified, 65 of which were differentially expressed between treatments. The most relevant pathways identified were hepatic oxidative phosphorylation and mitochondrial dysfunction. The abundance of several proteins related to these pathways was lower in the liver of HT cows relative to CL cows, including cytochrome c oxidase subunit 4 isoform 1(COX4I1, $P < 0.04$), NADH dehydrogenase 1 α subcomplex subunits 10, 11, and 12 (NDUFA10, $P < 0.002$; NDUFA11, $P < 0.01$; NDUFA12, $P < 0.04$), and thioredoxin-dependent peroxide reductase (PRDX3, $P < 0.04$). NADH dehydrogenase and cytochrome c oxidase are 2 of the 4 enzyme complexes in the inner mitochondrial membrane involved in the redox reactions that create the proton gradient necessary to power ATP synthesis. Thioredoxin-dependent peroxide reductase is an antioxidant and as such protects enzymes from oxidative damage. These results suggest that cooling late gestation cows improves liver function during early lactation.

Key Words: oxidative phosphorylation, heat stress, mitochondrial dysfunction

---

1281 A rumen bolus is a useful tool to monitor core body temperature in lactating dairy cows in a sub-tropical summer.

P. A. Gonzalez-Rivas[1], M. Sullivan[2], J. J. Cottrell[1], B. J. Leury[1], J. B. Gaughan[2], and F. R. Dunshea[*1], *[1]Faculty of Veterinary and Agricultural Sciences, The University of Melbourne, Parkville, Australia, [2]The University of Queensland, Gatton, Australia.*

The ability to vary body temperature is a common thermoregulatory response in mammals and rumen boluses may allow frequent monitoring of such variations during heat stress episodes. Twenty four Holstein Friesian lactating dairy cows were fed either a total mixed ration plus wheat (TMRW), TMR plus Bioprotect, a starch binding agent (TMRB), or TMR plus Corn (TMRC). The only difference between diets was the type of grain contained in the TMR. Cows had ad libitum access to water and feed in shaded pens at the University of Queensland, Gatton Campus, Dairy research facilities, 27.4986°S, 153.0155°E, 89 m elevation during 29 d in summer 2015. Rumen temperature (RuT) was recorded over 15 d at 20 min interval using transponder rumen boluses (RFID

transmitters; Smartstock, USA) placed in the ventral sac of the rumen. Rectal temperature (RT) was measured once every 4 d in the morning (0700 to 1000 h) and the temperature humidity index (THI) was calculated from an on-site weather station. Data were analyzed using the restricted maximum likelihood (REML) and Pearson correlation analysis procedure for GenStat V15. Treatment groups were considered statistically different at $P \leq 0.05$. Average THI during the experimental days was 72.4 ± 2.0 (mean ± SD) with 76% of the days having THI $\geq$ 72 which is the critical THI threshold for dairy cows. TMRC fed cows had lower RT than TMRW and TMRB (38.8 vs. 39.1 and 39.1°C respectively; $P < 0.001$) and RT was directly correlated to THI and RuT in all diets ($P < 0.001$). Diet had no significant effect on RuT (39.6, 39.7, 39.5°C for cows fed TMRB, TMRC and TMRW respectively; $P > 0.05$). Cows had large variations in RuT during the day that weren't associated with THI. For example, RuT was higher overnight (2000 to 0500 h) than during the day with the maximum occurring between 2100 and 0300 h. The minimum RuT occurred around the AM feeding (0600 to 1000 h) after which RuT gradually increased during the day. There was a positive association between RuT and mean daily THI during the bolus data collection period ($P < 0.001$). The data obtained from our study demonstrated that the variation in RuT follows daily THI and that the association between RT and RuT is positive. Therefore, RuT enables a sensitive prediction of RT when cows are exposed to high ambient temperatures.

Key Words: dairy cows, heat stress, rumen temperature

1282 Activity and rumination in an organic vs. a conventional grazing herd.

G. M. Pereira[*1,2], B. J. Heins[3], and M. I. Endres[4], *[1]University of Minnesota, St.Paul, [2]West Central Research and Outreach Center, Morris, MN, [3]University of Minnesota West Central Research and Outreach Center, Morris, [4]University of Minnesota, St. Paul.*

The objectives of this study were to evaluate activity and rumination of organic and conventional Holstein and crossbred cows during the grazing and winter months and to investigate the correlation between ambient air temperature and daily rumination and activity. The study was conducted for 2 yr (March 2014 to March 2016) at the University of Minnesota West Central Research and Outreach Center, Morris grazing dairy. During the grazing season (May to October) organic cows were on pasture and supplemented with 2.72 kg of corn per cow per day whereas conventional cows were supplemented with a TMR of corn silage, alfalfa haylage, corn, soybean meal, and minerals. During the winter season, both organic cows and conventional cows were supplemented with a TMR. Activity and rumination time (daily and 2-h periods) were monitored electronically using HR-LD Tags (SCR Engineers Ltd., Netanya, Israel) for the 2-yr period. Activity is reported in "activity units" from SCR DataFlow II software. The PROC MIXED of SAS was used for statistical analysis, and independent variables were herd (conventional or organic), month (January to December), year and their interactions, and date was a random effect. Daily activity was greater ($P < 0.05$) for the organic herd compared to the conventional herd (544 vs. 533), respectively. Daily rumination (min/d) was also greater ($P < 0.05$) for the organic herd (553 min/d) compared to the conventional (538 min/d) herd. Daily activity was greatest ($P < 0.05$) during July (791) and least during January (334) for the organic herd, and greatest ($P < 0.05$) during July (752) and least during January (289) for the conventional herd. Daily rumination was greater ($P < 0.05$) during December (592 min/d) compared to July (482 min/d) for the organic herd, and was greater ($P < 0.05$) during December (563 min/d) compared to March (496 min/d) for the conventional herd. Greater daily rumination of cows on a herd basis was negatively correlated (−0.39) with increased ($P < 0.01$) ambient air temperature in the organic herd, and there was a slight negative correlation (−0.10, $P < 0.01$) of daily rumination and air temperature in the conventional herd. In summary, organic cows had greater daily activity, and greater daily rumination compared to conventional grazing cows. Monthly activity and rumination patterns of grazing organic and conventional dairy cattle in this study were influenced by the weather.

Key Words: rumination, organic, activity

1283 Understanding behavior patterns of cattle adaptation to heat stress.

G. Nogueira[*1], P. Ajmone-Marsan[2], M. Milanesi[2], L. Zavarez[3], T. Sayuri Aguiar[4], D. Sandre[5], M. A. Maioli[6], G. Ferreira[7], G. Bispo[8], S. Stabile[7], S. Stabile[7], R. Caputo[7], C. Toyama[7], J. F. Garcia[9], and J. C. P. Lima[5], *[1]Unesp, Aracatuba-SP, Brazil, [2]Università Cattolica del Sacro Cuore, Piacenza, Italy, [3]UNESP, Jaboticabal, Brazil, [4]UNESP, Aracatuba, Brazil, [5]UNESP- FMVA, Araçatuba-SP, Brazil, [6]Unesp, Araçatuba, Brazil, [7]UNESP- FMVA, Aracatuba-SP, Brazil, [8]UNESP-FMVA, Aracatuba, Brazil,[9]UNESP Univ Estadual Paulista, Araçatuba, Brazil.*

Changes in climate may have negative effect on livestock that will have to adapt to more extreme environment in the near future. Therefore understanding how different breeds developed mechanisms to thrive under extreme conditions may help livestock production. This research compared the movement, ruminating time and weight gain between 2 breeds, Nellore (indicine, n = 24, 210 ± 15 kg) and Angus (taurine, n = 24, 227 ± 25kg) aging 10 mo and kept for 80 d at pasture during tropical spring (average temperature 26°C, maximum 32.2°C, minimum 21.5°C). Animals were sons of the same bull (Nellore or Angus) to minimize genetic variation. Concentrate supplement was provided twice a day (1.5% LW/day), netted shade was available (80% sun block, 10 m^2/animal). Animal motility (using an accelerometer, measured

relative movement-RM) and rumination time (minutes/day, using a sound sensitive sensor) were evaluated through a collar-sensor (SCR, Systems Heat time) by radio telemetry. Live weight (kg) was measured with a chute scale every 15 d. Data were compared by unpaired *t* test, two-way ANOVA and Pearson correlation analysis. We observed that Angus remained under the netted shade during daytime and grazed after sunset, Nellore on the other hand stayed on the sun despite the available shade. Nellore (781 ± 16 RM) moved less ($P < 0.001$) than Angus (919 ± 17 RM) but ruminated for longer periods ($P < 0.0001$; Nellore: 496 ± 9 min/day) compared to Angus (370 ± 8 min/day). Nellore (268 ± 27 kg) were lighter ($P = 0.0003$) than Angus 303 ± 24 kg) at the end of the 80 d period, average daily gain was lower ($P = 0.029$) in Nellore (0.65 ± 0.04 kg/day) compared to Angus (0.85 ± 0.05 kg/day). In summary Nellore moved less and ruminated more compared to Angus. It is possible that a reduction on movement is part of the Nellore adaptation to heat stress. By being less active Nellore produces a lower amount of heat to be dispersed but to move less, it selects the grass ingested in a worst way. The consequence is a need to ruminate more that can be done without much muscle activity and less heat production. Despite of moving more and ruminating less, Angus animals were more efficient than Nellore considering average daily gain. Samples from blood, muscle, skin, liver and semen were collected to be evaluated for metabolic, gene expression and epigenetic modifications induced by heat stress.

Key Words: Nellore, Angus, time ruminating

1284 Plasma insulin and glucose concentrations of feedlot cattle during summer.

A. M. Lees*[1], S. T. Anderson[2], V. Sejian[3], and J. B. Gaughan[1], *[1]The University of Queensland, Gatton, Australia, [2]School of Biomedical Sciences, The University of Queensland, Gatton, Australia, [3]ICAR-National Institute of Animal Nutrition and Physiology, Bangalore, India.*

Periods of heat stress are typically associated with an increase in basal insulin (INS) concentration and a decrease in basal glucose (GLU) concentration, thereby altering energy metabolism. The purpose of this study was to investigate circulating INS and GLU of shaded and un-shaded *Bos indicus* and *Bos taurus* feedlot cattle during summer. Thirty-six steers (12 Angus, Charolais and Brahman) with an initial BW of 318.5 ± 6.7 kg were used in a 180 d feedlot study with 2 treatments: un-shaded and shaded (3 m^2/animal; 90% solar block shade cloth). There were 6 steers (2/breed) per pen (162 m^2) and 3 pens/treatment. Blood samples were collected via jugular venepuncture on 5 occasions (period 1 to period 5). Plasma concentrations of INS and GLU were analyzed using a repeated measures model (PROC MIXED; SAS Inst. Inc. Cary, NC). Plasma INS were highly variable across breed × treatment groups, therefore concentrations were Log_{10} transformed analysis. The model included breed ($P = 0.03$; $P = 0.03$), treatment ($P = 0.81$; $P = 0.97$), period ($P < 0.0001$; $P = 0.0003$), treatment × breed ($P = 0.38$; $P = 0.39$), treatment × period ($P = 0.06$; $P = 0.09$), breed × period ($P = 0.03$; $P < 0.0001$) and treatment × breed × period ($P = 0.50$; $P = 0.48$) as fixed effects for Log_{10} INS and GLU (mmol/L), repectively. Pen nested within treatment and treatment × breed × animal ID nested within pen were included as random effects. Overall the Brahmans had higher plasma GLU than Angus, particularly during periods 1 ($P < 0.0001$) and 2 ($P = 0.003$). However as days on feed increased, the variability of GLU on a breed × treatment group basis decreased. There was a trend for increasing INS and GLU over time, which can be partly explained by the high starch, high energy diet that was fed. In other species, feeding diets with a high glycaemic index is known to be associated with insulin resistance characterized by persistent hyperglycemia despite increased insulin secretion. In the current study, plasma GLU concentrations increased but GLU homeostasis was maintained but with a marked increase in circulating INS. Together these results may indicate the development of insulin sensitivity in feedlot cattle during summer on a diet designed for weight gain and fat deposition.

Key Words: feedlot cattle, glucose, heat stress, insulin

1285 Impact of heat stress on immune status of sheep.

J. B. Gaughan*, M. Sullivan, A. J. Cawdell-Smith, H. Owen, and G. Wijffels, *The University of Queensland, Gatton, Australia.*

The objective of this study was to examine the effects of heat stress on sheep physiology. Australian Merino wethers (n = 144; 44.02 ± 0.32 kg) were randomly allocated to treatment in a climate controlled facility (CCF: 4 rooms; 3 pens/room; 6 sheep/pen; pen = 2.32 m^2). The treatments were: hot (HOT) and thermoneutral (TN). Treatment were replicated 4 times and each replication ran for 29 d. Dry bulb temperature (DBT) and relative humidity was obtained every 10 min. From these data a temperature humidity index (THI) was calculated: THI = DBT– {(0.31– 0.31× RH/100) × (DBT– 14.4)}. During HOT means for DBT, RH and THI were: 32.5 ± 0.40°C, 62.5 ± 7.22% and 30.5 ± 0.55, respectively. During TN the values were 19.7 ± 0.40°C, 79.9 ± 7.22% and 19.4 ± 0.55. Respiration rate (RR) were obtained 3 hly between 0800 and 1700 h. Rumen temperature (TRUM) was recorded at 10 min intervals using RFID rumen temperature boluses. Blood (2 × 10 mL) was collected by jugular venipuncture on entry and then every 7 d. Plasma concentrations of interleukin-1β (IL-1β), interferon-γ, tumor necrosis factor α, lipopolysaccharides (LPS), haptoglobin, alkaline phosphate (ALP), γ-glutamyl transpeptidase (GGT), creatine kinase (CK) and creatinine were determined. The MIXED procedure (SAS Inst. Inc. Cary, NC) was used. The model fitted included terms for replicate and treatment, a term for collection and a collection × treatment interaction. Mean RR of HOT was greater ($P < 0.01$)

at 140.0 ± 3.55 breaths per minute (bpm) compared with TN at 74.9 ± 3.55 bpm. The HOT group had a greater ($P < 0.05$) TRUM (40.4 ± 0.03°C) than the TN group (39.9 ± 0.04°C). ALP ($P = 0.0003$), GGT ($P = 0.0158$) and IL-1β ($P < 0.05$) were all lower in the HOT sheep. Creatinine concentration ($P = 0.0038$) and CK ($P > 0.05$) were higher in the HOT sheep. LPS concentration was greater ($P < 0.05$) in HOT compared with TN. The remaining parameters were not affected ($P > 0.05$) by treatment. Elevated CK, creatinine and TRUM suggest that the HOT sheep were heat stressed. There is some evidence pointing to impaired immune status. However, the data is equivocal, and in some cases confounding (e.g., greater IL-1β expression in TN, but greater LPS in HOT).

Key Words: sheep, heat stress, blood parameters

1286 Stocking rates and parasite load in yearling steers grazed season long in the Northern Great Plains.

F. A. Brummer*[1], G. L. Stokka[2], B. Patton[3], and C. Miller[4], *[1]North Dakota State University, Central Grasslands Research Extension Center, Streeter, [2]Department of Animal Sciences, North Dakota State University, Fargo, [3]North Dakota State University, Central Grassland Research Extension Center, Streeter, [4]North Dakota State University, Fargo.*

Intestinal parasitism of grazing ruminants can result in poor performance and compromised systems, especially in younger animals. Twelve pastures (12.9 ± 0.8 ha) were stocked at four stocking rates: light 1.83 ± 0.38 AUM · ha^{-1}, moderate 3.26 ± 0.30 AUM· ha^{-1}, heavy 4.98 ± 0.78 AUM · ha^{-1}, and extreme 6.18 ± 0.68 AUM · ha^{-1}. Yearling steers (317 ± 32 kg) were grazed on the pastures from mid-May to mid-September, 2015. Before turnout, the steers were dewormed with an injectable dewormer, as well as implanted with Revalor GTM to maximize live weight gains. The steers were also supplemented with dry distillers grains with solubles at 0.3% of body weight. Steers were weighed monthly during which time fecal grab samples were collected. Results demonstrated that initially the worming treatment before turnout proved effective in the early part of the grazing season as there was no difference ($P > 0.05$) among treatments in egg counts per gram (epg) in June, with corresponding low epg. However, a significant difference ($P < 0.05$) in epg was detected between the light and extreme treatment groups in July, with low levels in the light treatment, and higher levels in the extreme treatment. Egg counts over 35 epg, which has been proved as a performance threshold in grazing yearling cattle, were noted in individual animals on all treatments except the lightly grazed treatment in August and September. This study demonstrates an association between high stocking rates and increases in detectable parasite load, and supports the conclusion that individual yearling cattle that are susceptible to parasitism may be negatively impacted by season long systems that are stocked from moderate to extreme levels in the northern Great Plains.

Key Words: parasitism, northern Great Plains, yearling cattle, season long grazing

PRODUCTION, MANAGEMENT AND THE ENVIRONMENT SYMPOSIUM: IMPACTS OF LIVESTOCK PRODUCTION ON ENVIRONMENTAL REACTIVE NITROGEN

1287 The world's nitrogen cycle and human impacts.

J. Ham*, *Colorado State University, Fort Collins.*

Perhaps 40% of the people alive today are sustained from increased grain yields attributed to the use of synthetic nitrogen fertilizer. While the Haber-Bosch process of converting atmospheric nitrogen to ammonia (i.e., fertilizer) has transformed agricultural production, it has also caused an unprecedented shift in the global nitrogen balance. Despite many improvements in nitrogen use efficiency in both crop and livestock systems, a large fraction of agricultural nitrogen inputs are lost to the environment. This "fugitive" nitrogen is causing a host of environmental problems at local and global scales. Excess nitrogen has been shown to alter biogeochemical processes and ecosystem function across the globe. Because nitrogen can be easily transported in water or air through natural processes, or by the transport of grain and livestock; the impacts of agriculture nitrogen are often observed far from where the nitrogen was initially used. A good example of this process is the observed increases in the atmospheric deposition of reactive nitrogen across many areas, including many pristine ecosystems. Nitrogen deposition is often linked to ammonia-derived aerosols, compounds that can travel hundreds of kilometers from the source before being redeposited back to the surface. Because livestock account for over 50% of all ammonia emissions in many regions; beef feedlots, dairies, and swine and poultry operations are often linked to this air quality issue. While there is no question that livestock ammonia emissions are large, quantifying the actual impact of reactive nitrogen on the environment is a complex question. One must consider atmospheric transport at both local and regional scales, chemical reactions with pollutants from other industries, and other non-livestock sources and forms of nitrogen. Perhaps nowhere has this issue been more investigated than along the Front Range of Colorado, where a mature cattle feeding industry is located relatively close to the pristine ecosystems in Rocky Mountain National park. This presentation will begin with the role of livestock in the global and U.S. nitrogen cycle, and then narrow the scope to specific issues facing livestock producers in Colorado regarding atmospheric ammonia. Summary comments will suggest how animal scientists and industry leaders might respond to these growing concerns.

Key Words: Colorado producers, atmospheric ammonia, nitrogen

1288 Reactive N emissions from beef cattle feedlots. R. W. Todd*, H. M. Waldrip, D. B. Parker, and N. A. Cole, *USDA Agricultural Research Service, Bushland, TX.*

Large amounts of nitrogen (N) are fed to meet the nutritional needs of beef cattle in feedlots. However, only from 10 to 15% of fed N is retained in animals. Most N is excreted. Chemical and biological processes transform manure N into ammonia (NH_3), nitrous oxide (N_2O) and nitrate (NO_3^-). These reactive forms of N (N_r) are those most readily lost into the environment. Our objectives are to outline the forms and impacts of N_r lost from beef feedlots, present patterns and magnitudes of emissions, and examine ways to mitigate emissions. We will focus on NH_3, the major form of $N_r$emitted from beef feedlots. Fugitive NH_3 is a precursor to particulates in the atmosphere that cause air quality problems or overburden N-sensitive terrestrial ecosystems and initiate species changes and loss of diversity. Reactive N contributes to the eutrophication of surface waters and the creation of hypoxic zones in the Gulf of Mexico. Nitrous oxide is a greenhouse gas with almost 300 times the global warming potential of carbon dioxide (CO_2). Stringent regulations to control runoff have virtually eliminated NO_3^- as a source of N_r from beef feedlots. Direct N_2O emissions from beef cattle production are only about 0.1% of the national greenhouse gas inventory of CO_2–equivalent emissions. However, animal agriculture is the major source of U.S. NH_3 emissions (81%), and beef cattle production contributes about 15% to the total national NH_3 emissions. Research on NH_3 emissions has matured to where we have a good understanding of the pattern and magnitude of emissions. Ammonia volatilization depends on temperature, reflected in the daily and annual patterns of emission, with peak emissions during the warmest time periods. The magnitude of NH_3–N emissions is consistent across the cattle-feeding region from Texas to Nebraska. Reported winter emissions range from 25 to 35% of fed N, while summer emissions range from 50 to 75% of fed N. Research on multiple scales shows that crude protein content of diets is a critical driver of emissions. Diets that meet NRC guidelines for crude protein lose about 50% of fed N as NH_3–N. Diets with byproducts like distillers grains often exceed recommendations, with increases in NH_3 emissions from 25 to 50%. Several technologies offer promises of NH_3 emission mitigation, but most are expensive and hard to apply. Carefully managed cattle diets remain the most effective and practical way to limit the loss of NH_3 from beef feedlots.

Key Words: nitrogen

1289 Reactive nitrogen losses from dairy production systems. A. B. Leytem*[1] and C. A. Rotz[2], *[1]USDA-ARS, Kimberly, ID, [2]USDA-ARS Pasture Systems and Watershed Management Research Unit, University Park, PA.*

Reactive nitrogen (N_r) losses from dairy production vary depending on housing type, manure storage system, and manure land application practices. To illustrate on farm N_r losses, we compared 3 systems: a dry-lot in ID with 213 lactating and 137 young cattle, a free-stall operation in NY with 1,261 lactating and 925 young cattle, and a free-stall and grazing operation in the Netherlands (De Marke) with 78 lactating and 57 young cattle. The De Marke farm was designed to reduce N_r losses through an efficient feeding program, barn flooring to reduce ammonia (NH_3) losses, enclosed manure storage, injection of manure on cropland and the use of cover crops. Farms were modeled using the Integrated Farm System Model (IFSM) to estimate N_r losses and evaluate effects of mitigation strategies on the ID and NY dairies. Total estimated Nr losses ranged from 5,727 to 139,455 kg N yr^{-1} and comprised 34%, 46% and 50% of imported N from the ID, NY, and De Marke dairies, respectively. The N_r lost per animal equivalent (AE) was 121, 98, and 65 kg N AE^{-1} for the ID, NY, and De Marke dairies, respectively. The N_r losses differed between production systems with 80% of N_r lost as NH_3 (63% from housing) on the ID dairy, while the NY dairy lost 49% of N_r as NH_3 (52% land application of manures) and 46% due to leaching from crop fields. On the De Marke dairy the majority of N_r loss was due to leaching from crop fields and pasture comprising 52% of total N_r lost. To mitigate N_r losses at the ID dairy, strategies targeted the housing sector by feeding a balanced ration that reduced overall dietary CP, reducing housing emissions by 10 kg AE^{-1}along with a 1 kg AE^{-1}reduction from manure storage. Immediate incorporation of land applied manure decreased N_r losses by 1.7 kg AE^{-1}. These combined practices led to a 12.5% reduction in total N_r lost. A reduction in dietary CP on the NY dairy coupled with covering the lagoon reduced N_r losses from housing and manure management combined by 5.4 kg AE^{-1}, while immediate incorporation of land applied manure reduced field losses by 7.8 kg AE^{-1}. These practices combined reduced total farm N_r loss by 27%. While Nr losses from dairy production can be large, mitigation strategies are available, however they must be targeted to address issues within each production system individually to ensure system-wide reductions.

Key Words: nitrogen, dairy production, environment

1290 Reactive N emissions from crops and pastures.
C. Wagner-Riddle* and K. Congreves, *University of Guelph, Guelph, ON, Canada*

1291 Measurement and mitigation of reactive nitrogen species from swine and poultry production facilities.
W. Powers* and M. Capelari, *Michigan State University, East Lansing.*

Reactive nitrogen (Nr) species include oxides of nitrogen (nitric oxide, nitrogen dioxide and nitrous oxide [N_2O]), anions (nitrate and nitrite) and amine derivatives (ammonia [NH_3], ammonium salts and urea). Of the different Nr species, air emissions from swine and poultry facilities are dominantly NH_3 followed by N_2O. Excreta emissions are NH_3, ammonium ions, and urea with trace amounts of nitrate and nitrite. Farm systems and practices that handle manure as a wet product without pH modification favor almost exclusive NH_3 production while systems and practices associated with dry manure handling and bedded systems emit more NH_3 and result in greater N_2O production than that produced in wet systems. Results from a turkey grow-out study estimated that just under 1% of consumed nitrogen was emitted as N_2O from housing, compared to just under 11% emitted as NH_3. Despite generally lower N_2O emissions from animal housing compared to crop field emissions, N_2O emissions from housing are greater than often estimated. Lagoon systems emit more N_2O than either slurry or deep pit swine systems. Deep pit swine buildings emit as much as two-thirds less N_2O than deep bedded swine systems and laying hen, broiler chicken and turkey buildings emit over 4 times as much N_2O as swine housing, on an animal unit basis. Critical control points for mitigation center on 1) reducing the amount of nitrogen excreted and therefore excreted nitrogen available for loss to air or water during housing, manure storage or following land application of manures, 2) capturing excreted nitrogen to prevent release of nitrogen-containing compounds to air, water or soil resources or 3) conversion/treatment of nitrogen-containing compounds to non-reactive nitrogen gas.

Key Words: air emissions, poultry, swine

1292 Modeling atmospheric reactive nitrogen.
J. O. Bash*[1], K. Foley[1], J. T. Walker[1], M. W. Shepard[2], K. E. Cady-Pereira[3], S. Napelenok[1], D. K. Henze[4], and E. J. Cooter[1], *[1]USEPA, Research Triangle, NC, [2]Environmental Canada, Toronto, ON, Canada, [3]Atmoshperic and environmental Research Inc., Lexington, MA, [4]University of Colorado, Boulder.*

Nitrogen is an essential building block of all proteins and thus an essential nutrient for all life. Reactive nitrogen, which is naturally produced via enzymatic reactions, forest fires and lightning, is continually recycled and cascades through air, water, and soil media. Human activity has perturbed this cycle through the combustion of fossil fuels and synthesis of fertilizers. The anthropogenic contribution to this cycle is now larger than natural sources in the United States and globally. Until recently, little progress has been made in modeling of the nitrogen cycle in the environment due to the complexity of and uncertainty in its transport and transformation between soil, water and atmospheric media. The lack of understanding of these multimedia transport processes is due to the typical focus of research on specific media and the difficulty in parameterizing the human dimension of anthropogenically fixed reduced nitrogen and input into the environment, primarily through mineral fertilizer application to crops, the largest source of environmental reactive nitrogen. Here we will focus on modeling of the atmospheric component of the nitrogen cascade, with an emphasis on ammonia, emerging measurement techniques, and the potential for model improvements using emerging measurements, existing networks and modeling. The USEPA's Community Mulitscale Air Quality (CMAQ) model will be evaluated against observational trends in nitrogen deposition and ambient air quality from 2002 to 2012 and the sensitivity of CMAQ to NH_3 emissions will be explored. These findings will be presented with an emphasis on how the sensitivity of the modeling system to animal husbandry emissions and how the representation of these emissions can be improved.

Key Words: nitrogen cycle, emissions, environment

BIG DATA IN ANIMAL SCIENCE: USES FOR MODELS, STATISTICS AND META-APPROACHES

1293 Modeling in animal science: an introduction to quantitative understanding and prediction.
J. Dijkstra*, *Animal Nutrition Group, Wageningen University, Wageningen, Netherlands.*

In animal science, continuous advances in technology, computing, and engineering result in the generation of data at a rapidly increasing rate. Mathematical models enable quantitative analysis and integration of data to study the behavior and complexity of biological systems. This review highlights several aspects of modeling in the context of understanding, predicting and modifying complex processes in farm animal systems, and offers a current perspective for animal scientists without requiring specialized knowledge of mathematics or bioinformatics. A mathematical model is an equation or set of equations which represents the behavior of a system, and can be viewed as an idea, hypothesis or relation expressed in mathematics. In animal science, the system may range from the molecules in cells up to herd or flock level, with any level of the system being composed of subsystems lying at a lower

level, or being a subsystem of higher level systems itself. In empirical models, experimental data are used directly to quantify relationships based at a single level. Alternatively, mechanistic models are process-based and seek to understand causation in the system of interest by describing a system level in terms of components and associated processes at subsystem levels. Furthermore, models may be static, capturing behavior of the system at a particular point in time, or dynamic, describing how quantities in the system change with time. Several key benefits have been attributed to modeling. First, models can provide an integrative, quantitative understanding of mechanisms and associated relationships between responses of a system at various levels. Second, building a model may pinpoint areas where data or knowledge are lacking, and may indicate priorities for further research and development. Third, models provide quantitative assessments of management practices for the animal production sector including policymakers. This aspect becomes particularly important when observations are hardly possible because of time scale (changes emerging after several years or decades only) or technical difficulty of measurements. Two areas are in need of further development. Emerging–omics data on genetic and metabolic regulatory networks at the molecular and cellular level require further modeling methodology efforts to integrate such data with processes at a higher system level. Second, further advances in understanding and prediction at integrated levels will be obtained on combination of models that differ in underlying methodology. Examples include the integration of mechanistic models of animal metabolism with linear programming and life cycle assessment models.

Key Words: modeling; animal science; system

1294 Traditional versus structure-based model development strategies. L. O. Tedeschi[*1], R. R. White[2], C. F. Nicholson[3], B. L. Turner[4], M. A. Fonseca[1], and M. D. Hanigan[2], *[1]Texas A&M University, College Station, [2]Virginia Tech, Blacksburg, [3]The Pennsylvania State University, University Park, [4]Texas A&M University-Kingsville, Kingsville.*

An important challenge in agriculture modeling is deciding how to mathematically represent biological phenomena. The objective of this paper is to compare more traditional model development methods (e.g., empirical models) with structure-based modeling (SBM) such as system dynamics (SD). Substantial overlap exists between traditional and SBM approaches, but there are important differences. The overall steps of the modeling process and scientific rigor are quite similar, but their focus and implementation can differ substantially. The steps of both modeling approaches often comprise the 1) identification of a problem (research objective), 2) formulation of the mathematical (and/or statistical) statements, 3) data collection (experimentation), 4) model evaluation and quantitative analysis relevant to the modeling objectives. SBM often differs from traditional approaches in each of these phases such as defining the problem as the replication of observed dynamic behavioral modes (e.g., s-shaped growth or oscillations) rather than situational point prediction or statistical estimation of parameters (step 1), giving more attention to system structure based on cause-effect relationships in terms of the stock-flow (i.e., level variables and rate variables) and feedback processes that generate observed behavior and visualizing these relationships in causal loop diagrams (CLD) and stock and flow diagrams (SFD) (step 2), and data collection that encompasses a broader range of sources (experimental, secondary, expert opinion, participatory exercises) and may include concepts hypothesized to be important but for which limited data are available (step 3). Model evaluation criteria can also differ due to the intrinsic nature of SBM as greater focuses are given to behavioral mode replication and feedback loop dominance analysis (step 4). In general, traditional modeling approaches focus on defining analytical functions and their statistical consistency with observed biological responses, whereas SBM focus on the mechanistic explanations for system behaviors and the feedback relationships that led to them. For example, a traditional modeling approach could use a saturating function to describe movement of a substrate across a membrane, whereas SBM would focus on feedback processes that represent decreasing affinity of the membrane for that substrate as concentration increases. Although they can differ substantially in their implementation, these 2 mathematical modeling strategies should be viewed as complementary rather than competing tools.

Key Words: modeling, simulation, methodology

1295 Big data analysis techniques. N. St-Pierre*, *Ohio State University, Columbus.*

The term ‘big data’ has recently entered our lexicon. Data scientists and statisticians have loosely defined big data as datasets with billions (10^9) of rows (tupples) of data. Hence, very few datasets in the animal sciences would qualify as true big data. At best, we deal with large datasets in the millions of tupples. Regardless, some of the same issues surrounding big data analyses are shared with large data: 1) near certainty of the presence of outliers, and 2) low signal to noise (irrelevant variables, subtle relationships, data imbalance, near collinearity). In large datasets, outliers are more than unidimensional: higher dimensions must be scrutinized. An example of this involved the characterization of feed composition data. Techniques used to address the low signal to noise issue can be classified into 2 groups: opaque techniques and black box techniques. The most prevalent techniques in the first group are: visualization through smoothing, regression, principal component analysis (PCA), decision trees, clustering methods, and multivariate adaptive splines (MARS). Black box techniques include neural networks, k-nearest neighbor

(KNN), K-mean, support vector machines and genetic algorithm. Each technique will be briefly explained using an example. With PCA, we first find a direction that has maximum variance. A second direction is then found, which has maximum variance of all directions perpendicular to the first. The process is repeated until there are as many directions (vectors) as original variables. Advantages of PCA are the dimension reduction and the ability to handle more predictors than observations. Disadvantages are that they often lack interpretation, and are linear models. Issues when only summary statistics are available (i.e., meta-analysis) will be explained, including the importance of properly weighing observations and accounting for the inherent blocking in the meta-design.

Key Words: big data, principal component analysis, meta-analysis

1296 Evaluation of multilevel mixed effect models.

E. Kebreab*, *University of California, Davis, Davis.*

Simple mixed effect models have been extensively used in animal science literature. However, in some instances biological relationships require that models account for deviations of individual animals from that of the population. Furthermore, some animals might share similar genetic background because they are closely related (e.g., pig littermates) thus specification of animal within litter relationship (i.e., nested random effects) is necessary to model the hierarchical data structure. In some cases measurements taken on the same individual may not be independent (e.g., weekly BW measurements). This will result in models with heteroskedastic and serial correlated errors, which need to be evaluated and the errors minimized. Recent developments in statistical theory and computational power allow for specification of multilevel mixed effect models, especially nonlinear models. To demonstrate implementation of such models, an example is provided using data collected from an experiment with 40 pigs of 3 sexes originating from 17 litters and their BW measured weekly or every 2 wk up to 1,007 d. A multilevel mixed effects model was used within a growth function because it allows for estimation of all growth profiles simultaneously, and different sources of variation. Furthermore, variance in-homogeneity and within-animal correlation were introduced to the growth function. In the basic model, the variance was assumed to equal to identity matrix, i.e., the within-animal errors are independent, identical and random vectors. The basic model fit suggested that the within-animal variability increased with increasing BW and auto-correlation was also present. The variance-covariance matrix was then relaxed and decomposed into variance structure component and a correlation structure component that allows specification of model variance heterogeneity and serial correlation. Variance of the within-animal errors was modeled using a variance function, which when implemented reduced Bayesian Information Criteria (BIC) values to 8,950 compared to 9,861 for the basic model but did not remove the strong auto-correlation in the residuals. A continuous time autoregressive process of first order was applied to the within-animal errors because it deals with unequally spaced observations. This further reduced BIC to 7,146 due to removal of the serial correlated errors and thus inclusion of a continuous auto regressive process of first order is recommended when modeling frequently sampled growth data.

Key Words: multilevel mixed effect model, variance structure, autocorrelation

RUMINANT NUTRITION

1297 Effect of lactose inclusion in calf starters on rumen fermentation of weaned calves.

A. Saegusa*[1], K. Inouchi[2], M. Ueno[3], Y. Inabu[4], S. Koike[3], T. Sugino[4], and M. Oba[5], *[1]ZEN-RAKU-REN, Fukushima, Japan, [2]ZEN-RAKU-REN, Nishi-shirakawa, Japan, [3]Hokkaido University, Sapporo, Japan, [4]Hiroshima University, Higashi-hiroshima, Japan, [5]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

The objective of this study was to evaluate the effects of lactose inclusion in calf starters on ruminal pH and VFA profile. Sixty Holstein bull calves were raised on an intensified nursing program using milk replacer containing 28% CP and 15% fat, until 56 d of age. Calves were fed texturized calf starters containing lactose at 0% (Control), 5.0% (LAC5), or 10.0% (LAC10; $n = 20$ for each treatment) on a DM basis. All calf starters were formulated for 23.1% CP. All calves were fed treatment calf starters ad libitum from d 7 and their hay (Klein grass) intake was limited to 150 g/d (as fed). Ruminal pH was measured every 2 min using small ruminant rumen pH loggers (Dascor, CA) immediately after weaning (d 55 to 62) for 15 calves (5 calves per treatment), and 3 wk after weaning (d 77 to 80) for the other 45 calves (15 calves per treatment). Daily mean, minimum, maximum ruminal pH, and duration and area under rumen pH 5.8 were not affected by treatment for both periods (d 55 to 62 and d 77 to 80). However, Spearman's correlation coefficient (r_s) was 0.306 ($P < 0.05$) between lactose intake and minimum ruminal pH for d 77 to 80, indicating that actual lactose consumption may affect ruminal pH. In addition, hay intake was not affected by treatment, but it was positively correlated with daily mean ($r_s = 0.338$, $P < 0.05$) and maximum ruminal pH ($r_s = 0.408$, $P < 0.01$), and the variation in hay intake might have masked treatment effects on ruminal pH. Ruminal molar ratio of acetate (mean ± SE) was 40.6 ± 1.26 (Control), 42.8 ± 1.26 (LAC5), and 45.3 ± 1.26% (LAC10), molar ratio of propionate was 40.2 ± 0.98 (Control), 38.1 ± 0.98 (LAC5), 35.3 ± 0.98% (LAC10), and acetate/propionate ratio was 1.01 ± 0.06 (Control), 1.15 ± 0.06 (LAC5), 1.29 ± 0.06% (LAC10) on d 80, and the differences were significant

between Control and LAC10 ($P < 0.05$) for ruminal fluid samples collected on d 80. However, molar ratio of butyrate was not affected by treatment. These results indicate that inclusion of lactose in calf starter affects ruminal VFA profile, but its effects on rumen pH warrants further investigation.

Key Words: calf, lactose, rumen

1298 Methionine:lysine ratio for crossbred suckling calves fed milk replacer and an amino acid complex. J. C. Chagas[1], M. A. Ferreira[1], M. R. Entjes[2], F. S. Machado[3], L. F. Costa e Silva[4], and M. I. Marcondes[*5], *[1]Universidade Federal Rural de Pernambuco, Recife, Brazil, [2]VHL University of Applied Sciences, Leeuwarden, Netherlands, [3]EMBRAPA, Juiz de Fora, Brazil, [4]Universidade Federal de Vicosa, Vicosa, Brazil, [5]Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Brazil.*

Knowledge about the amino acid (AA) requirements of dairy cattle is rare, and information regarding limiting AAs for suckling calves does not exist. Due to the difficulties in studying the AA requirements for ruminants, research is necessary to evaluate and determine optimal levels when including these AAs in the diet. Based on studies demonstrating lysine (Lys) and methionine (Met) as limiting AAs for neonates, we hypothesized that it is possible to determine the Met:Lys ratio that maximizes the performance of suckling dairy calves. This study evaluated the effect of increasing dietary Met:Lys ratios (DMLR) on performance and body composition of crossbred suckling calves of two different ages. Thirty-six male calves (Holstein-Gyr) were introduced in the experiment on the eighth day of age and randomly distributed among two slaughter ages (16 animals slaughtered at 30 d of age, and 20 animals slaughtered at 60 d of age) and four DMLR (44, 48, 52, and 56%), which were provided in the form of an AA complex (18.93 g) added to 905 g of milk replacer. The experimental diets were provided without permission of refusals, so the intake of dry matter and nutrients were the same for all animals, regardless of DMLR. Average daily gain (ADG), gain composition and body composition were evaluated separately for the two age groups for the linear and quadratic effects of DMLR. When necessary, the linear-plateau model was adjusted. Calves from 0 to 30 d of age did not show an improved performance due to increased DMLR; it is possible that animals up to 30 d of age had other metabolic priorities over body growth and protein deposition. For calves from 30 to 60 d of age, a linear-plateau response was observed for ADG and crude protein gain (CP); the greatest ADG observed was 590 g/d for a DMLR of 52.56% ($P = 0.001$), and the greatest CP deposition observed was 89 g/d for a DMLR of 52.33% ($P = 0.027$). Total body CP presented a quadratic behavior, with a maximum of 11.72 kg of CP for a DMLR of 53.91% ($P = 0.040$). The increased DMLR did not influence performance of calves from 0 to 30 d, and the optimal DMLR that ensured the best performance of calves from 30 to 60 d of age was situated between 52 and 54%.

Key Words: bovine, body composition, crude protein

1299 Effects of organic or inorganic Co, Cu, Mn, and Zn supplementation to weaned calves during preconditioning on their productive and health responses. K. Lippolis[*1], R. F. Cooke[1], L. G. T. da Silva[2], K. M. Schubach[1], A. P. Brandao[1,2], R. Marques[1], C. K. Larson[3], T. DelCurto[4], and D. W. Bohnert[1], *[1]Oregon State University- EOARC Burns, Burns, [2]UNESP- FMVZ, Botucatu, Brazil, [3]Zinpro Corporation, Eden Prairie, MN, [4]Oregon State University- EOARC Union, Union.*

This experiment compared productive and health parameters of weaned calves receiving or not supplemental Co, Cu, Mn, and Zn from an organic or inorganic source during a 45-d preconditioning program. Ninety Angus × Hereford calves were weaned on d −1 and immediately allocated according to weaning BW and age (BW = 261 ± 2 kg, age = 224 ± 2) to a18-pen drylot with 5 calves per pen (steers, $n = 4$; heifers, $n = 1$). Pens were randomly assigned to receive: 1) supplementation with inorganic sulfate sources of Cu, Co, Mn, and Zn (INR), 2) supplementation with an organic source of Cu, Mn, Co, and Zn (ORG; Availa®4; Zinpro Corporation, Eden Prairie, MN), and 3) no supplementation of Cu, Co, Mn, and Zn (CON). During the preconditioning phase (d 0 to 45), calves received mineral treatments while offered free-choice hay and 2.7 kg/d of corn-soybean meal concentrate. The INR and ORG were included into the concentrate, and formulated to provide the same daily amount of Cu, Co, Mn, and Zn. Calf ADG during preconditioning was calculated based on average initial BW (d −1 and 0) and final BW (d 44 and 45). Liver samples were collected via needle biopsy on d 0, 22, and 45. Calves received vaccination on d 15 and 29. Blood samples were collected on d 15, 29, and 45, and analyzed for plasma concentrations of antibodies against *Mannheimia haemolytica*. No differences were detected ($P \geq 0.15$) among CON, INR, and ORG calves for initial (d 0) liver Co, Cu, Mn, and Zn concentrations. On d 22 and 45, liver Cu and Co concentrations were greater ($P < 0.01$) for INR and ORG calves compared with CON. Moreover, ORG calves had greater ($P = 0.05$) liver Co concentrations on d 45, but similar ($P = 0.35$) liver Co on d 22 and similar ($P \geq 0.63$) liver Cu on d 22 and 45 compared with INR calves. Liver Zn and Mn concentrations were similar ($P \geq 0.14$) among CON, INR, and ORG calves on d 22 and 45. No differences ($P \geq 0.17$) were detected among treatments for feed intake, BW gain, health variables, or antibodies against *M. haemolytica*. Therefore, supplementation with inorganic or organic Co, Cu, Mn, and Zn during a 45-d preconditioning period

did not impact performance and health response of weaned feeder calves.

Key Words: beef cattle, performance, preconditioning, trace minerals

1300 Dynamics of prepartum β-carotene supplementation among cow, colostrum, and calf. C. M. Prom*[1], M. A. Engstrom[2], and J. K. Drackley[1], [1]*University of Illinois, Urbana,* [2]*DSM Nutritional Products, LLC, Parsippany, NJ.*

Little is known about transfer of dietary β-carotene into colostrum, its absorption by the calf, and its effects on vitamins A and E in the cow when dietary vitamin A is adequate. Our objective was to assess the impact of β-carotene supplementation during the close-up dry period on the cow, colostrum, and calf. The study was conducted on a large commercial dairy farm in Indiana during early summer of 2015. Ninety-four multiparous Holstein cows were assigned to either control (CON) or β-carotene (BC) treatments. While locked in headgates each morning, each cow received a topdress of β-carotene (Rovimix, 8 g/d; provided 800 mg β-carotene) or carrier from 21 d before expected calving until calving. Blood samples were collected at 21 d before expected calving (before treatments began), 7 d before calving, immediately following parturition, and 7 d postpartum. Colostrum was collected immediately following parturition. Calf blood samples were obtained within 2 h of birth before receiving the dam's colostrum, at 24 h after birth, and at 7 d and 60 d of age. Blood serum was analyzed for vitamins A and E, cholesterol, and β-carotene. Colostrum was analyzed for β-carotene, vitamins A and E, and colorimetry profile. Data were assessed using the MIXED procedure in SAS. Calf serum β-carotene data were analyzed using the FREQ procedure. Compared with CON cows, BC cows had higher concentrations of β-carotene ($P < 0.01$), vitamin A ($P < 0.01$), and vitamin E ($P < 0.01$), and a greater vitamin E:cholesterol ($P < 0.01$) in serum at all times. Colostrum β-carotene was higher for BC cows ($P < 0.01$). Colostrum from BC cows had increased a* ($P < 0.01$) and b* ($P < 0.01$) colorimeter values, indicating that β-carotene altered colostrum color. Before receiving colostrum, the concentration of β-carotene in calf serum was below the detectable threshold of 0.05 ug/mL. At 24 h of age, the number of calves with detectable β-carotene concentrations increased, with more calves from BC cows (52.1%) having detectable concentrations than calves from CON cows (6.1%, $P < 0.01$). No differences in concentrations of vitamins A or E were observed in calves. In pregnant cows already receiving adequate vitamin A, supplementation of β-carotene increased concentrations of β-carotene, vitamin A, and vitamin E, increased concentration of β-carotene in colostrum, and increased serum β-carotene in calves.

Key Words: β-carotene, transition cows, colostrum

1301 Effect of supplementing increasing levels of RUP on growing performance in calves fed a silage-based diet. C. R. Oney*[1], R. G. Bondurant[1], F. H. Hilscher[1], A. K. Watson[1], G. E. Erickson[1], J. C. MacDonald[2], and T. J. Klopfenstein[1], [1]*University of Nebraska, Lincoln,* [2]*University of Nebraska-Lincoln, Lincoln.*

An 84-d growing study, utilizing 60 steers (initial BW = 290; SD = 18 kg), evaluated the effects of supplementing increasing levels of RUP on growing performance of calves fed a silage-based diet. All steers were individually fed using the Calan gate system. Five levels of supplementation were evaluated with 12 steers per level of supplement. Supplement levels consisted of 0, 3.25, 6.5, 9.75, and 13% RUP (as a % of diet DM). The RUP supplement consisted of 60% SoyPass and 40% Empyreal. The diet consisted of 85% corn silage with the remaining 15% of the diet being accounted for in the supplement (DM basis). Supplement included RUP, urea, minerals, and carrier replaced by RUP. Initial and ending BW were obtained by collecting BW across 3 consecutive days and averaging after cattle had been limit fed a 50% Sweet Bran and 50% alfalfa diet at 2% of BW for 5 d. Cattle were assigned to treatment based on d −1 and 0 BW. Interim BW were collected on d 36 and 37 and shrunk 4% to account for gut fill. There were no differences in DMI ($P = 0.33$) among treatments for period 1 (d 1 to 37). However, ADG ($P < 0.01$) and G:F ($P < 0.01$) both increased linearly as RUP inclusion increased during period 1. Using the NRC model, MP balance for period 1 increased from −200 to +65 g/d as RUP inclusion increased from 0 to 13%. At 9.75% RUP inclusion MP balance was reached at +2 g/d. There were no differences in DMI ($P = 0.16$), ADG ($P = 0.11$) or G:F ($P = 0.32$) for period 2 (d 38 to 84). For the overall growing period (d 1 to 84), as supplemental RUP inclusion increased from 0 to 13%, a linear increase was observed in ending BW ($P < 0.01$). With no difference in DMI ($P = 0.19$) between the five treatments, averaging 7.67 kg/d, and a linear increase in ADG ($P < 0.01$), G:F linearly increased ($P < 0.01$) from 0.148 to 0.174 as RUP inclusion increased. The MP balance increased from −186 to +98 g/d as RUP inclusion increased from 0 to 13%, at 9.75% RUP inclusion MP balance was reached at +26 g/d. Increasing the amount of RUP in silage growing diets increases ending BW, ADG and G:F by meeting MP requirements.

Key Words: corn silage, growing cattle, rumen undegradable protein

1302 The effects of a high- or low-plane of nutrition pre-weaning on growth and starter intake of group-housed calves. J. Haisan[*1], M. Oba[1], D. J. Ambrose[2], and M. Steele[1], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]Livestock Research Branch, Alberta Agriculture and Forestry, Edmonton, AB, Canada.*

The objective was to determine the effects of plane of nutrition, when fed through an automated calf feeder, on starter intake and growth of group-housed calves. Twenty-six female Holstein calves were fed 8L of colostrum in the first 36 h of life before being offered pasteurized whole milk and randomly assigned to either a HIGH (10L/d; n = 12) or LOW (5L/d; n = 14) plane of nutrition. All calves were allowed 2.5L of milk per meal until d 48 when a 10-d weaning transition began, where milk was reduced by 10% per day, resulting in all calves being weaned at d 58. Calf starter and water were provided ad libitum starting on d 3. Calves were housed in individual pens for the first 21 ± 3 d and fed using the Calf Rail system (Förster-Technik, Germany) before moving to a group pen where they were fed through an automated calf feeder. Individual starter intake was measured via an automated system on a daily basis from d 25 to 70, and body weights (BW) were measured weekly from birth to d 70. Blood samples were taken in the first week of life and with no differences observed in serum protein (5.3 ± 0.32 vs. 5.3 ± 0.32 mg/dL; P = 0.95) or immunoglobin concentration (17.67 ± 1.80 vs. 15.35 ± 1.80 g/L; P = 0.37). Birthweight of calves was not different between the treatment groups (40 ± 1.25 vs. 42 ± 1.25 kg; P = 0.27) however BW at d 70 was greater for HIGH than LOW calves (113.5 ± 2.03 vs. 100.11 ± 2.03 kg; P < 0.01). Pre-weaning average daily gain was greater for HIGH than LOW (0.90 ± 0.03 vs. 0.65 ± 0.03 kg/d; P < 0.01), however no difference was seen post-weaning (1.30 ± 0.06 vs. 1.29 ± 0.06 kg/d; P = 0.96). Before the weaning transition (d 42 to 48) starter intake (g/d) was greater in calves on the LOW than HIGH plane of nutrition (591 ± 89 vs. 1,273 ± 93, P < 0.01, respectively). Starter intake over the 10-d weaning transition tended to be greater for LOW than HIGH calves (1,490 ± 112 vs. 1,181 ± 116; P = 0.07), however post-weaning no difference was seen between treatments (2,723 ± 200 vs. 3,188 ± 200; P = 0.11). Results indicate that feeding more milk pre-weaning may suppress starter intake, however, the effect is not carried post-weaning and does not compromise growth.

Key Words: feeding system, group housing, starter intake

1303 Evaluation of stay strong for new born dairy calves. K. Froehlich[*1] and D. P. Casper[2], *[1]South Dakota State University, Brookings, [2]Dairy Science Department, South Dakota State University, Brookings.*

Stay Strong (SS) is a blend of essential oils designed to help diminish health challenges and stresses experienced by newborn calves. Current feeding inclusion rates are unknown to achieve optimal performance in the first 8 wk of life. Study objectives were to determine feeding inclusion rates of SS when added to milk replacer (MR) to achieve optimal performance, while comparing performance to a yeast cell wall (YCM) gut health technology. One hundred Holstein calves were used for the study blocked by birth date and randomly assigned to 1 of 5 treatments; 24:20 control MR (C), 24:20 MR with an inclusion rate of either 1.25 g (SS-0.5), 2.5 g (SS-1.0) or 3.75 g (SS-1.5) calf/feeding, or 24:20 MR with an inclusion of YCM at a rate of 2 g/calf/feeding. Calves were sourced from a commercial SD dairy farm where they were fed colostrum for the first 2d and then were transported to SDSU. 24:20 MR was fed at a rate of 0.28 kg/calf/d at 2x/d for 14d via bucket, and then increased to a feeding rate of 0.43 kg/calf/d at 2x/d until 35d. Feedings were reduced to 1x/d at 36d to facilitate weaning at 42d. Decoquinate was added to MR at 37.8 g/ton for coccidiosis control. Calves were housed in individual Calf-Tel hutches bedded with straw with ad libitum access to a 20% CP calf starter (CS) and water. SS-0.5 average daily gain (ADG) through 56d was greater (P < 0.05) compared to SS-1.0 and YCM, and tended (P < 0.10) to be greater for C and SS-1.5. ADG averaged 1.44, 1.57, 1.41, 1.40, and 1.39 kg/d for C, SS-0.5, SS-1.0, SS-1.5, and YCM, respectively. Total gain was increased for SS-0.5 vs. SS-1.0 and YCM, with body gains averaging 81.2, 87.89, 78.32, 78.9, and 78.04 kg for C, SS-0.5, SS-1.0, SS-1.5, and YCM, respectively. Body length gain was similar among treatments with an exception of SS-0.5 having a greater gain vs. SS-1.5 (P < 0.02). Hip width was similar among treatments. Wither height gain through 56d was greater for SS-0.5 vs. C, SS-1.0, SS-1.5, and YCM. Hip height gain was also increased for SS-0.5 vs. C, SS-1.0, SS-1.5 and was similar for SS-0.5 and YCM. This data demonstrates that feeding SS at 1.25 g/calf/d to a 24:20 MR will enhance growth rates compared to calves fed a modified accelerated 24:20 MR and a 24:20 MR containing YCW technology.

Key Words: calf, essential oils

1304 Effects of supplementing pasteurized waste milk with vitamins A, D and E on fat-soluble vitamin status, growth, and health of calves. L. Blakely*[1], M. Kweh[1], M. Poindexter[1], R. L. Stuart[2], and C. D. Nelson[3], [1]*Department of Animal Sciences, University of Florida, Gainesville,* [2]*Stuart Products Inc, Bedford, TX,* [3]*University of Florida, Gainesville.*

The objective of this study was to determine the effects of a milk supplement, MILKADE® (Stuart Products, Inc.), on growth, health and fat-soluble vitamin status of calves fed pasteurized whole milk. The MILKADE supplement contained 50,000 international units (IU) vitamin A as retinyl-palmitate, 50,000 IU vitamin D_3, and 500 IU vitamin E as *RRR-α-tocopherol* per milliliter of product. Forty Holstein calves (19 bulls, 21 heifers) were enrolled at birth and assigned to either control (n = 18, no supplement), 0.25 mL MILKADE (0.25ADE, n = 12), or 0.5 mL MILKADE (0.5ADE, n = 10) treatments. Calves were provided 2.85 L of pasteurized waste milk twice per day and the supplement was added individually to the calves' milk at the morning feeding. Feed intake and health scores were recorded daily. Bodyweight and height and serum samples were collected weekly from birth until 3 wk (bulls) or 6 wk (heifers) of age. Responses to treatments were analyzed as repeated measures. Serum retinol concentrations averaged near 400 ng/mL during the trial and were not different (P = 0.45) between treatment groups. In contrast, control calves were vitamin D deficient throughout the trial with average 25-hydroxyvitamin D (25(OH)D concentrations < 10 ng/mL of serum, whereas, 25(OH)D concentrations of 0.25ADE and 0.5ADE calves reached 90 and 150 ng/mL of serum, respectively, after 3 wk (P < 0.001). Similarly, serum α-tocopherol concentrations of control calves remained below 1.5 μg/mL throughout the trial but reached approximately 4.5 μg/mL of serum for both 0.25ADE and 0.5ADE groups after 5 wk (P < 0.05). There was a treatment effect on overall body weight (P = 0.004) such that 0.25ADE and 0.5ADE calves weighed less than control calves (49.3 kg and 46.4 kg vs. 52.1 kg, P = 0.013 and P < 0.001, respectively) at 3 wk of age. However, there was no difference in BW of heifers at week 6 of the trial (P = 0.171). There was no difference in feed intake or fecal and respiratory scores between groups (P > 0.05). In conclusion, calves fed pasteurized whole milk are deficient in vitamins D and E. Daily intakes for vitamins A and E were within ranges determined optimal for calves. Upper limits for supplemental vitamin D have not been established but the high serum 25(OH)D of the supplemented calves indicates vitamin D intakes above 10,000 IU/d are perhaps excessive for neonatal calves.

Key Words: dairy calves, nutrition, vitamins

1305 Effect of phytogenic compounds fed to preweaned calves. B. G. Miller*[1] and C. Scheider[2], [1]*Biomin USA, Warrenton, MO,* [2]*BIOMIN Holding GmbH, Herzogenburg, Austria.*

Maximizing early muscle growth is important in lifetime muscle development. Additionally, growth promoting antibiotics that have been typically used in the past may not be available in the future. Phytogenic (herbal) compounds may represent a potential to replace growth promoting antibiotics. A trial was conducted using Belgian Blue and Simmental bull calves in which mixed phytogenic products included in milk replacer and calf starter. Calves were separated into group based on breed and initial weight. (Control calves weighed 93 kg, Treatment calves weighed 94 kg) Calves were fed for 52 d. Control calves received a diet of calf milk replacer, for the first 3 wk. Cereal grains and a "calf starter feed" were offered from the first week on. Hay was made available throughout the trial and corn silage was offered from Day 21 to 52. Treatment calves received the same diet as control with the exception of Digestarom Milk (phytogenic product) added to the milk replacer at a rate of 500 gm/MT of calf milk replacer. The treatment calves also received Digestarom Calf in the calf starter at a rate of 300 gm/MT. Feed intake for calves was measured throughout the trial period. Calves were weighed on Days 21, 42, and 56. Data was analyzed via independent t test (SPSS). Control calves consumed numerically, but not statistically (P > 0.10) less average intake per day through out the total period, Days 1 to 56, than did treatment calves, 2.41 vs. 2.46 kg, respectively. Calves receiving Digestarom products improved in average daily gain throughout the trial at each weighing, and for the 56 d period demonstrated and increase of 0.10 kg in average daily gain (P < 0.05). Control calves gained 1.23 kg per day, while treatment calves gained at 1.33 kg per day (P < 0.05). Feed conversion improved numerically from 1.97 for control calves to 1.86 for treatment calves (P > 0.10). This work supports previous work with these and similar phytogenic products that have demonstrated a positive effect on the growth rate of neonatal and young ruminants. As such these and similar products represent a potential replacement of alternative growth promoting technologies.

Key Words: phytogenic calves

1306 Feeding steers extruded flaxseed and hay in a total mixed ration or sequentially can have substantial effects on beef fat polyunsaturated fatty acids and biohydrogenation intermediates.
P. Vahmani*[1], D. C. Rolland[1], T. A. McAllister[2], H. C. Block[1], S. D. Proctor[3], L. L. Guan[3], N. Prieto[1], J. L. Aalhus[1], and M. E. R. Dugan[1], *[1]Agriculture and Agri-Food Canada, Lacombe, AB, Canada, [2]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, Lethbridge, AB, Canada, [3]University of Alberta, Edmonton, AB, Canada.*

There has been growing interest in increasing the content of polyunsaturated fatty acid (PUFA; esp. α-linolenic acid, ALA) and their biohydrogenation intermediates (BHI) in beef, particularly *trans* 11–18:1 (VA, vaccenic acid) and *cis* 9, *trans* 11–18:2 (RA, rumenic acid) due to their potential positive health effects. However, high variability in PUFA and BHI have been found in beef between and within trials. The present trial was designed to determine if feeding steers extruded flaxseed (Linpro-R™; O&T Farms Ltd.,SK, Canada) and hay (25% and 75%; DM basis) together as a total mixed ration (TMR), or sequentially (non-TMR) would result in different enrichments of PUFA and BHI in different beef adipose tissues. Forty-eight Continental crossbred steers (325 ± 16 kg SD) were stratified by weight to 6 pens of 8 steers, pens were randomized to either TMR or non-TMR and steers were fed ad libitum for 240 d. At slaughter, subcutaneous fat (SCF) and perineal fat (PRF) samples were collected, freeze dried and directly methylated with 0.5 M sodium methoxide, and analyzed by GC using a 100 m CPSil 88 capillary column. Data were analyzed as a one-way ANOVA using the PROC MIXED procedure of SAS with diet as the main factor and pen as the experimental unit. Treatment means were generated and separated using the LSMEANS and PDIFF options, respectively. Compared to TMR steers, non-TMR steers had greater proportions of PUFA, *trans*-18:1, conjugated linoleic acids, and conjugated linolenic acids in both SC (+9.7%, +9.8%, +43.4%, +63.7%) and PR (+14.1%, +10.5%, +52.9%, +75.6%). In SCF, the percentages of ALA, VA and RA were increased ($P < 0.001$) from 0.91%, 4.92% and 1.91% in TMR steers to 1.10%, 6.82% and 2.69% in non-TMR steers. In PRF, the percentages of ALA,VA and RA were increased ($P < 0.001$) from 0.89%, 7.29% and 0.72% in TMR steers to 1.06%, 10.32% and 1.13% in non-TMR steers. Our results suggest that the method of feeding PUFA sources (e.g., flaxseed) can profoundly affect the enrichment of PUFA and their BHI in beef fat. In addition, the enrichment of these fatty acids also depends on fat depot, with PRF having greater proportions of VA, while SCF being higher in RA, which is likely due to the greater delta-9 desaturation of VA to RA in SCF.

Key Words: beef, flaxseed, feeding management, omega-3, rumenic acid, vaccenic acid

1307 Fatty acid composition of intramuscular lipids from Nellore and Brangus bulls fed diets supplemented with cottonseed.
S. R. Medeiros*[1], G. D. Feijó[1], M. Mele[2], P. E. P. Barros[3], C. T. Marino[1], F. Ciucci[2], M. N. Bonin[4], and N. V. Verbisck[1], *[1]Embrapa Beef Cattle, Campo Grande-MS, Brazil, [2]University of Pisa, Pisa, Italy, [3]Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina-MG, Brazil, [4]Federal University of Mato Grosso do Sul, Campo Grande-MS, Brazil.*

Finishing bulls were used in a factorial design with 2 breeds and 2 diets with contrasting fat levels to evaluate changes in marbling and fatty acid profile of intramuscular lipids. Nellore ($n = 20$) and Brangus ($n = 20$) bulls were randomly assigned to a low (LFD) or a high fat diet (HFD): 3.2% vs. 6.4% ether extract. The diets had similar energy and protein levels and were composed by sorghum silage (30% DM), soybean hulls, ground corn, soybean meal, urea and a mineral mixture. HFD additional fat derived from cottonseed (18% DM), in substitution to ground corn (31% vs. 52%, on HFD and LFD, respectively). The experiment lasted 71-d. All carcass were evaluated for marbling (1 to 18 scale) and back fat thickness (BFT). *Longissimus dorsi* (LD) samples were randomly selected from four animals of each treatment for fatty acid analysis by gas-chromatography. Fatty acid composition is expressed as g/100 g of total lipids. All data were analyzed using the GLM procedure of SAS (SAS, 2011) with animal as the experimental unit and genetic group, diets and the interaction between them as class variables. Back fat thickness was similar among treatments (5 mm, on average), but marbling was higher for Brangus. There was significant breed vs. diet interaction ($P < 0.01$), mainly because marbling with LFD was much more intense for Brangus than Nellore (8.0 vs. 3.3), while for HFD it was quite similar (Brangus = 5.8 vs. Nellore = 5.3). Fatty acid composition of intramuscular lipids showed that samples from Brangus bulls had more palmitic (C16; 17.7% vs. 15.3% $P < 0.05$), stearic (C18; 11.9% vs. 8.9% $P < 0.05$), oleic (C181c9; 28.1% and 23.3%), and elaidic (C181t9; 0.15% and 0.12%, $P < 0.05$) acids. They also had 20% and 18% greater saturated (SFA) and monounsaturated (MUFA) fatty acids ($P < 0.05$), respectively. HFD diet increased the amount of stearic acid (C18; 11.5% vs. 9.3% $P < 0.05$) and resulted in more than 20% higher ($P < 0.05$) elaidic acid and C18:2 non conjugated isomers, whereas the content of rumenic acid (C182c9t11, mean 0.19%) was unaffected by genetic group or diet. Differences in fatty acid content among Brangus and Nellore LD are in accordance with higher marbling from the former. Cottonseed fatty acid profile may have been extensively biohydrogenated, as suggested by the higher levels of stearic acid in HFD samples. Marbling differences among breeds had more impact in intramuscular fatty acid profile than supplementation with cottonseed.

Key Words: Meat, Lipid, Zebu

1308 Effects of dietary fat on fertility of dairy cattle: a meta analysis and meta-regression.

R. M. Rodney*[1,2], P. Celi[3], W. Scott[2], I. J. Lean[1,2], and K. Breinhild[2], *[1]University of Sydney, Camden, Australia, [2]Scibus, Camden, Australia, [3]Faculty of Veterinary and Agricultural Sciences, the University of Melbourne, Parkville, Australia.*

There is increasing evidence of positive effects of feeding fats during transition on fertility and the adaptation to lactation. This study utilized meta-analytic methods to explore the effects of including fats in the transition diet on the risk of pregnancy to service ('proportion pregnant') and calving to pregnancy interval. Meta-analysis was used to integrate smaller studies, and increase the statistical power over that of any single study and explore new hypotheses. We explored the effect of fats and diet composition on fertility using meta-regression methods. There were relatively few highly controlled studies providing detailed descriptions of the diets used that examined interactions between fat nutrition and reproductive outcomes. Only 17 studies containing 26 comparisons were suitable for inclusion in statistical evaluations. Reproductive variables evaluated were risk of pregnancy 'proportion pregnant', primarily to first service, and calving to pregnancy interval. Production variables examined were milk yield, milk composition, and body weight. The sources of heterogeneity in these studies were also explored. A 27% overall increase in pregnancy to service was observed (RR = 1.27; 95% Confidence interval Knapp Hartung 1.09 to 1.45) and results were relatively consistent (I^2 = 19.9%). A strong indication of a reduction in calving to pregnancy interval was also identified, which was consistent across studies (I^2 = 0.0%) supporting a conclusion that overall, the inclusion of fats does improve fertility. Further exploration of the factors contributing to proportion pregnant using bivariate meta-regression identified variables that reflected changes in diet composition or animal response resulting from inclusion of the fat interventions in the experimental diets fed. Increased fermentable neutral detergent fiber and soluble fiber intakes increased the proportion pregnant while increased milk yield of the treatment group decreased this measure. Unexpectedly, the estimated energy costs of urea production also had a positive association with proportion pregnant. The limited number of suitable studies for the analysis highlights the need for more work to improve understanding of the critical nutritional factors affecting fertility. These factors include specific fatty acids in dietary interventions that contribute to increasing fertility of cows in dairy production systems.

Key Words: dietary fat, fertility, conjugated linoleic acid

1309 Altering the ratio of palmitic, stearic and oleic acids in diets with or without whole cottonseed impacts production responses and energy partitioning of dairy cows.

J. de Souza*, C. L. Preseault, and A. L. Lock, *Michigan State University, East Lansing.*

We evaluated the effects of varying the ratio of dietary palmitic (C16:0), stearic (C18:0), and oleic (*cis*-9 C18:1) acids in diets with or without whole cottonseed on nutrient digestibility and production response of dairy cows. Twenty-four mid-lactation Holstein cows were used in split plot Latin square design. Cows were allocated to a main plot receiving either a basal diet without whole cottonseed (SH, n = 12) or a basal diet with whole cottonseed (CS, n = 12; 8% diet DM). Within each plot a 4 × 4 Latin square arrangement of treatments was used in four consecutive 21-d periods. Fatty acid (FA) treatments were: 1) Control (CON; no supplemental fat); 2) C16:0 supplement (PA; ~80% C16:0); 3) C16:0 and C18:0 supplement (PA+SA; ~40% C16:0 + ~40% C18:0); and 4) C16:0 and *cis*-9 C18:1 supplement (PA+OA; ~45% C16:0 + ~35% *cis*-9 C18:1). The final 5 d of each period were used for sample and data collection. The statistical model included the random effect of cow and the fixed effects of basal diet, FA treatment, period, and their interactions. Compared with SH diets, CS diets increased milk fat yield (1.71 vs. 1.51 kg/d; P = 0.05), yield of preformed milk FA (623 vs. 507 g/d; $P < 0.01$), and BW gain (1.0 vs. 0.71 kg/d; $P = 0.04$), tended to increase yield of de novo milk FA (396 vs. 383 g/d; $P = 0.06$), but reduced NDF digestibility (41.9 vs. 46.4%; $P < 0.01$) and total FA digestibility (74.2 vs. 76.3% $P = 0.05$). Compared with other treatments, PA increased yield of milk fat (1.60, 1.70, 1.64 and 1.64 kg/d; $P < 0.05$) and 3.5% FCM (45.2, 47.8, 46.8 and 46.5 kg/d; $P < 0.01$) for CON, PA, PA+SA and PA+OA, respectively. PA+OA increased BW gain compared with other treatments (0.82, 0.84, 0.70 and 1.05 kg/d; $P < 0.05$) for CON, PA, PA+SA and PA+OA, respectively. PA and PA+OA tended to increase NDF digestibility compared with PA+SA and CON (43.2, 44.9, 43.1 and 44.5%; $P < 0.10$) for CON, PA, PA+SA and PA+OA, respectively. Compared with the other treatments, PA+SA reduced 16-carbon (77.6, 73.0, 66.0 and 79.1%; $P < 0.01$), 18-carbon (79.2, 79.5, 72.0 and 79.7%%; $P < 0.01$), and total FA digestibility (78.6, 77.4, 68.2 and 79.4%; $P < 0.01$) for CON, PA, PA+SA and PA+OA, respectively. In conclusion, diet inclusion of C16:0 increased energy output in milk, while inclusion *cis*-9 C18:1 increased BW gain. The combination of C16:0 and C18:0 reduced NDF and FA digestibilities, which likely explains its reduced performance compared with other treatments.

Key Words: fat supplementation, animal performance, fatty acids

1310 Effect of high-oleic acid whole, heated soybeans or extruded soybean meal on production performance, milk fatty acid composition, and enteric methane emission in dairy cows.
J. C. Lopes[1], M. T. Harper[1], F. Giallongo[1], J. Oh[1], L. G. Smith[1], A. M. Ortega-Perez[1], S. Dixon[1], D. M. Kniffen[1], R. A. Fabin[2], and A. N. Hristov[*1], *[1]The Pennsylvania State University, University Park, [2]Fabin Bros. Farms, Indiana, PA.*

The objective of this study was to investigate the effect of 3 soybean sources differing in fatty acid profile and processing method on productivity, milk composition, and enteric CH_4 emission in lactating dairy cows. The soybean sources were: extruded conventional soybean meal (SBM; 48% CP and 8.7% ether extract; 22% oleic acid), extruded Plenish® (DuPont Pioneer, Johnston, IA), a high-oleic acid variety SBM (51.4% and 8.4%, respectively; 75% oleic acid), and whole, heated Plenish® soybeans (40.0% and 20.2%, respectively). The study involved 15 Holstein cows (54 ± 8.3 d in milk) in a replicated 3 × 3 Latin square design experiment with 3, 28-d periods. The inclusion rate of the 3 soybean sources in the diet was (all data are on DM basis): 17.1, 17.1, and 7.4%, diets CESBM, PESBM, and WHPSB, respectively, providing 1.4 to 1.5% soybean oil. The rest of the dietary ingredients were: corn silage, 41%; alfalfa haylage, 16%; grass hay/straw mix, 4%; ground corn grain, 10%; cottonseed hulls, 4%; molasses, 4.9%; and a mineral/vitamin premix, 3%. The WHPSB diet also contained 9.7% solvent-extracted SBM. The diets had similar content of CP (17.0 and 17.6%), NDF (31.0 and 32.0%), ether extract (3.8 and 4.0%), and NE_l (1.53 and 1.54 Mcal/kg). Compared with CESBM, the Plenish® diets tended to increase ($P = 0.09$) DMI (27.1, 27.8, and 27.8 kg/d, CESBM, PESBM, and WHPSB, respectively). Milk yield was not affected ($P \geq 0.10$) by treatment (average of 42.2 kg/d; SEM = 1.41). The Plenish® diets increased ($P < 0.01$) milk fat content (3.55, 3.74, and 3.76%, respectively). Feed efficiency was decreased ($P < 0.001$) by the Plenish® diets, compared with CESBM (1.50 and 1.51 vs. 1.57 kg/kg, respectively). Treatments had no effect ($P \geq 0.13$) on enteric CH_4 (average of 463 g/d, SEM = 29.7) or CO_2 (average of 12,113 g/d, SEM = 241.5) emissions and methane emission yield (16.6 to 17.2 g/kg DMI). Diets had a marked effect on milk fatty acid profile. Generally, the Plenish® diets increased ($P \leq 0.01$) mono-unsaturated and *cis*-9 18:1 and decreased ($P \leq 0.01$) poly-unsaturated, total trans-, and conjugated linoleic fatty acids concentrations in milk fat. In this study, compared with conventional extruded SBM, the Plenish® soybean treatments had no effect on milk yield, increased milk fat concentration, decreased feed efficiency, and modified milk fatty acid profile in a manner expected from the greater concentration of oleic acid in Plenish® soybean oil.

Key Words: high-oleic acid soybean, milk fatty acid, methane, dairy cow

1311 Biohydrogenation kinetics of oleic, linoleic and α-linolenic acids in vivo.
M. Baldin[*1], J. G. de Souza[1,2], N. L. Urrutia[1], J. Y. Ying[3], and K. J. Harvatine[1], *[1]Penn State University, University Park, [2]Federal University of Bahia, Salvador, Brazil, [3]Penn State University, State College.*

Biohydrogenation (BH) of unsaturated fatty acids (FA) has been extensively studied in vitro; however, in vitro BH rates and extents may not parallel BH pathways in vivo. The objective was to assess rate and extend of oleic (OA), linoleic (LA) and α-linolenic acid (ALA) biohydrogenation in vivo. Each FA was characterized in a separate experiment (EXP.1– oleic, EXP.2– linoleic, and EXP.3– α-linolenic) using 4 ruminally cannulated lactating Holstein cows in each experiment. A single bolus consisting of 200 g of an oilseed (EXP.1 87% OA sunflower, EXP.2 70% LA safflower, and EXP.3 54% ALA flaxseed) and 12 g of heptadecanoic acid (17:0) was mixed with rumen contents. Rumen digesta was collected at −1, −0.25, 0.1, 0.25, 0.5, 0.75, 1, 1.5, 2, 3, 4, and 6 h relative to the bolus. Samples were immediately placed on dry ice, stored at −20°C, freeze-dried, methylated and analyzed by GC-FID. On the day of infusion, cows were fed at a rate of 4.2%/h of expected daily DMI. The geometric mean of the 4 cows was calculated and the disappearance of 17:0, OA, LA, and ALA was fit to a single exponential decay model using the nonlinear procedure of JMP Pro. Overall, the boluses increased total fat in the rumen from 4.1 to 7.4% and enriched 17:0 from 0.4 to 2.5% of FA. The bolus enriched OA from 9.0 to 30.1% of FA in EXP. 1, LA from 12.5 to 35.9% of FA in EXP.2, and ALA from 1.9 to 19.8% of FA in EXP.3. The fractional rate of 17:0 disappearance was 10.9, 8.5, and 6.7%/h in EXP.1, 2, and 3, respectively, and was used as a marker of FA passage. The fractional rate of disappearance of OA was 55%/h, LA was 61.2%/h, and ALA was 93.9%/h in EXP.1, 2, and 3, respectively, and all three unsaturated FA reached pre-bolus concentration within 4 h. Based on kd/(kd+kp), the extent of BH was 83.4% for OA, 87.8% for LA, and 93.3% for ALA in EXP.1, 2, and 3, respectively. Assuming that BH equals disappearance minus passage, the BH rates were 44.0, 52.7, and 87.1%/h for OA, LA, and ALA in EXP.1, 2, and 3, respectively. In conclusion, the extent of oleic, linoleic, and α-linolenic biohydrogenation was near expected values, but the rate of ruminal biohydrogenation was higher than that commonly observed in vitro for these three unsaturated FA.

Key Words: rumen, biohydrogenation

1312 Production response, nutrient digestibility, and energy partitioning of post-peak dairy cows when palmitic acid-enriched supplements are included in diets: a meta-analysis and meta-regression. J. de Souza*, R. J. Tempelman, M. S. Allen, and A. L. Lock, *Michigan State University, East Lansing.*

This analysis was performed to evaluate the effects of palmitic acid-enriched supplements (PA; > 80% C16:0) on production response, nutrient digestibility, and energy partitioning of post-peak dairy cows. The database was formed with 1,056 individual observations from 215 dairy cows in 12 studies. Diet mean nutrient content (% DM) was 30% NDF (range 24 to 37%), 17% CP (range 16.7 to 17.8%), 27% starch (range 22 to 32%), and 3.95% fatty acids (FA; range 2.1 to 5.6%). PA was fed on average at 1.8% of diet DM (range from 0.75 to 2.25%) replacing either soyhulls or ground corn in diets. The effects of PA were compared to non-fat supplemented diets used as controls (CON). The meta-analysis was performed to calculate the mean difference in least square means between CON and PA treatments using a model considering the random effects of study and cow. The meta-regression evaluated the effect of C16:0 intake using a random regression model. PA compared with CON did not affect DMI ($P = 0.32$), milk yield ($P = 0.37$), BW ($P = 0.70$), or BCS ($P = 0.75$), but increased milk fat content (3.81 vs. 3.58%; $P < 0.01$), milk fat yield (1.59 vs. 1.49 kg/d; $P < 0.01$), 3.5% FCM (44.8 vs. 43.0 kg/d; $P < 0.01$), and feed efficiency (3.5% FCM/DMI; 1.60 vs. 1.53; $P < 0.01$). PA increased 16-carbon milk FA yield (590 vs. 475 g/d; $P < 0.01$) compared with CON but did not affect de novo ($P = 0.23$) or preformed ($P = 0.76$) milk FA yields. PA increased NDF digestibility (44.3 vs. 41.5%; $P = 0.02$), 18-carbon FA digestibility (80.3 vs. 78.4%; $P = 0.02$) and DM digestibility (68.2 vs. 66.7%; $P = 0.01$), but reduced 16-carbon FA digestibility (68.4 vs. 74.3%; $P < 0.01$), and total FA digestibility (71.5 vs. 75.8%; $P < 0.01$) compared with CON. PA increased net energy intake (47.4 vs. 46.0 Mcal/d; $P = 0.04$), milk energy output (31.1 vs. 29.9 Mcal/d; $P = 0.01$) and partitioned more dietary energy to milk (66.6 vs. 65.0%, $P = 0.03$) compared with CON. Using the random regression model we observed positive linear relationships between C16:0 intake and milk fat yield ($P < 0.01$; $R^2 = 0.57$), 3.5% FCM ($P < 0.01$; $R^2 = 0.53$), and 16-carbon milk FA ($P < 0.01$; $R^2 = 0.87$), as well as NDF digestibility ($P = 0.01$; $R^2 = 0.55$) and energy partitioned toward milk ($P = 0.01$; $R^2 = 0.47$), but a negative linear relationship for total FA digestibility ($P = 0.01$; $R^2 = 0.64$). In conclusion, supplementation of palmitic acid-enriched supplements increased yields of milk fat and 3.5% FCM, feed efficiency, and NDF digestibility with no reduction in DMI or loss of BW or BCS.

Key Words: fat supplementation, meta-analysis, production response

1313 Effect of potassium carbonate and soybean oil supplementation on rumen microbial population linked to lipid metabolism. A. R. Alfonso-Avila*[1], J. Chiquette[2], P. Y. Chouinard[3], E. Charbonneau[1], and R. Gervais[3], *[1]Département des sciences animales, Université Laval, Quebec, QC, Canada, [2]Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada, [3]Département des sciences animales, Université Laval, Québec, QC, Canada.*

The rumen microbial ecosystem plays a crucial role in productivity through digestion of feeds and supply of nutrients to the host animal. It was suggested that milk fat synthesis in dairy cows is stimulated by a positive dietary cation-anion difference (DCAD). Despite that rumen bacteria are largely involved in hydrolysis and biohydrogenation of dietary lipids, the impact of DCAD on rumen microbiome is unknown. The objective of this study was to evaluate the effect of increasing DCAD, using K_2CO_3, in diets containing soybean oil (SBO) on rumen microbial population associated with lipid metabolism. Twenty four early lactation Holstein dairy cows (39 ± 22 DIM) were used in a randomized complete block design (6 blocks) based on DIM and number of calving with a 2 × 2 factorial arrangement of treatments. Within each block, cows were fed a basal diet formulated to achieve 40% forage (58% corn silage), 60% concentrate, and 47% non-fibrous carbohydrates, with 0 (DCAD: +95 mEq/kg) or 1.5% K_2CO_3 (DM basis; DCAD: +316 mEq/kg), and 0 or 2% SBO. Effects of K_2CO_3, SBO and the interaction K_2CO_3 × SBO were evaluated. Treatment period lasted 28 d; the last 5 d were used for data and sample collection. Equal volumes (?1.0 L) of rumen fluid and solid digesta were collected from different rumen sites 4-h postfeeding. Extracted DNA was amplified by quantitative real-time PCR. The absolute amount for each microbial group was expressed as logarithm (base 10) of DNA copies/g of fresh matter. A companion abstract showed an interaction between K_2CO_3 and SBO on milk fat yield and *t*10/*t*11 ratio (JDS 98-Suppl. 2:128). Supplementing diets with K_2CO_3 stimulated the growth of *Butyrivibrio hungatei* (5.79 vs. 5.62; $P = 0.03$), a bacteria recognized to produce *t*11 18:1 during biohydrogenation. Conversely, feeding SBO reduced the growth of i) *Butyrivibrio*/*Pseudobutyrivibrio* group (8.60 vs. 8.80; $P = 0.04$), also known to produce *t*11 18:1, ii) fibrolytic *Fibrobacter succinogenes* (9.34 vs. 9.63; $P = 0.04$), iii) *Butyrivibrio proteoclasticus,* a bacteria involved in 18:0 production (6.67 vs. 6.79; $P = 0.06$), and iv) amylolytic *Streptococcus bovis* (6.84 vs. 7.01; $P = 0.06$). Feeding K_2CO_3 had no effect on these four bacteria. Total eubacteria and total protozoa did not differ between treatments ($P > 0.13$). Feeding K_2CO_3 and SBO had distinct effects on rumen bacteria. However, the absence of interaction between treatments on microbial population does not allow to establish a clear link with

previously observed effects on milk fat yield and *t*10/*t*11 ratio.

Key Words: DCAD, rumen bacteria, biohydrogenation

1314 Abomasal infusions of linoleic and linolenic acid in lactating dairy cows differentially alter the fatty acid composition of plasma lipid fractions and immune cells.

S. E. Schmidt*, V. E. Ryman, C. L. Preseault, L. M. Sordillo, and A. L. Lock, *Michigan State University, East Lansing.*

The balance of n-3 and n-6 fatty acids (FA) in immune system tissues can influence the degree of inflammatory responses in dairy cattle. Linoleic acid (C18:2 n-6) and linolenic acid (C18:3 n-3) are the most abundant n-6 and n-3 FA in lactating dairy cow rations, and are associated with pro-inflammatory and anti-inflammatory responses, respectively. Our objective was to evaluate the incorporation of these FA, and their downstream oxidized FA (oxylipids), into plasma and white blood cells (WBC) following supplementation. Six mid-lactation dairy cows were abomasally infused 4x/d for 7-d treatment periods with 7-d washout intervals in a replicated balanced Latin square design with 3 treatments: 1) CON = ethanol carrier, 2) LA = 45 g/d C18:2 n-6, and 3) LNA = 45 g/d C18:3 n-3. Blood was collected on d 7 of the treatment periods and analyzed for WBC and plasma lipid fraction FA and plasma oxylipid composition. Yields of milk and milk components were calculated for d 6 and d 7 of the treatment periods. Statistical analysis was performed using linear mixed models. Dry matter intake was not affected by treatment ($P = 0.68$). LA treatment increased the yield of milk and milk protein compared to CON and LNA ($P \leq 0.05$). LNA treatment increased milk fat concentration compared to CON and LA ($P \leq 0.05$). The concentration of C18:3 n-3 in WBC was increased by LNA (0.86 g/100 g FA; $P \leq 0.05$), compared to LA (0.39 g/100 g FA) and CON (0.34 g/100 g FA), but C18:2 n-6 was unaffected by treatment ($P = 0.15$). LNA increased C18:3 n-3 (3.17 g/100 g FA) and C20:5 n-3 (0.43 g/100 g FA) in the phospholipid fraction of plasma, compared to CON and LA ($P \leq 0.01$), while LA increased C18:2 n-6 (38.7 g/100 g FA), compared to the other treatments ($P < 0.01$). Plasma phospholipid C20:4 n-6 concentration was not altered by treatment ($P = 0.65$). LNA decreased C20:4 n-6-derived 8,9-DiHETrE ($P < 0.01$) and tended to decrease C18:2 n-6-derived 12,13 EpOME in plasma ($P = 0.09$). When C18:3 n-3 and C18:2 n-6 were abomasally infused at the same dose, C18:3 n-3 had a greater influence on the profile of plasma FA and oxylipids and the FA composition of WBC. These changes have the potential to mediate inflammatory responses in cattle at risk of infection.

Key Words: linoleic acid, linolenic acid, abomasal infusion

1315 Effect of increasing doses of abomasally infused linseed oil on animal performance and oxidative stability of milk in Holstein dairy cows.

D. E. Rico*[1], R. Gervais[2], S. M. Peña-Cotrino[1], C. Cohou[1], Y. Lebeuf[1], and P. Y. Chouinard[2], *[1]Département des sciences animales, Université Laval, Québec, QC, Canada, [2]Département des sciences animales, Université Laval, Québec, QC, Canada.*

To evaluate the effect of increasing doses of post-ruminal supply of linseed oil (LO), as a source of polyunsaturated fatty acids (PUFA), on animal performance and oxidative stability of milk, five Holstein dairy cows (36 ± 2 DIM, 38.7 ± 4.7 kg milk/d; Mean ± SD) were randomly distributed in a 5 × 5 Latin square design (14-d periods; 11 d of adaptation). All cows were fed the same ration and LO was abomasally infused continuously at 0, 75, 150, 300, and 600 g/d using peristaltic pumps. Oxidation measurements were done on fresh non-homogenized milk and on homogenized milk stored at 4°C during 11 d under fluorescent light. Data were analyzed using a mixed model including the random effects of period and cow, and the fixed effects of treatment, time and their interaction in the repeated measures analyses. A peroxidability index (PI) was calculated as: 0.025×Monoenoates + 1×Dienoates + 2×Trienoates + 4×Tetraenoates + 6×Pentaenoates + 8×Hexaenoates, to account for individual oxidation sensitivity of FA. Dry matter intake and yield of energy corrected milk decreased linearly with increasing dose of LO ($P < 0.05$). Milk fat concentration decreased quadratically ($P < 0.05$) reaching a nadir at 300 g of LO/d, whereas the yields of fat and protein decreased linearly ($P < 0.05$). The concentration and yield of lactose were not different among treatments. The concentration of PUFA increased linearly with LO dose ($P < 0.001$). Accordingly, the PI of fresh milk increased linearly with dose from 2.0 mg/g milk in the control, to 10.8 mg/g milk at the highest dose ($P < 0.001$). Conjugated diene hydroperoxides in fresh milk increased linearly with dose ($P < 0.001$), whereas conjugated triene hydroperoxides and redox potential were not affected. Volatile lipid oxidation products such as propanal, hexanal, *trans*-2-hexenal/hex-*cis*-3-enal, and hept-*cis*-4-enal increased linearly with dose ($P < 0.001$), whereas 1-octen-3-one was not affected, and *trans*-2, *cis*-6-nonadienal and *trans*-2, *trans*-4-nonadienal were not detected in fresh milk. During storage, similar increasing trends were observed across treatments for propanal, hexanal, *trans*-2-hexenal/hex-*cis*-3-enal, hept-*cis*-4-enal, and *trans*-2, *cis*-6-nonadienal in homogenized milk (time $P < 0.001$). Treatment by time interactions were detected for 1-octen-3-one and *trans*-2, *trans*-4-nonadienal. In conclusion, increasing doses of abomasally infused LO negatively affected animal performance. Despite small differences among individual oxidation products, overall, a linear increase in milk PUFA led to a quadratic response in total identified volatile compounds

which tended to reach a plateau at 300 g of LO/d.

Key Words: dairy cows, n-3 fatty acids, oxidation

1316 Palmitic acid feeding increases ceramide availability in association with increased milk yield, NEFA availability, and adipose tissue responsiveness to a glucose challenge. J. E. Rico, A. T. Mathews, and J. W. McFadden*, *West Virginia University, Morgantown.*

Reduced insulin action facilitates glucose partitioning for milk synthesis and facilitates lipolysis during early lactation. Insulin sensitivity increases beyond peak milk yield, while circulating NEFA and milk production decline. Palmitic acid (C16:0) promotes insulin resistance in monogastrics through ceramide-dependent mechanisms, and ceramides are elevated in hyperlipidemic insulin resistant early lactation cows. We hypothesized that feeding C16:0 to mid-lactation cows would enhance circulating ceramide, and ceramide would be positively associated with milk yield. Twenty multiparous Holstein cows were enrolled in a study consisting of a 5 d covariate, 49 d treatment, and 14 d post-treatment evaluation. Cows were randomly assigned to a sorghum silage-based diet containing no supplemental fat (control; n = 10; 138 ± 45 DIM) or C16:0 at 4% of ration DM (PALM; 98% C16:0; n = 10; 136 ± 44 DIM). Blood was collected at routine intervals and milk yields were recorded. Intravenous glucose tolerance tests (GTT) were performed at d −1, 21, and 49 relative to start of treatment. Plasma sphingolipids were quantified using liquid chromatography tandem mass spectrometry. Data were analyzed as repeated measures using a mixed model (fixed effects of treatment and time). Pearson correlations were analyzed. The most abundant sphingolipids included C24:0-ceramide, C24:0-monohexosylceramide (GlcCer), and C16:0-lactosylceramide (LacCer). Relative to control, plasma concentrations of total ceramide, GlcCer, and LacCer decreased as lactation progressed (P < 0.01). Total ceramide and C24:0-ceramide were increased by d 8 of treatment in PALM, and remained elevated throughout the 7 wk treatment period (+80% average; P < 0.001). Similarly, C16:1-, C22:0-, C22:1-, C24:1-, and C26:0-ceramide levels were greater in PALM (P < 0.05). Post-treatment, total ceramide concentrations in PALM returned to control levels. PALM increased total GlcCer and C24:0-GlcCer levels in plasma by 32 and 33% at wk 3 and 7, respectively (P < 0.01). Also, PALM increased C16:0-, C22:0-, C22:1-, and C24:1-GlcCer in plasma (P < 0.01), but had no effect on LacCer levels. We observed a decline in GlcCer and LacCer concentrations as lactation progressed (e.g., C24:0-GlcCer; P < 0.01). Plasma C24:0-ceramide was positively correlated with plasma NEFA and milk yield, and inversely correlated with NEFA disappearance following GTT (r = 0.52, 0.44, and −0.57, respectively; P < 0.001), relationships shared by most detected ceramides. We conclude that increasing C16:0 intake to augment ceramide supply delayed the decline in ceramide supply observed with the progression of lactation. Future research should evaluate whether ceramide is intrinsically involved in the homeorhetic adaptation to lactation.

Key Words: ceramide, insulin resistance, lactation

1317 Effect of supplemental enriched palmitic acid in free fatty acid form vs. calcium salts of palm fatty acids on production performance in early postpartum cows. J. E. Nocek*[1], C. Wan[2], and T. M. Londergan[2], *[1]Overture Enterprises, LLC, Auburn, NY, [2]Centriq, Seattle, WA.*

Sixty multiparous cows were randomly assigned at calving to one of three treatment regimens to evaluate fat supplementation on production performance in postpartum dairy cattle. Cows entered the pens at calving and remained through 12 wk. postpartum. There were 4 cows/pen and 5 pens/trt. Pens were identical in layout. Treatments were Control (no supplemental fat), Control diet with supplemental calcium salts of fatty acids (MegaLac, Princeton, NJ,: ML) and Control diet with high palmitic acid (98%) fatty acids (PrimaFat 16, Centriq, Seattle, WA,: PF). Cows were fed a Fresh (1 to 21 d) and High (22 to 84 d) diet. Corn meal was removed from the Control diet to provide equal supplemental fat content in both Fresh and High diets among treatments (Fresh:1.95 and 1.55% of DM and High: 1.78 and 1.46% of DM for ML and PF, respectively). Daily pen intakes and milk weights (3X) were recorded and averaged by week. Milk samples were collected weekly for milk composition. Blood samples were collected for NEFA and BHBA analysis on wk. 1 and 3 postpartum. Pen was the experimental unit. Mean group DMI was similar among treatments. Milk yield was similar for both fat products and higher (P < 0.01) than Control (47.3, 47.8 and 46.4kg for ML. PF and Control respectively). Both FCM and ECM were higher (P < 0.01) for PF compared to Control and ML (54.9, 50.8 and 52.2, and 52.7, 48.8 and 50.2 kg for FCM and ECM respectively). Milk Fat (% and yield) were higher (P < 0.01) for PF compared to Control and ML (4.42, 4.11, and 4.17%, and 2.10, 1.89, and 1.95 kg, respectively). Milk protein yield was higher (P < .01) for PF compared to Control, with ML not being different from either (1.36, 1.27, and 1.31 kg, respectively). MUN was lower (P < 0.01) for PF compared to ML and Control (11.8, 12.6, and 13.1 mg/dL, respectively). There was no effect of trt on BHBA, however, wk 1 NEFA tended to be lower (P = 0.14) for PF compared to ML and Control (0.55, 0.83, and 0.81 mEq/L), whereas wk 3 NEFA were lower (P = 0.04) for PF and Control compared to ML (0.46, 0.42, and 0.85 mEq/L). These results demonstrate that early postpartum cows supplemented with fat produced more milk than non-supplemented cows and supplementing with an enriched C16 fat increased fat percentage and yield compared to Ca-salts of palm fatty acid and increased protein

yield compared to no fat supplementation.

Key Words: palmitic acid, milk fat, dairy cows

1318 Hepatic oxidation is responsive to prepartum energy and peripartum rumen protected choline supplementation. V. Caprarulo[*1,2], T. L. Chandler[1], M. G. Zenobi[3], B. A. Barton[4], C. R. Staples[3], and H. M. White[1], *[1]Department of Dairy Science University of Wisconsin, Madison, [2]Department of Health, Animal Science and Food Safety, University of Milan, Milan, Italy, [3]Dep. of Animal Sciences, University of Florida, Gainesville, [4]Balchem Corporation, New Hampton, NY.*

Controlling prepartum energy intake or supplementing rumen-protected choline (RPC) during the periparturient period, are 2 strategies to preserve hepatic metabolic function. The objective of this study was to examine the regulation of hepatic gluconeogesis and oxidation during the transition to lactation. At −48 d relative to calving (DRTC), multiparous Holstein cows were assigned to either a controlled (1.40 Mcal of NEL/kg DM; CE) or high (1.63 Mcal NEL/kg DM; HE) energy prepartum diet with or without RPC (top-dressed daily from −21 to +21 DRTC). Postpartum diets only differed by addition of RPC. Liver tissue biopsy samples were collected at −14, +7, +14, and +21 DRTC for RNA isolation and cDNA generation (n = 16/treatment). Quantitative PCR was performed and mRNA abundance was normalized to reference genes. Data were analyzed by Proc Mixed (SAS 9.4) with repeated measures in a model that accounted for the main effects of RPC, energy, DRTC, and corresponding 2-way and 3-way interactions, and the random effect of cow (energy × choline). When interactions were significant ($P < 0.05$), energy × choline means were separated by Tukey's and time interactions were separated within time point by slice. Data are presented as least squares means ± SE, arbitrary units (AU). *Pyruvate carboxylase* (*PC*) expression increased ($P < 0.05$) after calving. There was an energy×choline ($P < 0.05$) and choline×DRTC ($P < 0.05$) interaction where RPC increased PC expression at −14 and +7 DRTC. There was no interaction ($P > 0.1$) of prepartum energy and DRTC. Expression of *cytosolic phosphoenolpyruvate carboxykinase* (*PEPCKc*) was greatest ($P < 0.05$) at +14 and lowest at −14 and +7 DRTC (1.62a, 0.75b, and 0.62b ± 0.16 AU, respectively). Expression of *PEPCKc* was decreased ($P < 0.05$) in cows fed HE+RPC compared with other treatments (0.57b, 1.00ab, 1.26a, 1.21a ± 0.09 AU; HE+RPC, HE, CE+RPC, CE). Expression of *glucose-6-phosphatase* was increased ($P < 0.05$) at +14 and +21 DRTC, and decreased (energycholine; $P < 0.05$) in cows fed the CE+RPC (1.36 vs. 2.32, 2.33, 2.24 ± 0.17 AU; CE+RPC, CE, HE+RPC, HE). Expression of *carnitine palmitoyltransferase 1A* was greatest at +21 DRTC ($P < 0.05$) but was unaltered ($P > 0.1$) by energy or choline. The transcription factor *PPARalpha* was increased ($P < 0.05$) in CE+RPC (1.35 vs. 0.86, 0.68, 0.90 ± 0.08 AU; CE+RPC, CE, HE+RPC, HE). Increased *PC* peripartum with RPC, across energy treatments, may support increased oxidative capacity at calving. Decreased*PEPCKc*in HE+RPC may serve to increase oxidation of increased circulating NEFA by maintaining the oxaloacetate pool.

Key Words: gluconeogenesis, TCA cycle, transition cow

1319 Rumen-protected methyl donors during the transition period: hepatic short-chain acyl CoA concentration in response to supplemental methionine or choline. Z. Zhou[*1], C. L. Girard[2], B. Ouattara[2], M. Vailati Riboni[1], D. N. Luchini[3], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, [3]Adisseo S.A.S., Alpharetta, GA.*

Hepatic short-chain acyl CoAs are key intermediary metabolites of liver metabolism. Elevated concentration of acetyl CoA was associated with lower dry matter intake (DMI) in lactating dairy cows. Objectives were to measure hepatic acyl-CoA profiles in response to rumen-protected methionine (MET) or rumen-protected choline (CHO) supplemented during the transition period. Forty multiparous Holstein cows were used in a randomized complete block design with 2 × 2 factorial arrangement of MET and CHO level (with or without). Treatments were control (CON), no MET or CHO; CON+MET (SMA); CON+CHO (REA); and CON+MET+CHO (MIX). Cows received the same diet (1.52 Mcal NE_L/kg DM) from −21 d (close-up) to calving. From calving to 30 d, cows were on the same diet (1.71 Mcal NE_L/kg DM) and continued to receive the same treatments through 30 d. MET supplementation was adjusted daily at a rate of 0.08% (DM basis) of diet and CHO was supplemented at 60 g/cow/d. Liver samples were harvested at −10, 7, 20, and 30 d relative to calving. Free CoA, acetyl-CoA, propionyl-CoA, succinyl-CoA, malonyl-CoA, and methylmalonyl-CoA were determined by HPLC. Data were analyzed using PROC MIXED in SAS. The CORR procedure of SAS was used to evaluate correlations between selected variables. Both pre- and post-partum DMI was greater with MET ($P = 0.01$) but did not change with CHO ($P > 0.05$). MET supplementation led to greater ($P = 0.03$) hepatic total CoA and had a strong tendency ($P = 0.07$) for increasing free CoA compared with other treatments. Positive correlations (168 observations, $P < 0.01$) were obtained for both total and free CoA with DMI ($r = 0.27$ and 0.30, respectively) and NE_L intake ($r = 0.29$ and 0.34, respectively). Hepatic acetyl-CoA concentration has been reported to be negatively correlated with DMI, but no correlation ($P > 0.05$) was detected between acetyl-CoA, DMI, or NE_L. In fact, acetyl-CoA was lower ($P < 0.01$) with CHO and did not change with MET ($P > 0.05$). Although MET cows had lower ($P < 0.01$) propionyl-CoA, succinyl-CoA concentration was greater ($P = 0.02$) and overall positively correlated (168 observations, $P <$

0.01) with DMI ($r = 0.23$) and NE_L ($r = 0.25$). Overall, results indicate that methyl donor supplementation altered hepatic short-chain acyl-CoA concentrations during the peripartal period. The greater DMI in response to MET supplementation might have been associated with higher hepatic succinyl-CoA concentration, potentially leading to greater gluconeogenesis.

Key Words: methionine, choline, CoA

1320 Development and validity of a lipid accessibility index that quantifies reaction exposure of internal fatty acids in animal feeds.

T. C. Jenkins*[1], K. Murphy[2], and R. Ward[3], [1]*Clemson University, Clemson,* [2]*Virtus Nutrition, LLC, Corcoran, CA,* [3]*Cumberland Valley Analytical Services Inc., Hagerstown, MD.*

Excessive lipid in the diet of dairy cattle can shift the pathways of biohydrogenation and the accumulation of conjugated linoleic acid isomers that cause milk fat depression. However, computer models that predict animal performance from unsaturated fatty acid load have been inconsistent in assessing the consequences of dietary lipid. One reason for their failure is the inability to determine the extent that lipid within the natural structure of plant matter will be released and exposed to the ruminal microorganisms. The purpose of this experiment was to develop and verify a lipid accessibility index (LAI) that could predict exposure of plant lipid to the microbial population. Based on the assumption that plant factors that limit microbial exposure would also limit chemical exposure of internal lipid, a LAI was developed by determining the proportion of fatty acids in samples quantified in a 10 min methylation relative to fatty acids quantified in the normal 2 h methylation. The 4 samples tested were alfalfa pellets, corn, cottonseed, and soybeans that were each tested in duplicate at four particle sizes; unground, finely ground through a 0.5-mm sieve in a centrifugal mill, and 2 intermediate sizes obtained by grinding for different lengths of time in a coffee grinder. Data were analyzed as a completely randomized design with a 4 × 4 factorial arrangement of treatments that included the effects of feed source, grind size, and the feed source × grind size interaction. The LAI for the main effect of grind size ($P < 0.05$) averaged 21.6, 35.2, 53.5, and 97.2% (SEM = 1.79%) going from unground to the most finely ground. For the main effect of feed source ($P < 0.05$), the LAI averaged 30.7, 45.4, 47.5, and 83.9% (SEM = 1.79%) for soybeans, corn, cottonseed, and alfalfa pellets, respectively. Relationships between grind size and LAI were linear for alfalfa, corn, and cottonseed with R^2 of 0.828, 0.937, and 0.957, respectively. A second order polynomial ($R^2 = 0.961$) best described the relationship between grind size and LAI for soybeans (0, 6.7, 17.1, and 99.1% LAI for whole to finely ground). The LAI proposed in this study was successful in reflecting differences in chemical reaction exposure of internal fatty acids across several feed sources and particle sizes suggesting it might also serve to quantify feed lipid exposure to microbial reaction in the rumen.

Key Words: lipid accessibility, feedstuffs, particle size

1321 Comparison of flax oil with varying lipid supplements in dairy ration: A meta-analysis.

M. Leduc*[1,2], M. P. Létourneau Montminy[1], R. Gervais[1], and P. Y. Chouinard[1,2], [1]*Département des sciences animales, Université Laval, Québec, QC, Canada,* [2]*INAF, Université Laval, Québec, QC, Canada.*

Feeding flax oil, a source of trienoic fatty acids (TRI-FA), to dairy cows contributes to improve fertility, reduce methane emissions and increase milk fat content of n-3 FA. However, studies on the effect of flax TRI-FA on milk production and composition have yielded contradictory results. The objective of this meta-analysis was to evaluate the effects of flax TRI-FA on lactation performance when compared with different sources of dietary lipids in which dienoic (DI), monoenoic (MONO), or saturated (SAT) FA were predominant. Three databases including 30, 20, and 15 studies, published between 1998 and 2015, were used for the comparisons of flax TRI-FA vs. DI-FA, vs. MONO-FA, and vs. SAT-FA supplements, respectively. For each database, dairy cow performance was adjusted with a linear mixed model where lipid source and supplemental lipid concentration were the independent variables, and study effect was included as a random variable. Concentrations of supplemental lipids, determined by ether extraction, varied from 0.7 to 6.0% (DM basis) for flax TRI-FA (3 databases combined), 0.5 to 6.6% for DI-FA, 0.9 to 5.9% for MONO-FA, and 1.0 to 4.1% for SAT-FA supplements. The interactions between lipid sources and their dietary concentrations were never significant and were removed from the models. Feeding flax TRI-FA tended to increase DMI (0.38 kg/d; $P = 0.07$) compared with SAT-FA, but no difference was observed with DI-FA or MONO-FA supplements. Actual, fat corrected, and energy corrected milk yields were not different between flax TRI-FA and the lipid categories evaluated. Feed efficiency of cows receiving flax TRI-FA was lower (−0.03 kg milk/kg DMI) compared with SAT-FA ($P = 0.03$), whereas no difference was observed with DI-FA and MONO-FA supplements. Milk fat and protein concentrations and yields were not different between flax TRI-FA and the other three lipid categories. Feeding flax TRI-FA increased lactose concentrations compared with DI-FA and SAT-FA supplements by 0.02 ($P = 0.03$) and 0.03 ($P = 0.03$) percentage unit, respectively. Despite minor effects on lactose, there was no difference between flax TRI-FA and other dietary unsaturated lipids on animal performance. Nevertheless, as a result of an increase in DMI, efficiency of milk production was reduced by feeding flax TRI-FA compared with SAT-FA supplements.

Key Words: dietary lipids, linseed, milk composition

1322 Milk bioactive fatty acids decrease in cows grazing pearl millet versus a cool-season pasture.

M. L. Bainbridge*, E. Egolf, J. W. Barlow, J. P. Alvez, J. Roman, and J. Kraft, *University of Vermont, Burlington.*

Use of warm-season annuals, such as pearl millet (PM), has increased on northeast organic dairy farms because of their ability to grow in the mid-summer heat when cool-season perennial pastures experience less growth. The objective of this study was compare animal performance and milk bioactive fatty acids (FA) in milk of cattle grazed on PM versus cool-season pasture (CSP). Eight multiparous (parity: 2.9 ± 0.6 lactations) mid-lactation (114 ± 20 d in milk) Holstein cows were used in a repeated-measures design with three 4-wk periods. Cattle were grazed on CSP or PM in the following sequence: PM, CSP, and PM. Dry matter intake (DMI) was estimated using a calibrated rising plate meter. Individual milk weights and samples, representing a 24h period, were obtained during the last 2 wk (sampling days: 16 and 23) of each period. Milk samples were analyzed for components (fat, protein, organic solids) by mid-infrared spectrometry. Milk and forage FA proportions were determined using gas-liquid chromatography. Data were analyzed using a repeated measures ANOVA in the PROC MIXED procedure of SAS (vs. 9.4). CSP forages provided a higher content of n-3 FA when compared to PM (12.07 vs. 6.51 mg/g DM; $P < 0.05$), and higher content of polyunsaturated FA (17.17 vs. 8.33 mg/g DM; $P < 0.01$). Forage type had no effect ($P \geq 0.05$) on estimated DMI (17.2 and 17.4 kg/day for PM and CSP, respectively), milk production (13.8 and 13.1 kg/d for PM and CSP, respectively), fat yield (0.44 and 0.43 kg/d for PM and CSP, respectively), or protein yield (0.41 and 0.40 kg/d, for PM and CSP, respectively). Milk saturated FA were lower when cows grazed CSP compared to PM (59.5 vs. 63.0 g/100 g FA, respectively; $P < 0.001$). The content of CLA was higher during CSP treatment (2.11 g/100 g FA) than PM treatment (1.67 g/100 g FA; $P < 0.01$). Similarly, milk from cows grazing CSP had a twofold higher proportion of total n-3 FA when compared to PM (1.06 vs. 0.59 g/100 g FA; $P < 0.001$) and higher proportion of total n-6 FA in milk fat (1.29 and 1.04 g/100 g for CSP and PM, respectively; $P < 0.01$). Total branched-chain FA in milk fat were higher when cows grazed PM than CSP (3.12 vs. 2.86, respectively; $P = 0.01$). In conclusion, there was no difference in animal performance of cows grazing a CSP or PM, however, the contents of various bioactive FA were higher in milk fat of cows grazing a CSP compared to PM.

Key Words: milk production, n-3 fatty acids, branched-chain fatty acids

1323 Effect of early lactation feeding strategy on production, metabolic and endocrine responses of primiparous dairy cows.

M. Carriquiry*[1], M. Cariani[2], A. Jasinsky[2], M. L. Adrien[3], and D. A. Mattiauda[2], *[1]Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay, [2]Facultad de Agronomia, Universidad de la Republica, Paysandu, Uruguay, [3]Facultad de Veterinaria, UDELAR, Paysandu, Uruguay.*

Primiparous Holstein cows ($n = 18$; 528 ± 40 kg BW, 3.2 ± 0.2 BCS) calved in fall were used in a randomized block design to study the effect of feeding strategy on production, metabolic, and endocrine responses in early lactation. At calving, cows were assigned within block to 1 of 2 feeding strategies during the first 65 d postpartum (DPP). Feeding strategies were either (G0) total mixed ration (TMR) ad libitum (17 kgDM/d offered; 70% forage, 30% concentrate) or (G1) grazing of alfalfa (*Medicago sativa*; 6-h am grazing in 3-d strips; pasture allowance = 20 kgDM/d) + TMR (70% of ad libitum TMR; 12 kgDM/d offered). Both groups consumed 2.2 kgDM/d of a commercial ration at each milking. Cows were milked twice a day, milk yield was recorded daily and samples were collected weekly for milk composition. Cow BW and BCS were recorded every 2 wk from −40 to +65 DPP. Blood samples were collected for metabolite and hormone analyses at −7 ± 2 and +42 ± 3 DPP. Data were analyzed as repeated measures with a mixed model that included: feeding strategy, DPP, and its interaction as fixed effects, block as random effect and calving date as a covariate. Milk yield (26.7 vs. 25.1 ± 0.58 kg/d), total solids (3.38 vs. 3.1 ± 0.09 kg/d) and NEL output (20.9 vs. 19.2 Mcal NEL/d) tended ($P < 0.07$) to be greater for G0 than G1 cows, being differences more marked from +30 to +60 DPP. Cow BW and BCS did not differ ($P > 0.30$) between feeding strategies. Concentrations of plasma NEFA decreased ($P < 0.01$) at +42 DPP when compared to −7 DPP and at +42 DPP tended ($P = 0.10$) to be greater for G0 than G1 cows (0.34 vs. 0.25 ± 0.03 mmol/L. Plasma BHB concentration at +42 DPP was greater ($P = 0.02$) for G0 than G1 cows (0.46 vs. 0.27 ± 0.05 mmol/L) as it decreased from −7 to +42 DPP only in the latter group. In contrast, plasma insulin was reduced ($P = 0.05$) in G0 than G1 cows at +42 DPP (11.7 vs. 7.2 ± 1.3 uU/mL) as it increased from −7 to +42 DPP only in the latter group. Concentrations of cortisol, leptin and adiponectin were not different ($P > 0.20$) at −7 than +42 DPP and neither differed between feeding strategies at +42 DPP. Metabolic and endocrine profile would indicate a greater lipolysis in early lactation in G0 than G1 cows which would be probably associated to their greater milk production.

Key Words: TMR, dairy cows and grazing

1324 Ratios of milk fatty acids accurately estimates plasma non-esterified fatty acid concentrations as an indicator of animal energy balance.

J. R. R. Dórea*[1], E. A. French[2], and L. E. Armentano[1], [1]*University of Wisconsin- Madison, Madison,* [2]*DeLaval USA, Madison, WI.*

Negative energy balance and elevated plasma NEFA in dairy cows can negatively affect animal health and milk production. Also, in short term feeding trials, failing to correct for negative energy balance can lead to overestimating the energy content of a given diet or the true feed efficiency for a given cow. The objective of this study was to evaluate the precision and accuracy of individual milk fatty acid proportions (IMFAP, g/100 g milk total fatty acids) or milk fatty acids ratios (MFAR) to predict plasma NEFA concentrations. Four models were developed using a dataset from three studies (n = 204 observations, individual animal). The developed models were: model 1 (IMFAP including the terms: C14:0, C15:0, C17:0, and C18:1), model 2 (MFAR C18:1 to C15:0), model 3 (MFAR C17:0 to C15:0) and model 4 (MFAR C18:1 to C14:0). Predicted model output for plasma NEFA was compared to 90 treatment means from an independent data set from 21 papers published in the literature. All models were developed based on an individual animal-level dataset, and validated with average values from groups of animals (literature dataset). Quality of the original prediction models was evaluated using the r^2 between the observed and predicted values, mean bias (MB), concordance correlation coefficient (CCC) and root mean square error of prediction (RMSEP). Results indicated that plasma NEFA predicted by model 2 (NEFA = 71.13 (± 68.04) + 8.87 (± 0.67) * C18:1/C15:0, r^2 = 0.55) and model 3 (NEFA = −47.50 (± 36.3) + 625.30 (± 40.63) * C17:0/C15:0, r^2 = 0.54) yielded more precise and accurate predictions (model 2: r^2 = 0.89, MB = −27.39 μEq/L, CCC = 0.92, RMSEP = 51.86 μEq/L, and model 3: r^2 = 0.89, MB = −77.79 μEq/L, CCC = 0.86, RMSEP = 102.32 μEq/L,) than the NEFA predicted by model 1 (r^2 = 0.74, MB = −186.08 μEq/L, CCC = 0.54, RMSEP = 233.17 μEq/L), and model 4 (r^2 = 0.81, MB = −69.75 μEq/L, CCC = 0.41, RMSEP = 110.65 μEq/L). Milk C18:1 to C15:0 and C17:0 to C15:0 ratios can be used as an indicator of herd energy balance and therefore the status of herd health.

Key Words: energy balance, fatty acids, transition cow

1325 Effect of linseed oil supplementation on milk fatty acid profile of dairy cows fed diets based on red clover silage or corn silage.

F. Hassanat*[1], R. Gervais[2], and C. Benchaar[1], [1]*Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada,* [2]*Département des sciences animales, Université Laval, Québec, QC, Canada.*

The objective of this study was to examine the effect of linseed oil (LO) supplementation on milk fatty acid (FA) composition of dairy cows fed diets based on red clover (RCS) or corn silage (CS). Twelve lactating, multiparous Holstein cows (days in milk = 91 ± 25; milk yield = 45.2 ± 4.7 kg) were used in a replicated 4 × 4 Latin square design (35-d periods; 14-d adaptation) with a 2 × 2 factorial arrangement of treatments. Cows were fed (ad libitum; 5% orts on an as-fed basis) a TMR (60:40, forage:concentrate ratio) not supplemented or supplemented with 4% LO (DM basis) and with the forage portion of the TMR consisting of either RCS or CS. Milk FA profile was determined on samples collected over 6 consecutive days. Main effects of forage source, LO supplementation and their interaction were determined using the MIXED Procedure of SAS and significance was declared at $P \leq 0.05$. The *t*10/*t*11 18:1 ratio was unaffected by adding LO to the RCS-based diet, which is consistent with no change in milk fat yield reported in our previous study (JDS, 98:7993). In contrast, the *t*10/*t*11 18:1 ratio increased (2.04 vs. 0.77) and milk fat yield decreased (JDS, 98:7993) when LO was added to the CS-based diet. Milk fat concentration of *c*9*c*12*c*15–18:3 increased in cows fed LO-supplemented diets compared to cows fed non-supplemented diets (0.88 vs. 0.57) and in cows fed RCS compared to cows fed the CS-based diet (1.04 vs. 0.41). An increase in*c*9*t*11*c*15–18:3 concentration was observed when LO was supplemented to the RCS-based diet (0.12 vs. 0.04), but no effect was observed with LO supplementation to the CS-based diet (interaction, $P < 0.01$). Diets supplementation with LO increased the concentrations of *t*11–18:1, *c*9t11–18:2 and *t*11*c*15–18:2, but these increases were more pronounced when LO was added to the RCS-based diet than to the CS-based diet (interaction, $P < 0.01$). Regardless of the forage source, supplementation with LO decreased milk FA from de novo synthesis (< 16 carbon) and from rumen microbial origin (odd- and branched-chain FA) by 21% and 24%, respectively. It is concluded that the effect of LO supplementation (4% DM) on milk FA and more specifically on those originating from ruminal biohydrogenation of *c*9*c*12*c*15–18:3 is modulated by dietary forage source (CS vs. RCS).

Key Words: linseed oil, forages, milk fatty acid

1326 Characterization of rumen bacterial and protozoal fatty acid compositions from lactating Jersey cows offered alternative forage crops. L. M. Cersosimo[*1], R. Tacoma[1], S. Greenwood[1], K. Juntwait[2], A. F. Brito[2], and J. Kraft[1], *[1]University of Vermont, Burlington, [2]University of New Hampshire, Durham.*

Alternative forage crops (AFC) include cool and warm season grasses and legumes that could be used to overcome periods of limited pasture production. Rumen bacteria and protozoa cell membranes consist of varying proportions of fatty acids (FA) that contribute to milk FA. The objective of this study was to compare the rumen bacterial and protozoal membrane FA compositions from lactating Jersey cows fed pasture strip-tilled with AFC vs. a traditional grass-legume pasture mix. In spring (SPR) and summer (SUM), two separate, 21-d experiments were conducted using 16 lactating Jersey cows (SPR, 85 ± 46 DIM; SUM, 143 ± 58 DIM). Cows were divided into control (CON, $n = 8$) and treatment (TRT, $n = 8$) groups, matched by parity, DIM, and milk production, and offered (DM basis) 40% pasture as AFC or traditional and 60% TMR. On a DM basis, SPR TRT pasture consisted of AFC (barley, hairy vetch, triticale, rye, and wheat) representing 2.4% of total diet DM, while the SUM TRT pasture consisted of AFC (buckwheat, chickling vetch, and oats), representing 10% of total diet DM. Individual whole ruminal digesta samples (500 mL) were collected via esophageal intubation on d 20 and 21 of each experiment. Bacterial and protozoal fractions were isolated by differential centrifugation. Microbial FA were analyzed by GLC. Student's *t* tests (JMP Pro 12) were used to determine if least-squares means differed between groups. Total protozoal and bacterial branched-chain FA, PUFA, as well as *trans* 18:1 isomers and 18:0, the products of rumen bacterial biohydrogenation, did not differ by group in either experiment. In the SPR, bacterial *cis*-11 18:1 (CON, 0.57 g/100 g FA; TRT, 0.50 g/100 g FA), *cis*-13 18:1 (CON, 0.44 g/100 g FA; TRT, 0.37 g/100 g FA), and *cis*-15 18:1 (CON, 0.76 g/100 g FA; TRT = 0.68 g/100 g FA) were less abundant in the TRT than CON group ($P < 0.05$). Protozoal levels of CLA from SPR TRT (1.13 g/100 g FA) cows were higher than SPR CON (0.85 g/100 g FA). In the SUM, bacterial 17:0 was lower in cows grazing TRT pasture (0.67 g/100 g FA) than CON pasture (0.71 g/100 g FA; $P < 0.01$). In the SUM, no differences in the protozoal FA compositions were observed. In conclusion, few differences were identified in the microbial FA compositions in cows consuming pasture with or without AFC.

Key Words: branched-chain, microbial, pasture

1327 Effect of frequency of supplementation with Megalac-R on non-esterified fatty acids and blood urea nitrogen concentration in lactating beef cows. M. E. Garcia-Ascolani[*1], T. M. Schulmeister[1], M. Ruiz-Moreno[1], D. D. Henry[1], F. M. Ciriaco[1], P. L. P. Fontes[1], G. C. Lamb[1], N. M. Long[2], and N. DiLorenzo[1], *[1]University of Florida, North Florida Research and Education Center, Marianna, [2]Clemson University, Clemson, SC.*

An experiment was conducted to determine the effects of supplementing a ruminally-protected lipid (Megalac-R, Church & Dwight, Princeton, NJ) under 3 different frequencies, on the metabolic blood profile of suckled beef cows. Eighteen early lactating beef cows (first 90 d of lactation) were used in a completely randomized design. For 2 wk (d 0 to 14), all cows were individually supplemented an isocaloric, isonitrogenous amount of corn gluten feed (CGF) pellets (4.54 kg/wk, as is), at 3 frequencies (treatments): 3, 5, or 7 d/wk. For the duration of the study, cows and calves were grazing on a ryegrass pasture. From d 11 to 13, blood samples were collected before supplementation, and at 8 and 16 h later. Beginning on d 14, supplementation with Megalac-R was added to the CGF pellets at a rate of 1.59 kg/wk (as is). Supplementation frequency was maintained for the same 6 cows in each treatment for 3 wk. For the last 3 d of the study (d 32 to 34), blood samples were taken pre and post supplementation, similar to d 11 to 13. Blood samples were analyzed for concentrations of serum NEFA and blood urea nitrogen (BUN). Data were analyzed as a completely randomized design with double repeated measures, using cow as the experimental unit. The model included the fixed effects of treatment, day, hour (day), treatment × day, treatment × hour (day) interactions, and the random effect of cow. No effects of treatment ($P = 0.42$) or treatment × hour (day) ($P = 0.86$) were observed on serum NEFA concentrations. An effect of hour (day) ($P = 0.001$), and a treatment × day interaction ($P < 0.001$) were observed for NEFA concentrations; however, within each sampling day, no difference among treatments was observed ($P > 0.10$). No effects of treatment ($P = 0.74$), treatment × day ($P = 0.16$), or treatment × hour (day) ($P = 0.39$) were observed on BUN concentrations. There was an effect of day and hour (day) ($P < 0.001$), however, within each day, no difference among treatments was observed ($P > 0.10$). In conclusion, supplementing a mixture of CGF and Megalac-R either 3, 5, or 7 d/wk provided similar results with respect to concentrations of serum NEFA and BUN of lactating beef cows, thus implying that the frequency of supplementation could be reduced without compromising their health or metabolism.

Key Words: frequency of supplementation, lactating beef cows, Megalac-R

1328 Supplementation of palm oil to lactating dairy cows fed a high fat diet during summer.

R. P. Melo[1], L. P. Castro[1], F. F. Cardoso[1], E. F. Barbosa[1], L. Q. Melo[1], R. B. Silva[1,2], R. A. N. Pereira[2,3], and M. N. Pereira[*1,2], *[1]Universidade Federal de Lavras, Lavras, Brazil, [2]Better Nature Research Center, Ijaci, Brazil, [3]Empresa de Pesquisa Agropecuaria de Minas Gerais, Lavras, Brazil.*

Dairy cows subjected to heat stress can benefit from fat supplementation. We evaluated the response of lactating cows to the supplementation of a basal diet containing fat from whole cottonseed and roasted soybeans [3.2% of DM as ether extract (EE) from oilseeds] with 2 palm oil sources (1.1% of DM as EE from supplements). Thirty cows were fed a standard diet for 14 d and were assigned to a treatment for 63 d, in a covariate adjusted randomized block design with repeated measures over time. Treatments were: Control (CTL), fractionated palm oil (F, 73.5% of fatty acids as C16:0 and 14.7% as C18:1), and calcium salt of palm oil (S, 41.5% of fatty acids as C16:0 and 38.4% as C18:1). Pre-planned contrasts were: CTL vs. (F + S) and F vs. S. The EE concentration of the diet was 7.3% of DM in CTL and 8.4% in F and S. The temperature humidity index was above 68 for 17.1 h/d during the experiment. Palm oil reduced rectal temperature ($P < 0.02$) and respiratory frequency ($P = 0.05$), but had no effect on sudoresis ($P = 0.97$) and jugular blood acid-base balance ($P > 0.31$). Rectal temperature at 2 PM was 38.9°C for S and 39.1°C for F ($P = 0.02$). Palm oil increased milk yield (31.0 vs. 30.1 kg/d, $P = 0.02$) and reduced DMI (19.2 vs. 19.9 kg/d, $P = 0.01$), increasing feed efficiency (1.65 vs. 1.54, $P = 0.01$), and S tended do reduce DMI ($P = 0.07$) and increase feed efficiency ($P = 0.01$) more than F. Secretions of milk fat and lactose were increased by 47 g/d ($P = 0.04$) and 37 g/d ($P = 0.08$) with palm oil, respectively. Plasma glucose concentration was similar among treatments ($P = 0.63$), as well as total tract apparent digestibility of EE ($P = 0.97$) and NDF ($P = 0.43$), the intake of TDN ($P = 0.17$), and BW ($P = 0.87$). The acetate to propionate ratio in ruminal fluid was 2.39 for F and 1.98 for S ($P = 0.05$), suggesting that palm oil sources differed in ruminal inertness. Ingestion time/DMI was 17.3 min for S and 14.9 min for F ($P = 0.01$). Lactating cows fed a diet rich in fat from oilseeds had increased feed efficiency and reduced signs of heat stress when fat from palm oil was supplemented.

Key Words: fat supplementation, heat stress, palm oil

1329 Effects of dietary fat source on performance of lactating dairy cows fed a pre-mixed concentrate.

C. M. Ylioja[*1], C. Schulte[2], R. A. Stock[2], and B. J. Bradford[1], *[1]Kansas State University, Manhattan, [2]Cargill Corn Milling, Blair, NE.*

Inclusion of a pre-blended concentrate (OneTrak; Cargill Corn Milling, Blair, NE) in the total mixed ration for dairy cows can benefit the producer by simplifying the daily mixing of dietary ingredients and providing a more uniform mix of dietary ingredients. Cow responses to fat supplementation can be affected by other dietary ingredients, but few studies have evaluated responses to dietary fat in diets reliant on non-forage fiber. OneTrak is a blend of feed ingredients from the wet corn milling industry supplemented with additional protein, minerals, and vitamins for high producing dairy cows. Our

objective was to evaluate productivity responses to dietary fat source when the ration contained 44.1% OneTrak, 35.8% corn silage, 10.8% corn grain, 7.8% alfalfa hay, and 1.5% soyhulls or fat source (DM basis). Seventy-two Holstein cows between 94 and 220 DIM (166 ± 25 DIM, parity 1.7 ± 0.9) were blocked by parity, stratified by DIM, and randomly assigned to pens (n = 6) within strata. Pens were randomly assigned to treatment sequence in a 3 × 3 Latin square design with 21-d periods ending with 4 d of data collection. Treatments consisted of a prilled saturated fat (SAT; Energy Booster 100, Milk Specialties Co., Dundee, IL), calcium salts of long-chain fatty acids (UNS; Megalac, Church and Dwight Co. Inc., Princeton, NJ), or no added dietary fat (CON), with fat sources included to provide 1.2% added fat (DM basis). Milk yield and composition, DMI, BW change, and BCS change were analyzed with mixed models using pen as the experimental unit. Contrasts were used to assess impact of added fat and the source of fat; significance was declared at $P < 0.05$. Milk yield tended to increase with added fat ($P = 0.06$; 33.5, 34.2, and 34.3 ± 1.3 kg/d for CON, SAT, and UNS, respectively). Protein content decreased with fat supplementation, to a greater degree for UNS (3.43, 3.37, and 3.31 ± 0.05% for CON, SAT, and UNS, respectively), but protein yield did not differ. Fat content, fat yield, and energy-corrected milk yield were not affected by treatment. Conversion of feed to milk tended to increase for UNS compared with SAT (1.41 vs. 1.38 ± 0.05; $P = 0.06$). No effects were observed for BW or BCS. Responses to dietary fat in diets containing OneTrak were similar to previous findings with more traditional diets.

Key Words: dietary fat, pre-mixed concentrate, non-forage fiber

1330 Effects of feeding different forms of polyunsaturated fatty acids on performance, plasma metabolites and milk fatty acid composition of dairy cows.

1331 Milk production responses to palmitic acid supplementation when fed as fatty acids or triglycerides. J. de Souza* and A. L. Lock, *Michigan State University, East Lansing.*

We evaluated the effects of feeding a palmitic acid-enriched supplement (PA; 85% C16:0) either as fatty acids (FA) or triglycerides (TG) on production responses of mid-lactation dairy cows. Fifteen Holstein cows (137 ± 49 DIM) were randomly assigned to treatment sequence in a 3 × 3 Latin square design. Treatments were a control diet (CON; no added PA), or 1.5% of FA added either as a FA supplement (PA-FA), or a TG supplement (PA-TG). PA replaced soyhulls and diets were balanced for glycerol content. Diets contained (% DM) 21% forage NDF, 17% CP, and 26% starch. Periods were 21 d in length with the final 5 d used for sample and data collection. The statistical model included the random effect of cow and the fixed effect of treatment, period and interaction between treatment and period. Two preplanned contrasts were used to evaluate: 1) the overall effect of PA treatments [CON vs. PA; 1/2 (PA-FA + PA-TG)]; and 2) the effect of PA as a FA or triglyceride supplement (PA-FA vs. PA-TG). PA treatments increased milk fat content (3.60 vs. 3.41%; $P < 0.01$), milk fat yield (1.69 vs. 1.60 kg/d; $P < 0.01$), yield of 16-carbon milk FA (570 vs. 471 g/d; $P < 0.01$), 3.5% FCM (47.6 vs. 46.5 kg/d; $P = 0.01$), and feed efficiency (3.5% FCM/DMI; 1.69 vs. 1.58; $P < 0.01$). PA did not affect DMI compared with CON (28.5 vs. 29.2 kg/d; $P = 0.13$), milk yield (47.0 vs. 47.4 kg/d; $P = 0.67$), milk protein yield (1.42 vs. 1.45 kg/d; $P = 0.15$), milk lactose yield (2.29 vs. 2.31 kg/d; $P = 0.46$), yield of de novo milk FA (360 vs. 370 g/d; $P = 0.23$), yield of preformed milk FA (642 vs. 630 g/d; $P = 0.56$), BW (720 vs. 723 kg; $P = 0.80$), or BCS (3.14 vs. 3.23; $P = 0.17$). PA-FA increased DMI compared to PA-TG (29.1 vs. 27.8 kg/d; $P = 0.05$), yield of 16-carbon milk FA (596 vs. 545 g/d; $P < 0.01$), and tended to increase milk yield (47.6 vs. 46.4 kg/d; $P = 0.06$), milk fat yield (1.71 vs. 1.66 kg/d; $P = 0.10$), and 3.5% FCM (48.1 vs. 47.2 kg/d; $P = 0.09$). In conclusion, the production response of dairy cows to PA tended to be greater for a FA than a TG supplement. Overall, PA increased milk fat yield, 3.5% FCM and feed efficiency in mid-lactation dairy cows.

Key Words: dairy cows performance, degree of esterification, palmitic acid

1332 Comparison of a palmitic acid-enriched triglyceride supplement and a calcium salts of palm fatty acids supplement on milk production responses of dairy cows. J. de Souza*and A. L. Lock, *Michigan State University, East Lansing.*

We evaluated the effects of feeding a palmitic acid-enriched triglyceride supplement (85% C16:0) and a calcium salts of palm fatty acids (45% C16:0 and 38% *cis*-9 C18:1) supplement on production responses of mid-lactation dairy cows. Fifteen Holstein cows (139 ± 39 DIM) were randomly assigned to treatment sequence in a 3 × 3 Latin square design. Treatments were a control diet (CON; no fat supplement), or 1.5% of fatty acids (FA) added either as a palmitic acid-enriched triglyceride supplement (PA-TG), or calcium salts of palm FA supplement (Ca-FA). The supplements replaced soyhulls and diets were balanced for glycerol and calcium content. Diets contained (% DM) 21% forage NDF, 17% CP, and 26% starch. Periods were 21 d in length with the final 5 d used for sample and data collection. The statistical model included the random effect of cow and the fixed effect of treatment, period and interaction between treatment and period. Ca-FA tended to decrease DMI compared with CON and PA-TG (29.5, 29.6 and 28.7 kg/d; $P = 0.10$; for CON, PA-TG and Ca-FA, respectively). PA-TG tended to increase milk yield compared

with CON, but did not differ from Ca-FA (48.3, 49.5 and 48.9 kg/d; $P = 0.10$; for CON, PA-TG and Ca-FA, respectively). Compared with CON and Ca-FA, PA-TG increased milk fat concentration (3.40, 3.57 and 3.50%; $P < 0.01$) and milk fat yield (1.64, 1.77 and 1.72 kg/d; $P < 0.01$; for CON, PA-TG and Ca-FA, respectively). Compared with CON, both PA-TG and Ca-FA increased 3.5% FCM (47.1, 49.7 and 48.9 kg/d; $P < 0.01$) and feed efficiency (3.5% FCM/DMI) (1.60, 1.68 and 1.71 for CON; $P < 0.01$ for CON, PA-TG and Ca-FA, respectively). Ca-FA tended to increase BW change compared with PA-TG and CON (0.61, 0.62 and 0.78 kg/d; $P = 0.08$) and BCS change (0.05, 0.06 and 0.12; $P = 0.10$; for CON, PA-TG and Ca-FA, respectively). Ca-FA decreased yield of de novo milk FA compared with CON and PA-TG (401, 393, and 371 g/d; $P = 0.01$), but increased yield of preformed milk FA (618, 640, and 700 g/d; $P = 0.01$), whereas PA-TG increased yield of 16-carbon milk FA compared with other treatments (500, 576, and 540 g/d; $P = 0.01$; for CON, PA-TG and Ca-FA, respectively). In conclusion, feeding a palmitic acid-enriched triglyceride supplement increased milk energy output due to increased yields of milk and milk fat, whereas feeding a calcium salts of palm FA supplement increased BW gain.

Key Words: calcium salts of fatty acids, dairy cow performance, palmitic acid

1333 Changes in milk odd and branched-chain fatty acids during induction and recovery from biohydrogenation-induced milk fat depression.

E. Palmer[1], M. Baldin[*1], D. E. Rico[2], and K. J. Harvatine[1], *[1]Penn State University, University Park, [2]Université Laval, Québec, QC, Canada.*

We have observed that the concentration of odd and branched-chain fatty acids (OBCFA) in milk fat markedly changes during biohydrogenation (BH) induced milk fat depression (MFD). The objective was to characterize the time course of changes in milk OBCFA during induction and recovery of BH-induced MFD. Nine Holstein cows were randomly assigned to a treatment sequence in a repeated design that allowed analysis of recovery from a MFD diet. A 36.9% NDF and 1.1% PUFA diet was fed during the control and recovery periods, and a 29.5% NDF and 3.7% PUFA diet was fed during the induction period. Treatment periods were 21 d long and milk was sampled every other day. Data were analyzed using the MIXED procedure of SAS with repeated measures, time was the repeated variable, and cow by treatment was the subject. Preplanned contrasts were control versus induction and control versus recovery at each time point. The production data has been previously published (Rico and Harvatine, 2013 JDS 96:6621). Briefly, milk fat percentage and yield decreased progressively during induction and were lower than control by d 3 and 5, respectively. Milk fat concentration and yield increased progressively when cows were fed the recovery diet and were not different from control on d 19 and 15, respectively. During induction of MFD milk fat content of *iso*-14:0, *iso*-15:0, *anteiso*-15:0, 15:0, *iso*-16:0,*anteiso*-17:0, 17:0, and total OBCFA decreased rapidly (3.8 to 3.0% of total FA; $P < 0.01$ for all) and generally the concentration of these fatty acids was lower than control by d 3 ($P < 0.05$ for all). Contrarily, during recovery milk fat content of *iso*-14:0, *iso*-15:0, *anteiso*-15:0, 15:0, *iso*-16:0,*anteiso*-17:0, 17:0, and total OBCFA increased rapidly and the concentration of these fatty acids was not different from control on d 3 ($P > 0.1$ for all). In conclusion, the changes in milk OBCFA during induction and recovery of MFD occur rapidly, suggesting that these milk fatty acids could be used as markers of altered rumen biohydrogenation during milk fat depression.

Key Words: fatty acids, milk, rumen

1334 Dynamics of enrichment of omega-3 fatty acids in plasma lipid fractions following a bolus dose in dairy cows.

N. L. Urrutia[*1], M. Baldin[1], J. Y. Ying[2], S. R. McKinney[1], and K. J. Harvatine[1], *[1]Penn State University, University Park, [2]Penn State University, State College.*

Transfer of dietary omega-3 fatty acids (n-3 FA) to milk is low. Understanding the trafficking of n-3 FA in plasma lipid fractions may allow improvements in this transfer. The objective of this experiment was to investigate the fate of n-3 FA in plasma lipids after an abomasal bolus infusion of n-3 FA. Ten ruminally cannulated, multiparous Holstein cows were used in a crossover design with 7 d periods. Treatments were abomasal infusion of 120 g (infused over 1 h) of a free FA mixture enriched in α-linolenic acid (EALA; 80 g of ALA) or in very long chain n-3 (EVLC; 45.5 g of Eicosapentaenoic acid [EPA] + 33 g of Docosahexaenoic acid [DHA]). Blood samples were collected at −6, 0, 6, 12, 30, 54, and 102 h relative to the bolus infusion. Data was analyzed as repeated measures and the model included random effects of cow nested in sequence, sequence and period and fixed effect of treatment, time and treatment by time (SAS). Plasma concentration of total n-3 FA peaked 6 h post infusion in both treatments and was higher in EVLC than in EALA ($P < 0.001$). At peak, plasma EPA and DHA were enriched 8.3 and 60 fold, respectively, in EVLC and plasma ALA was enriched by 1.3-fold in EALA. After peak, plasma ALA in EALA and EPA in EVLC gradually decreased over time, while plasma DHA in EVLC remained 40-fold enriched over baseline at 102 h. Treatments had no effect on plasma cholesterol esters (CE), phospholipids (PL) and NEFA concentration. In the plasma PL fraction, ALA in EALA and EPA in EVLC (mg/dL) peaked at 1.8 and 11 fold enrichment, respectively, 6 h post infusion and then gradually decreased over time while accumulating in CE, where they reached 1.2 and 2.8-fold enrichments at 102 h. Plasma DHA peaked at 6 h in CE and decreased rapidly back to pre bolus values, however it peaked later (30 h) and remained high in PL (0.03 to 1.28 mg/dL from −6 to 102 h). In conclusion, n-3

FA differ in their enrichment and depletion in specific plasma lipid fractions and their transfer to milk might be limited due to trafficking of very long chain n-3 FA into plasma lipid pools unavailable to the mammary gland.

Key Words: omega-3, fatty acids, plasma lipids

1335 Intravenous nicotinic acid suppresses adipose tissue lipolysis in Holstein dairy cows.

A. N. Davis*, J. L. Clegg, and J. W. McFadden, *West Virginia University, Morgantown.*

The mobilization of adipose tissue is linked with insulin resistance in dairy cattle. Feeding rumen-protected nicotinic acid (NA) or abomasal infusion of free NA can suppress lipolysis; however, the efficacy of intravenous NA to lower circulating NEFA is uncertain. Therefore, our objective was to evaluate the effects of intravenous NA infusion on lipolysis and insulin tolerance. Nine non-pregnant, non-lactating Holstein cows (617 ± 51 kg BW) were utilized in a 3 × 3 balanced Latin square crossover design. Treatments consisted of ad libitum feeding, fasting, or fasting with intravenous NA infusion (5 mg of NA/h per kg BW in saline) for 32 h. Equal volumes of saline were infused in cows not administered NA. Post-treatment, all cows were provided ad libitum access to feed and monitored for 8 h. Two 14-d washouts were included. When provided access, cows were fed a mixed ration of grass hay and ground corn to meet or exceed requirements. Fasted cows were provided vitamins and minerals. Jugular catheters were inserted 16 h before use. An insulin tolerance test (0.1 IU/kg BW; ITT) was performed at h 32, relative to initiation of treatment. Blood was collected routinely. Serum was analyzed using colorimetry. Data were analyzed using a mixed model with repeated measures with fixed effects of treatment and time. Relative to feeding, fasting increased lipolysis by h 2 (114 vs. 65 μM; $P < 0.01$), a response that progressively increased to h 32 (749 vs. 76 μM; $P < 0.01$). NA caused a consistent elevation in NEFA compared to fed cows, beginning at h 10 (77 vs. 51 μM; $P < 0.05$). NA reduced fasting NEFA area under the curve (0 to 32 h) by 55% ($P < 0.01$). Characteristic of NA, serum NEFA surged to 2,936 μM following removal ($P < 0.01$), a response accompanied by a treatment-specific increase in serum triacylglycerol and glucose ($P < 0.01$). In contrast, serum glucose and triacylglycerol were not modified with treatment. Relative to feeding, fasting without NA elevated serum cholesterol by h 16 ($P < 0.01$), a response delayed for fasted cows infused NA (h 24; $P < 0.05$). Fasting without NA reduced insulin-stimulated glucose uptake 38% by min 30 of ITT ($P < 0.01$), relative to feeding; however, NA did not improve glucose uptake. We conclude that the intravenous infusion of NA can inhibit lipolysis in dairy cattle; however, complete suppression of NEFA mobilization is not sustained with prolonged infusion.

Key Words: dairy cow, lipolysis, nicotinic acid

1336 Ruminal metabolism of fatty acids from fish oil or algae in steers fed a finishing diet.

A. Pesqueira*, *University of Kentucky, Lexington.*

Supplementing cattle with sources of unsaturated fatty acids in the diet could improve the fat profile of the meat, but unsaturated fats suffer biohydrogenation by rumen bacteria. The objective of this study was to evaluate heterotrophically grown microalgae as a source of omega-3 fatty acids in steers fed a high grain finishing diet. Eight steers were used in a replicated 4 × 4 Latin square (LS) design experiment with each period lasting 21 d. The diet was based on cracked corn (75%), corn silage (7.5%) and fescue hay (7.5%) offered at 1.75 × NEm. The treatments were control, tallow (60 g/d), fish oil (60 g/d) and intact algae (100 g/d). All treatments were dosed through a ruminal fistula mixed with 450 g of diet. Total urine and feces were collected d 15 to 21. Reticulum and omasal samples were obtained for each hour from 0700 to 1800 during d 16 to 18. Omasal contents were collected using a vacuum sampling pump and reticulum samples by placing a collection bottle in the reticulum. Rumen fluid was collected at 2 h intervals from 0700 to 1700 on d 19 for pH and VFA analysis. Blood plasma was collected on d 21 of sample collection for fatty acid profile. The experiment was analyzed as a LS design with a 2 × 2 factorial using mixed models in SAS. There was no difference among treatments for DMI, urine or fecal excretion, N balance, total VFA concentrations, omasal or reticular flow, and apparent digestibility. Reticulum samples indicated greater amounts of DM exiting the rumen and were not used for measures of rumen digestibility. Control animals had lower ruminal pH when compared to other treatments ($P = 0.0012$). Animals consuming algae had higher fecal crude fat digestibility ($P = 0.02$) when compared with fish oil. Algae and fish oil had highest percent of total long chain fatty acid digestibility in feces when compared to tallow ($P = 0.0830$). Fish oil, algae and tallow had lower blood plasma C18:0 than control ($P = 0.01$). Algae increased flow of C18:1 isomers compared with fish oil ($P = 0.04$) and increased DHA in plasma ($P = 0.02$) but this was not evident from omasal fatty acid flow. These data indicate that algae feeding may have potential to alter the fatty acid profile of finishing steers.

Key Words: algae, fat, omasum, polyunsaturated fatty acid, DHA

1337 Increases in milk fat yield are maintained with prolonged palmitic acid supplementation in mid-lactation dairy cows.

A. T. Mathews[1], J. E. Rico*[1], N. T. Sprenkle[1], A. L. Lock[2], and J. W. McFadden[1], *[1]West Virginia University, Morgantown, [2]Michigan State University, East Lansing.*

Supplementing palmitic acid (C16:0) increases yields of milk and milk fat in mid-lactation dairy cows. Because previous research has characterized the effects of short-term C16:0

Table 1338.

CON= Control; NUT= Nutrigordura®, ruminally protected soil bean oil; BRP= Blend of ruminally protected vegetable oils.
Considered statistically significant differences at the 10% significance by f test.
DMI = dry matter intake; ADG= average daily gain; G:F = gain-to-feed ratio; FC = feed conversion; HCW= hot carcass weight; Dressing Percentage = ((HWC/BW)*100); Carcass gain = (HWC – Initial Carcass Weight (which was obtained by regression of carcass weight of six animals slaughtered at the beginning of the experiment).
C1= CON vs NUT+BRP; C2= NUT vs BRP.

feeding (~14 to 28 d) on production parameters, our objective was to determine whether prolonged C16:0 supplementation can maintain milk fat yield and FA incorporation into milk fat. Twenty multiparous Holstein cows were enrolled in a study consisting of a 5 d covariate, 49 d treatment, and 14 d post-treatment evaluation. Cows received a sorghum silage-based diet and were randomly assigned to treatments consisting of no added fat (control; soyhull pellets; n = 10; 138 ± 45 DIM) or C16:0 at 4% of ration DM (98% C16:0; PALM; n = 10; 136 ± 44 DIM). Milk yields were recorded and samples were composited at wk 0, 3, and 7 relative to the start of the treatment period, and 2 wk post-treatment. Data were analyzed as repeated measures using a mixed model with the fixed effects of treatment and time. Effects of PALM are presented as changes relative to control. We observed that PALM increased yields of milk and milk fat by wk 3 and 7 (P < 0.05), without changing milk fat concentration (P = 0.33). PALM increases in milk fat yield were preserved post-treatment (P < 0.05). PALM increased milk C16:0 yield by 52 and 46% by wk 3 and 7, respectively (P < 0.01). Similar observations were observed for yields of milk *cis*-9 C16:1. Although yields of de novo synthesized and preformed FA in milk remained unchanged, milk saturated FA yield increased in PALM by wk 3 and 7 (P < 0.01). Post-treatment, the yields of C16:0 (P = 0.19) and *cis*-9 C16:1 (P = 0.49) in PALM were comparable to control. Post-treatment, the sustained increase in milk fat yield with PALM was due to increased yields of de novo and preformed FA in milk (P < 0.01). Comparable to changes in milk FA yields, PALM increased milk C16:0 concentrations by 26 and 21% by wk 3 and 7, respectively (P < 0.01). Concentrations of milk de novo synthesized and unsaturated FA were lower in PALM-fed cows (P < 0.01). We did not observe any differences in the concentrations of milk FA post-treatment. We conclude that feeding mid-lactation dairy cows C16:0 for 7 wk maintained milk fat synthesis for the duration of supplementation because of sustained C16:0 and *cis*-9 C16:1 incorporation.

Key Words: fatty acid, milk fat, palmitic acid

1338 Feedlot performance of Nellore bullocks fed with two different types of ruminally protected fat.

F. D. A. Nascimento[1], N. C. D. Silva[1], F. P. Monção[*1], R. D. L. Pacheco[2], B. J. Johnson[3], F. D. D. Resende[4], and G. R. Siqueira[4], *[1]UNESP- Univ Estadual Paulista, Jaboticabal, Brazil, [2]Empresa Matogrossense de Pesquisa, Assitência e Extensão Rural-EMPAER-MT, Campo Grande, Brazil, [3]Texas Tech University, Lubbock, [4]APTA- Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil.*

The objective of the study was to evaluate two different sources of ruminally protected fat on feedlot performance of Nellore bullocks. It was used 53 intact Nellore males with 315 ± 5,9 kg of initial body weight (IBW) and 20 mo old. Six animals were random selected and harvested at the first day of study for carcass gain calculation while 47 animals were allocated in individual pens for feedlot performance evaluation. Trial design was randomized blocks (based on IBW) divided in 3 treatments: Control– no addition of fat (CON, n = 16), Nutrigordura®- ruminally protected soybean oil (NUT, n = 16) and a blend of ruminally protected vegetable oils containing both saturated and unsaturated sources (BRP, n = 15). Animals were fed for 140 d with a 88% concentrate diet (14.2% of CP and 2.74 of Mcal/kg of DM, for NUT and BRP; 14.4% of CP and 2.63 Mcal/kg of DM for CON) composed of grounded corn, citrus pulp, peanut meal, trace minerals supplement and sugarcane bagasse. Diets of NUT and BRP treatments were isoproteic and isoenergetic with the same inclusion of protected fat (3.36% of DM). Animals were fed twice daily with total mixed ration management. Animals were considered as

experimental unit and variables were analyzed using ANOVA ($P \leq 0.10$; PROC MIXED of SAS), and means were compared by contrasts (C1 = CON vs. NUT+BRP; and C2 = NUT vs. BRP). No difference was observed for Dressing Percentage ($P = 0.18$; Table 1). However, differences ($P < 0.01$) were observed for final BW, DMI, and ADG, for animals fed NUT or BRP, compared to CON (C1). Additionally, it was observed differences in both contrasts (C1: $P < 0.01$, C2: $P < 0.10$) for feed efficiency (G:F), Hot Carcass Weight (HCW), Carcass Gain and ADG of carcass, whereas animals fed BRP presented better feedlot performance than CON and NUT (C2). Bullocks fed BRP presented carcasses 13 kg heavier ($P = 0.03$) than NUT. In conclusion, ruminally protected fat increases feedlot performance of Nellore bullocks and BRP provides better benefits (ADG, G:F, HCW and Carcass Gain) than a ruminally protected fat derived from soybean oil.

Key Words: nutrition, protected fat, saturated fatty acid

1339 Studies on different energy density of close-up diets on energy metabolism and lactation performance in montbeliarde-sired crossbred holstein cows.

S. Dong, Z. Cao, S. Li, and Y. J. Wang*, *State Key Laboratory of Animal Nutrition, Beijing Engineering Technology Research Center of Raw Milk Quality and Safety Control, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

The objective of the experiment were to evaluate the effects of prepartum dietary energy density on dry matter intake (DMI), lactation performance, energy metabolism in montbeliarde-sired crossbred holstein cows. Eighteen dry cows (Half primiparous and half multiparous) were blocked and assigned randomly to three groups fed a low concentrate diet (Concentrate is 0.3% of body weight), middle concentrate diet (Concentrate is 0.6% of body weight), high concentrate diet (Concentrate is 0.9% of body weight) from 21 d before expected day of calving, and corn stover was free to access choice. After parturition, all cows were fed the same lactation diet to 28 d in milk. The DMI, net energy intake (NEI) and energy balance (EB) of prepartum were significantly decreased by the reduced amount of concentrate added. The 0.9% group consumed 43.52% more DMI, compared with 0.3% group in the last 1 wk before calving. The different amount of concentrate added had no effect on DMI and NEI, EB, milk yield in first 4 wk of lactation. Overall, energy metabolism and lactation performance of postpartum were not affected by energy density of the three treatments during the close-up period, and the 0.3% group is more economical compared with other groups.

Key Words: transition cow, dietary energy density, energy metabolism

1340 Prepartum body condition score and plane of nutrition affect the hepatic transcriptome during the transition period in grazing dairy cows.

M. Vailati Riboni*[1], S. Meier[2], C. Burke[2], J. K. Kay[2], M. D. Mitchell[3], C. G. Walker[2], M. A. Crookenden[2], A. Heiser[4], S. L. Rodriguez Zas[1], J. R. Roche[2], and J. J. Loor[1], *[1]University of Illinois, Urbana, IL, [2]DairyNZ, Hamilton, New Zealand, [3]University of Queensland, Queensland, Australia, [4]AgResearch, Palmerston North, New Zealand.*

A transcriptomic approach was used to evaluate potential interactions between prepartum degree of body condition (BCS) and feeding management in the weeks before calving on hepatic metabolism during the transition period. Thirty-two mid-lactation grazing dairy cows of mixed age and breed were randomly allocated to one of four treatment groups in a 2 × 2 factorial arrangement: two prepartum BCS categories [4.0 (thin, BCS4) and 5.0 (optimal, BCS5); based on a 10-point scale], and two levels of energy intake during the 3 wk preceding calving (75 and 125% of estimated requirements). Liver samples were obtained at −7, 7, and 28 d relative to parturition and subsequent RNA was hybridized to the Agilent 44K Bovine (V2) Microarray chip. Data were adjusted for dye and array effect and a MIXED model with repeated measures was then fitted to the normalized $\log_2$–tranformed adjusted ratios using Proc MIXED. Differentially expressed genes (DEG) with fold change ≤ -1.5 and ≥ 1.5, and P-value ≤ 0.01 were considered for downstream analysis. The Dynamic Impact Approach was used for pathway analysis, and Ingenuity Pathway Analysis was used for gene network analysis. The greater number of differentially expressed genes in BCS4 cows in response to prepartum feed allowance underscored that these animals were more responsive to prepartum nutrition management than optimally-conditioned cows. Independent of prepartum BCS, however, pathway analysis revealed that prepartal feeding level had a marked impact on carbohydrate, amino acid, lipid, and glycan metabolism. Altered carbohydrate and amino acid metabolism indicated a greater and more prolonged negative energy balance post-calving in BCS5 cows overfed prepartum. This was surmised by the opposite effect of pre-calving feeding in BCS4 compared with BCS5 cows on pathways related to amino acid, vitamin, and co-factor metabolism. The prepartum feed restriction ameliorated the metabolic adaptation to the new lactation in BCS5 cows, while detrimentally affecting BCS4 cows, which seemed to better adapt when overfed. Alterations in the glycosaminoglycan synthesis pathway supported this idea, indicating better hepatic health status in feed-restricted BCS5 and overfed BCS4 cows. The IPA network analysis indicated liver damage in feed-restricted thin cows, likely due to metabolic overload. Overall, the data indicate that overfeeding in late-pregnancy should be limited to underconditioned cows, while cows with optimal degree of body condition should be maintained on an

1341 Application of *Pediococcus pentosaceus* and chitinase to high moisture alfalfa hay at baling: effects on nutrient digestion and on growth performance of beef cattle.

L. Jin[1], E. Chevaux[2], T. A. McAllister[3], and Y. Wang[*1], *[1]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, [2]Lallemand SAS, Blagnac, France, [3]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, Lethbridge, AB, Canada.*

The objective of this study was to assess the effect of applying a *Pediococcus pentosaceus* and chitinase mixture (PED+CH) at baling on nutrient digestion and on growth performance of beef cattle. Pure alfalfa was harvested and sun-cured to either 23 to 30% (HMH) or 10 to 13% (NMH) moisture. The HMH (Treatment) was baled with application of PED (6.5×10^{11} cfu/tonne)+CH (1.5 g/tonne) and NMH was baled without additives (Control). A crossover experiment (Exp 1) used eight cannulated heifers that were divided into two groups and fed diets containing 77% of control or treated alfalfa hay and 33% concentrate (DM basis). Each period consisted of a 10-d adaption, 2-d for measuring rumen fermentation products and 7-d for measuring total tract digestibility using chromium oxide (Cr_2O_3) as an indigestible marker. In Exp 2, fifty Angus×Hereford crossed-bred steers (270 ± 1.12 kg) were stratified by BW and allocated randomly to two groups in 10 pens, and fed diets containing 57% (DM basis) of treated or control alfalfa hay for 112 d and DMI, ADG and feed efficiency (FE) were measured. Data were analyzed as a completely randomized design using PROC MIXED procedure of SAS with cattle (Exp 1) or pen (Exp 2) as the statistical unit. Differences among means were identified using LSMEANS with the PDIFF in SAS. Cattle fed both diets had similar ($P > 0.05$) DM, NDF and ADF digestibility. However, HMH alfalfa treated with PED+CH had lower ($P < 0.05$) CP digestibility as compared with NMH alfalfa hay. Both groups of cattle had similar rumen pH, VFA and ammonia concentrations and cellulolytic enzyme activity. The two groups of cattle also had similar ($P > 0.05$) DMI, ADG and FE over the 112-d backgrounding period. The similar rumen fermentation characteristics, nutrient total tract digestibility and growth performance between the 2 groups of cattle indicate that alfalfa HMH preserved with PED+CH exhibited similar ruminal and total tract digestibility and feed value to NMH alfalfa. The PED+CH additive has the potential to conserve high-moisture alfalfa hay so that its nutritive and feeding value is similar to that of sun-dried alfalfa hay.

Key Words: high moisture alfalfa hay, inoculant, digestibility beef cattle, growth performance

1342 The impact of *Saccharomyces cerevisiae* and *Lactobacillus acidophilus* on colon histomorphology and gene expression in rumen and ileum tissues of young dairy calves.

B. Fomenky[*1,2], J. Chiquette[1], P. Y. Chouinard[3], and É. M. Ibeagha-Awemu[1], *[1]Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada, [2]Département des sciences animales, Université Laval, Québec, QC, Canada, [3]Département des sciences animales, Université Laval, Québec, QC, Canada.*

Direct fed microbials (DFM) are increasingly used as a replacement for antibiotics growth promoters to maintain animal health, enhance performance and reduce environmental contamination. However, little information exists on the impact of DFM on the morphology of the gastro intestinal tract of calves and innate immune response during early life. The aim of this study was to evaluate the impact of *Lactobacillus acidophilus* and *Saccharomyces cerevisiae* on colon histomorphology and innate immune gene expression of rumen and ileum tissues of calves.

Forty eight Holstein calves (2 to 7 d-old) were grouped according to body weight and circulating IgG and randomly separated into 4 treatments: Control (CTRL)- fed milk replacer and starter diet introduced after the second week; CTRL supplemented with *Saccharomyces cerevisiae boulardii CNCM I-1079* (7.5×10^9 cfu/L milk replacer + 3×10^9 cfu/kg feed) (SCB); CTRL supplemented with *Lactobacillus acidophilus BT1386* (2.5×10^8 cfu/L milk replacer + 1×10^9cfu/kg feed) (LA); and CTRL supplemented with tetracycline (528 mg/L) and neomycin (357 mg/L) before weaning and chlortetracyclin (55 mg/kg) after weaning (ATB). Four calves per treatment were euthanized on Days 33 (d33; pre-weaning) and d96 (post-weaning) for RNA isolation and colon histomorphological studies. The expression levels of Muc1, Muc20, Claudin 3, TLR4, TLR6, TLR9 and TLR10 genes were analyzed by qPCR. Morphometric measurements of stained (hematoxylin & eosin and periodic acid Schiff) colon sections were used for the determination of crypt depth (NDPview 2 software) and goblet cell (imageJ software). The effects of treatments were analyzed following a complete randomized block design with repeated measures and Tukey adjustments for multiple comparisons. The levels of expression of genes were low in the ileum. In the rumen, Muc1 gene increased $P = 0.014$ whereas the expression of TLR 6 ($P = 0.07$) and TLR10 ($P = 0.081$) genes tended to increase with SCB when compared to CTRL. Crypt depth for both SCB and ATB decreased significantly ($P < 0.01$) on d33 and d96 as compared to LA and CTRL. Similarly, neutral mucins were increased ($P < 0.05$) with SCB (d33 and d96) and ATB (d33) as compared to LA and CTRL. Muc1 gene was up-regulated in the rumen but not in the ileum on d33 and d96. Data shows that feeding SCB altered the colon morphology and increased neutral mucin; an indication of early

maturation in the SCB treated group. Our results suggest that SCB could improve colon development in young dairy calves.

Key Words: Histomorphology, *Saccharomyces cerevisia, calf, Muc1 gene,* development

1343 Aflatoxin M1 levels reduction in milk after *Saccharomyces cerevisiae* or mannanoligosaccharides addition to aflatoxin B1 contaminated diet of dairy cows.

M. Aronovich*[1], C. Perali[2], C. A. D. R. Rosa[3], A. A. Castagna[1], and E. Rodrigues[1], *[1]PESAGRO-RIO, NITEROI, Brazil, [2]Castelo Branco University, Rio de Janeiro, Brazil, [3]Veterinary Microbiology/ UFRRJ, Rio de Janeiro, Brazil.*

The purpose of this study was to evaluate the ability of *Saccharomyces cerevisiae* (SC47) and a mananoligosaccharide (MOS) to bind aflatoxin B1 (AFB_1) in the diet of dairy cows fed with 200 ppb an AFB_1–contaminated diet daily and, consequently, to reduce the aflatoxin M_1 levels in milk. Toxigenic fungi that grow on crops can produce highly carcinogenic metabolites called aflatoxins (B_1, B_2, G_1, G_2). Aflatoxin M_1 is a hydroxylated AFB_1 metabolite secreted (0.3 to 6.2%) in milk of mammary glands of lactating animals. Thirty six early to mid-lactation dairy cows averaging 90 d were used in a 4 × 4 Latin square design with 3 replicates. Cows were blocked by parity, body weight and milk production. Ad libitum access to feed and water was provided. Within each replicate, cows were randomly assigned to 6 dietary treatments for 2 consecutive 7-d periods. Dietary treatments included: T1 Basic Diet (BD); T2 BD + AFB_1 [200 μg of AFB_1/kg of diet dry matter (DM)]; T3- BD + 10 g MOS/cow/day; T4- BD +AFB_1 [200 μg of AFB_1/kg of diet dry matter (DM)] + 10 g MOS/cow/day; T5- BD + 10 g SC47/cow/day and T6- BD + AFB_1 + 10 g SC47/cow/day. Milk samples were collected from first to fourth day, seventh and 10th to 14th day of the experimental period. The cows of treatments T2, T4 and T6 were feed with the AFB_1 contaminated diet until the 10th day of experiment. The AFM_1 analysis was performed using immunoaffinity clean-up and detection by HPLC with fluorescence detector. Adding SC47 or MOS to basal or AFB_1–contaminated diets at 10 g/day/animal had no effect on lactation performance. The maximum levels of AFM_1 averaged at 11th day were 2,04 +0,18 μg/L, 0,7+0,12 μg/L and 0,14+0.03 μg/L, respectively for cows fed BD + AFB_1 (T2), BD + AFB_1 + MOS (T4) and BD + AF + SC47. Transfer rates of AFB_1 from feed to milk (AFM_1) averaged 1.02, 0.35, 1.42, and 0.07% for cows fed BD + AFB_1 (T2), BD + AFB_1 + MOS (T4) and BD +AFB_1 + SC47, respectively. Results indicated that strain SC47 and MOS at 10 g/animal/day were effective in reducing milk AFM_1 concentrations in cows consuming a total mixed ration containing 200 μg of AFB_1/kg of DM.

Key Words: Yeast, mycotoxin, milk quality

1344 Effects of a plant extract-based feed additive on feed intake, milk production and composition, rumen fermentation, digestibility, and nitrogen utilization in lactating dairy cows.

J. Oh*, M. Harper, F. Giallongo, J. C. Lopes, and A. N. Hristov, *The Pennsylvania State University, University Park.*

The objective of this study was to investigate the effect of a plant extract-based feed additive (PE, Laboratoires Phodé, France) on performance, rumen fermentation, nutrient digestibility, and nitrogen utilization in lactating dairy cows fed diets with 2 concentrations of CP. The study involved 21 Holstein cows (123 ± 58.4 d in milk) in a replicated 3 × 3 Latin square design experiment with 3, 28-d periods. Treatments were control (15.8% CP), a low CP diet (LCP, 14.0% CP), and LCP supplemented with 35 g/d PE (LCPPE). PE was mixed with one-third of the ration and top-dressed. The low CP diets decreased ($P < 0.01$) DMI compared with the control and there was no effect of PE on DMI (28.4, 27.4, and 26.9 kg/d for control, LCP, and LCPPE, respectively). Milk yield was similar (36.6 kg/d; SEM = 1.66, $P = 0.27$) among treatments. Treatment had no effect ($P = 0.14$) on feed efficiency (1.31, 1.33, and 1.36 kg/kg, respectively). Milk yield adjusted to 4% fat (FCM) was not affected by treatment; however, FCM feed efficiency as proportion of RUP intake (4% FCM ÷ RUP intake) was increased ($P = 0.05$) by LCPPE compared with the control and LCP (22.8, 20.7, and 20.2 g/g, respectively). Concentrations of milk fat, protein, and lactose and milk fat and protein yields were not affected ($P \geq 0.35$) by treatment. Milk N efficiency was higher ($P < 0.01$) for the low-protein diets compared with the control. Ruminal pH, lactate, ammonia, and VFA concentrations, except valerate, which was lowered ($P < 0.01$) by LCP, were also not affected ($P \geq 0.36$) by treatment. The low-protein diets had slightly higher ($P \leq 0.02$) total tract apparent digestibility of DM and organic matter, but lower CP digestibility than the control. PE did not affect ($P \geq 0.22$) nutrient digestibilities. The low-CP diets decreased ($P < 0.01$) urinary and fecal nitrogen excretions; nitrogen losses were not affected by PE. Excretion of purine derivatives in urine was not affected ($P = 0.17$) by treatment. Ruminal in situ degradability of dietary DM, CP, NDF, and ADF was also similar ($P \geq 0.31$) among treatments. In this study, dietary supplementation of PE had no effect on feed intake, production variables, feed efficiency, or nutrient digestibility, but increased FCM efficiency as proportion of RUP intake in lactating dairy cows.

Key Words: plant extract, dietary protein, milk production, feed efficiency, dairy cow

1345 Monensin and levels of narasin on rumen metabolism in lambs during adaptation to high-concentrate diets. D. M. Polizel*[1], S. S. Marques[2], M. F. Westphalen[3], M. H. Santos[1], M. V. C. Ferraz Junior[1], M. V. Biehl[3], R. G. Silva[1], I. Susin[3], and A. V. Pires[1,3], *[1]FMVZ/University of Sao Paulo, Pirassununga, Brazil, [2]Ponta Grossa State University, Ponta Grossa, Brazil, [3]ESALQ/University of Sao Paulo, Piracicaba, Brazil.*

The objective in this trial was to determine the effects of monensin and levels of narasin on short chain fatty acids (SCFA) profile and ruminal pH during adaptation of lambs fed high-concentrate diets. Fifteen White Dorper × Santa Inês and 15 Dorper × Santa Inês lambs, cannulated in the rumen, were assigned to a randomized complete block design, defined by breed and initial BW. Experimental diets were control (without ionophore), monensin (25 mg/kg DM) and 3 doses of narasin (5, 10, or 15 mg/kg DM), corresponding to the experimental diets C, M, N5, N10, and N15, respectively. The experimental period lasted 29 d. Rumen fluid was collected on Days 1, 7, 14, and 21, every 3 h, starting prior feeding, 3, 6, 9, and 12 after feeding. In every sampling time 20 mL of rumen fluid per animal were collected and these samples were stored in the same vial (1 vial per animal per day). Data were analyzed using the MIXED procedure (SAS Inst. Inc.). There were 2 contrasts previously defined (I: control vs. ionophores; II: monensin *vs*narasin). Orthogonal polynomials for the effects of levels of narasin (control, N5, N10, and N15) responses were determined by linear and quadratic effects. The effects were considered significant when $P < 0.10$, and tendency when $P < 0.15$. Experimental diets did not affect molar proportion of acetate (54.54 ± 1.05 mM/100mM), propionate (32.23 ± 2.00 mM/100mM), butyrate (9.07 ± 0.89 mM/100mM), isovalerate (1.61 ± 0.25 mM/100mM) and valerate (1.42 ± 0.12 mM/100mM). There was a tendency for quadratic effect of levels of narasin on isobutirate (C: 0.64; M: 0.72; N5: 0.85; N10: 0.70; N15: 0.70 mM/100mM; $P = 0.11$). Acetate:propionate ratio (2.04 ± 0.14) and ruminal pH (5.94 ± 0.07) were not affected by experimental diets. Animals fed the diet containing monensin tended to had lower total SCFA than animals fed narasin (C: 113.21; M: 102.24; N5: 110.22; N10: 111.32; N15: 109.25 mM/l; $P = 0.11$). There was no interaction between experimental diets and days for all variables. Monensin and narasin had a tendency to alter SCFA profile without affecting ruminal pH in lambs fed high concentrate diets during dietary adaptation.

Key Words: ionophores,lambs, rumen pH.

1346 Effect of narasin on rumen metabolism and dry matter intake in wethers fed high-forage diets. D. M. Polizel[1], M. F. Westphalen*[2], A. A. Miszura[1], M. H. Santos[1], R. G. Silva[1], A. V. Bertoloni[1], G. B. Oliveira[1], M. V. Biehl[2], M. V. C. Ferraz Junior[1], A. V. Pires[2], and I. Susin[2], *[1]FMVZ/University of Sao Paulo, Pirassununga, Brazil, [2]ESALQ/University of Sao Paulo, Piracicaba, Brazil.*

The objectives in this trial were to determine the effects of increasing levels of narasin on short chain fatty acid profile, pH and rumen protozoa concentration in whethers fed high-forage diets. Five White Dorper × Santa Inês wethers (BW 68.7 ± 2.1 kg), cannulated in the rumen, were used in 5 × 5 Latin Square design. Animals were fed daily and diet was composed of coastcross hay (91.0% DM; 67.2% NDF; 32.1% ADF; 6.8 CP; 5.5% ash). Narasin was offered twice a day and levels were 0 (control), 8, 16, 24 or 32 mg/kg DM, corresponding to 0, 80, 160, 240, and 320 mg of Zimprova 100®. The delivery vehicle of narasin was 20 g of ground corn containing the set dosage of narasin in 1 kg of DM. Every experimental period lasted 20 d and rumen fluid was collected in the last day, every 3 h, starting prior feeding, 3, 6, 9, and 12 h after feeding. Dry matter intake (DMI) was measured on d 20. Short-chain fatty acids (SCFA) and pH were analyzed as repeated measures over time. Protozoa concentration was analyzed at 3 h after feeding. Data were analyzed using MIXED procedure (SAS Inst. Inc.) and the LSMEANS option was used to generate individual means. Orthogonal polynomials for diet responses were determined by linear and quadratic effect. The effects were considered significant when $P < 0.10$. Increasing levels of narasin did not affect DMI (1.00 ± 0.12 kg/d; $P = 0.45$). There was an increased linear response for total SCFA (77.24, 81.30, 90.04, 83.65, 89.60 mM/L, $P = 0.02$). Acetate (78.40 ± 0.64 mM/100Mm, $P = 0.93$), propionate (15.03 ± 0.41 mM/100mM, $P = 0.79$), isobutyrate (0.62 ± 0.11 mM/100mM, $P = 0.97$), butyrate (4.34 ± 0.24 mM/100mM, $P = 0.62$), isovalerate (0.97 ± 0.19 mM/100mM, $P = 0.95$), valerate (0.64 ± 0.07 mM/100mM, $P = 0.30$) acetate-propionate ratio (5.28 ± 0.28, $P = 0.76$), pH (6.64 ± 0.13, $P = 0.46$) and rumen protozoa concentration ($2.44 \pm 0.22 \times 10^5$/ml, $P = 0.69$) were unaffected by the experimental diets. Increasing doses of narasin resulted in higher concentration of total SCFA.

Key Words: SCFA, ionophore, protozoa

1347 Monensin and levels of narasin on rumen metabolism in lambs fed high-concentrate diets.

D. M. Polizel*[1], S. S. Marques[2], M. F. Westphalen[3], M. H. Santos[1], M. V. C. Ferraz Junior[1], M. V. Biehl[3], R. G. Silva[1], I. Susin[3], and A. V. Pires[3], *[1]FMVZ/University of Sao Paulo, Pirassununga, Brazil, [2]Ponta Grossa State University, Ponta Grossa, Brazil, [3]ESALQ/University of Sao Paulo, Piracicaba, Brazil.*

The objective in this trial was to determine the effects of monensin and narasin on rumen metabolism of lambs fed high-concentrate diets. Thirty Dorper × Santa Inês lambs, cannulated in the rumen, were assigned to a randomized complete block design, defined initial BW. Animals were fed daily and diets were composed of 90% concentrate and 10% hay. Diets were control, monensin (25 mg/kg DM) and doses of narasin (5, 10, or 15 mg/kg DM), corresponding to the experimental diets C, M, N5, N10, and N15, respectively. The experiment lasted 29 d. The first 24 d were used to adapt the lambs with experimental diets and the remaining 5 d were used for data collection. In the last day, rumen fluid was collected every 3 h, starting prior feeding, 3, 6, 9, and 12 h after feeding. Short chain fatty acids (SCFA) profile and pH were determined. Data were analyzed using the MIXED procedure (SAS). There were 2 contrasts previously defined (I: control vs. ionophores; II: monensin *vs*narasin). The effects of levels of narasin (control, N5, N10, and N15) were evaluated using linear and quadratic orthogonal contrasts. The effects were considered significant when $P < 0.10$. Animals fed diets containing ionophores had higher molar proportion of propionate than animals fed the control diet (C: 26.6; M: 33.3; N5: 31.0; N10: 33.7; N15: 30.2 mM/100mM; $P = 0.07$). There was an increased isobutyrate for animals fed narasin then animals fed monensin (C: 0.8; M: 0.7; N5: 0.8; N10: 0.8; N15: 0.8 mM/100 mM; $P = 0.06$). Diets containing monensin had lower butyrate than narasin ($P = 0.08$), however, the control diet had higher butyrate than the diets containing ionophore (C: 13.5; M: 9.4; N5: 11.5; N10: 11.1; N15: 11.4 mM/100 mM; $P = 0.02$). Experimental diets did not affect acetate (50.0 ± 2.4; $P = 0.41$), isovalerate (1.5 ± 0.2; $P = 0.70$) and valerate (1.3 ± 0.1; $P = 0.42$). Animals fed diets containing ionophore had lower acetate:propionate ratio than animals fed the control diet (C: 2.2; M: 1.7; N5: 1.9; N10: 1.6; N15: 2.0; $P = 0.06$). There was a decreased linear response of narasin levels on total SCFA (C: 133.4; M: 124.3; N5: 135.6; N10: 122.4; N15: 115.7; $P = 0.02$). Treatments did not affect ruminal pH (5.9 ± 0.1; $P = 0.90$). Monensin and narasin altered SCFA profile without effecting ruminal pH in lambs fed high-concentrate diets.

Key Words: acetate-propionate ratio, pH, propionate.

1348 Daily supplementation with an active dry yeast improved feed efficiency in lactating dairy cows.

N. D. Walker*[1] and W. V. Straalen[2], *[1]AB Vista Feed Ingredients, Marlborough, United Kingdom, [2]Schothorst, Lelystad, Netherlands.*

Research has demonstrated that supplementation with an active dry yeast (ADY) can have a positive effect on dairy cow performance. The aim of the current experiment was to test a new ADY which had been selected because it improved rumen fermentation in vitro and to measure its effects in vivo. The trial was split into a 3 wk pre-period followed by a 12 wk test period, which was further split into 3 wk periods. Forty-four cows (16 primiparous, 28 multiparous cows) with average DIM = 123 (ranging from 55 to 165) were allocated to 22 blocks on the basis of calving date, parity, weight, milk production and composition in the pre-period. Within block, cows were randomly assigned to either control (CTL) or treatment (LY). In the test period, CTL received 100 g of wheat pollards daily and the LY received 97 g wheat pollards + 3 g live yeast, delivering 60 billion cfu/cow/day, top-dressed on a partial TMR consisting of (on a DM basis) corn silage (65%), grass silage (29%) and protein supplement (6%). Concentrate requirement was delivered via an automated dispenser 3 times daily. Throughout the trial, individual milk yield, weight, and DMI (measured via Calan gates) was measured daily, averaged weekly. Milk composition was measured 4× a week, and BCS every 3 wk. Statistical analysis was performed by ANOVA using the pre-period as a covariate to assess LY effect on feed intake, milk production, milk composition and energy balance. Significance was declared at $P < 0.05$ and trends discussed at $0.05 < P < 0.1$. Results showed that over the total test period, LY tended to increase FPCM (32.25 vs. 31.53 kg/day, $P = 0.09$) and significantly increased feed efficiency kg FPCM yield/kg DMI (1.47 vs. 1.43, $P = 0.032$). Interestingly, in the last 3 wk, the effects on FPCM were higher, and the effects of LY reached significance (31.4 vs. 30.0, $P = 0.025$), driven by a significant increase in butterfat yield (1259 vs. 1193 g/day, $P = 0.009$). There were no significant effects of treatment on any of the other parameters measured. To conclude, daily supplementation of live yeast resulted in a significant increase in feed efficiency. There appeared to be a lag effect on performance and it was hypothesized this was due to time needed for the rumen microflora to adapt. Further trials will test this hypothesis.

Key Words: feed efficiency, lactation, yeast

1349 Effect of saponite (EcoMix) on toxin binding capacity, ruminal fermentation, diet digestibility and growth of steers fed high concentrate diets.

N. A. Lancaster*[1], D. Silva Antonelo[2], C. R. Muegge[1], and J. P. Schoonmaker[1], *[1]Purdue University, West Lafayette, IN, [2]University of Sao Paulo, Pirassununga, Brazil.*

Three experiments were conducted to determine the effect of increasing concentrations of the clay mineral, saponite (EcoMix, United Minerals Group), on toxin binding, ruminal fermentation, diet digestibility and growth of feedlot cattle. In experiment one, 150 mg of EcoMix was incubated in 10 mL of rumen fluid with 3 incremental concentrations of aflatoxin B_1 (AFB_1) or ergotamine tartate (ET) to determine binding capacity. In experiment two, 6 steers (initial BW = 596 ± 22.2 kg) were randomly allotted to 3 treatments in a replicated 3 × 3 Latin square design (21-d periods) to determine the effects of increasing amounts of EcoMix (0, 1, or 2%) on ruminal pH, VFA, and nutrient digestibility. EcoMix was top-dressed on an 80% concentrate diet at a rate of 0, 113, or 226 g/steer/d to achieve the 0, 1, and 2% treatments, respectively. In experiment three, 72 Angus × Simmental steers were blocked by BW (395 ± 9.9 kg) and allotted to the same 3 treatments (4 pens/treatment, 6 steers/pen) to determine the effects of EcoMix on performance. Steers were slaughtered at a target BW of 606 kg. EcoMix was able to effectively bind AFB_1 and ET at concentrations well above the normal physiological range (52 and 520 μg/mL), but % adsorption was decreased to 35.5 and 91.1% at 5200 μg/mL ($P < 0.0001$) for AFB_1 and ET, respectively. EcoMix linearly decreased ruminal lactate and propionate, and VFA production efficiency ($P \leq 0.04$), linearly increased formate and acetate:propionate ($P \leq 0.03$), and tended ($P = 0.07$) to linearly increase butyrate. EcoMix tended to linearly increase organic matter and crude protein apparent digestibility ($P = 0.06$). Ruminal pH, urine pH, and other digestibility measures did not differ among treatments ($P \geq 0.15$). During the first month there was a quadratic response of EcoMix on ADG ($P = 0.009$) and gain:feed ($P = 0.0003$), increasing from 0 to 1% EcoMix, and then decreasing from 1 to 2% EcoMix. However, during the second month, EcoMix decreased ADG and gain:feed linearly ($P \leq 0.03$) and overall ADG, DMI, or gain:feed were not impacted ($P \geq 0.46$). EcoMix linearly decreased marbling score ($P = 0.05$). Hepatic enzyme activity did not differ among treatments on d 0 or at slaughter ($P \geq 0.15$). In conclusion, EcoMix effectively binds ruminal toxins, decreases ruminal lactate, and improves performance during adaptation to a high concentrate feedlot diet.

Key Words: clay mineral, saponite, feedlot performance

1350 Use of *Aspergillus oryzae* extract containing α-amylase activity in finishing diets for Nellore cattle.

C. F. Nascimento*[1], L. L. Oliveira[2], W. D. C. Amancio[2], N. C. D. Silva[1], F. D. Santos[2], P. H. Gonçalves[1], G. R. Siqueira[3], and F. D. D. Resende[3], *[1]UNESP- Univ Estadual Paulista, Jaboticabal, Brazil, [2]UNIFEB, Barretos, Brazil, [3]APTA- Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil.*

The objective was to evaluate effects of supplementing *Aspergillus oryzae* extract containing α-amylase activity (Amaize®) in high concentrate diets fed finishing diets for Nellore cattle. The experiment was conducted at the Experimental Confinement Unit of Agência Paulista de Tecnologia dos Agronegócios-Colina/SP/Brasil. Fifty-four Nellore bulls (average age 24 mo.) with initial body weight 353 ± 13 kg were used in the study. Six animals were slaughtered initially (for subsequent calculation of carcass gain) and 48 individually-penned animals were used to evaluate performance. The experimental design was a randomized complete block with two treatments: 1) Control– no enzyme, and 2) Enzyme −5 g/Amaize® (Alltech Inc) per head daily. The experiment lasted 96 d, (24 d adaptation and three periods of 24 d each). The diet consisted

Table 1350.

Table 1. Means and mean standard error of Nellore performance variables in treatment with absence (control) and presence of *Aspergillus oryzae* extract containing α-amylase activity (Amaize®) with high concentrate in finishing diets for Nellore cattle

Variables	Tratament		SEM	*P-Value*
	Control	Enzyme		
DMI, kg/d	8.32	9.07	0.44	0.11
ADG, kg/d	1.187	1.330	0,055	0.08
G:F, kg ganho/kg MS	0.142	0.146	0.002	0.44
HCW, kg	267	276	4.74	0.09
Dressing Percentage, %	57.2	57.4	0.40	0.65
Carcass gain, kg	81.5	90.0	4.76	0.09
ADG Carcass, kg/d	0.87	0.96	0.05	0.09

Differences considered statistically significant at the 10% significance by t test.
ADG= average daily gain; DMI = dry matter intake; G:F = gain:feed; FC = feed conversion; HCW= hot carcass weight; Dressing Percentage = ((HWC/BW)*100); Carcass gain = (HWC – Initial estimated carcass weight (which was obtained by regression of carcass weight of six animals slaughtered at the beginning of the experiment).

of sugarcane bagasse (12.47% DM), ground corn (4 mm-hammer mill) (62.59% DM), citrus pulp (16.96% DM) and protein blend (52% soybean meal, 12% Optigen® (sustained release N), 36% mineral salt. Forage:concentrate was 12:88 and contained MS: 14.1% CP, 23.5% NDF and 2.62 Mcal/kg. The data were analyzed using the MIXED procedure with a fixed effect of treatment and weight block as a random effect, the differences between the means were compared by *t* test at 10% probability. No differences were observed for DMI, G:F and dressing percentage between animals receiving enzymes compared to controls (Table 1). However, there was an effect of Amaize on ADG ($P = 0.08$), which represented ~140 g over ADG when compared to controls. HCW, carcass gain and carcass ADG were numerically superior in cattle fed Amaize in carcass weight, and slaughter with an additional average weight of ~9 kg, which represents 3.37% more when compared to control weight values. Therefore the supplementation of *Aspergillus oryzae* extract containing α-amylase activity (Amaize®) with high concentrate finishing diets improves the performance of Nellore cattle.

Key Words: additives, enzymes, performance

1351 Inclusion of pelleted calcium hydroxide-treated corn stover in lactating Holstein cow diets: Effects on milk production and milk composition.

B. A. Casperson*[1], A. E. Wertz-Lutz[2], and S. S. Donkin[1], *[1]Purdue University, West Lafayette, IN, [2]ADM Alliance Nutrition, Quincy, IL.*

Chemical treatment of corn stover with 6.6% $Ca(OH)_2$ (TCS) increases the availability of cellulose and hemicellulose, improving the feeding value of this abundant crop residue. The low bulk density limits transportation and the broader use of TCS. Manufacturing techniques were used to densify and fortify TCS to improve its nutritional value potentially making TCS an alternative to traditional forage sources. The objectives of this study were to evaluate the effects of feeding TCS as part of a pelleted feed supplement blended to have a nutrient profile that resembles corn gluten feed, a common byproduct feed used in US dairy and beef operations. Eight mid-lactation multiparous Holstein cows were used in a replicated 4 × 4 Latin square consisting of four 21-d periods to evaluate the effects of feeding pelleted TCS (PTCS) on milk production and composition. Diets were: 1) control (CON) containing corn silage and alfalfa haylage as the primary forages, or 2) the partial replacement of these forages with 21 (21PTCS) or 3) 40% (40PTCS) of the diet DM with PTCS, or 4) a combination of all ingredients used to manufacture PTCS that were not pelleted and fed at 40% (40NPTCS) of the diet DM. Milk production and 4% energy corrected milk did not differ ($P > 0.05$) among treatments. Compared to the CON, DMI was reduced ($P < 0.05$) with the inclusion of TCS regardless of physical form in the 40 PTCS and 40 NPTCS diets but was not different in the 21 PTCS diet (24.2, 23.0, 21.7, 21.3, and ± 0.97 kg/d, CON, 21PTCS, 40PTCS, and 40NPTCS, respectively). Milk fat percentage was reduced ($P < 0.05$) with the inclusion of TCS in the 21PTCS and 40PTCS diets and tended ($P = 0.09$) to be reduced in the 40NPTCS diet. However, milk fat yield was only reduced when cows were fed the 40PTCS diet. Percent milk protein and percent milk lactose were not affected by the inclusion of TCS in the diet ($P > 0.05$). Data indicate that partial replacement of corn silage and alfalfa haylage with a pelleted feed supplement containing TCS has no impact on 4% energy corrected milk yield although inclusion of PTCS at 40% of the diet DM reduces milkfat yield. These results suggest pelleted feed supplements containing TCS may serve as a valuable replacement for a portion of typical forages fed to lactating dairy cows.

Key Words: pelleted corn stover, milk fat, alternative forage

1352 Influence of adding slow release urea and zeolite in growth performance and carcass traits of feedlot lambs.

H. Dávila-Ramos*[1], J. N. Sanchez-Perez[2], J. C. Robles-Estrada[3], F. G. Rios-Rincon[4], J. J. Portillo-Loera[5], and A. Plascencia[6], *[1]Universidad Autonoma de Sinaloa, Culiacán, Sinaloa, Mexico, [2]Universidad AutÃ³noma de Sinaloa, Sinaola, Mexico, [3]Universidad Autonoma de Sinaloa, Culiacan, Mexico, [4]Universidad Autonoma de Sinaloa, Culiacn, Sinaloa, Mexico, [5]Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico, [6]Instituto de Investigaciones en Ciencias Veterinarias. Universidad AutÃ³noma de Baja California, Mexicali 21100, Baja California, MÃxico, MEXICALI, BC, Mexico.*

Twenty-four Pelibuey × Katahdin (45.4 ± 1.1 kg) crossbred male lambs were used in a 42-d feeding trial (6 pens per treatment in a randomized complete block design), to evaluate the influence of slow release urea and zeolite on growth performance and carcass characteristics. Lambs were fed a dry-rolled corn-based finishing diet (1.42 Mcal/kg of NEg; 14.6% of PC). Treatments consisted: 1) Control (C), 2) Slow release urea (SRU) (0.8%), 3) Zeolite (Z) (3%) and 4) combination of SRU and Z; DM intake averaged 1.282 ± 0.042 kg/d and was not affected ($P = 0.40$) by treatments. Compared with control lambs, SRU supplementation increased gain efficiency (13.14%, $P < 0.04$), average daily gain (17.8%, $P < 0.03$) and final body weight (3.60%, $P < 0.04$). Combination of slow release urea and zeolite supplementation affected ($P = 0.032$) hot carcass weight, longissimus muscle area (LM) and carcass dressing percentage (2.3%, $P = 0.04$), kidney-pelvic fat was not affected. Addition of slow release urea and zeolite combination improved growth performance and carcass traits of feedlot lambs.

Key Words: lambs, slow-release urea and zeolite

1353 Effect of different doses of a *Bacillus*-based probiotic on the in vitro digestibility of concentrates and forages. C. A. Oliveira[1], D. O. Sousa[1], J. F. Penso[1], P. F. Menegucci[2], and L. F. P. Silva[*1], [1]*University of Sao Paulo, Pirassununga, Brazil,* [2]*Chr. Hansen, Valinhos, Brazil.*

The objective was to evaluate the effect of different doses of probiotic containing $1.6x10^9$ CFU/g of *Bacillus licheniformis* and $1.6x10^9$ UFC/g of *Bacillus subtilis* (BioPlus® PS, Chr. Hansen) on in vitro digestibility of concentrates and forages. The feedstuffs analyzed included 2 types of concentrates: corn and sorghum, and 2 types of forages: sugarcane silage and *Megathirsus maximus* cv. Mombaça (mombaça-grass). The probiotic was added to the ruminal fluid simulating doses of 0, 1, 2, and 3 g head^{-1} d^{-1}. The doses of probiotic added to the rumen fluid was calculated supposing a volume of 37 L of rumen fluid per animal. Dry matter, NDF, and starch in vitro digestibility of feedstuffs were determined in 0.5 g of sample, in triplicate, after incubation for 6 and 12 h (concentrates); or for 24 and 48 h (forages), using the Daisy Incubator (ANKOM®Technology Corp., Fairpoint, NY, USA). The residues after fermentation were analyzed for NDF in the case of forages, and for starch in the case of concentrates. The experiment was repeated three times. Statistical model included the fixed effect of probiotic, feedstuff, and interaction between both factors, with the experiment repetitions as the random effect. Addition of probiotic improved 24-h NDF digestibility of both roughages (P = 0, 05), without a Dose × Feedstuff interaction (P = 0.36). There was a cubic effect of dose of probiotic on 24-h NDF digestibility, with the dose of 1 g head^{-1} d^{-1} promoting higher NDFD than the control (20.2 vs. 16.3%, P = 0.01). When analyzed after 48 h of incubation, there was a significant Dose × Feedstuff interaction (P < 0.01). Addition of 1 g head^{-1} d^{-1} of probiotic increased (P < 0.01) 48-h digestibility of mombaça-grass, but not of sugarcane silage (P = 0.73). Considering the effects on starch digestibility of concentrates, there was no effect of probiotic after 6 h of incubation (P > 0.05). However, after 12 h of incubation, there was a positive linear effect of addition of probiotic on starch digestibility of both concentrates (P < 0.01), with no Dose × Feedstuff interaction (P = 0.50). The addition of 3 g head^{-1} d^{-1} of probiotic increased by 10.9% starch digestibility after 12 h of incubation. In conclusion, addition of increasing doses of a bacillus based probiotic promoted a cubical increase in NDF digestibility of roughages, and a linear increased in starch digestibility of concentrates.

Key Words: fiber digestibility, starch digestibility, probiotic

1354 Net choline absorption of abomasally infused choline and rumen-protected choline in the lactating dairy cow. M. J. de Veth[*1], V. M. Artegoitia[2], S. R. Campagna[2], H. Lapierre[3], F. M. Harte[4], and C. L. Girard[3], [1]*BioNarus LLC, Cary, NC,* [2]*University of Tennessee, Knoxville,* [3]*Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada,* [4]*The Pennsylvania State University, University Park.*

Choline metabolites have a critical role in many biological processes and choline supplementation to the peripaturient dairy cow improves hepatic lipid metabolism. However, variability in responses to choline supplementation has highlighted a lack of understanding of choline absorption and metabolism in the lactating dairy cow. Our objective was to estimate net choline absorption by measuring net portal fluxes of choline and choline metabolites in cows receiving either dietary supplements of rumen-protected choline (RPC) or abomasal infusion of choline (AIC). Five lactating Holstein cows (237 ± 17 DIM) were used in a 5 × 5 Latin Square design, with 5-d treatment periods and a 2-d interval between periods. Treatments were 1) control (0 g/d choline), 2) 12.5 g/d choline fed as RPC, 3) 25 g/d choline fed as RPC, 4) 12.5 g/d choline provided as AIC, 5) 25 g/d choline provided as AIC. Choline chloride (CC) was the choline form for both sources; RPC (Reashure, Balchem Corporation) and AIC (CC70, Balchem Corporation) contained 21.6% and 52.3% choline ion, respectively. Cows were fed every 2 h to minimize post-prandial variation. On the last day of each period 9 blood samples were collected simultaneously from an artery and portal vein at 30-min intervals and analyzed for betaine, free choline (Cho), lysophosphatidylcholine, phosphocholine and sphingomyelin, using liquid chromatography-tandem mass spectrometry. The net portal flux of Cho (control- 1.7 mmol/h) increased linearly (P < 0.001) with AIC (4.0 and 7.1 mmol/h for 12.5 and 25 g/d AIC, respectively) indicating that the net absorption of Cho was 54% (95% confidence interval of 30 to 79%). No relationship was found between dose of RPC and net portal flux of Cho (P = 0.52). Net portal fluxes of the choline metabolites were not altered by choline treatment. However, the plasma arterial concentrations of betaine and phosphocholine increased (P < 0.001) in response to AIC: 30.6, 102.7 and 151.2 μ*M* and 3.47, 4.21 and 4.96 μ*M* for control, 12.5 and 25 g/d. In addition, plasma arterial concentration of phosphocholine increased (P < 0.01) with RPC, averaging 3.47, 3.81 and 4.08 μ*M* for control, 12.5 and 25 g/d, respectively). The results of this study suggests that AIC taken up by the gastrointestinal wall reached the portal circulation only as Cho and the incomplete recovery may indicate that a portion of AIC is metabolized by the portal-drained viscera of the lactating dairy cow.

Key Words: bioavailability, choline, cow

1355 Effects of Trigestamace on performance of lactating dairy cows. M. M. Masiero*[1], A. L. Kenny[1], R. L. Barnett[1], R. Morrison[2], and M. S. Kerley[1], [1]*University of Missouri, Columbia,* [2]*R&D LifeSciences, Menomonie, WI.*

Objective of this experiment was to determine if Trigestamace (mannan-oligosaccharide, β glucans and enzyme preparation), fed for 60 d to lactating dairy cows, altered milk production, efficiency and composition in early lactation (study initiated 14 to 45 d in milk). Sixty lactating Holstein cows were stratified by previous milk production and parity (2.2 ± 0.03 lactation number) and assigned randomly to control (CON) or CON with Trigestamace included (TRT) diets. Both diets (CON, 48.1% DM, 14.4% CP; TRT 48.1% DM, 15.0% CP) contained (DM basis) 32.5% alfalfa hay, 21.2% corn silage, 13.8% ground corn, 3.8% soybean hulls, 2.6% brewers grain, 26% protein and mineral. Treatment was added at a rate of 0.032% in the diet (as fed basis) providing about 17.7 g/d of Trigestamace based on feed intake. Cows were fed using Calan gates and individual intake measured. Milk yield was recorded twice daily and milk sampled once weekly and analyzed for protein (%), fat (%), lactose (%), somatic cell count (cells/mL) and milk urea nitrogen (%). Data were analyzed as a randomized complete design. Milk yield did not differ (P = 0.50; SEM = 0.22; CON 44.5, TRT 44.2 kg/d) between diets. Dry matter intake was greater (P = 0.01; SEM = 0.11) for cows fed CON (24.6 kg/d) compared to TRT (24.2 kg/d). Milk efficiency was greater (P = 0.02; SEM = 0.007) for cows fed TRT diet (1.86 kg milk/kg DMI) compared to CON (1.83 kg milk/kg DMI). Energy corrected milk (P = 0.97; SEM = 1.44; CON 43.52, TRT 43.44 kg/d) and 3.5% fat corrected milk (P = 0.93; SEM = 1.53; CON 45.1, TRT 44.9 kg/d) did not differ between diets. Milk fat (P = 0.92; SEM = 0.09; CON 3.80%, TRT 3.78%), milk protein (P = 0.42; SEM = 0.03; CON 2.79, TRT 2.82%), lactose (P = 0.59; SEM = 0.02; CON 4.89, TRT 4.91%), milk urea nitrogen (P = 0.96; SEM = 0.32; CON 13.3, TRT 13.4%) and somatic cell count (P = 0.89; SEM = 26.8; CON 79,779, TRT 71,837 cells/mL) did not differ between diets. In conclusion, adding Trigestamace to an early lactation dairy cattle diet reduced DMI without changing milk yield, resulting in a greater milk efficiency.

Key Words: milk performance, mannan-oligosaccharide, β glucans

1356 Effect of imprinted polymer based ergot-alkaloid adsorbent on in vitro ruminal fermentation. M. B. Kudupoje*, *Alltech-University of Kentucky Nutrition Research Alliance, Lexington.*

Previously, we have described the development and characterization of a synthetic polymer designed as an ergot-alkaloid adsorbent. Here, effects of ergotamine imprinted (MIP) and non-imprinted (NIP) methacrylate based polymer adsorbents on in vitro ruminal fermentation were evaluated in an experiment with a completely randomized design. Each adsorbent was evaluated at four different inclusion levels (0.3, 3, 30, 300 mg/0.5 g DM) and compared with a control which contained no adsorbent. Ruminal fluid for inoculum was pooled from 4 steers grazing endophyte-free fescue. Triplicate vessels were inoculated for each treatment in the 2 × 4 + 1 treatment structure. In each vessel, strained ruminal fluid (20 mL) was diluted with buffer (80 mL) under anaerobic conditions and incubated for 30 h at 39°C with 500mg (DM) alfalfa hay substrate. Gas pressure was monitored using an ANKOM RF gas production system at 1 min intervals. Fluid samples were collected following termination of fermentation at 30 h for ammonia-N, VFA and pH measurement. The cumulative gas production and production rate were determined using a Fitzhugh model [$y = (1 \pm e^{-rt})^n$] fit using nonlinear least squares methods. Statistical analysis was conducted using the GLM procedure of SAS, with model terms for polymer type, inclusion amount, and their interaction and orthogonal polynomial contrasts were used to evaluate effects of polymer inclusion level. There were no interactions ($P > 0.10$) between polymer type and inclusion level and no differences ($P > 0.10$) between polymer types. Although there was a quadratic effect ($P < 0.05$) on gas production rate with increasing polymer inclusion level, total gas production (plateau) was unaffected ($P > 0.10$) by inclusion level. Polymers did not affect ($P > 0.10$) total or individual VFAs or ammonia-N concentrations at any inclusion level. The pH declined linearly ($P < 0.01$) with increasing amount of polymer. However, given the logarithmic increase in polymer dose level, the influence on pH was minor (< 0.07 pH units) for all except the 300 mg inclusion level, which depressed pH an average of 0.24 units relative to control. Supplementation of methacrylate based polymer at inclusion rates from 0.3 to 300 mg/500 mg DM did not affect VFA profiles, total VFA concentrations, ammonia-N, or total gas production in rumen fluid containing alfalfa hay substrate. High inclusion levels of both imprinted and non-imprinted polymers lowered pH. However, the inclusion level at which this effect was observed far exceeds levels that would be used in practical supplementation strategies.

Key Words: Ergot alkaloid imprinted polymer rumen fermentation

1357 Effects of *Ascophyllum nodosum* meal and monensin on performance and iodine metabolism in lactating dairy cows. S. F. Reis[*1], A. F. Brito[1], C. P. Ghedini[1], D. C. Moura[2], and A. S. Oliveira[3], *[1]University of New Hampshire, Durham, [2]Universidade Federal de Mato Grosso, Cuiabá, Brazil, [3]Instituto de Ciências Agrárias e Ambientais, Universidade Federal de Mato Grosso– Campus Sinop, Sinop, Brazil.*

Ascoplyllum nodosum meal (ANOD) is a mineral-rich supplement with antimicrobial and antioxidant properties. The objective of the current study was to evaluate the impact of incremental amounts of ANOD on performance and iodine metabolism in lactating dairy cows. It was also of particular interest to compare the effects of ANOD against the ionophore monensin (MON) on animal performance. Five ruminally-cannulated lactating Jerseys cows were randomly assigned to 1 of 5 dietary treatments: 0 g (negative control), 57 g, 113 g, or 170 g of ANOD or 300 mg of MON (positive control) in a 5 × 5 Latin square design. Each experimental period lasted 28 d with 21 d for diet adaptation and 7 d for data and sample collection. Treatments were administered daily placed directly in the rumen. Cows were fed a TMR consisted (DM basis) of 40.5% mixed-mostly grass haylage, 25.5% corn silage, 21% corn meal, 3.5% roasted soybean, 7.5% soybean meal, and 2.0% minerals-vitamins premix. The TMR averaged (DM basis) 15.8% CP, 37.3% aNDFom, and 24.8% ADF. Milk samples were collected and analyzed for components using mid-infrared reflectance spectroscopy. Spot urinary and fecal grab samples were collected with internal markers used to estimate urinary volume (creatinine) and fecal output of DM (indigestible ADF). Blood was collected approximately 4 h after the morning feeding. Milk, feces, urine, and serum were analyzed for iodine using inductively coupled plasma mass spectrometry. The degrees of freedom for treatment were partitioned into 4 single-degree-of-freedom non-orthogonal contrasts: linear, quadratic, ANOD diets vs. MON diet, and 170 g ANOD diet vs. control diet. Results are shown in Table 1. Dry matter intake and serum concentrations of T_3 and T_4were not affected by treatments. Milk yield, concentrations and yields of milk fat and protein, and MUN responded quadratically in cows fed increasing amounts of ANOD. Iodine output in milk, urine, and feces, and serum iodine concentration increased linearly with feeding incremental amounts of ANOD. Concentrations of milk fat, protein, MUN, and yield of milk fat were greater when feeding MON vs. ANOD, and the difference was particularly larger when comparing MON vs. 170 g ANOD. Overall, ANOD supplementation linearly increased the concentration of iodine in serum, and the output of iodine in milk, feces, and urine. Feeding MON improved concentration and yields of milk components, but increased MUN when compared with ANOD.

experiment consisted of five 14 d periods in which d 1 through 7 of each period were considered for data collection and d 8 through 14 were considered a wash-out phase. In each period, cows were randomly assigned to 1 of 5 dietary treatments: 1) control (CON), consisting of a basal total mix ration (TMR); 2) high dose NSP diet (NSP-1%), consisting of TMR plus 230 g of NSP; 3) aflatoxin diet (AFD), consisting of the TMR plus AF challenge; 4) low dose NSP with AF (NSP-0.5%+AFD), composed of TMR plus 115 g of NSP and AF challenge; 5) high dose NSP with AF (NSP-1%+AFD), consisting of TMR plus 230 g of NSP and AF challenge. Feed intake was recorded daily, TMR, milk and fecal samples were collected on d 6 and 7 of each period. Indigestible acid detergent fiber was used as an internal marker. Data were analyzed using the MIXED procedure of SAS where square, period within square and treatment were fixed effects and cow within square was random. Feed intake ($P = 0.34$) and fecal output ($P = 0.74$) were similar across treatments and averaged 19.7 ± 0.56 kg/d and 7.2 ± 0.56 kg/d, respectively. Digestibility of dry matter ($P = 0.75$), acid detergent fiber ($P = 0.74$), neutral detergent fiber ($P = 0.51$), and organic matter ($P = 0.75$) was similar across treatments averaging 64.0 ± 2.0%, 40.0 ± 3.2%, 41.6 ± 2.9%, and 68.0 ± 1.6%. Addition of NSP reduced milk AFM_1 from 1.10 ± 0.06 µg/L with the AF diet to 0.58 and 0.32 ± 0.06 µg/L with the NSP-0.5%+AF and NSP-1%+AF diets, respectively with no effect on milk yield. These results demonstrate that inclusion of calcium montmorillonite clay is an effective way to reduce aflatoxin excretion in milk with no deleterious effects digestibility of nutrients by dairy cows.

Key Words: food safety, mycotoxins

1359 Impact of a ferulic acid esterase producing lactobacilli on nutrient digestion of barley silage.

L. Jin[1], Y. Wang[*2], and T. A. McAllister[3], *[1]Lethbridge Reserarch and Development Centre, AAFC, Lethbridge, AB, Canada, [2]Lethbridge Reserach and Development Centre, AAFC, Lethbridge, AB, Canada, [3]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, Lethbridge, AB, Canada.*

Ferulic acid esterase (FAE) producing *Lactobacillus buchneri* inoculants have been shown to improve aerobic stability and ruminal fiber digestion. This study aimed to assess the effects of a FAE-producing inoculant applied at ensiling on rumen metabolism and nutrient total tract digestibility of whole crop barley silage. Approximately 100 tonnes of whole crop barley was cut at mid-dough and ensiled without (Control) or with a FAE producing-*L buchneri* mixed inoculant (Inoculated) in bunker silo. A crossover experiment was conducted using 8 cannulated heifers fed diets containing 73% (DM basis) of either control or inoculated silage that was ensiled for 104 d. Each period consisted of a 10-d adaption, 2-d sampling of rumen fluid and 7-d for measurement of digestibility using chromium oxide (Cr_2O_3) as an indigestible marker. Inoculated silage contained greater ($P < 0.01$) concentrations of acetic acid, propionic acid, NDF, and ADF concentration, but less ($P < 0.001$) water soluble carbohydrate than control silage after 104-d ensiling. Heifers fed diets containing inoculated silage had lower ($P < 0.05$) DMI than those fed the control diet, likely due to greater concentrations of acetic and propionic acid. Cattle consuming both diets had similar ($P > 0.05$) DM, NDF, ADF and CP digestibility, suggesting that the inoculant had no effects on total tract digestibility of these nutrients. Both groups of cattle had similar ($P > 0.05$) ruminal pH, protozoal numbers and fibrolytic enzyme activity. Ruminal concentration of total VFA tended ($P = 0.078$) to be lower whereas NH_3 tended ($P = 0.071$) to be greater in heifers fed inoculated as compared to control silage. Ruminal molar proportion of propionate was greater ($P < 0.001$) but molar proportion of butyrate was lower ($P < 0.001$), resulting in a lower ($P < 0.05$) acetate: propionate ratio in heifers fed inoculated as compared to control silage. These results indicate that FAE-producing inoculant applied at ensiling altered fermentation from a homolactic to heterolactic pattern during ensiling, had no effect on nutrient total tract digestibility but did have a positive impact on the acetate:propionate ratio.

Key Words: ferulic esterase-producing lactic acid bacteria, barley silage, total tract digestibility, rumen metabolism

1360 Excretion of fumonisin B1 by dairy cows supplemented with calcium montmorillonite clay during a mycotoxin challenge.

E. M. Jimenez[1], A. D. Thomas[*2], C. Maki[3], S. E. Elmore[3], R. B. Harvey[4], T. Phillips[3], L. A. Kinman[1], and H. A. Ramirez Ramirez[2], *[1]Tarleton State University, Stephenville, TX, [2]Iowa State University, Ames, [3]Texas A&M University, College Station, [4]United States Department of Agriculture, College Station, TX.*

Six multiparous Holstein cows (662 ± 52 kg BW) in early lactation were used in a 2 × 2 crossover design to evaluate the effects of feeding calcium montmorillonite clay (Nova-Sil Plus, NSP) on excretion of fumonisin B1 (FB1) during a 3-d challenge consuming this mycotoxin. It was predicted that cows would consume 26 kg of dry matter, therefore NSP was fed at a dose equivalent to 0.5% of predicted dry matter intake equivalent to130 g/d. The FB1 challenge was performed by feeding 80 mg FB1/d via top dressed supplement. The experiment consisted of two 7-d periods in which d 1 through 3 of each period were considered for data collection and d 4 through 7 were considered a wash-out phase. In each period, cows were randomly assigned to 1 of 2 dietary treatments: 1) challenge diet (FBCH), consisting of a basal total mix ration (TMR) plus FB1 challenge; and 2) treatment diet with FB1 (NSP-0.5%+FBCH), consisting of basal TMR plus NSP supplement and FB1 challenge. Feed intake and

milk production were recorded daily, milk and urine samples were collected in the morning and evening from d 1 through 3 of each period. Data were analyzed using the MIXED procedure of SAS where period, treatment and period×treatment were fixed effects and cow within sequence was random. Milk yield was similar across treatments (P = 0.44) and averaged 40.5 ± 3.2 kg/d with no differences in milk composition for any treatment; presence of FB1 was not detected in milk samples. Concentration of FB1 in urine was not affected by treatment (P = 0.68) and averaged 0.51 and 0.47 ± 0.09 for FBCH and NSP-0.5%+FBCH, creatinine adjusted excretion was similar for both treatments (P = 0.86) averaging 0.89 ± 0.17 ng FB1/mg creatinine. These results demonstrate that dietary FB1 is not transferred to mammary secretions and that bovine urine is a suitable biomarker of fumonisin B1 exposure; further research is warranted to fully elucidate the effects of including calcium montmorillonite clay to reduce FB1 absorption by dairy cows.

Key Words: food safety, mycotoxins, milk quality

1361 Effect of rumen-protected *Capsicum* oleoresin on productivity and responses to a glucose tolerance test in lactating dairy cows.

J. Oh*[1], M. Harper[1], F. Giallongo[1], E. H. Wall[2], D. M. Bravo[2], and A. N. Hristov[1], [1]*The Pennsylvania State University, University Park,* [2]*Pancosma, Geneva, Switzerland.*

The objective of this experiment was to investigate the effects of rumen-protected *Capsicum* oleoresin (RPC) on productivity and responses to a glucose tolerance test in dairy cows. Nine multiparous Holstein cows (100 ± 9.1 d in milk; 665 ± 83.3 kg BW) were used in a replicated 3 × 3 Latin square design experiment balanced for residual effects with 3, 28-d periods. Treatments were 0 (control), 100, and 200 mg RPC/cow/d. RPC was mixed with a small portion of the total mixed ration and top-dressed. DMI (29.5 kg/d; SEM = 0.74) was not affected (P = 0.72) by RPC. Milk yield tended to increase (P = 0.06; SEM = 1.27) for RPC compared with the control: 42.8, 44.7, and 43.9 kg/d for the control, 100, and 200 mg RPC/cow/d, respectively. Feed efficiency was linearly increased (P < 0.01; SEM = 0.056) by RPC supplementation: 1.48, 1.52, and 1.57 kg/kg, respectively. Concentrations of fat, true protein, and lactose in milk were not affected ($P \geq 0.69$) by RPC. On the day of the glucose challenge, glucose was intravenously administered at 0.25 g/kg BW and blood samples were collected at 0, 5, 10, 15, 20, 30, 40, 50, 65, 80, and 110 min following administration. Serum glucose concentration peaked 5 min post-glucose administration. RPC did not affect serum glucose concentration during the glucose tolerance test. Insulin concentration at 5, 10, and 40 min and the area under the insulin concentration curve were lower ($P \leq 0.04$) for both RPC application rates compared with the control. Peak concentration of insulin tended to be decreased (P = 0.07) by RPC. Concentration of NEFA in serum was linearly increased (P = 0.03) by RPC at and after 65 min following glucose administration. Concentration of β-hydroxybutyrate in serum was not affected (P = 0.17) by RPC during the glucose tolerance test. In summary, milk yield and feed efficiency were increased by RPC in this experiment. RPC increased serum NEFA and decreased insulin concentration during the glucose tolerance test whereas glucose concentration was not affected by treatment. Data suggest that dietary supplementation of RPC increased insulin sensitivity and likely redirected glucose for lactose synthesis and milk production and also slightly enhanced fat mobilization in lactating dairy cows.

Key Words: capsicum, insulin sensitivity, milk production

1362 Supplementation of β-mannanase (CTCZYME) to lactating dairy cattle diets improves feed conversion efficiency and somatic cell count.

E. Kebreab*[1], T. Tewoldebrhan[1], R. Appuhamy[1], M. Niu[1], S. Seo[2], S. Jeong[2], and J. J. Lee[3], [1]*University of California, Davis, Davis,* [2]*Chungnam National University, Daejeon, The Republic of Korea,* [3]*CTC Bio Inc, Seoul, The Republic of Korea.*

Improving feed conversion efficiency (FCE) and health status of animals has economic and environmental benefit in dairy operations. Fibrolytic enzymes such as mannanases may improve nutrient digestion and utilization by releasing compounds contained within non-structural carbohydrates such as mannan and xylan, and may also help immune status. A trial was conducted to investigate the effects of β-mannanase supplementation on nutrient digestibility, FCE, and enteric methane emissions in lactating dairy cows. Twelve post peak-lactation multiparous Holstein cows producing 45.5 ± 6.6 kg/d milk at 116 ± 19.0 DIM were randomly allocated to one of 3 treatments in a 3 × 3 Latin square design with 3 18-d periods. Cows were fed the same basal diet with treatment 1 used as control and treatments 2 and 3 contained β-mannanase supplementation at 0.1% (low supplement [LS]), or 0.2% (high supplement [HS]) of DM. Effects of β-mannanase supplementation on nutrient intake and utilization, milk production efficiency, BW change, and methane emissions were determined using the MIXED procedure of SAS (version 9.4). Supplementation of β-mannanase enzyme did not affect DMI, milk yield, and milk composition. Somatic cell counts in milk was lower (P = 0.023) for cows fed the LS diet compared to cows fed control and HS diets. Methane yield (per unit of DMI) and intensity (per unit of milk yield or milk protein yield) were not affected by β-mannanase supplementation. Cows fed LS diet had lower DM, OM, and CP digestibility compared to cows fed control and HS diets. Starch, NDF, and ADF digestibility were not affected. Cows fed LS significantly improved (P < 0.05) FCE, BW gain, and efficiency of converting dietary N to milk protein compared to cows fed the control diet. β-mannanase supplementation had no effect on N excreted in

feces and urine. Dietary supplementation of β-mannanase can improve FCE, BW gain, and udder health of mid-lactating dairy cows without affecting methane emissions and manure N excretions. The role of β-mannanase supplementation may be more critical for early lactating cows, which are generally under significant metabolic and immune challenges and more likely to be in negative energy balance.

Key Words: dairy, feed efficiency, b-mannanase

1363 Effects of essential oils and exogenous enzyme in feedlot finishing cattle diets high in flint corn ground at different particle sizes.

M. A. P. Meschiatti[1], J. M. M. D. Moraes[1], T. S. Acedo[*2], L. F. M. Tamassia[2], C. S. Cortinhas[2], V. N. D. Gouvea[2], J. R. Dórea[3], and F. A. P. Santos[4], *[1]USP, Sao Paulo, Brazil, [2]DSM Nutritional Products SA, Sao Paulo, Brazil, [3]University of Wisconsin, Madison, [4]University of São Paulo, Piracicaba, Brazil.*

The objective of this study was to evaluate the interaction between 2 feed additives– MON (Sodium Monensin, Tortuga®) vs. CRINA-RUM (the combination of essential oils- Crina® Ruminants, DSM® and α-amylase- Ronozyme® RumiStar™) and 2 different groundflint corn particle sizes- ground corn (GC = 1.82 mm average particle size) vs. coarsely ground corn (CGC = 2.53 mm average particle size) on performance of finishing Nellore bulls. Two hundred fifty-six Nellore bulls (initial BW = 360 kg ± 38) were fed during 99 d with diets containing 82.5% ground corn (1.82 or 2.53 mm), 8.5% sugarcane bagasse, 5% soybean meal, 3% minerals-vitamins supplement and 1% urea. Animals were blocked based on initial BW and randomly allocated in 48 pens. Treatments were: GC + MON (1.82 mm ground corn and sodium monensin- 26 mg/kg DM), GC + CRINA-RUM (1.82 mm ground corn and the combination of essential oils- 90 mg/kg DM + α-amylase- 560 mg/kg DM), CGC + MON (2.53 mm ground corn and sodium monensin- 26 mg/kg DM) and CGC + CRINA-RUM (2.53 mm ground corn and the combination of essential oils- 90 mg/kg DM + α-amylase- 560 mg/kg DM). The data were analyzed using PROC MIXED of SAS in a 2 × 2 factorial arrangement (2 ground corn particle sizes and 2 feed additives). Pen was considered the experimental unit. No effect of treatment ($P > 0.05$) was observed for final BW. Animals fed CGC (2.53-mm) showed a tendency to greater average daily gain (ADG; $P = 0.08$) than animals fed GC (1.82 mm) – 1.60 and 1.50 kg, respectively. Effect of additive was also observed for DMI. Sodium Monensin (MON) decreased ($P = 0.013$) DMI compared to the combination of essential oils and α-amylase (CRINA-RUM) – 8.70 and 9.34 kg, respectively. No effects of treatment ($P > 0.05$) were observed on feed efficiency (G:F) and dressing percentage. There was an interaction effect ($P = 0.02$) between ground corn particle size and feed additives for hot carcass weight (HCW). Animals fed CGC diets and CRINA-RUM presented 11.5 kg greater HCW ($P < 0.05$) compared to animals fed CGC and MON- 295.2 and 283.7 kg, respectively. On the other hand, no effects ($P > 0.05$) of additives were observed for HWC on GC diets. The CRINA-RUM combination for finishing cattle fed flint CGC diets increases HCW and can be an effective substitute for sodium monensin.

Key Words: beef, carcass, starch

1364 The potential of a buffer (calcified marine algae) or plant extract (*Capsicum*) in combination with or to replace an ionophore (monensin) in lamb feedlot diets.

R. F. Gouws[*1], F. M. Hagg[2], L. J. Erasmus[1], R. H. van der Veen[2], and D. E. Holm[3], *[1]Department of Animal and Wildlife Science, University of Pretoria, Pretoria, South Africa, [2]Allied Nutrition, Pretoria, South Africa, [3]Department of Production Animal Studies, Faculty of Veterinary Science, University of Pretoria, Pretoria, South Africa.*

Ionophore antibiotic supplementation is standard practice in almost all feedlots in South Africa and many other countries due to its positive effects on feed efficiency and feed intake. Public concern over the emergence of antibiotic resistant bacteria and the consumers' demand for safe, high quality nutritious food has stimulated the search for natural alternatives to ionophores in ruminant diets. The objective of this study was to evaluate the effect of a buffer (calcified marine algae [AB]) and/or plant extract (*Capsicum* [Caps]) in combination with or replacing an ionophore (monensin [Mon]) on the performance of lambs in a commercial feedlot. Two thousand three hundred and twenty-seven lambs were randomly allocated to 6 different treatments with 6 pens per treatment with pen being the experimental unit. Treatments were: 1) Mon; 2) AB; 3) Caps; 4) AB + Mon; 5) Caps + Mon and 6) AB + Caps. Mean starting live weight of lambs was 30.9 kg. The lambs were individually weighed on Day 0, 10, 21, 35, 50 and at slaughter. All lambs were slaughtered at a pre-determined end live weight of ± 48 kg. Average daily gain, dry matter intake, feed conversion ratio, cold carcass mass, rumen fluid pH and rumen score were among the parameters determined. The corn (23% to 37%), alfalfa hay (20% to 10%) based diets (starter, grower and finisher) were the same for all treatments with adjustments to the specific treatments. Days on feed were different between some treatments ($P < 0.05$). Difference in rumen pH (Day 30 minus Day 13) as well as rumen pH on day 1 and 3 were different between some treatments ($P < 0.05$). Other performance parameters such as average daily gain and feed conversion ratio did not differ between treatments ($P > 0.05$). Results suggest that monensin can be successfully replaced in lamb feedlot rations with natural alternatives (AB and/or Caps) with little impact on production performance. Further research, however, is needed on determining the dietary dependant responses and adaptation of rumen microbial populations. Furthermore, the cost: benefit

ratio should be determined under the prevailing conditions in different countries.

Key Words: ionophore, calcified marine algae, *Capsicum*

1365 Health, milk yield and milk quality records evaluated in 787 dairy herds before and during OmniGen-AF® supplementation to dry and lactating cows. J. D. Chapman[1], S. S. Bascom[1], L. O. Ely[2], G. A. Holub[1], J. P. Jarrett*[1], J. S. Lanier[1], D. Kirk[1], D. E. Nuzback[1], A. D. Rowson[1], and T. J. Wistuba[1], *[1]Phibro Animal Health Corporation, Quincy, IL, [2]University of Georgia, Athens.*

Health, milk yield and milk quality records representing 473,711 cows from 787 dairy herds from the U.S. and Canada were collected to evaluate herd effects of feeding *OmniGen-AF*® (Phibro Animal Health Corp., Quincy, IL) to the entire herd. *OmniGen-AF* (OG) was fed at 56 g/hd/d to all dry and lactating cows for a minimum of 90 d (Post-OG). Health and production metrics were compared to the previous 90 d period (Pre-OG). Herds were enrolled in all months of the year (Jan-Mar, $n = 239$; Apr-June, $n = 224$; Jul-Sep, $n = 176$; Oct-Dec, $n = 149$) and herd size ranged from 31 to 9,046 cows. Health and production records were collected from DC305, DRMS and PCDART systems and the data were analyzed using paired *t* test (SAS, Statistical Analysis System) comparing the Pre-OG to Post-OG health events and production. The data were analyzed for all herds ($n = 787$) by herd size ($\leq$ 100 hd, $n = 188$; 101 to 500 hd, $n = 340$; 501 to 1,000 hd, $n = 120$; $\geq$ 1,001 hd, $n = 141$). Monthly cases of mastitis, late term abortions, dead cows, and number of hospital cows/d, expressed as a % of total herd cows, differed ($P < 0.001$) between the Pre- and Post-OG 90 d periods (−24.6%, −28.6%, −23% and −17.4%, respectively). Health event responses to feeding OG were observed to vary by herd size and Pre-OG SCC; however significant reductions in cases/mo. of mastitis, abortions, deaths and metritis were common in all herds regardless of size and SCC during the Pre-OG period. Herds were also stratified by Pre-OG SCC cells/ml (< 200,000, $n = 309$; 200,001 to 300,000, $n = 237$; 300,001 to 400,000, $n = 146$; $\geq$ 400,001, $n = 95$).The average Pre-OG SCC across all herds was 275,753 cells/ml with 73% of herds reporting a reduction in SCC during the Post-OG period. Changes in SCC were proportional to the Pre-OG SCC level. Significant reductions ($P < 0.001$) in SCC were observed in herds with Pre-OG SCC of 200,001 to 300,000 (−23,087), 300,001 to 400,000 (−57,850) and > 400,001 (−128,465) cells/ml. Milk production was reported by 532 herds with an average milk yield change from Pre-OG to Post-OG of +0.35 kg/hd/d ($P <$ 0.001). Maintaining good health is a key component to cow productivity and these data suggest that feeding *OmniGen-AF* along with sound nutrition and management practices for dry and lactating cows can influence health, milk yield and milk quality in commercial dairies.

Key Words: Health, SCC, *OmniGen-AF*

1366 Comparison of the effects of laidlomycin propionate plus chlortetracycline vs. monensin plus tylosin and multiple β-agonist feeding strategies on feedlot performance and carcass characteristics. A. J. Thompson*[1], Z. K. F. Smith[1], M. Corbin[2], L. B. Harper[2], and B. J. Johnson[1], *[1]Texas Tech University, Lubbock, [2]Zoetis, Florham Park, NJ.*

One hundred ninety-two steers (initial BW = 354 ± 23.5 kg) were used in randomized complete block design to examine the effect of various ionophore and ractopamine hydrochloride (RH) supplementation strategies on performance and carcass characteristics. Twelve pens of 4steers were assigned to each of the following treatments: unsupplemented control (CON), laidlomycin propionate plus chlortetracycline (CTC) with or without RH (LP and LPRH, respectively), and monensin sodium plus tylosin with RH (MON). Steers were fed for a total of 151 d, of which RH supplemented treatments received the β-agonist for the final 32 d. Laidlomycin propionate and CTC were removed during this period for the LPRH treatment, as no combination clearance exists for the commercially applied β-agonist (Actogain; Zoetis LLC, Florham Park, NJ). When included in the diet, LP, CTC, monensin, tylosin, and RH were supplemented at 10.7 g/ton, 343 mg/(head · d), 32.0 g/ton, 10.7 g/ton, and 255 mg/(head · d) (DM basis), respectively. Upon harvest, carcass data was collected by trained personnel. Before RH supplementation (d 0 to 118), both LP and LPRH treatments had greater ADG ($P < 0.02$) and G:F ($P < 0.01$) than CON, while MON was intermediate. During the RH supplementation period (d 119 to 150), LP maintained greater DMI ($P < 0.01$) than both RH treatments; however, over the same period, MON treated cattle had improved G:F ($P < 0.02$) compared to LP supplemented cattle and CON. Feeding LP without RH increased final BW ($P = 0.02$) over CON, and all ionophore supplemented treatments had improved ADG ($P < 0.05$) and G:F ($P < 0.05$) over the entire 151 d feeding period. Hot carcass weight was significantly greater ($P =$ 0.04) in cattle fed LP with no β-agonist than CON, where LP cattle yielded an average of 12 kg more HCW, while both RH supplemented treatments were intermediate. Monensin plus tylosin with RH yielded significantly greater LM area ($P =$ 0.03) than unsupplemented controls; however LP and LPRH treatments were unaffected. All other carcass characteristics were not significantly different. The results of this study indicate that LP supplementation without the use of a β-agonist may yield similar live performance and carcass responses associated with the administration of RH. These results also suggest that performance and carcass characteristics for cattle fed LP plus CTC are similar to those of cattle fed monensin

plus tylosin throughout the feeding period.

Key Words: β-agonist, ionophore, laidlomycin propionate

1367 Effect of different inclusion rates of Fermenten on performance, carcass characteristics, and total tract digestibility of growing Angus crossbred steers. M. E. Garcia-Ascolani*[1], T. M. Schulmeister[1], M. Ruiz-Moreno[1], D. D. Henry[1], F. M. Ciriaco[1], G. M. Silva[2], P. L. P. Fontes[1], G. C. Lamb[1], and N. DiLorenzo[1], *[1]University of Florida, North Florida Research and Education Center, Marianna, [2]UF/IFAS, Range Cattle Research and Education Center, Ona, FL.*

The objective of this study was to assess the effects of including increasing inclusion rates of the feed additive Fermenten (FER; Church & Dwight Co., Inc., Princeton, NJ) on performance, carcass characteristics, and total tract digestibility of growing steers. Eighty-one Angus crossbred steers (189 ± 22 kg) were used in a generalized randomized block design. Initial BW was used as the blocking factor. Steers were randomly assigned to one of 3 treatments: 0, 2, and 4% FER in the diet DM of a backgrounding diet comprised of peanut hulls, corn gluten feed, soybean hulls and soybean meal. Diets were formulated to contain equal amounts of RDP and energy (6.5% RDP, 70.6% TDN, DM basis). From d 0 to 56, steers were housed in 9 pens (9 steers/pen), with ad libitum access to diets. Individual intake was recorded using a GrowSafe feed intake monitoring system. From d 57 to d 112, steers were moved to a paddock with ad libitum access to a basal diet common to all animals, without FER, to assess potential residual effects of FER feeding. Every 14 d, unshrunk BW was recorded, and blood samples were collected to measure glucose, blood urea nitrogen (BUN) and NEFA in serum. Every 28 d carcass ultrasound was performed to assess fat thickness (FT) and longissimus dorsi area (LDA). Apparent total tract digestibility of nutrients was measured in a subsample of 27 steers (9/treatment) using indigestible NDF as a marker. Data were analyzed as a generalized randomized block design, using steer as the experimental unit. The model included the random effect of steer, and fixed effect of treatment, block and pen. Steers fed 4% FER had decreased ($P < 0.05$) DMI, BW (d 56), ADG (d 0 to 56), and G:F compared with 0 and 2% FER. No differences were observed ($P \geq 0.05$) in blood parameters, LDA, FT, DMI as a percentage of BW, final BW at d 112, and ADG from d 56 to 112. The inclusion of 4% FER increased the digestibility of DM, OM, NDF, and ADF compared with 2, and 0% FER ($P \leq 0.05$). Inclusion of Fermenten above 2% of the diet DM may reduce DMI, thus decreasing the performance and feed efficiency of growing Angus crossbred steers.

Key Words: fermenten, beef cattle, performance

1368 A meta-analysis of lasalocid effects on rumen measures, beef and dairy performance, and carcass traits in cattle. H. M. Golder*[1], T. Cowper[2], and I. J. Lean[1], *[1]Scibus, Camden, Australia, [2]Zoetis Australia, Sydney, Australia.*

The objective of this study was to evaluate the effects of feeding lasalocid on rumen measures, beef and dairy performance, and carcass traits in cattle, using meta-analytic methods. Meta-regression was used to investigate sources of heterogeneity. Rumen measures were assessed using 10 studies (20 comparisons). Lasalocid increased total VFA and ammonia concentrations by 6.46 and 1.44 m*M*, respectively. Lasalocid increased propionate and decreased acetate and butyrate molar percentage (M%) by 4.62, 3.18, and 0.83%, respectively. Valerate M% and pH were not affected. Meta-regression found butyrate M% increased linearly with duration of lasalocid feeding (DUR; $P = 0.017$). When > 200 mg/d was fed, propionate and valerate M% were higher and acetate M% was lower ($P = 0.042$, 0.017, and 0.005, respectively). Beef performance was assessed using 31 studies (67 comparisons). Lasalocid increased ADG by 40 g/d, improved feed-to-gain (F:G) by 410 g/kg, and improved feed efficiency (FE; combined measure of G:F and the inverse of F:G). Lasalocid did not affect DMI, but heterogeneity in DMI was influenced by DUR ($P = 0.004$) and linear effect of entry BW ($P = 0.011$). Heterogeneity of ADG was influenced by the linear effect of entry BW ($P = 0.028$) but not DUR. Combining entry BW $\leq$ 275 vs. > 275 kg and DUR showed cattle entering at > 275 kg fed $\leq$ 100 d had the highest ADG. The FE ($P = 0.025$) and F:G ($P = 0.015$) improved linearly with dose, and entry BW > 275 kg improved F:G ($P = 0.038$). Fourteen studies (25 comparisons) were used to assess carcass traits. Lasalocid increased HCW by 4.73 kg, but not dressing percentage, mean fat cover, or marbling score. Heterogeneity of carcass traits was low and not affected by DUR or dose. Seven studies (11 comparisons) were used to assess dairy performance but the study power was relatively low. Lasalocid decreased DMI in TMR-fed cows by 0.89 kg/d, but had no effect on milk yield, milk components, or component yields. Dose linearly decreased DMI ($P = 0.049$). The DUR did not affect heterogeneity of dairy measures. This work showed lasalocid improved ADG, HCW, FE, and F:G for beef production. These findings may reflect improved energy efficiency from increased propionate and decreased acetate and butyrate M%. Large dairy studies are required for further evaluation of effects of lasalocid on dairy performance.

Key Words: feedlot, ionophore, meta-regression

1369 Close-up diet DCAD, urine pH, and total plasma calcium at calving on a commercial Jersey herd. A. Valldecabres*, D. Rolle, V. J. Ramírez, S. Rodríguez, and N. Silva-del-Rio, *Veterinary Medicine Teaching and Research Center, University of California Davis, Tulare.*

The objectives of this study were to 1) evaluate the daily variability of close-up dietary cation-anion difference (DCAD) and the DCAD feedbunk distribution, 2) evaluate the daily variability of urine pH, 3) determine if acidification levels were maintained as parturition approached, 4) investigate if DCAD and urine pH were associated, and 5) evaluate if peri-partum urine pH and pospartum calcium levels were related on a commercial 3,500 Jersey herd. Before enrollment all cows had to be fed close-up diet > 10 d. Over a 40 d period feedbunk samples were collected daily for wet chemistry. Mixing uniformity was evaluated weekly by sampling 5 feedbunk locations. Midstream urine of 70 multiparous cows was collected via manual stimulation from enrollment to calving. Urinary pH was measured cow-side with a handheld meter (Horiba, Montpellier, FR). Coccygeal blood samples were collected after calving for total plasma calcium analysis (47 cows). Changes on urinary pH −10 to 0 d relative to calving (RC) was conducted with MIXED procedure of SAS with repeated measurements. The association between DCAD and urine pH was evaluated using CORR procedure of SAS. DCAD ranged from −136 to 151 mEq/kg of DM with a coefficient of variation (CV) of 216% and DCAD distribution throughout the feedbunk was highly variable (CV = 36 to 182%). The within-day variation on urine pH ranged from 3 to 19% of CV. There was a tendency for an effect of day of the week ($P = 0.07$) on urine pH, greatest on Monday (6.2) and lowest on Saturday (5.9). Urine pH was lower from −10 to −6 d RC (from 5.6 to 6.1) compared to −5 to 0 d RC (from 6.0 to 6.2; $P = 0.08$). There was a tendency for a weak association between the dietarian DCAD fed 24 h prior and the urine pH ($r = 0.31$; $P = 0.09$). Although urine pH was not associated with postpartum total plasma calcium from −10 to −4 d RC, it was from −3 to 0 d RC ($P = 0.02$); mostly because cows with acidic urine (pH < 5.8) had lower calcium levels. Our results indicate that in the study herd there was a wide within and across day variation in DCAD as well as urinary pH, and suggest that urine pH might not be a good indicator of postpartum plasma calcium levels.

Key Words: DCAD, urine pH, total plasma calcium

1370 Effects of bismuth subsalicylate and calcium-ammonium nitrate on in vitro fermentation of bahiagrass hay with supplemental molasses. D. D. Henry*[1], F. M. Ciriaco[1], R. C. Araujo[2], M. E. Garcia-Ascolani[1], P. L. P. Fontes[1], N. Oosthuizen[1], C. D. Sanford[1], T. M. Schulmeister[1], M. Ruiz-Moreno[1], G. C. Lamb[1], and N. DiLorenzo[1], *[1]University of Florida, North Florida Research and Education Center, Marianna, [2]GRASP Ind. & Com. LTDA, Curitiba, Brazil.*

A randomized complete block design was used to determine the effects of increasing amounts of bismuth subsalicylate (BSS) and calcium-ammonium nitrate (CAN) on in vitro fermentation of bahiagrass hay (*Paspalum notatum*). Serum bottles (125-mL) containing 100 mL of a 4:1 buffer:ruminal fluid inoculum and 0.7 g of an 80:20 bahiagrass hay:molasses substrate (DM basis) were incubated for 48 h. Three d (block) of incubation were performed. Treatments were arranged as a 4 × 3 factorial with 4 concentrations of BSS (0.00, 0.33, 0.66, and 1.00% of diet DM) and 3 concentrations of CAN (0.0, 1.2, and 2.4% of diet DM). Treatments were made isonitrogenous with urea. Two ruminally cannulated crossbred steers (348 ± 29 kg BW) fed bahiagrass hay ad libitum and 2.27 kg/d (as is) of a 50:50 molasses:crude glycerol mixture, were used as ruminal fluid donors. In vitro OM digestibility (IVOMD) was determined in a separate set of tubes. Data were analyzed using PROC MIXED of SAS with fixed effects of BSS, CAN, BSS × CAN, and random effect of day. Gas production and IVOMD were linearly decreased ($P \leq 0.001$) as CAN and BSS increased. Ammonia-N was linearly decreased ($P = 0.001$) as CAN increased. Methane production (mmol/g substrate fermented) was linearly reduced ($P < 0.001$) as CAN and BSS increased. Both CAN ($P = 0.032$) and BSS ($P < 0.001$) reduced H_2S production, with 0.33% BSS reducing production by 61% compared with 0.00%. There was no effect ($P > 0.05$) of CAN on concentrations or molar proportions of any VFA analyzed. As BSS increased, concentration of acetate ($P = 0.002$), propionate ($P = 0.007$), and total VFA ($P = 0.003$) decreased linearly. When comparing treatment means, no difference ($P = 0.119$) in total VFA was observed between 0.33% and 0.00% BSS. The acetate:propionate (A:P; $P = 0.005$) and molar proportions of acetate ($P = 0.041$), and propionate ($P = 0.005$) were quadratically affected by BSS inclusion, where 0.33% BSS decreased A:P compared with 0.00% BSS ($P = 0.050$). Including BSS at 0.66% and 1.00% of the diet DM had negative effects on in vitro fermentation of bahiagrass hay. However, when BSS was included at 0.33%, A:P was decreased and total VFA concentrations were unaffected. Nitrate inclusion reduces methane production without negatively affecting fermentation. A combination of BSS and CAN may favorably affect ruminal fermentation while decreasing methane emissions.

Key Words: bismuth subsalicylate, nitrate, fermentation

1371 The effect of a monensin controlled release capsul at prepartum on betahydroxy butyrate, milk yield, fat, protein, postpartum diseases, rectal temperature, and body condition in Holstein cows. P. Melendez[*1], A. Arevalo[2], P. J. Pinedo[3], and M. Duchens[2], *[1]University of Missouri, Columbia, [2]University of Chile, Santiago, Chile, [3]Colorado State University, Fort Collins.*

The objective was to evaluate the effect of a monensin controlled release capsule given prepartum on blood BHB, milk yield, fat and protein, incidence of postpartum diseases, rectal temperature, and BCS in confined Holstein cows. The study was conducted in a 400-cow dairy operation (ME 305 12,500 kg). Cows were housed in a free-stall system, fed a TMR and milked 3X. Eighty cows of parity $\geq$ 2 were randomly assigned either a treatment (n = 40) or a control group (n = 40) at 30 d before expected parturition. Treatment group received a capsule of monensin orally (Rumensin®, ELANCO, Chile, releasing 300 mg of monensin daily for 95 d). Control cows were randomly matched by parity and expected due date. The outcome variables were blood BHB at 7, 14, 21, and 28 d postpartum, rectal temperature up to 3 d postpartum, incidence of retained fetal membranes, metritis, endometritis, monthly test day milk yield, fat (%) and protein (%) and changes in BCS from prepartum (~ 30 d before calving) to calving and from parturition to 30 DIM. Continuous variables over time were analyzed by repeated measure ANOVA. Postpartum disorders were analyzed by logistic regression. BCS changes were analyzed by ANOVA. Monensin group had lower rectal temperature at Day 1 postpartum (40.3 vs. 38.9°C; P = 0.08) and higher protein % on test Day 1 (3.51% vs. 3.20%) than controls (P = 0.0007). There were no differences for milk yield, blood BHB, fat % over time and incidences of postpartum disorders (P > 0.05). The change in BCS from prepartum to parturition was 0.01 and 0.17 for controls and treated cows, respectively (P = 0.01). The change in BCS from parturition to 30 DIM was –0.31 and –0.13 for controls and treated cows, respectively (P = 0.008). It is concluded that monensin improved milk protein on test Day 1, decreased rectal temperature on Day 1 postpartum and modulated positively the changes in BCS both prepartum and postpartum.

Key Words: monensin, milk yield, diseases

1372 Effects of essential oils and exogenous enzyme in low starch diets for finishing feedlot cattle. T. S. Acedo[1], L. F. M. Tamassia[1], C. S. Cortinhas[1], V. N. D. Gouvea[*1], V. R. M. Couto[2], and J. J. D. R. Fernandes[3], *[1]DSM Nutritional Products SA, Sao Paulo, Brazil, [2]Universidade Federal de Goiás, Goiânia, Brazil, [3]UFG, Goiania, Brazil.*

The objective of this study was to evaluate the effects of the combination of essential oils (Crina® Ruminants) and α-amylase (Ronozyme® RumiStar™) on performance of Nellore bulls finished in feedlot. One hundred twelve Nellore bulls (initial BW = 349 kg ± 33) were fed during 90 d with diets containing 54.5% ground corn, 8.5% sugarcane bagasse, 16% soybean hulls, 12% whole cottonseed, 5% soybean meal, 3% minerals and vitamin supplement and 1% urea. Animals were blocked based on initial BW and randomly allocated in 14 pens. Treatments were: MON (Sodium Monensin, Tortuga®– 26 mg/kg DM) or CRINA-RUM (Crina® Ruminants, DSM®, 90 mg/kg DM and Ronozyme® RumiStar™, DSM®, 560 mg/kg DM). Response variables included: final body weight (FBW); dry matter intake (DMI), average daily gain (ADG), feed efficiency (G:F), hot carcass weight (HCW) and dressing percentage (dressing, %). Pen was considered the experimental unit. The data were analyzed using PROC MIXED of SAS and means were compared by Tukey test considering the block as random effect and treatments as fixed effects. Animals fed with CRINA-RUM had 9.9% greater DMI (10.30 *vs*. 9.28 kg; P < 0.001) and a tendency for greater FBW (529 vs. 523 kg*; P* = 0.07) compared with animals fed MON, respectively. There was no effect of treatments on ADG (1.65 and 1.72 kg, for MON and CRINA-RUN respectively, P = 0.14). Animals fed MON had greater G:F compared with CRINA-RUN (0178 vs. 0166, P < 0.01). The combination of essential oils and α-amylase increased HCW and dressing percentage. Animals fed CRINA-RUM had 6.4 kg more carcass compared with MON (298.2 vs.291.8 kg respectively, P = 0.015) and dressing percentage were 56.3 *vs* 55.8% for CRINA-RUM and MON respectively (P < 0.01). In conclusion, the use of essential oil combined with α-amylase improved intake, carcass dressing and weight in animals fed low starch diets combined with coproducts and can be an alternative to monensin.

Key Words: beef, coproducts, starch

1373 Optimal blood sampling time points to determine bioavailability of rumen-protected Met products using the plasma free AA dose–response method.

N. L. Whitehouse*[1], D. L. Chirgwin[2], C. G. Schwab[3], D. N. Luchini[4], and A. F. Brito[1], [1]*University of New Hampshire, Durham,* [2]*Univerity of New Hampshire, Durham,* [3]*Schwab Consulting, LLC, Boscobel, WI,* [4]*Adisseo S.A.S., Alpharetta, GA.*

Determination of bioavailability of rumen-protected AA products using the plasma free AA dose–response method has relied on blood sampling 2, 4, 6, and 8 h after the morning feeding the last 3 d of each period in Latin square experiments with cows fed every 8 h. The objective of this study was to determine if this sampling protocol captured the diurnal variation in plasma Met concentrations that exists and adequately measures the bioavailability of Met in Smartamine M (SM; Adisseo Inc., Alpharetta, GA). Five multiparous lactating Holstein cows were used in a 5 × 5 Latin square design with 7-d periods. Treatments were: 1) control diet with no supplemental Met; 2) 12 g/d of abomasally-infused Met; 3) 24 g/d of abomasally-infused Met; 4) 15 g/d of fed Met from SM; and 5) 30 g/d of fed Met from SM. Blood samples were collected via jugular catheters every 2 h starting at 0700 h on d 5, 6, and 7 of each period. Plasma Met analysis was conducted using gas chromatography after chloroformate derivatization (EZ:-faast, Phenomenex). Data were analyzed using the MIXED procedure of SAS. Plasma Met concentrations (μ*M*) increased with infused Met or supplemental SM ($P < 0.001$). There was no diurnal variation in plasma Met concentrations ($P = 0.18$). Plasma Met concentrations were averaged across days for the 2 to 8, 10 to 16, 18 to 24, and 2 to 24 h blood sampling periods. Plasma Met concentrations were regressed on 0, 12, and 24 g of infused Met and 0, 15, and 30 g of fed Met using the REG procedure of SAS. Slopes for the 2 to 8, 10 to 16, 18 to 24, and 2 to 24 h sampling periods for infused Met were 1.356 (SE = 0.145), 1.369 (SE = 0.147), 1.329 (SE = 0.120), and 1.346 (SE = 0.123), respectively. Slopes for the 2 to 8, 10 to 16, 18 to 24, and 2 to 24 h sampling periods for fed Met were 1.148 (SE = 0.038), 1.156 (SE = 0.059), 1.197 (SE = 0.038), and 1.140 (SE = 0.030), respectively. There was no effect of sampling period on the slopes for infused ($P \geq 0.91$) or fed Met ($P \geq 0.26$). The bioavailabilities of Met in SM averaged 84.7, 84.4, 90.0, and 84.6% for the 2 to 8, 10 to 16, 18 to 24, and 2 to 24 h sampling periods, respectively. The similarity in estimates of bioavailability for SM for the 2 to 8 and 2 to 24 h sampling periods indicates our blood sampling protocol is adequate for determining the bioavailability of RP-Met products.

Key Words: bioavailability, methionine, sampling

1374 Effects of prophylactic supplementation with oral calcium boluses on peripartum calcium, urine pH and health in a commercial Jersey herd supplemented with anionic salts.

A. Valldecabres*, D. Rolle, A. Belaid, S. Rodríguez, and N. Silva-del-Rio, *Veterinary Medicine Teaching and Research Center, University of California Davis, Tulare.*

The objectives of this study were to evaluate the effect of prophylactic supplementation with oral calcium boluses after calving on peripartum serum calcium and urine pH levels, as well as the prevalence of ketosis and endometritis. Multiparous Jersey cows from a 3,500 herd were randomly assigned to control (no calcium supplementation [$n = 67$]) or treatment (2 oral calcium boluses [$n = 64$], [QuadriCalMINI, Bio-Vet, Barneveld, WI]). The first calcium bolus was given at 2:30 h after calving (SD ± 1:54 h) and the second at 18:21 h after calving (SD ± 11:56 h). Coccygeal blood and midstream urine were collected immediately before the first and second bolus administration and 1 h after each bolus was administered. Serum samples were analyzed for total calcium. Urinary pH was measured cow-side with a handheld meter (LAQUAtwin B-712, Horiba, Montpellier, FR). Blood Beta-hydroxybutyrate (BHBA) concentrations were determined at 5, 8, and 11 d postpartum, using a handheld meter (Precision Xtra; Abbot, Alameda, CA). Ketosis was defined as ≥ 1.4 mmol/L of BHBA in blood at least once during the sampling period. Clinical endometritis was evaluated based on the observation of purulent or mucopurulent vaginal mucus retrieved with Metricheck (Simcro, NZ) from 28 to 40 d postpartum. Treatment effects on serum calcium and urine pH were evaluated with linear mixed models with repeated measures using the MIXED procedure of SAS (Cary, NC). The prevalence of ketosis and endometritis was evaluated with the chi-square option of the FREQ procedure (SAS). Subclinical hypocalcemia (≤ 8.5 mg/dL) before treatment administration was 58% for control and treatment ($P = 0.96$). One hour after bolus administration, serum calcium concentration was significantly greater in treated cows at first (8.65 vs. 8.01 mg/dL; $P < 0.0001$) and second (8.71 vs. 8.23 mg/dL; $P < 0.001$) bolus administration. However, no significant differences were observed before second bolus administration (8.23 vs. 8.01 mg/dL; $P = 0.12$). There was a treatment effect on urine pH (7.0 control vs. 6.1 treatment; $P < 0.0001$) and a significant treatment by time interaction ($P = 0.02$). No treatment effects were observed on ketosis (26.7%; $P = 0.97$) or endometritis (47%; $P = 0.93$). These results suggest that postpartum total serum calcium levels can be increased with oral bolus administration; however, serum calcium levels might not be maintained by the time the second bolus is administered.

Key Words: oral calcium supplementation, urine pH, serum calcium

1375 Effects of supplemental zinc sulfate concentrations on growth performance and carcass characteristics of feedlot heifers, and in vitro ruminal fermentative activity. C. L. Van Bibber-Krueger*, C. I. Vahl, and J. S. Drouillard, *Kansas State University, Manhattan.*

Effects of supplemental Zn as Zn sulfate on feedlot performance and carcass characteristics were evaluated using 480 crossbred heifers (BW = 385 kg ± 13.08) in a randomized complete block design. Heifers were blocked by BW and randomly assigned within block to receive 0, 30, 60, or 90 mg supplemental Zn/kg diet DM. Heifers were housed in dirt-surfaced pens (20 animals/pen; 6 pens/treatment) equipped with fence-line feed bunks and automatic water fountains. Heifers were fed once daily ad libitum. Plasma was collected Days 0, 63, and 115 from 4 or 5 heifers/pen to determine changes in plasma Zn concentrations. Heifers were transported on d 144 to a commercial abattoir where HCW and incidence of liver abscesses were recorded at harvest and carcass data were recorded after 36 h of refrigeration. Plasma Zn concentration increased linearly in response to increasing concentrations of dietary Zn ($P = 0.02$). Final BW and ADG were not affected by supplementation ($P \geq 0.29$). Increasing supplemental Zn concentrations tended to decrease DMI (linear effect, $P = 0.07$), resulting in a linear improvement in feed efficiency with increasing Zn concentration ($P = 0.03$). No differences were detected for HCW, dressing percentage, LM area, 12th rib fat, percentages of carcasses grading Select or Choice, or yield grade ($P > 0.53$). There was a tendency for a quadratic effect of Zn concentration on percentage of carcasses graded as USDA Prime, with percent Prime peaking at 60 mg/kg added Zn. Carcasses from heifers supplemented 60 mg Zn/kg diet DM yielded the greatest numerical increase ($25/carcass) in carcass value compared to other treatments ($P = 0.32$). In vitro fermentations were performed using ruminal fluid cultures containing 0, 30, 60, 90, 120, 150 mg Zn/kg substrate DM to determine impact of Zn on gas production, VFA concentrations, and IVDMD. There was no Zn × time interaction or effect of Zn on in vitro gas production ($P \geq 0.59$). Zinc supplementation tended to reduce acetate (quadratic effect; $P = 0.07$), and decreased isovalerate (linear effect; $P = 0.05$), but did not affect other VFA ($P \geq 0.17$) or IVDMD ($P \geq 0.20$). Overall, Zn supplementation up to 150 mg/kg substrate weight minimally affected in vitro fermentation. Supplementing up to 60 mg Zn/kg diet DM improves feed efficiency of feedlot cattle.

Key Words: feedlot cattle, feed efficiency, gas production, zinc

1376 Evaluating the effects of an injectable trace mineral product on steers raised in a natural beef feedlot program. E. K. Niedermayer*, O. N. Genther-Schroeder, and S. L. Hansen, *Iowa State University, Ames.*

To determine effects of an injectable trace mineral (TM) on growth and TM status of steers fed in a natural program 168 certified natural Angus steers (359 ± 36.6 kg), blocked by BW (6 steers per pen), received an injection of sterilized saline (SAL) or Multimin90 (MM) on d 0 at 1 mL/68 kg BW (n = 14 pens, 84 steers per treatment). Multimin90 contains 15 mg Cu, 60 mg Zn, 10 mg Mn, and 5 mg Se/mL. Steers received a growing diet for 56 d, followed by 3 wk of transition. On d 84 steers started a corn-based finishing diet and received a second injection of SAL or MM, creating 4 treatments (n = 7 pens, 42 steers per treatment): 1) d 0 Saline, d 84 Saline (SAL/SAL); 2) d 0 Saline, d 84 Multimin90 (SAL/MM); 3) d 0 Multimin90, d 84 Saline (MM/SAL); and 4) d 0 Multimin90 and d 84 Multimin90 (MM/MM). Blood and liver mineral concentrations were determined (n = 7 per treatment) on d −5, 14, 79, and 98. Steers were harvested on Day 162. Data were analyzed in SAS with the fixed effects of block and treatment (2 treatments for growing, 4 treatments for finishing), with mineral data as repeated measures. Steer was experimental unit except for DMI and G:F, where experimental unit was pen. Treatment did not affect growing or finishing ADG, DMI, or G:F ($P \geq 0.14$). There was a treatment × day interaction for finishing period ADG ($P = 0.01$), where ADG was similar across treatments from d 84 to 113, and greatest in SAL/SAL from d 113 to 144; however, MM/MM was greatest from d 140 to 161. There was a treatment × day interaction for liver Se ($P < 0.001$), where concentrations increased on d 14 in MM-treated steers, were similar across treatments on d 79, but increased on d 98 in SAL/MM and MM/MM. Liver TM concentrations tended ($P = 0.08$) to display treatment × day interactions where MM/MM had greater Mn and Cu on d 14, tended to have greater liver Mn and Cu than MM/SAL and SAL/SAL on d 79, and had greater liver Cu compared to SAL/SAL and MM/SAL on d 98. Adequate steer TM status at onset of this trial likely negated any potential benefits of injectable minerals and injectable TM can be utilized safely in natural finishing programs.

Key Words: beef, natural, mineral

1377 Interactive effects of supplemental Zn sulfate and ractopamine hydrochloride on growth performance, carcass traits, and plasma urea nitrogen in feedlot heifers. C. L. Van Bibber-Krueger[*1], J. M. Gonzalez[1], R. G. Amachawadi[2], H. M. Scott[3], and J. S. Drouillard[1], *[1]Kansas State University, Manhattan, [2]Kansas State Univeristy, Manhattan, [3]Texas A&M University, College Station.*

Interactive effects of supplemental Zn and ractopamine hydrochloride (RH) were evaluated using 156 crossbred heifers (initial BW = 527 kg ± 6.61; gross BW × 0.96) to determine impact on feedlot performance, plasma urea nitrogen (PUN) and carcass characteristics. The study was conducted as a randomized complete block design with a 2 × 2 factorial arrangement. Factors consisted of: 1) 30 or 100 mg supplemental Zn/kg diet DM (30Zn or 100Zn) as Zn sulfate, and 2) 0 or 200 mg RH/animal daily. Heifers were blocked by BW and, assigned randomly within block to treatments. Heifers were housed in partially covered feeding pens (3 heifers/pen; 13 pens/treatment), fed once daily ad libitum, and RH was fed for 42 d and removed from the diet until cattle were harvested on d 43. Plasma samples were collected on d 0 and 36 to assess changes in plasma Zn and PUN. On d 43, heifers were transported to a commercial abattoir where HCW and incidence of liver abscesses were recorded. Carcass data were collected after 32 h of refrigeration. No Zn × RH interactions were observed for plasma Zn or PUN ($P \geq 0.58$); however, there was a tendency for RH × d interaction for PUN ($P = 0.08$). Supplementing 100Zn increased plasma Zn concentration ($P = 0.02$) compared to 30Zn. No interactions were observed for feedlot performance ($P \geq 0.24$). Final BW and ADG increased with RH supplementation ($P \leq 0.02$), but DMI was not affected ($P = 0.63$), thus feed efficiency improved ($P < 0.01$) when cattle were fed RH. Supplementing 100Zn tended to reduce ADG ($P = 0.07$), but did not affect other measures of feedlot performance or incidence of liver abscesses ($P \geq 0.12$). Zinc × RH interactions were observed for LM area and yield grade ($P \leq 0.01$); LM area decreased and yield grade increased when cattle were supplemented 100Zn with no RH compared to other treatments. A tendency for Zn × RH interaction was detected for dressing percentage ($P = 0.08$), but no other interactions or effects of Zn were observed for carcass traits ($P \geq 0.11$). Supplementing RH increased HCW ($P = 0.03$), but did not affect other carcass traits ($P \geq 0.13$). In conclusion, supplemental Zn had little impact on feedlot performance or PUN concentration, but may alter muscle and fat deposition when fed in conjunction with RH.

Key Words: feedlot cattle, urea nitrogen, ractopamine, zinc

1378 SafeGain™ (ruminally-protected lysine) for growing beef cattle. V. De Aguiar Veloso[*1], C. L. Van Bibber-Krueger[1], K. Karges[2], and J. S. Drouillard[1], *[1]Kansas State University, Manhattan, [2]H.J. Baker, Animal Health and Nutrition Division, Little Rock, AR.*

Crossbred heifers ($n = 448$; 287 ± 14.1 kg initial BW) were used in a randomized complete block experiment to assess growth response to SafeGain, a lipid-encapsulated, ruminally-protected form of lysine sulfate. The basal diet consisted of (DM basis) of 45% brome hay, 25% steam-flaked corn, 25% wet corn gluten feed, and supplement. Based on Level 2 estimates from the Nutrient Requirements of Beef Cattle Update 2000, heifers were projected to consume 134% of their lysine requirement with the basal diet alone. Treatments consisted of dietary additions of 0, 15, 30, or 45 g/d of SafeGain. Heifers were blocked by initial BW; implanted with Component TE-IH; allocated within strata to 64 partially-shaded, concrete-surfaced (4.3 m × 8.6 m) pens with 7 heifers/pen and 16 pens/treatment; and fed once daily for 112 d. At the end of the 112-d growing trial, a subset of 12 blocks was consolidated, such that 2 pens from each growing treatment were combined to make one finishing pen. Cattle were weighed, re-implanted with Component TE-200, relocated to finishing pens, and fed a common finishing diet (no supplemental lysine) for 94 d until harvest to evaluate possible carryover effects of SafeGain. At the end of the finishing period pens of cattle were weighed, loaded onto trucks, and transported 450 km to a commercial abattoir for harvest. Liver abscess incidence and HCW were collected the day of harvest, and carcass traits were evaluated following 32 h of refrigeration. Growing phase performance and resulting HCW are summarized in the table, below. SafeGain was effective for improving performance of cattle fed roughage-based backgrounding diets.

Key Words: lysine, growing cattle, SafeGain™

1379 Effects of rotating antibiotic and ionophore feed additives on enteric methane and rumen microbial populations of steers consuming a high forage diet. W. L. Crossland[*1], L. O. Tedeschi[1], T. R. Callaway[2], M. D. Miller[1], and W. B. Smith[3], *[1]Texas A&M University, College Station, [2]USDA-ARS, College Station, [3]Texas A&M AgriLife Research, Overton.*

Ionophore and antibiotic feed additives have been shown to decrease ruminal methanogenesis, but evidence of long-term mitigation is lacking. We proposed a rotation of feed additives as an alternative to reduce methane (CH_4) production. Rumen-cannulated steers ($n = 12$) were fed a basal high forage diet at 2% of BW (DM) for 13 wk in a Calan gate facility receiving 1 of 6 treatments (trt): 1) control (Con) no additive, 2) bambermycin (B) = 20 mg B/hd/d, 3) monensin (M) = 200 mg M/hd/d, 4) B7M = rotating B and M treatments weekly, 5) B14M

= rotating B and M treatments every 14 d, and 6) B21M = rotating B and M treatments every 21 d. Steers were blocked by weight in a RCBD with repeated measures. Rumen fluid was collected weekly for analysis (n = 13) and results were normalized according to organic matter intake (kg OMI). Trt did not significantly affect CH_4 production (P = 0.60), but tended to affect CH_4 to Propionate ratio (CH_4:Pro) (P = 0.06) being highest for Con and lowest for M, B21M, and B14M (0.42 vs. 0.36, 0.36, and 0.33, respectively). Week affected both CH_4 and CH_4:Pro ($P < 0.05$) with significant reductions by wk 3 but this effect was not sustained beyond wk 6. Microbial analysis revealed rotationally treated steers had greater populations of gram positive (G^+) bacteria than continuously fed steers and Con ($P < 0.01$) and wk 0 populations were different from wk 5 and 6 but similar to wk 12 (51.1 vs. 37.5 and 35.1 vs. 44%, respectively; $P < 0.01$). A class of G^- bacteria (*Sphingobacteriia*), phylum *Bacteroidetes,* was not affected by trt or wk but was positively correlated with CH_4 production (r = 0.24, P = 0.04). Archaeal populations of *Methanobrevibacter spp.* and *Methanosphaera sp.*correlated with CH_4 production (r = 0.22 and r = 0.37, respectively) and were not affected by trt. Wk tended to affect *Methanobrevibacter spp*. populations being lowest during week 3 and highest during week 12 (53.64% vs. 68.89% of Archaea; P = 0.06). *Methanosphaera sp*. populations were lowest during week 5 and higher during week 0 and 12 (0.02% vs. 1.31 and 0.53% of Archaea respectively; $P < 0.05$). Our results suggest microbial adaptation to trt between 4 and 6 wk. Rotating monensin and bambermycin did not reduce CH_4 or delay microbial adaptation, more than continuously fed steers.

Key Words: CH_4, feed additives, microbes

1380 Effects of supplementing lactating dairy cow ration with sodium sesquicarbonate on reticulorumen pH, rumination, and dry matter intake. M. L. Jones*[1], J. D. Clark[1], N. A. Michael[2], and J. M. Bewley[1], [1]*University of Kentucky, Lexington,* [2]*Arm & Hammer Animal Nutrition, Princeton, NJ.*

The objective of this study was to assess the effects of sodium sesquicarbonate (SQ-810), a reticulorumen buffer, on rumen pH, rumination time, and dry matter intake (DMI). Sixteen early lactation multiparous, Holstein cows were housed in a tie-stall barn and milked twice daily at the University of Kentucky Coldstream Dairy from October 31, 2015 to January 1, 2016. Cows were balanced by parity and milk production then split into 2 treatment groups for a crossover study with a low buffer (LB, n = 8) group and a high buffer (HB, n = 8) group. The base TMR contained 16kg/d sodium bicarbonate. The LB group did not receive any SQ-810 while the HB group received 0.30 kg of SQ-810 as fed. Eight cows proceeded through sequence 1: three, 21 d periods receiving the LB diet in period 1, HB diet in period 2, and the LB diet in period 3. The remaining 8 cows proceeded through sequence 2: three, 21 d periods receiving the HB diet in period1, LB diet in period 2, and the HB diet in period 3. Each group was fed ad-libitum and dry matter intake (DMI) was collected. All cows were administered an iNovotec Animal Care (iNovotec Animal Care, Austria) reticulorumen pH and temperature bolus. Daily rumination time was recorded using HR tags (SCR Engineers Ltd., Netanya, Israel) and CowManager SensOor (SENRUM) tags (Agis Automatisering, Harmenlen, Netherlands). Low pH was calculated as the total time where pH was < 5.80. The MIXED procedure of SAS (SAS Institute, Inc., Cary, NC) was used to evaluate the effects of cow, sequence, treatment and period on each parameter measured. Rumen pH and low pH time (pH < 5.80) were significantly influenced by treatment ($P < 0.01$). Rumen pH was 5.82 ± 0.07 for LB cows and 5.85 ± 0.07 for HB cows. Low pH time (pH < 5.80) was greater ($P < 0.01$) for LB Days 10.70 ± 0.23 h/d than for HB days, 9.40 ± 0.23 h/d. Dry matter intake was 25.68 ± 0.61 kg/d with LB cows and 26.53 ± 0.61 kg/d for HB cows. Treatment affected SCR rumination times ($P < 0.01$) LB 457.84 ± 19.15 min/d and HB 435.02 ± 19.15 min/d. However, the rumination time measured using SENRUM was not significantly different between treatments. The addition of SQ-810 to the TMR increased reticulorumen pH and DMI significantly ($P <$ 0.01). This research demonstrates the positive effects of SQ-810 rumen buffer in a lactating cow diet.

Key Words: sodium sesquicarbonate, rumen pH

1381 Comparison of Titanium® 5 PH-M versus Titanium® 5 plus NUPLURA® PH with the presence or absence of monensin on health and performance of newly received feedlot calves fed RAMP®. R. M. Jones*[1], C. J. Bittner[1], F. H. Hilscher[1], R. A. Stock[2], and G. E. Erickson[1], [1]*University of Nebraska, Lincoln,* [2]*Cargill, Blair, NE.*

Crossbred steers (n = 704; initial BW = 269; SD = 22 kg) were utilized in a randomized block designed experiment with a 2 × 2 factorial arrangement of treatments. Factors included vaccine type and the presence or absence of monensin (Elanco Animal Health, Greenfield, IN) in the receiving diet. Vaccines were, Titanium® 5 PH-M (VacPH-M, Elanco Animal Health) or Titanium® 5 plus NUPLURA® PH (VacPH, Elanco Animal Health). VacPH-M is labeled to deliver effective immune response against bacteria (*Mannheimia haemolytica* and *Pasteurella multocida*) and viruses (BVD types 1 and 2, IBR, PI_3 and BRSV). VacPH is labeled similar to VacPH-M excluding protection against *Pasteurella multocida*. All steers were fed RAMP® product (Cargill Corn Milling, Blair, NE) with monensin included at 0 or 27.6 mg/kg. Steers were weighed on d 1 to establish initial BW. Steers were assigned to pen based on processing order, with every fourth steer being assigned to 1 of 4 treatments. Once a pen replicate was filled, new pen replicates were started until all steers were assigned to 40 pens (10 pens per simple effect treatment). The receiving trial lasted 28

d. Ending BW was an average of 2 consecutive day weights collected after limit feeding for 5 d. There were no significant monensin × vaccine interactions ($P > 0.27$) observed for growth performance or morbidity. Vaccine treatments (VacPH-M or VacPH) did not affect DMI ($P = 0.52$), ADG ($P = 0.95$), or G: F ($P = 0.79$). Monensin level (0 or 27.6 mg/kg) did not affect DMI ($P = 0.28$), ADG ($P = 0.94$), or G: F ($P = 0.65$). The number of steers pulled and treated for bovine respiratory disease one or more times was not different ($P = 0.17$) for VacPH-M compared to VacPH. Furthermore, no difference ($P = 0.34$) was observed when comparing second pull rates between vaccine types. There was a tendency ($P = 0.09$) for steers fed 27.6 mg/kg of monensin to have a lower percentage of first and second pulls as compared to steers receiving 0 mg/kg of monensin. We concluded that neither vaccine type nor monensin concentration affected steer growth performance or morbidity rate for the first 28 d of receiving.

Key Words: monensin, receiving, vaccine

1382 Effect of Bovamine® on performance of lactating dairy cows.

C. Dickey*[1] and M. Eastridge[2], [1]*The Ohio State University, Columbus,* [2]*ASDA, The Ohio State University, Columbus.*

The objective of this study was to determine if feeding Bovamine® has an effect on the production performance of dairy cows. Bovamine® (Nutritional Physiology Company, LLC, Overland Park, KS) is a direct-fed microbial consisting of *Lactobacillus acidophilus* and *Propionibacterium freudenreichii*. Thirty lactating Jersey cows (147 ± 49 d in milk) were used in a randomized complete block design for 12 wk with a 2-wk covariate period and 10-wk experimental period. The cows were blocked by parity, calving date, and milk yield. There were 2 treatments: a control group and cows that were fed Bovamine®. As a top dress, control cows received 454 g/d of ground corn and the cows fed Bovamine® were given 1 g/d of Bovamine® and 453 g/d of ground corn. All cows were milked and fed the same TMR twice daily. DMI and milk yield were recorded each day. DMI for the control cows (20.3 kg/d) was similar ($P > 0.10$) to that for the Bovamine®-fed cows (20.5 kg/d). There was a trend ($P = 0.07$) for greater milk yield in cows fed Bovamine® (25.3 kg/d) compared to control cows (24.4 kg/d). Percentage of fat and protein in the milk was similar ($P > 0.10$) between the 2 treatments, with control cows averaging 4.58% fat and 3.67% protein compared to 4.65% fat and 3.69% protein by the Bovamine®-fed cows. Milk urea nitrogen (MUN) was greater ($P < 0.05$) in the Bovamine®-fed cows (15.9 mg/dL) compared to the control cows (15.1 mg/dL). Fat corrected milk (FCM) and energy corrected milk (ECM) also tended to be greater ($P = 0.08$ and 0.07, respectively) in the Bovamine®-fed cows, averaging 29.8 kg/d for FCM and 30.5 kg/d for ECM compared to 28.6 and 29.3 kg/d for FCM and ECM by the control cows, respectively. BW was greater ($P = 0.02$) for the control cows with an average of 426.7 kg compared to 418.1 kg for the Bovamine®-fed cows. FCM/DMI and ECM/DMI were not different between the two treatments ($P > 0.10$) with the control cows averaging 1.42 and 1.45 and the Bovamine®-fed cows averaging 1.46 and 1.50, respectively. With a trend for increased milk yield, FCM, and ECM, results from this study indicate that Bovamine® may be a viable option to increase production in dairy cows without an increase in DMI.

Key Words: Bovamine®, direct-fed microbial, production

1383 Effects of rumen-protected choline (RPC) supplementation to periparturient dairy cows did not depend on prepartum energy intake.

M. G. Zenobi*[1], R. Gardinal[1], A. L. G. Dias[1], J. E. Zuniga[1], R. Moreira[1], B. A. Barton[2], J. E. P. Santos[3], and C. R. Staples[1], [1]*Dep. of Animal Sciences, University of Florida, Gainesville,* [2]*Balchem Corporation, New Hampton, NY,* [3]*University of Florida, Gainesville.*

Objectives were to evaluate the effect of prepartum energy intake on performance of dairy cows supplemented without or with RPC (0 or 60 g/d ReaShure, Balchem Corp., New Hampton, NY). At 48 d before calculated calving date, 93 multiparous Holstein cows were assigned to 1 of 4 treatments. Cows were fed prepartum high energy (HE; 1.63 Mcal NEL/kg DM; 58% corn silage) or controlled energy (CE; 1.40 Mcal NEL/kg DM; 43% wheat straw) diets in ad libitum amounts with or without RPC. The RPC was top-dressed daily from 21 d prepartum to 21 d postpartum. After calving, cows were fed the same diet balanced for methionine, apart from RPC supplementation, through 15 wk. Liver tissue was collected for biopsy at −14, 7, 14, and 21 d relative to calving. Data were analyzed by ANOVA for repeated measures using the MIXED procedure of SAS. Cows fed the HE diet consumed energy at 24% above requirement whereas cows fed the CE-based diet consumed energy at 0.7% above requirement during the last 15 d prepartum. Cows fed RPC tended ($P < 0.10$) to produce more milk (43.5 vs. 41.3 kg/d) and energy-corrected milk (44.2 vs. 42.0 kg/d) without increasing DM intake (23.7 vs. 23.2 kg/d) and tended to have greater mean body condition (3.32 vs. 3.24) during the first 15 wk postpartum. Over the first 40 wk postpartum, feeding RPC in transition increased milk yield of cows ($n = 91$) fed HE (37.4 vs. 33.4 kg/d) or CE diets (36.5 vs. 36.1 kg/d) prepartum (RPC by prepartum energy diet interaction, $P = 0.16$). Cows fed the CE compared with the HE diet consumed more feed postpartum (24.0 vs. 22.9 kg/d, $P < 0.01$) but did not produce more milk (43.1 vs. 41.6 kg/d). Thus, postpartum cows fed the CE diet prepartum were in less mean negative energy balance ($P < 0.05$) and tended to have lower ($P = 0.10$) mean NEFA and had lower ($P < 0.01$) mean BHBA concentrations in plasma compared with cows fed HE diets prepartum. Mean postpartum concentration

of liver triacylglycerol was greater ($P < 0.05$) for cows fed the HE compared with the CE diet (10.7 vs. 8.3% DM) whereas RPC had no effect on hepatic triacylglycerol (Control = 9.0 vs. RPC = 9.9%DM). Compared with an HE diet, feeding a CE diet prepartum improved energy balance and DM intake postpartum. Feeding RPC during the transition period increased yield of milk for 40 wk regardless of prepartum energy intake.

Key Words: choline, transition, wheat straw

1384 Effects of Peptein supplementation on ruminal microbiota and feed digestibility in dairy cows.

A. Arís[*1], J. Polo[2], C. Rodriguez[2], and A. Bach[3], *[1]Department of Ruminant Production, IRTA, Caldes de Montbui, Spain, [2]APC Europe, S.A. Research and Development Department, Barcelona, Spain, [3]ICREA, Barcelona, Spain.*

The aim of this study was to evaluate the performance of Peptein (APC Europe, Spain), a protein hydrolysate derived from red blood cells with 2 degrees of hydrolysis, either high (HDH) or low (LDH) as a N source for rumen microbial growth in comparison with other N supplements including urea, pork peptone, fish peptone, soy peptone, and spray dried red blood cells (SDRBC), and to determine the potential consequences on feed degradation. In experiment 1, four replications of Tilley Terry incubations with all N sources providing an isonitrogenous supply of 0.3% N were performed from rumen aliquots obtained from 3 cows. Growth of Gram positive and Gram negative bacteria was estimated by quantitative RT-PCR. In experiment 2, 4 cows (2 dry and 2 lactating) received 320 g/d of Peptein HDH via a rumen cannula split in 2 doses of 160 g for 12 d, and 4 other cows (2 dry and 2 lactating) received an equivalent amount of N in the form of 100 g/d of urea per day via a rumen cannula, split in 2 daily doses. On Day 10, in situ bags containing 0.8 ± 0.06 g of corn, soybean hulls, alfalfa, or beet pulp were placed in the rumen for 2, 4, 8, 12, 16, 24, and 48 h. Each sample was run in duplicate bags at each time point on two consecutive days. Data were analyzed using a mixed-effects model. In Experiment 1, Peptein HDH and LDH and pork peptone increased ($P < 0.05$) the growth of Gram negative bacteria in comparison with the other peptones and SDRBC, but contrarily, fostered ($P < 0.05$) a slight decrease in the growth of Gram positive bacteria. In Experiment 2, the effective rumen degradation of DM from beet pulp in dry cows supplemented with Peptein HDH (68.1 ± 1.11%) tended ($P = 0.07$) to be greater than when incubated in unsupplemented dry cows (64.6 ± 1.11%). The effective rumen degradation of CP and NDF from corn was greater ($P < 0.05$) in lactating cows supplemented with Peptein HDH (52.7 ± 0.96 and 44.8 ± 0.23%, respectively) than in unsupplemented lactating cows (44.6 ± 0.96 and 37.5 ± 0.23%, respectively). It is concluded that Peptein fosters the growth of Gram negative and decreases that of Gram positive bacteria in the rumen and improves degradation of CP and NDF from corn.

Key Words: bacteria, nitrogen, rumen

1385 Effects of different doses of sodium monensin on nutrient digestibility on feedlot Nellore cattle.

L. A. Tomaz[*1], M. C. Pereira[2], A. L. Rigueiro[1], D. H. M. Watanabe[1], A. A. Santos[1], A. C. J. Pinto[1], M. D. Arrigoni[2], and D. D. Millen[1], *[1]São Paulo State University (UNESP), Dracena campus, Dracena, Brazil, [2]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil.*

The objective of this research was to examine the effects of different doses of sodium monensin (MON) on digestibilities of DM, NDF and starch of feedlot Nellore cattle. This study, conducted at the São Paulo State University feedlot, Dracena campus, Brazil, was designed as a completely randomized block, replicated 12 times, in which 60 20-mo-old yearling Nellore bulls (402.52 ± 33.0 kg) were fed in individual pens for 84 d according to the different doses of MON (DM basis): 1) 0 ppm (D0); 2) 9 ppm (D9); 3) 18 ppm (D18); 4) 27 ppm (D27), and 5) 36 ppm (D36). The adaptation program consisted of ad libitum feeding of two adaptation diets over period of 14-d with concentrate level increasing from 68% to 84% of diet DM. The finishing diet contained: 71.5% cracked corn grain, 16.0% sugarcane bagasse, 7.7% soybean meal, 3.0% supplement, 1.2% urea, and 0.6% limestone (DM basis). Diet samples were collected just after morning delivery (0830) on Days 7, 8, 19, and 20 of experimental period, and composite samples were made per pen for Days 7 and 8, and 19 and 20. Samples of orts and feces were collected just before morning (0800) meals on Days 8, 9, 20, and 21 of experimental period, and composite samples were made per pen for Days 8 and 9, and 20 and 21. The digestibility of DM, NDF and starch was determined by using chromium dioxide as an external marker. Orthogonal contrasts were used to evaluate linear, quadratic, and cubic relationship between doses of MON and the dependent variable. The use of different doses of sodium monensin did not affect ($P > 0.10$) DM and starch digestibility in the adaptation period; however, NDF digestibility increased ($P = 0.01$) linearly (D0: 56.77%; D9: 59.39%; D18: 65.75%; D27: 63.22%; D36: 70.74%) as doses of MON increased. In the finishing period (d-21), as doses of MON increased, NDF digestibility decreased ($P = 0.01$) linearly (D0: 74.00%; D9: 65.35%; D18: 69.83%; D27: 64.50%; D36: 52.30%) and starch digestibility was affected ($P = 0.03$) cubically (D0: 91.38%; D9: 95.05%; D18: 90.32%; D27: 94.63%; D36: 96.03%). Thus, based on the results of this study, increasing doses of MON affected nutrient digestibility of feedlot Nellore cattle. Also, the dose of 36 ppm per kilogram of DM seemed to be the best option.

Key Words: ionophore, NDF, starch

1386 Effects of carbohydrases on the digestibility of fibrous feed ingredients using a rumen simulation model. V. R. Vasconcelos[1], K. G. Arriola[2], A. F. Campos[3], F. Amaro[4], M. C. Walsh[5], and A. T. Adesogan[*2], *[1]Universidade Federal do Piaui, Piaui, Brazil, [2]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [3]IFC (Instituto Federal Catarinense), Videira, Brazil, [4]Federal University of Vicosa, Vicosa, Brazil, [5]Danisco Animal Nutrition, DuPont Industrial Biosciences, Marlborough, UK, United Kingdom.*

The objective of this experiment was to determine the effect of an enzyme mixture on the digestibility of fibrous feed ingredients under simulated rumen conditions. Feed ingredients evaluated included 1) ground corn, 2) corn distillers dried grains (cDDGs), 3) Corn stover (CS), 4) dilute ammonia pretreated CS (DACS), 5) caustic delignified CS (DCS), 6) caustic delignified switchgrass (DSG), and 7) enzyme-treated CS (ECS), 8) DACS (EDACS), 9) DCS (EDCS), and 10) DSG (EDSG). Each substrate was incubated in duplicate in Ankom bags (0.5 g) within 250-mL gas-tight culture bottles. The enzyme was a mixture of a cellulase/hemicellulose enzyme preparation and β1–4, endoxylanase (Danisco, UK) at respective rates of 15 and 1 g/kg on as fed basis. Enzymes were diluted in 2 mL of 0.1 M citrate-phosphate buffer (pH = 6.0) and added with 52 mL of buffered-rumen fluid to the substrate in culture bottles sealed with screw-on caps on which a pressure sensor-syringe assembly was fitted. Bottles were incubated for 24 h at 39°C in a forced-air incubator. Rumen fluid was collected from 2 non-lactating, non-pregnant ruminally-cannulated Holstein cows 3 h after feeding. The experiment had a completely randomized design with ten treatments, two replicates/treatment and five runs. Data were analyzed with the GLIMMIX procedure of SAS and the model included treatment, run and treatment × run. Ground corn was more digestible than all other feed ingredients. The DM digestibility (DMD) of cDDGs was greater than those of CS and DSG (42.2 vs. 19.8 and 25%). Ammonia pretreatment (35.7 vs. 44.9%) and caustic delignification (35.7 vs. 46.2%) increased the DMD of CS ($P < 0.0001$). Enzyme treatment also increased the DMD of DSG (25.0 vs. 33.8%). Enzyme treatment increased total gas production during fermentation of DCS and DSG but did not affect those of other substrates. Pretreatment of CS by either delignification or dilute ammonia increased the NDF and ADF digestibility compared to untreated CS but addition of enzymes did not further enhance the digestibility of the pretreated CS. Dilute ammonia pretreatment of CS had no effect on ammonia-N concentration compared to CS, however caustic delignification resulted in a reduction in ammonia-N concentration ($P < 0.01$). Enzyme treatment had no effect on total VFA concentration but decreased acetate proportion of DCS and increased the propionate proportion from both DCS and ACS. Enzyme treatment decreased the acetate to propionate ratio of all substrates except untreated CS.

Key Words: corn stover, enzyme, in-vitro

1387 Microbial and chemical additives inhibit the growth of *Escherichia coli* O157:H7 in corn silage. I. M. Ogunade*, D. Kim, Y. Jiang, A. A. P. Cervantes, K. G. Arriola, D. Vyas, and A. T. Adesogan, *Dep. of Animal Sciences, IFAS, University of Florida, Gainesville.*

This study examined if adding bacterial inoculants or propionic acid to corn silage contaminated with *Escherichia coli* O157:H7 at ensiling, at silo opening, or after aerobic exposure would inhibit the growth of the pathogen. Corn forage was harvested at approximately 35% dry matter, chopped to 10-mm lengths, and ensiled after treatment with one of the following: 1, distilled water (Control); 2, 1×10^5 cfu/g of *E. coli* O157:H7 (EC); 3, EC and 1×10^6 cfu/g of *Lactobacillus plantarum* (ECLP); 4, EC and 1×10^6 cfu/g of *Lactobacillus buchneri* (ECLB); and 5, EC and 2.2 g/kg of propionic acid (ECA). Each treatment was ensiled in quadruplicate in laboratory silos for 0, 3, 7, and 120 d and analyzed for EC counts, pH, and organic acids. Samples from d 120 were also analyzed for chemical composition, ammonia-N, yeasts and molds, and aerobic stability. Data were analyzed with the GLIMMIX procedure of SAS. The pH of silages from all treatments decreased below 4 within 3 d of ensiling and remained low until d 120. Consequently, the pathogen was eliminated within 3 to 7 d of ensiling. The ECLB and ECA silages resulted in fewer ($P < 0.05$) yeast counts, and greater ($P < 0.05$) acetate and propionate concentrations, respectively, and hence increased ($P < 0.05$) aerobic stability compared to the control, EC and ECLP silages. Subsamples of d 120 silages were reinoculated with 5×10^5 cfu/g of *E. coli* O157:H7 either immediately after silo opening on d 120 or after 168 h of aerobic exposure (d 127), and the pathogen was enumerated after 6 and 24 h, respectively. All silages had similar low pH values and no EC was detected after 6 h of aerobic exposure. Twenty-four h later, the EC and ECLP silages reinoculated with the pathogen after 168 h of aerobic exposure had relatively higher ($P < 0.05$) pH values (5.50 and 6.13) and EC counts (5.39 and 5.3 log cfu/g), respectively. Whereas those treated with *L. buchneri* or propionic acid had low pH values (4.24 or 3.96, respectively), and lower (1.32 log cfu/g) or no EC count, respectively. *Escherichia coli* O157:H7 was eliminated during ensiling of corn within 7 d of ensiling across treatments. Application of propionic acid or *L. buchneri* at ensiling suppressed the growth of the pathogen in aerobically exposed silage

Key Words: corn silage, *Escherichia coli* O157:H7, propionic acid

1388 Effect of glucoamylase, particle size, and duration of silage storage on dry matter loss and digestibility of ground corn rehydrated and ensiled. N. M. Lopes[1], P. C. Cardoso[2], and M. N. Pereira[*1,3], *[1]Universidade Federal de Lavras, Lavras, Brazil, [2]University of Illinois, Urbana, [3]Better Nature Research Center, Ijaci, Brazil.*

Storing mature corn grain by rehydration and ensiling can improve digestibility by prolamin degradation in the silo. Particle size (PS) can determine the rate of grinding during ensiling and the duration of silage storage (D) determines farm cash flow. We evaluated the digestibility and DM loss of rehydrated and ensiled corn (REH) in response to PS, D, and glucoamylase addition at ensiling (G). Treatments were formed by a 2 × 2 x 2 factorial combination of PS (584 vs. 844 µm geometrical mean PS), D (30 vs. 250 d), and G (CTL vs. GAM. Sanferm Yield, 120 AGU/g, Novozymes. 0.35 mL/kg of corn). Particle distribution of fine and coarse corn were (% above screen): 2360 µm: 0.2 and 9.9. 2000 µm: 0.5 and 10.6. 1180 µm: 2.2 and 14.4. 850 µm: 21.3 and 21.8. 425 µm: 57.9 and 24.8. 300 µm: 4.7 and 3.9. Bottom pan: 13.1 and 14.5. Mature corn (86.8% DM, 49.2% vitreous endosperm, 4.3% prolamin/starch) was hydrated to a targeted DM concentration of 65%. Approximately 1 kg of corn DM was ensiled in heat sealed, nylon-polyethylene vacuum pouches, 5 silos per treatment combination. At opening, silages were frozen, dried at 55°C for 72 h, and ground through a 1 mm mesh diameter screen for determination of ruminal in vitro DM degradation in 3, 7, and 18 h. Coarse corn had higher pH and DM loss and lower DM concentration than fine corn. There was no effect of PS on digestibility and prolamine concentration. Longer D reduced pH and prolamine concentration, increased DM concentration and degradation in 18 h, and had no effect on DM loss. Glucoamylase reduced pH and DM concentration and increased DM loss and degradation in 3 h, and also induced greater decrease in silage pH and greater increase in DM loss when added to coarse (4.20 vs. 4.71 and 5.65 vs. 2.25% of ensiled) than to fine corn (3.98 vs. 4.19 and 3.09 vs.2.34% of incubated). The increase in DM loss induced by GAM was smaller when D was 30 d (4.21 vs. 2.25% of ensiled) than 250 d (4.52 vs. 2.35% of ensiled). Glucoamylase increased the proportion of rapidly degradable fraction in corn grain, but at the expense of increased DM loss, especially with coarse grinding. Longer storage increased prolamin degradation and the potentially degradable grain fraction.

Key Words: amylase, corn ruminal degradation, corn grain silage.

1389 Effect on a crude fermentation extract derived from *Trichoderma* on the performance of early lactation primiparous cows. N. D. Walker[*1] and G. Povey[2], *[1]AB Vista Feed Ingredients, Marlborough, United Kingdom, [2]ADAS, Stratford on Avon, United Kingdom.*

Research has demonstrated that pre-treating rations with fermentation extracts (FE) derived from Trichoderma sp., may improve the digestibility of the ration. The aim of the current study was to evaluate the effect of pre-treating a ration with FE on the performance of early lactation primiparous cows. Fifty early lactation primiparous cows (DIM 55 ± 15) were fed a diet containing (on a DM basis), grass silage (26%), corn silage (24%), and concentrate (50%). The trial was split into a 3 wk co-variate pre-period, followed by a 12 wk test period. Individual milk yield was measured daily, averaged weekly; BW and BCS were measured every 3 wk and fertility and health records were maintained throughout. Animals were placed into 25 blocks on the basis of DIM, milk production during the pre-period. Within each block, cows were randomly assigned to either Control (CTL) or treated (TRT) groups. Either water (750 mL/T DM, CTL) or FE (750

mL/T DM, TRT) were sprayed onto each group's TMR. Every week, CTL and TRT TMR samples were analyzed by NIR to determine whether there was any effect of pre-treatment on TMR composition (%DM, %CP, %Starch, %NDF, %ADF, theoretical D-value and theoretical ME value). The statistical model included effects of FE, week, their interactions, as well as covariate milk production and analyzed by ANOVA. Significance was declared at $P < 0.05$, while numerical trends were discussed at $0.05 < P < 0.1$. NIR analysis of the CTL and TRT TMR samples indicated that digestibility was affected by FE, with an average increase in the predicted D-value from 63% to 67% and in predicted ME value from 10.5 to 11.1 MJ/kg DM. Over the entire test period, milk yield tended ($P = 0.09$) to be increased in the TRT versus CTL group, 28.2 vs. 27.6 kg/day. In the last 3 wk of the trial, the effect of FE on milk yield reached significance ($P < 0.05$), 27.7 vs. 26.3 kg/day. Fertility was also significantly ($P < 0.05$) improved in the TRT group, with higher confirmed pregnancy rates (84% vs. 64%), and less inseminations required (2.3 vs. 3.2). Body weight change was also higher in the FE group. To conclude, pre-treating the ration with FE led to an increase in the predicted digestibility and ME of the ration as determined by NIR. Milk yield tended to be increased and fertility improved.

Key Words: pre-treatment, digestibility, Trichoderma

1390 Whey protein-based composite gels fed to Jersey cows to protect β-carotene from rumen degradation. K. P. Ortega*, M. Rosenberg, J. G. Fadel, and E. J. DePeters, *University of California, Davis, Davis.*

Cow's milk has a low concentration of β-carotene (BC) due in part to low BC concentrations in feedstuffs, limited absorption of BC in the small intestine, and metabolism by and storage in tissues. There is also a phenomenon not well understood where dietary BC appears to be degraded in the rumen. Previously, a whey protein-based composite gel was demonstrated to increase the omega-3 concentrations in cow's milk by protecting the unsaturated fatty acids from biohydrogenation in the rumen. Our hypothesis was that the same technology if applied to BC would increase the BC concentration in the milk of Jersey cows. Jersey cows were used because this breed tends to have a higher concentration of BC in their milk than Holstein cows. The objective was to test the efficacy of a whey protein-based composite gel to protect BC from rumen degradation and increase the BC concentration of Jersey milk. Four primiparous and four multiparous Jersey cows were fed a basal total mixed-ration with 500 mg BC fed in 2 physical forms, either in a whey protein-based composite gel (GEL) or as free, rumen available BC (CTL) in a crossover design. The BC was fed once daily at the morning feeding. Periods were 21 d with a 2-wk interval between periods to minimize carryover effects. Concentrations of BC were measured in blood plasma and milk. Feeding the GEL significantly increased BC concentration in plasma by 0.6619 μg/ml in primiparous cows 0.6620 μg/ml in multiparous cows ($P < 0.0001$), but no significant increase in BC concentration occurred in milk. The WPI gel was effective in increasing the BC concentration of plasma; however, further research should address the transfer of BC from blood into milk.

Key Words: β-carotene, whey protein, Jersey, plasma, milk

1391 Rumen morphometrics of Nellore cattle fed different combinations of sodium monensin and virginiamycin. M. C. Pereira*[1,2], A. L. Rigueiro[3], A. C. J. Pinto[3], A. M. Silvestre[2], A. Perdigao[2], L. V. Toledo[2], L. D. Miranda[2], F. P. Luiz[2], M. D. Arrigoni[2], C. L. Martins[2], and D. D. Millen[3], *[1]Grant provided by São Paulo State Foundation (FAPESP), São Paulo, Brazil, [2]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil, [3]São Paulo State University (UNESP), Dracena campus, Dracena, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu campus, Brazil, was designed to evaluate the effect of the combined use of monensin (MON) and virginiamycin (VM) in high-concentrate diets during adaptation and finishing periods on rumen morphometrics and rumenitis of Nellore cattle. The experiment was designed as a completely randomized block, replicated 6 times (3 animals/pen), in which 72 26-mo-old yearling Nellore bulls (388.0 ± 31.1 kg) were fed in 24 pens for 90-d according to the treatments: MON (30 mg per kg of diet DM) during both adaptation and finishing periods (MON-MON); MON (30 mg/kg of DM) plus VM (25 mg/kg of DM) during the adaptation period, and only VM (25 mg/kg of DM) during the finishing period (MONVM-VM); MON (30 mg/kg of DM) plus VM (25 mg/kg of DM) during both adaptation and finishing periods (MONVM-MONVM); and only VM (mg/kg of DM) during the adaptation period, and MON (30 mg/kg of DM) plus VM (mg/kg of DM) during the finishing period (VM-MONVM). The adaptation program consisted of ad libitum feeding of three diets over adaptation period of 19 d with concentrate level increasing from 69% to 84% of diet DM. The finishing diet contained: 72.2% high-moisture corn grain, 14.0% sugarcane bagasse, 8.0% peanut meal, 2.0% coast cross hay, 3.0% supplement, and 0.8% urea (DM basis). Also, cattle were fed ad libitum twice daily throughout the study. At harvest, rumenitis incidence was determined, on the entire washed rumen, using a scale of 0 (no lesions noted) to 10 (severe ulcerative RUM). Likewise, a 1-cm^2 fragment of each rumen was collect from cranial sac. The number of papillae per cm^2 of rumen wall (NOP) was determined, as well as the mean papillae area (MPA). The rumen wall absorptive surface area (ASA) in cm^2 was calculated as follows: 1 + (NOP*MPA)–(NOP*0.002). No significant ($P > 0.10$) treatment effects were observed for any of the variables evaluated in this study:

Table 1392.

	G		A			D		*P*-value		
	Sorghum	Corn	CTL	AMG	GAM	30	180	G	A	D
DM, % of as fed	65.0	65.2	66.1	64.7	64.5	66.7	63.6	0.34	<0.01	<0.01

kd of Fraction B, %/h	3.14	3.33	3.30	3.20	3.21	3.17	3.30	0.01	0.42	0.05
Degradation 0 h, % of DM	39.8	32.5	33.7	38.2	36.6	32.9	39.4	<0.01	0.02	<0.01
Degradation 3 h, % of DM	47.7	41.2	43.7	44.7	44.9	39.9	49.0	<0.01	0.80	<0.01
Degradation 6 h, % of DM	51.5	47.1	50.3	48.5	49.2	43.8	54.8	0.03	0.76	<0.01
Degradation 12 h, % of DM	56.8	55.4	55.2	55.9	57.2	52.3	59.9	0.42	0.66	<0.01
Degradation 18 h, % of DM	62.1	60.6	61.3	61.2	61.5	57.6	65.0	0.28	0.98	<0.01
Degradation 48 h, % of DM	86.8	86.3	86.8	86.5	86.3	85.1	88.0	0.51	0.89	<0.01
ERD6, % of DM	60.3	56.5	57.1	59.6	58.5	56.0	60.8	<0.01	0.17	<0.01

rumenitis incidence (MONVM-VM = 1.00, MON-MON = 1.11, MONVM-MONVM = 1.00, VM-MONVM = 1.22; P = 0.92), NOP (P = 0.34), MPA (P = 0.46), and ASA (MON-VM-VM = 38.9 cm^2, MON-MON = 38.3 cm^2, MONVM-MONVM = 41.8 cm^2, VM-MONVM = 36.5 cm^2; P = 0.57). Thus, based on the results of this study, the combined use of monensin and virginiamycin in high-concentrate diets during adaptation and finishing periods did not negatively impact rumen morphometrics and rumenitis incidence of Nellore cattle.

Key Words: adaptation, additive, papillae

1392 Effect of glucoamylase and duration of silage storage on ruminal degradation and dry matter loss of corn and sorghum grain rehydrated and ensiled. T. Fernandes[1], K. T. Silva[1,2], D. R. Gomide[2], R. A. N. Pereira[2,3], C. L. S. Avila[1], and M. N. Pereira[*1,3], *[1]Universidade Federal de Lavras, Lavras, Brazil, [2]Empresa de Pesquisa Agropecuaria de Minas Gerais, Lavras, Brazil, [3]Better Nature Research Center, Ijaci, Brazil.*

Flint corn and sorghum grain are slow rumen degradable starch sources. Storing grain by rehydration and ensiling can improve ruminal degradability, by prolamin degradation in the silo. We evaluated the ruminal degradation and DM loss of rehydrated and ensiled grains of sorghum and flint corn (G) and the interaction of G with glucoamylase addition at ensiling (A) and duration of silage storage (D). Treatments were a 2 × 3 × 2 factorial combination of G (Sorghum, 129 µm geometrical mean particle size vs. Corn, 211 µm geometrical mean particle size), A (CTLvs. AMG vs. GAM), and D (30 d vs. 180 d). Dosage of glucoamylases AMG (AMG, Novozymes) and GAM (Sanferm Yield, Novozymes) was 0.35 mL/kg of grain. Mature grain was rehydrated to a targeted DM concentration of 65%. Approximately 4 kg of rehydrated grain was ensiled in 10 cm diameter × 60 cm length PVC silos with Bunsen valves (6 silos/treatment combination). At opening, silages were frozen and dried at 55°C for 72 h for determination of ruminal in situ DM degradation in 0 (bag wash), 3, 6, 12, 18, and 48 h of incubation (3 rumen cannulated cows). Time 0 DM disappearance was the fast degrading Fraction A. The slowly degradable Fraction B was 100– Fraction A (a 2 pool model). The fractional rate of Fraction B degradation (kd) was calculated as the slope of the linear regression over time of the Ln of bag residue/incubated. Effective ruminal degradation (ERD6) was calculated as: A + B [kd/(kd + kp)], kp at 6%/h. Glucoamylases increased Fraction A, but had no effect on DM degradation at other incubation times and ERD6, and increased DM loss, especially in longer storage (P < 0.01 for the interaction of A and D). Corn had greater DM loss and kd than sorghum, but lower DM degradation up to 6 h of ruminal incubation and ERD6, the smaller particle size of ground sorghum may explain such response. Longer storage increased DM loss, kd, ruminal degradation at all incubation times, and ERD6. Glucoamylase increased the rapidly degradable grain fraction at the expense of increased DM loss. Longer storage increased ruminal degradation and DM loss. Rehydrated and ensiled sorghum was as degradable in the rumen as corn and had lower DM loss, but had lower starch concentration than corn.

Key Words: amylase in silage, corn grain silage, sorghum grain silage

1393 Effect of Optifeed on feed intake and live weight of Holstein calves. D. A. Vermeire*, *Nouriche Nutrition, Ltd., Lake Saint Louis, MO.*

Effect of a plant extract-based additive (Optifeed®, OF, Phode Laboratoires, Albi, France) on feed intake and live weight was tested in 154 Holstein calves raised for dairy beef in a naturally ventilated barn for a 42 d trial. Calves were individually housed and fed, and were fed 1 of 2 treatment feeds. Calves in pens 1, 2, 5, 6, 9, 10, etc. (Optifeed®) were assigned to the pre-starter feed (Smart Starter, BABY DOLL Nutrition Ltd, Lake St. Louis, MO) containing OF which was incorporated into the supplement pellet to provide 1 kg OF/1,000 kg of complete feed. Calves in pens 3, 4, 7, 8, 11, 12, etc. (Control) were assigned to receive the same pre-starter feed without OF. On d 43, calves were moved into group pens and fed a common starter feed. Calves were weighed on arrival (d 1), and d 14, 28, and 42. Daily feed provision was monitored with plastic cups which held an average 165 g (blue cup, d 1 to 21) or 316 g (white cup, d 22 to 42) of textured pre-starter feed. Data were analyzed using Statistix 10.0 using ANOVA for completely randomized experiment with calf as the experimental unit. Estimated (using cups) differed from actual (by weight) feed consumption by < 3% demonstrating that the cup delivery model was a good method for measuring daily intake of pre-starter feed by young Holstein calves. Calves fed OF consumed more feed from Day 35 to 42 (11,200 ± 365.8 vs. 10,155 ± 358.2 g, $P = 0.04$), tended to consume more feed over the entire 42 d trial (32,282 ± 1045.4 vs. 29,700 ± 1023.7 g, $P = .08$), and had heavier LW (60.4 ± 0.61 vs. 58.8 ± 0.60, $P = 0.05$) than calves fed control. Optifeed® appears to be an efficient plant extract-based additive to enhance early pre-starter intake and growth of calves.

Key Words: calves, feed intake

1394 Dose-dependent effects of a sensory additive on the eating behavior of TMR-fed dairy cows. F. Bargo*[1,2], I. Guasch[3], G. Tedo[1], A. Bach[4,5], and I. R. Ipharraguerre[1,6], *[1]Lucta S.A., Barcelona, Spain, [2]FAUBA, Buenos Aires, Argentina, [3]Blanca, Lleida, Spain, [4]ICREA, Barcelona, Spain, [5]IRTA, Caldes de Montbui, Spain, [6]University of Kiel, Kiel, Germany.*

Forty four Holstein dairy cows (156 DIM, 28.9 kg/d of milk, 648 kg of BW) were assigned to a 4 × 4 Latin Square design with 25-d periods replicated 11 times to evaluate the dose response to a sensory additive (ProEfficient, PE; Lucta S.A.) on eating behavior of dairy cows fed a TMR. Cows were grouped in 11 blocks and, within blocks, randomly assigned to 4 doses of PE: 0, 15, 30, and 45 g/d. The TMR averaged 16.4% CP, 31.4% NDF, and 1.63 Mcal NE_L/kg. Cows were fed ad libitum on electronic scales and eating behavior and feed consumption were recorded automatically. Data were analyzed using a model with fixed effects of dose (treatment), period, block, and the random effect of cow within block using PROC MIXED of SAS. Treatments effects were evaluated using linear, quadratic, and cubic orthogonal contrasts. Dose of PE affected ($P < 0.05$) eating time, intake rate, dry matter (DM) intake, and energy corrected milk (ECM) of dairy cows. Eating time responded cubically ($P < 0.05$) to PE dose because cows fed 30 g/d dedicated more time to eat than cows fed the other doses. There was a quadratic effect ($P < 0.05$) of PE dose on intake rate given that cows fed 15 and 30 g/d had lower rates than cows fed 0 and 45 g/d. Lying time was not affected ($P > 0.05$) by PE dose. DM intake and ECM responded cubically ($P < 0.05$) to PE dose because cows fed 30 g/d consumed the most DM and produced the largest amount of ECM. In summary, cows fed a TMR supplemented with 30 g/d of PE spent more time eating but at a lower rate than cows receiving other PE doses. These results confirm the positive impact of the sensory additive PE on the eating behavior of dairy cows and indicate that such an effect is most pronounced at 30 g/d.

Key Words: dose response, eating behavior and sensory additive

1395 Effect of rumen-protected capsicum on milk production in early lactating cows in a pasture-based system.

K. Stelwagen*[1], E. H. Wall[2], and D. M. Bravo[2], [1]*SciLactis, Hamilton, New Zealand,* [2]*Pancosma, Geneva, Switzerland.*

In monogastric animals capsicum affects insulin homeostasis, glucose metabolism and nutrient partitioning. Recent research has shown a beneficial response on milk production and glucose utilization in dairy cows fed rumen-protected *Capsicum* oleoresin. During early lactation, when cows are in negative energy balance, they are in a state of insulin resistance (IR), promoting increased lipolysis, decreased peripheral tissue sensitivity and making more glucose available for mammary milk synthesis (i.e., "glucose-sparing"). The hypothesis of the current study is that rumen-protected capsicum extract enhances milk production during early lactation. Multiparous New Zealand Holstein Friesian cows on a commercial farm were randomly assigned to a Control group (CON; $n = 25$) or a group receiving 100 mg/d per cow of rumen-protected capsicum oleoresin (Nexulin, Pancosma, NEX; $n = 25$) during the first 100d in milk to determine the effect of Nexulin on milk production and body weight during early lactation under pasture-grazing conditions. All cows were managed exactly the same, as a single group, and were milked using 3 automated milking systems, allowing daily measurements of milk yield and composition and body weight. Nexulin was provided in 0.22 kg/d concentrate to NEX cows. All cows received < 3kg concentrate, 0.5 kg molasses and ad libitum access to grass pasture. Data were analyzed by (multivariate) analysis of variance (M)ANOVA, using initial body weight as a covariate for production parameters. Average milk yield was increased in NEX cows (27.9 vs. 26.1 kg/d, ± 0.9, $P < 0.06$) during the first 100 d of lactation. However, the effect occurred after peak production (wk > 5; 27.7 vs. 25.7 kg/d, ± 0.9, $P < 0.04$). Milk composition did not differ, but yield of fat, protein and lactose were increased in NEX cows (respectively, g/d: 1,397 vs. 1,313, ± 60, $P < 0.17$; 1,118 vs. 1,014 ± 39, $P < 0.02$; 1,409 vs. 1,321 ± 48, $P < 0.07$). All cows maintained their body weights (no differences) and prevalence of subclinical ketosis, based on milk fat: protein > 1.5, was lower in the NEX group (1.7 vs. 10.2%, ± 1.0, $P < 0.02$; nonparametric analysis). Rumen-protected capsicum increased milk production during early lactation in cows on pasture, but not until after peak lactation (wk > 5). This delayed response is consistent with delayed glucose sparing and may be due to the previous observation that in the New Zealand pasture-adapted strain of Holstein Friesian cows, IR is lower and insulin levels are higher immediately post-partum compared to American Holstein cows.

Key Words: *Capsicum* oleoresin, early lactation, milkproduction

1396 Effects of Valkalor on feed intake and digestibility, rumen functions, milk yield and composition in mid lactating dairy cows.

M. Premi[1], P. Bani[1], A. Minuti[1], J. P. Ricaud[2], M. Aoun[2], A. Greuter[2], and E. Trevisi*[3], [1]*Università Cattolica del Sacro Cuore, Piacenza, Italy,* [2]*Idena, Sautron, France,* [3]*UniversitaÂ Cattolica del Sacro Cuore, Piacenza, Italy.*

The inclusion of feeds with nutraceutical properties in the livestock diets has been proposed to modulate rumen fermentations, improve post rumen-digestive processes and physiological status. This approach is considered a new tool to improve animal health and to increase feed efficiency. The aim of this research was to assess the effects of Valkalor (Idena, Sautron, France), a dietary supplement which contains yeast cell wall, an extract from *Hibiscus sabdariffa*, and minerals, on the health status, feed intake and digestibility, rumen functions, milk yield and composition of mid-late lactating cows. 36 Italian Friesians were used in a change-over design with 2 treatments in two 35-d periods, with a 1 wk washout period in between. Each period started with 14 d of adaptation. Cows were divided into 2 homogeneous groups, each one further divided in 3 boxes of 6 subjects. The control group (CTR) received a standard total mixed ration (TMR) diet for lactating dairy cows whereas the treated group (TRT) received the same diet supplemented with Valkalor (TRT) at 50 g/cow/day, included in the TMR. Daily feed intake of each box, individual milk yield, health status, BW and rumination time were recorded daily. In each period, BCS was evaluated at Day 14 and 35. Individual samples of milk and blood were taken at Day 14 and 34 to assess milk composition and metabolic profile. Samples of feces and TMR were collected at Day 33 and 34 to estimate the feed digestibility, using AIA as indigestible marker. At Day 35, rumen samples were taken 6h after the morning feeding, to assess the VFA profile. Treated

cows showed higher feed intake ($P < 0.05$), feed digestibility ($P < 0.05$ for DM, OM, CP and starch), rumination time (interaction treatment × day: $P < 0.05$) and total VFA concentration (CTR 121 vs. TRT 129 mmol/L; $P < 0.01$); BW showed a slight increase ($P < 0.05$) in TRT compared to CTR. Milk yield was higher in TRT (31.7 vs. 30.5 kg/d in TRT and CTR, respectively; $P < 0.01$), whereas milk composition was only slightly affected and the lactose and total protein yield were higher in TRT ($P < 0.01$ and NS respectively). At metabolic level, treated cows showed a better liver functionality (higher albumin, paraoxonase and lower ceruloplasmin; $P < 0.05$). Positive effects of the supplementation became progressively more evident during the treatment. Results suggest the effectiveness of Valkalor on the improvement of the production and the health status of dairy cows.

Key Words: nutraceutic, rumen fermentation, milk yield

1397 Screening for effects of live yeast or yeast derivative on dry matter disappearance in batch culture. P. X. Jiao[*1,2], F. Liu[2], Z. X. He[1,3], S. Ding[1], N. D. Walker[4], K. A. Beauchemin[1], T. W. Alexander[1], and W. Z. Yang[1], *[1]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Northwest Agriculture and Forestry University, Yangling, China, [3]Key Laboratory for Agro-Ecological Processes in Subtropical Region, Hunan Research Center, The Chinese Academy of Sciences, Changsha, China, [4]AB Vista Feed Ingredients, Marlborough, United Kingdom.*

The objective of this study was to screen for the effects of live yeast (LY) or yeast derivative (YD) on DM disappearance (DMD) in batch culture varying yeast products, media pH and dosage of yeast. The study was arranged in a 5 yeasts × 2 pH × 4 dosages + monensin (positive control) factorial design. Substrate was a high-grain diet containing 10% barley silage and 90% concentrate (DM basis). Five yeast products were 3 LY (LY1, LY2, LY3) and 2 YD (YD4, YD5). The buffer pH was low (5.8) and high (6.5). Doses of LY (cfu/ml) were control (no LY), 4×10^6, $8 \times 10^6$and 1.6×10^7, and doses of YD (mg/bottle) were control (no YD), 15, 30, and 60. The dose of monensin was 0.17 mg/bottle. Inoculum was obtained from 2 ruminally fistulated beef heifers fed the same diets to the substrate. Substrate (0.75 g) ground through a 1-mm sieve was weighed into a filter bag and incubated for 24 h in a gas-tight culture bottle in 3 replications by each combination of treatments. The culture was repeated at different day. Data were analyzed using mixed procedure of SAS with a model that includes fixed effects of yeast, pH, dosages, and 2 way interactions, and the random effects of day. There was interaction ($P < 0.05$) of LY2, LY3, YD4 and YD5 with media pH or yeast with its dosage. Supplementation of LY1 had higher ($P < 0.01$) DMD (61%) at pH 6.5, whereas the DMD was lowest ($P < 0.05$) for YD5 (54%) and medium for other yeasts (averaged 57%). Increased media pH from 5.8 to 6.5 improved ($P < 0.01$) DMD (low vs. high pH; averaged 47 vs. 59%). Increasing the dose of LY3 and YD5 linearly ($P < 0.05$) increased the DMD at pH 6.5 with no dose effect of other yeasts. Adding monensin overall improved ($P < 0.05$) the DMD (62 vs. 57%) compared with yeasts at pH 6.5; whereas, at pH 5.8, the DMD was lower with monensin (44%) vs. LY2 (47%; $P < 0.05$), LY3 (47%; $P < 0.05$) or YD5 (49%; $P < 0.01$). These results suggest that in vitro DMD of high-grain diet varied with source and dosage of yeast and media pH. The improved DMD at pH 5.8 with LY2, LY3 and YD5 over monensin would be beneficial to high-grain fed cattle.

Key Words: dry live yeast, yeast derivative, batch culture, fermentation pH

1398 Supplementation of β-mannanese (CTCZYME) tends to improve immune traits in early lactating dairy cows. M. L. C. B. Azevedo[1], T. Tewoldebrhan[2], R. Appuhamy[2], G. C. Reyes[2], K. J. Bolek[2], S. Seo[3], J. J. Lee[4], and E. Kebreab[*2], *[1]Wageningen University, Wageningen, Netherlands, [2]University of California, Davis, Davis, CA, [3]Chungnam National University, Daejeon, The Republic of Korea, [4]CTC Bio Inc, Seoul, The Republic of Korea.*

Early lactating dairy cows typically face metabolic and immune challenges. Therefore, improving health status, besides feed conversion efficiency, can affect their productivity and welfare positively. β-mannanase is a fibrolytic enzyme that breaks down the non-structural carbohydrate mannan. It is currently used in pig and poultry production to increase nutrient digestion and may also improve their immune status. However, information about the effects of β-mannanase on ruminants is scarce. In a previous experiment, β-mannanese supplementation improved feed conversion efficiency and reduced somatic cell count of mid-lactating dairy cows. The objective of this study was to examine immune responses to β-mannanese supplementation in early-lactating cows. Fourteen early-lactating Holstein cows, paired by parity and milk production, were allocated to 2 treatments; control (50:50 forage:concentrate) and β-mannanese supplemented (0.1% of concentrate DM) diet. Acute phase protein, haptoglobin, and Immunoglobulin G (IgG) levels in blood were measured weekly from 14 to 50 d in milk. The CD4 and CD8 lymphocytes percentages in blood drawn at one time point were also evaluated by flow cytometry. Absolute numbers of CD4 and CD8 lymphocytes, total white blood count and the differential count of the 5 major white blood counts (neutrophils, lymphocytes, monocytes, eosinophils and basophils) were measured. Significance of β-mannanese supplementation on the blood immune traits were analyzed using linear mixed effects model including fixed effects of treatment, parity and days in

milk, and random effect of cow. Blood haptoglobin concentration tended to decrease ($P = 0.088$) in cows fed β-mannanese supplemented diet (0.373 ± 0.042 mg/ml) compared to those receiving control diet (0.498 ± 0.048 mg/ml). Higher concentrations of plasma haptoglobin may indicate a response to inflammation. Blood IgG concentrations and CD4:CD8 ratio were numerically higher in cows fed β-mannanese, but not significantly different ($P = 0.376$ and $P = 0.181$, respectively). Results for total white blood count and the five major white blood counts were also not significantly different. Dietary supplementation of β-mannanase has a potential to improve immunity of early-lactating cows.

Key Words: β-mannanase, immune traits, lactating cows

1399 To guarantee its threshold concentration in the rumen, live yeast *Saccharomyces cerevisiae* (CNCM I-4407) needs to be supplemented daily to dairy cows. C. Julien[1], M. Rey[*1], J. P. Marden[1], E. Auclair[1], and C. Bayourthe[2], *[1]Phileo Lesaffre Animal Care, Marcq-en-Baroeul, France, [2]Université de Toulouse, INRA, INPT UMR1388 GenPhySE, Castanet-Tolosan, France.*

It has already been stated that live yeast (LYSc47, 10^{10} CFU/g DM, *Saccharomyces cerevisiae* CNCM I-4407, Phileo Lesaffre Animal Care, France) is unable to colonize the digestive tract of cows. But, is the LY ruminal concentration stable after few days of distribution and how does it change within the day? Four early-lactating Holstein cows fitted with permanent ruminal cannulas were assigned to 4 treatments in a 4 × 4 Latin square design: 2 control diets consisting of a corn-silage-based TMR with ground corn (CD) or ground wheat (WD) top dressed at 0 to 5.10^{10}CFU/cow/day of LYSc47 in the morning meal (YCD and YWD, respectively). Each 14-d experimental period consisted of 9 d of adaptation to the diet, 3 d of measurement (d 1 to d 3) and a 2-d transition phase. During d 1 to d 3, ruminal fluid of cows was individually sampled −1 h, +0.5 h and +7 h around the morning meal. The concentration of live LYSc47 was determined by the method for counting the CFU (CFU/mL of ruminal fluid) on YM agar containing 1% chloramphenicol. Data were analyzed using general mixed model procedure of SPSS (IBM SPSS Statistics V22) including fixed effect of day, diet and hour nested in day and cow as random effect. No LySc47 was detected in ruminal fluid of cows receiving WD or CD. For cows receiving LYSc47, ruminal concentration of LYSc47 was affected ($P < 0.001$) by time of sampling during the day: 3.91, 4.94 and 4.16 log CFU/mL at −1 h, +0.5 h and 7 h around morning meal, respectively. LYSc47 content significantly increased 30 min after ingestion of the daily dose: +1.03 log CFU/mL and then decreased significantly toward lower level (−0.78 log/mL over 7 h whatever is the diet). LYSc47 content at +7 h remained significantly higher than at −1 h, but after 9 d of daily supplementation, LYSc47 ruminal concentration remained similar ($P = 0.432$) over the 3 d of sampling whatever was the diet. It clearly showed that LYSc47 had a quick revival capacity in ruminal content and that its daily supplementation is essential to maintain a threshold concentration in ruminal ecosystem.

Key Words: live yeast, rumen, dairy cow

1400 Feedlot performance and carcass traits of Nellore cattle fed different combinations of sodium monensin and virginiamycin. A. L. Rigueiro[*1], F. P. Luiz[2], M. M. Squizatti[1], A. H. Assumpção[1], M. M. Ferreira[1], C. P. Garcia[2], L. R. Muller[2], A. P. D. Bueno[2], C. L. Martins[2], M. D. Arrigoni[2], and D. D. Millen[1,3], *[1]São Paulo State University (UNESP), Dracena campus, Dracena, Brazil, [2]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil, [3]SÃ£o Paulo State University (UNESP), Dracena campus, Dracena, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu campus, Brazil, was designed to evaluate the effect of the combined use of monensin (MON) and virginiamycin (VM) in high-concentrate diets during adaptation and finishing periods on feedlot performance and carcass characteristics of Nellore cattle. The experiment was designed as a completely randomized block, replicated 6 times (3 animals/pen), in which seventy-two 26-mo-old yearling Nellore bulls (388.0 ± 31.1 kg) were fed in 24 pens for 90-d according to the treatments: MON (30 mg per kg of diet DM) during both adaptation and finishing periods (MON-MON); MON (30 mg per kg of diet DM) plus VM (25 mg per kg of diet DM) during the adaptation period, and only VM (25 mg per kg of diet DM) during the finishing period (MONVM-VM); MON (30 mg per kg of diet DM) plus VM (25 mg per kg of diet DM) during both adaptation and finishing periods (MONVM-MONVM); and only VM (25 mg per kg of diet DM) during the adaptation period, and MON (30 mg per kg of diet DM) plus VM (25 mg per kg of diet DM) during the finishing period (VM-MONVM). The adaptation program consisted of ad libitum feeding of three diets over adaptation period of 19 d with concentrate level increasing from 69% to 84% of diet DM. The finishing diet contained: 72.2% high-moisture corn grain, 14.0% sugarcane bagasse, 8.0% peanut meal, 2.0% coast cross hay, 3.0% supplement, and 0.8% urea (DM basis). Also, cattle were fed ad libitum twice daily throughout the study. Cattle fed the combination of MON and VM during the adaptation period and only VM during the finishing period had greater ($P < 0.05$) final BW in kg (MONVM-VM = 536.1^{a}, MON-MON = 516.0^{b}, MONVM-MONVM = 512.7^{b}, VM-MONVM = 518.2^{b}), DMI in kg (MONVM-VM = 9.62^{a}, MON-MON = 8.73^{bc}, MONVM-MONVM = 8.47^{c}, VM-MONVM = 9.09^{b}), ADG in kg (MONVM-VM = 1.65^{a}, MON-MON = 1.42^{b}, MONVM-MONVM = 1.38^{b}, VM-MONVM = 1.44^{b}), as well as heavier HCW in kg (MONVM-VM = 284.2^{a}, MON-MON

= 266.4[b], MONVM-MONVM = 264.1[b], VM-MONVM = 270.8[b]) and increased dressing percentage (MONVM-VM = 53.0[a], MON-MON = 51.7[b], MONVM-MONVM = 51.5[b], VM-MONVM = 52.2[b]). No treatment effect on G:F ratio was observed ($P = 0.32$). Thus, Nellore yearling bulls should be fed high concentrate diets containing MON and VM during the adaptation period and only VM during the finishing period.

Key Words: adaptation, additive, ionophore

1401 Effects of supplementation of isoquinoline alkaloids and monensin on microbial protein synthesis, ruminal fermentation and nutrient digestibility in steers fed a finishing diet.

H. I. Rogge*[1], J. A. Aguilar-Hernández[2], S. Morin-Luogo[3], J. D. Urías-Estrada[3], M. A. López Soto[3], A. Barreras[3], V. González-Vizcarra[3], A. Plascencia[3], and R. A. Zinn[4], *[1]Phytobiotics Futterzusatzstoffe GmbH, Eltville, Germany, [2]Instituto de Investigaciones en Ciencias Veterinarias, UABC, Mexicali, Mexicali, Mexico, [3]Instituto de Investigaciones en Ciencias Veterinarias, UABC, Mexicali, Baja California, Mexicali, Mexico, [4]University of California-Davis, El Centro, CA.*

Four Holstein steers with ruminal and duodenal cannulas were used in a 4 × 4 Latin square design to examine the effect of different treatments on ruminal fermentation and digestive function. Treatments consisted of a steam-flaked corn-based finishing diet supplemented with Sangrovit® RS (IQs) and monensin sodium (MS) as follows: 1) no additives (Control), 2) 1.35 mg IQs/kg diet, 3) 30 mg MS/kg diet, and 4) 1.35 mg IQs/kg diet plus 30 mg MS/kg diet. Experimental periods consisted of a 10-d adjustment period followed by a 4-d collection period. Between each experimental period, steers were allowed a 7-d recovery period during which all steers were fed the control diet. There were no differences ($P > 0.05$) between controls and IQs on ruminal digestion of OM, starch and NDF, but ruminal microbial efficiency and protein efficiency increased ($P < 0.05$) 7.6 and 9.1%, respectively with IQs supplementation. IQs increased (6.1%, $P = 0.02$) postruminal digestion of N and tended (3.7%, $P = 0.06$) to increase total tract digestion of N. Compared to the control, duodenal flow of feed N was greater (14.7%, $P = 0.04$) for steers which were supplemented with MS and tended to be greater in the IQs group (11.9%, $P = 0.09$). There was no difference ($P = 0.17$) between IQs and the MS group. Duodenal flow of microbial N was lower ($P \leq 0.01$) in the MS group compared to control and IQs. Microbial efficiency and protein efficiency were greater in the IQs group (13.8 and 10%, respectively, $P < 0.01$) compared to the MS group. IQs supplementation increased ruminal molar proportion of acetate 11.9% ($P = 0.05$) with no differences ($P > 0.12$) in molar proportions of propionate or acetate:propionate molar ratio. Compared to the control diet, MS did not affect ($P > 0.80$) ruminal pH, molar concentrations of total VFA, ruminal VFA molar proportions or estimated methane production. Combining IQs + MS did not improve the responses on digestion nor ruminal fermentation compared to the IQs or the MS group. IQs represent a tool to improve N utilization in ruminants.

Key Words: isoquinoline alkaloids, steers

1402 Effect of pelleted feed products and bambermycins on performance when fed to cattle grazing corn residue.

C. A. Welchons*[1], R. G. Bondurant[1], F. H. Hilscher[1], J. C. MacDonald[2], and G. E. Erickson[1], *[1]University of Nebraska, Lincoln, [2]University of Nebraska-Lincoln, Lincoln.*

Two corn residue grazing trials (84 and 85-d) were conducted from November to January in successive years to evaluate the effects of a corn byproduct pellet and bambermycins (Gainpro) on growing cattle performance. Both trials were arranged as a 2 × 3 factorial, inclusion of bambermycins (0 or 10 mg/d and 0 or 20 mg/d for years 1 and 2, respectively) was the first factor. The second factor was level of supplemental pellet (year 1) and amount of RUP supplied in the supplemental pellet (year 2). Supplement was delivered daily via Calan gates. In year 1, 60 steers (initial BW = 254 kg; SD = 26) were supplemented a pellet consisting of 54% corn stover treated with calcium oxide, 32% dried distillers grains, and 14% solubles at 0.3, 0.7, or 1.1% of BW. In year 2, 60 steers (initial BW = 222kg; SD = 14) were supplemented a pellet consisting of 44.5% corn stover treated with calcium oxide, 40% Soypass, soybean meal (SBM), or processed SBM, and 15.5% solubles at 1.82 kg/d. In year 1, steers were dosed with 10 g of titanium dioxide daily to measure residue intake. Steers were limit fed 5-d and weighed on 2 consecutive days for beginning and ending BW. There was no interaction between bambermycin inclusion and level of supplement on ending BW, ADG, or DMI in year 1 ($P \geq 0.82$). Bambermycin inclusion did not affect ending BW, ADG, or DMI ($P \geq 0.78$). There was a linear increase ($P < 0.01$) for ending BW and ADG as pellet supplementation increased. For steers supplemented at 0.3, 0.7 and 1.1% of BW, ADG was 0.01, 0.28 and 0.56 kg/d, respectively. There was a quadratic decrease in DMI as the trial progressed and supplement increased ($P < 0.01$). In year 2, there was no interaction between inclusion of bambermycins and RUP supplied in the pellet for ending BW or ADG ($P \geq 0.61$). Bambermycin inclusion at 20 mg/steer daily did not affect ending BW or ADG ($P \geq 0.79$). Likewise, there was no main effect of pellet type on ending BW or ADG ($P \geq 0.57$). For steers receiving pellet with supplemental protein provided by SBM, Soypass, or processed SBM, ADG was 0.35, 0.35, and 0.33 kg/d, respectively. Neither bambermycins nor increased amounts of RUP in the supplemental pellet affected performance of steers grazing corn residue.

Key Words: growing, pellet, corn residue

1403 Mineral-glycinate supplementation improves the systemic immune response to lipopolysaccharide challenge in lactating dairy cows. E. H. Wall*[1], K. Tran[2], C. Wallinger[2], J. S. Hogan[2], and W. P. Weiss[2], *[1]Pancosma, Geneva, Switzerland, [2]Department of Animal Sciences, OARDC, The Ohio State University, Wooster.*

Previously, it was observed that supplementation of growing steers with a Zn-glycinate complex improved immunity compared to an inorganic Zn source. The objective of this experiment was to test the hypothesis that supplementation of dairy cows with minerals in glycinate form would improve immune responses. Twelve mid-lactation Holstein cows were fed either a diet (UNSUP) void of supplemental Cu, Zn, and Mn (containing approximately 8, 30, and 30 ppm of each mineral, respectively in inorganic form) or a diet (GLY) containing Cu, Zn, and Mn in the glycinate form (B-TRAXIM® 2C, Pancosma; 16, 60, and 60 ppm, respectively) for 30 d. After 30 d, blood samples were collected for measurement of Cu in the serum as well as isolation of neutrophils to assess function. Cows were then exposed to intramammary infusion with lipopolysaccharide (LPS) of*Escherchia coli* O111:B4 (10 mL of a 10 μg/mL solution infused into the teat canal) to compare host defense responses, which were monitored for 7 d. Milk samples were collected for analysis of SCC and visual characterization. Clinical scoring (1 = normal; 5 = severe) was conducted and rectal temperature was monitored to estimate the systemic response to the LPS challenge. As expected, concentrations of Cu in the serum were increased with GLY (0.77 vs. 0.91 μg/g; $P < 0.05$). Percentage of intracellular kill and phagocytic neutrophils were not affected by treatment ($P > 0.05$); however, the phagocytic index (number of bacteria ingested per phagocyte) was decreased in GLY cows (2.47 vs. 1.85; $P < 0.05$). Before, during, and after the LPS challenge there was a trend for decreased SCC in GLY cows ($P < 0.15$). By design, the LPS challenge elicited a marked increase in clinical score (peak score = 4) and this was not affected by supplementation ($P > 0.70$). Rectal temperature during the first 24h post-LPS challenge was lower in the GLY cows, characterized by a lower area under the curve (933.8 vs. 927.7; $P < 0.05$) and a lower peak temperature (40.5 vs. 40.0°C; $P < 0.05$). The decreased body temperature combined with the lower SCC in GLY cows indicates that mineral-glycinate supplementation influences immune responses in dairy cows and may improve the ability to fight off infection. This has implications for mammary health; however, additional research is needed to distinguish the role of each metal, and their form, in this response.

Key Words: glycinates, immunity, mastitis

1404 Effects of replacing soybean meal with canola meal or treated canola meal on ruminal digestion, and omasal nutrient flow in lactating dairy cows. E. Marostegan de Paula*[1], M. A Camargo Danes[2], N. E Lobos[3], F. L. Drago[4], G. I. Zanton[5], G. A. Broderick[6], and A. Faciola[1], *[1]University of Nevada, Reno, [2]Federal University of Lavras, Lavras, Brazil, [3]Kemin Industries, Des Moines, IA, [4]University of Sao Paulo, Piracicaba, Brazil, [5]USDA-Agricultural Research Service, U.S. Dairy Forage Research Center, Madison, WI, [6]Broderick Nutrition & Research, LLC, Madison, WI.*

Treated canola meal (TCM) was produced as an attempt to increase the RUP fraction of canola meal (CM) with the goal of increasing AA availability for absorption in the small intestine. The objective of this study was to measure nutrient and microbial omasal flow when CM and TCM replaced soybean meal (SBM) in the diet of dairy cows. Six rumen-cannulated

Table 1404.

Table 1. Intake, DM flow, and flow of N fractions at the omasal canal in dairy cows

	Diet				Contrasts *P* -value	
Item	SBM	CM	TCM	SEM	SBM vs. CM+TCM	CM vs. TCM
DM intake, kg/d	25.4	26.0	26.7	1.62	0.28	0.48
DM Flow, kg/d	18.9	19.3	19.8	1.33	0.34	0.52

[1]NAN = non-ammonia-N, NMNAN = nonmicrobial NAN; FAB - and PAB-NAN = fluid- and particle-associated bacterial NAN; OMTDR = OM truly digested in the rumen.

cows were blocked into 2 blocks of 3 cows and randomly assigned within blocks to 3 dietary sequences in a replicated, 3 × 3 Latin square design with 21 d of adaptation and 7 d of sampling. Treatments differed only in CP source, which were: SBM, CM, or TCM. The TCM was treated by extrusion, with added molasses to promote the browning reaction. All diets contained (DM basis) 30% alfalfa silage, 30% corn silage, 4% soy hulls, 2.4% mineral-vitamin premix and 16% CP. The SBM diet contained 25% high moisture corn (HMC) and 8.6% SBM; the canola diets contained 22% HMC and 11.4% CM or TCM. Omasal sampling was performed during the last week of each period. Data were analyzed using the MIXED procedure of SAS. Orthogonal contrasts were used to compare effects of different protein sources (SBM vs. CM + TCM) and (CM vs. TCM). Partial data are presented in Table 1. Compared to SBM, CM and TCM increased N intake ($P = 0.04$) and there was a trend ($P = 0.10$) to increase RDP supply (kg/d), and N truly digested in the rumen (kg/d). There were no differences in DMI, ruminal digestibility, efficiency of ruminal microbial synthesis, and flows of: RUP, non-microbial-non-ammonia-N, and total microbial-non-ammonia-N among diets. Results indicate that both canola diets may increase N intake and RDP supply. Treating CM by extrusion did not affect microbial N flow at the omasal canal. Under the conditions of the present study, treating CM by extrusion was not effective in increasing RUP flow in dairy cows.

Key Words: nitrogen metabolism, rumen undegraded protein, omasal flow

1405 Growth performance of dairy heifers limit-fed distillers dried grains with ad libitum forage.

A. K. Manthey* and J. L. Anderson, *Dairy Science Department, South Dakota State University, Brookings.*

Most previous research on feeding distillers dried grains with solubles (DDGS) to dairy heifers has been conducted using a set forage to concentrate ratio in total mixed rations. Our objective was to determine the growth performance and DMI of heifers when fed DDGS or a corn and soy products concentrate mix with ad libitum grass hay. Our hypothesis was that heifers fed DDGS would have improved G:F because of slightly greater dietary fat, but growth performance would be maintained. A 16-wk randomized complete block design study was conducted using 24 heifers (18 Holstein and 6 Brown Swiss; 219 ± 2 d of age; 230 ± 4 kg BW). Heifers were blocked based on age and breed. Treatments were: 1) a control corn and soy products concentrate mix (CON) and 2) DDGS based concentrate mix (DG). Both concentrate mixes were fed at 0.8% of BW (DM basis) and grass hay was fed ad libitum. Heifers were individually fed respective concentrate mixes at 0800 h and hay was offered at 0900 h using a Calan gate feeding system. Orts were recorded daily before feeding. Frame sizes, BW, and BCS were measured at 4 h post feeding on 2 consecutive d during wk 0 and then every 2 wk thereafter throughout the feeding period. Data were analyzed using the MIXED procedures of SAS 9.4 with means compared using Tukey's test. Significance was declared at $P < 0.05$ and tendencies were declared at $0.05 \leq P < 0.10$. There were no significant interactions of treatment by wk. Heifer DMI (6.18 and 6.31 kg/d; SEM = 0.276 for the CON and DG, respectively), BW (269.8 and 266.9 kg; SEM = 9.86), and ADG (0.99 and 0.96 kg/d; SEM = 0.050) were similar ($P > 0.05$) between treatments. The G:F (0.168 and 0.156 kg/kg; SEM = 0.0099) was also similar ($P = 0.38$) between treatments. There were no differences ($P > 0.05$) in hip height (123.3 and 122.8 cm; SEM = 0.38), heart girth (140.6 and 139.9 cm; SEM = 0.40), or hip width (36.6 and 36.2 cm; SEM = 0.71) between treatments. Body condition scores (3.10 and 3.11; SEM = 0.026) were similar ($P = 0.68$) between treatments. Feeding heifers DDGS at 0.8% of BW with ad libitum forage maintained frame growth, ADG, DMI, and G:F compared to the CON concentrate mix.

Key Words: distillers grains, dairy heifer, growth performance

---

1406 Effects of roughage inclusion and particle size on performance and rumination behavior of finishing beef steers.

W. W. Gentry*[1], C. P. Weiss[1], C. M. Meredith[1], C. L. Brauer[1], F. T. McCollum[1], N. A. Cole[2], and J. S. Jennings[1], *[1]Texas A & M AgriLife Research and Extension Center, Amarillo, [2]USDA-ARS Conservation and Production Research Laboratory, Bushland, TX.*

This experiment was conducted to determine the effects of feeding 5 or 10% corn stalks at various grind sizes with 30 or 25% wet corn gluten feed (WCGF), respectively, on rumination behavior, animal performance, and carcass characteristics of finishing beef steers. Fifty-one crossbred beef steers (BW = 881 ± 8 lbs), outfitted with rumination monitoring collars, were used in a randomized complete block design. Corn stalks were either passed through a commercial tub grinder once (large grind; LG) or twice (short grind; SG). Steam-flaked corn-based finishing treatment diets included: 10% SG with 25% WCGF (10%SG), 5% SG with 30% WCGF (5%SG), and 5% LG with 30% WCGF (5%LG). Animals were fed once daily at 0900 h using Calan head gates for an average of 155 d (heavy block = 148 d, light block = 162 d). Particle size of individual ingredients and treatment diets were quantified using the Penn State Particle Separator. Data were analyzed using the MIXED procedure of SAS with animal as the experimental unit. Means were separated using LSMEANS with the PDIFF option. There were no differences ($P = 0.52$) in final shrunk body weight between 5%SG, 5%LG, and 10%SG (1401, 1393, and 1373 ± 25.46 lbs, respectively), ADG (3.8, 3.8, and 3.7 ± 0.08 lbs, respectively; $P = 0.14$), or G:F (0.180, 0.175, and 0.176 ± 0.003, respectively; $P = 0.27$). However, DMI was greater ($P = 0.03$) for steers consuming the 5%LG

diet compared to the 10%SG (21.9 and 21.0 ± 0.31 lbs, respectively). Dressing percent also was greater ($P = 0.05$) for steers consuming 5%LG compared to 5%SG and 10%SG (64.3, 63.1, and 62.5 ± 0.007%, respectively). Hot carcass weight tended ($P = 0.10$) to be greatest for steers fed 5%LG. Steers consuming 10%SG had the greatest daily minutes of rumination ($P < 0.001$) followed by 5%LG, and 5%SG being the least (310, 288, and 244 ± 2.98 min/d, respectively). Steers consuming a longer particle size had increased dry matter intake and dressing percent, and tended to have greater carcass weights. With similar roughage inclusion rate, steers consuming a longer particle size also had increased daily rumination minutes. Therefore, increasing roughage particle size has the potential to allow a decrease in roughage inclusion without sacrificing feedlot performance and rumen function.

Key Words: rumination, corn stalks, corn gluten feed

1407 Automation of statistical procedures to screen raw data and construct feed composition databases.

H. Tran*[1,2], A. Caprez[1], P. J. Kononoff[1], P. S. Miller[3], and W. P. Weiss[4], *[1]University of Nebraska, Lincoln, [2]National Animal Nutrition Program, University of Kentucky, Lexington, [3]University of Nebraska-Lincoln, Lincoln, [4]Department of Animal Sciences, OARDC, The Ohio State University, Wooster.*

Millions of feed composition records have been generated from feed testing laboratories annually, providing high-valued assets that could be leveraged to benefit the animal nutrition community. Unfortunately, managing, handling, and processing feed composition data that originate from multiple resources are challenging, due in part to inconsistencies of how data are reported and the time needed to develop databases. Methods that consolidate and utilize these data are needed to develop accurate and precise feed composition databases. The objectives of this project were to: 1) develop automated statistical procedures to screen for outliers of feed composition data obtained from multiple resources; and 2) evaluate the efficiency of these procedures on classifying feedstuffs. A published statistical procedure (Yoder et al., 2014) was employed, modified, and programmed to operate using Python (Python Programming Language, v. 2.7) and SAS. A total of 2.761×10^6 records received from four commercial feed testing laboratories were used to develop the procedures and to construct tables summarizing feed composition. Briefly, feed names and variables across laboratories were standardized before the erroneous datapoints and duplicated samples were removed. Histogram, univariate, and principal component analyses were used to identify and remove outliers having key nutrients outside of the mean ± 3.5×SD. Clustering analyses were conducted to identify groups of feeds within a named feedstuff. Aside from the clustering step that was programmed in Python to automatically execute SAS, all steps were programmed and automatically conducted using Python followed by a manual evaluation of the resulting Pearson correlation matrixes and clusters. The input data contained 94, 162, 270, and 42 feeds, respectively, for laboratories 1 through 4 and were composed of 28 to 37 nutrients. The resulting database included 173 feeds (1.489×10^6records) with 111 feeds having more than 1 cluster. The developed procedures effectively classified byproducts (bakery byproducts, brewers grains, distillers grains and solubles, rice bran), forage (legume vs. grass, mature vs. immature and mid-maturity), and oilseeds vs. meal (cottonseed, canola seed, linseed/flaxseed, soybeans, sunflower) into distinct sub-populations. Results from these analyses provide a robust tool for the National Animal Nutrition Program (A National Research Support Project supported by USDA-NIFA and the State Agricultural Experiment Stations) to efficiently and consistently construct and update large feed datasets in an accurate, precise, and timely manner. This approach may also be used by commercial laboratories, feed manufacturers, animal producers, and other professionals to process feed composition datasets.

Key Words: automation, feed composition database, statistics

1408 Effect of pelleting at different temperatures and times on nutrient supply of co-products form canola oil processing.

X. Huang[1], V. Guevara*[1], B. Refat[2], and P. Yu[2], *[1]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada, [2]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, SK, Canada.*

The objective of this study was to evaluate effects of conditioning temperatures (70, 80, and 90°C) and conditioning time (50s and 75s) and their possible interaction during pelleting on predicted truly absorbed protein supply of canola meal. Truly absorbed protein supply were measured for dairy cows according to DVE/OEB system and NRC-2001 model. The treatments were designed in 3 × 2 factorial arrangement and experiment design was RCBD. Statistical analysis was performed using the PROC MIXED of SAS 9.3. The results showed that conditioning time had a quadratic effect ($P < 0.05$) on total protein supplied to the small intestine (TPSI), microbial protein synthesized in the rumen based on available nitrogen (N_MCP), truly absorbed microbial protein in the small intestine (AMCP),rumen bypass feed crude protein (BCP) and truly absorbed bypass protein(ABCP). Samples conditioned at 80°C were highest in AMCP and N_MCP while lowest in TPSI and ABCP between pellets. Pelleting decreased ($P < 0.01$) TPSI, BCP and ABCP (261.39 vs. 241.66 g/kg DM, 195.68 vs. 174.20 g/kg DM and 55.49 vs. 41.61 g/kg DM, respectively) but increased AMCP of canola meal (55.86 vs. 57.34 g/kg DM). Pelleting induced decreased truly digested protein in the small intestine (DVE; 99.26 vs. 86.77

g/kg DM) and increased degradable protein balance (OEB; 115.26 vs. 135.27 g/kg DM) were observed ($P < 0.01$). In NRC-2001 model, affected by quadratic effect of conditioning temperature ($P < 0.05$), samples conditioned at 80°C between pellets were lowest in rumen undegradable feed crude protein (RUP), truly absorbed rumen undegradable protein in the small intestine (ARUP) and metabolizable protein (MP). Rumen endogenous protein (ECP) and truly absorbed rumen endogenous protein in the small intestine (AECP) were decreased by increasing conditioning time (10.58 vs.10.21 g/kg DM and 4.23 vs. 4.08 g/kg DM, respectively; $P < 0.01$). Pelleting decreased ($P < 0.01$) MP, AECP and ECP of canola meal (107.09 vs. 94.65 g/kg DM, 4.43 vs. 4.16 g/kg DM and 11.08 vs. 10.39 g/kg DM, respectively). RUP and ARUP of canola meal were decreased by pelleting as well (176.29 vs. 156.94 g/kg DM and 49.99 vs. 37.49 g/kg DM, respectively; $P < 0.01$). Summarily, pelleting changed potential protein supply of canola meal; alteration of pelleting conditions caused differences between pellets in predicted protein supply profiles.

Key Words: co-products from oil processing, nutrient supply and pelleting conditions

Table 1409.

1409 Okara meal can completely replace soybean meal in diets of early to mid-lactation dairy cows.

R. A. V. Santana[1], A. F. Brito[*2], D. C. Moura[3], C. P. Ghedini[2], J. G. B. Galvão Jr.[4], F. A. Barbosa[5], A. S. Oliveira[6], A. B. D. Pereira[2], S. F. Reis[2], I. A. Souza[7], and K. A. Juntwait[2], *[1]Instituto Federal de Educação, Ciência e Tecnologia do Norte de Minas Gerais– Campus Arinos, Arinos, Brazil, [2]University of New Hampshire, Durham, NH, [3]Universidade Federal de Mato Grosso, Cuiabá, Brazil, [4]Instituto Federal de EducaÃ§Ã£o, CiÃªncia e Tecnologia do Rio Grande do Norte, IpanguaÃ§u, Brazil, [5]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [6]Instituto de Ciências Agrárias e Ambientais, Universidade Federal de Mato Grosso– Campus Sinop, Sinop, Brazil, [7]Universidade Estadual do Sudoeste da Bahia, Itapetinga, Brazil.*

Okara meal is a byproduct from the production of soy milk and tofu that can potentially replace soybean meal due to its high CP concentration. We aimed to evaluate the effects of okara meal as a replacement for soybean meal on performance and plasma concentration of metabolites in lactating dairy cows. Twelve multiparous (65 ± 33 DIM; 451 ± 45 kg of BW) and 8 primiparous (100 ± 35 DIM; 370 ± 51 kg of BW) Jersey cows were used in a crossover design with 21-d periods (14 d for diet adaptation and 7 d for data and sample collection). Diets were fed as TMR and formulated to be isonitrogenous and isofibrous and contained (DM basis) 50% grass-legume baleage, 2% liquid molasses, 2% minerals-vitamins premix, and: 1) 8.1% soybean meal, 10% soyhulls, and 27.9% corn meal (SBM treatment); 2) 15% okara meal, 8% soyhulls, and 23% corn meal (OKM treatment). The dietary nutrient composition averaged 15.4 vs. 15.9% CP, 35.3 vs. 36.3% NDF, and 24.1 vs. 24.1% ADF for SBM and OKM, respectively.

Table 1. Effects of a soybean meal (SBM)- or a okara meal (OKM)-based diet on performance and plasma metabolites in dairy cows

	Treatments			
Item	SBM	OKM	SEM	*P*-value
DMI, kg/d	18.1	17.9	0.58	0.30
Milk yield, kg/d	20.5	20.8	1.08	0.44
4% FCM, kg/d	24.1	24.2	1.05	0.73
ECM, kg/d	25.9	26.1	1.15	0.63
Milk fat, %	5.24	5.16	0.12	0.37
Milk fat, kg/d	1.05	1.06	0.04	0.59
Milk true protein, %	3.81	3.76	0.09	0.02
Milk true protein, kg/d	0.77	0.78	0.04	0.71
MUN, mg/dL	9.47	8.51	0.40	<0.01
PUN, mg/dL	22.2	21.1	0.41	0.03
Plasma Met, μ*M*	21.6	23.0	0.91	0.27
Plasma Lys, μ*M*	99.5	95.5	4.24	0.44
Plasma His, μ*M*	37.7	35.8	2.81	0.52
Plasma Leu, μ*M*	152	140	4.18	0.02
Plasma total EAA, μ*M*	109	103	3.03	0.09

Cows were fed and milked twice daily, and milk (d 15 to 16) and blood (d 16 to 17) samples were collected and analyzed for components and plasma metabolites [AA, urea-N (PUN)], respectively. Results are shown in Table 1. No significant differences were observed for DMI (mean = 18.0 kg/d), milk yield (mean = 20.7 kg/d), 4% FCM (mean = 24.2 kg/d), and ECM (mean = 26.0 kg/d) in cows fed SBM or OKM. Whereas milk fat concentration was not affected by treatments, milk true protein concentration was greater ($P = 0.02$) in cows fed SBM than OKM. Yields of milk fat and true protein did not differ significantly between treatments and averaged 1.06 and 0.78 kg/d, respectively. However, MUN ($P < 0.01$) and PUN ($P = 0.03$) were greater in cows fed SBM compared with those fed OKM suggesting an improvement in N use efficiency. Plasma concentrations of Met, Lys, and His did not differ significantly in cows fed SBM or OKM. Conversely, the plasma concentration of Leu was greater ($P = 0.02$), and that of total EAA tended ($P = 0.09$) to be greater in cows offered SBM vs. OKM, which may explain the observed increase in milk true protein concentration when feeding SBM. Overall, replacing soybean meal with okara meal maintained animal performance and appeared to improve N use efficiency.

Key Words: dairy cows, okara meal, soybean meal

1410 Effect of flax meal supplementation on oxidative stress and metabolic status of early lactation dairy cows infused with flax oil in the abomasum.

J. Lapointe[*1], C. Roy[2], D. Beaudry[2], N. Bergeron[2], I. Blanchet[2], H. Petit[1], and M. F. Palin[2], *[1]Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada, [2]Agriculture and Agri-Food Canada, Sherbrooke R & D Centre, Sherbrooke, QC, Canada.*

The addition of flax oil (FO) to the diet of high-yielding dairy cows is a good strategy to improve the energy balance during early lactation. Although polyunsaturated fatty acids have numerous healthy attributes, they are easily oxidized and promote oxidative stress. In this project, we tested if the inclusion of natural antioxidants, flax meal (FM) rich in plant lignans, in cow's diet could decrease oxidative stress and optimize the potential of FO as a source of energy. This experiment was conducted using twenty (20) multiparous high-yielding Holstein cows fitted with ruminal cannulas. Cows were assigned to two dietary treatments: (1) 250 g flax oil/d infused in the abomasum ($n = 10$, FO) and (2) FO + 15% flax meal (FM) in the dry matter ($n = 10$, FMFO). Treatments were administered over a 21 d (d) period from d 7 to d 28 post calving. Plasma and urine samples were collected on d 7 (before treatment initiation), 14, 21, 28 (end of treatment) and 49 (for carryover effect) to evaluate systemic oxidative damage to proteins (carbonyls) and DNA (8-hydroxy-2'-deoxyguanosine), and to determine the enzymatic activity of the antioxidants glutathione peroxidase (GPx) and superoxide dismutase (SOD), and diet had no effect ($P > 0.05$). Biopsies were taken from the liver and mammary gland tissue on d 7, 28, and 49 to measure the activity and mRNA expression of antioxidants and evaluate energy production in the form of adenosine triphosphate (ATP), and diet had no effect ($P > 0.05$) on activity of GPx and SOD. The mRNA expression of *SOD1* in mammary tissue was lowered by the addition of FM to the diet ($P < 0.01$). In the liver, *SOD1* mRNA levels remained stable throughout the experimental period in the FMFO group while it was higher on d 49 in cows infused with FO (interaction treatment × day, $P < 0.05$). Analysis of hepatic levels of ATP revealed that the addition of FM suppressed the increase in energy production observed on d 49 in the FO group (interaction treatment × day, $P < 0.05$). Infusion of FO in the abomasum decreased the level of proteins carbonyls in mammary gland tissue from d 7 to d 49, and this effect was counteracted by the addition of FM (interaction treatment × day, $P < 0.05$). Taken altogether, these results suggest that the oxidative status of early lactating cows infused with FO is not significantly affected by the addition of FM to the diet.

Key Words: dairy cows, oxidative stress, antioxidant

1411 The effect of by-product inclusion and concentrate feeding level on milk production and composition, pasture dry matter intake, body weight and body condition score of mid-late lactation spring calving grazing dairy cows.

S. A. Condren[*1], S. J. Whelan[2], T. M. Boland[1], G. Rajauria[1], S. Kirwan[1], M. B. Lynch[1], and K. M. Pierce[1], *[1]School of Agriculture and Food Science, University College Dublin, Belfield, Dublin 4, Ireland, [2]AHDB Dairy, Agriculture & Horticulture Development Board, Stoneleigh Park, Kenilworth, Warwickshire, United Kingdom.*

There is growing interest in the use of by-products (or co-products) as economical sources of nutrients that complement grazed grass when grass supply is not sufficient to meet the nutritional demands of lactation. The objective of this research was to investigate the effect of by-product inclusion and concentrate feeding rate on milk production and composition, pasture dry matter intake (DMI), body weight (BW) and body condition score (BCS) of mid-late lactation spring calving grazing dairy cows. Forty eight (41 multiparous, 7 primiparous) Holstein Friesian dairy cows were blocked according to parity, balanced for days in milk, predicted 305 d milk yield, BCS and pre-experimental milk yield and randomly assigned to one of four dietary treatments in a 2 × 2 factorial design. All cows were grazed in one group on a perennial ryegrass based sward. The dietary treatments (T) were: concentrate containing 35% by-products offered at either 3 kg (T1) or 6 kg (T2)/d or a concentrate containing 95% by-products offered at 3 kg (T3) or 6 kg (T4)/d. The by-products used were maize dried distillers grains (DDG), palm kernel expeller (PKE) and soybean hulls (SH), included in equal proportions on a DM

basis. The experimental diets were offered for 63 d. Pasture DMI (14.5 kg/d) was not affected by feeding rate ($P = 0.37$) or by-product inclusion level ($P = 0.27$). Similarly, there were no effects of treatment on BW change (−9.3 kg, $P = 0.20$) or BCS change (+0.07, $P = 0.94$). By-product inclusion level had no effect on milk yield (27.33 kg/d, $P = 0.65$) or fat and protein yield (2.00 kg/d, $P = 0.54$). However, cows offered 6kg of concentrate produced more milk (+1.94 kg/d, $P = 0.08$) and milk fat (+0.10 kg/d, $P = 0.02$) than cows offered 3kg of concentrate. In conclusion, the results of this research show that by-products (DDG, PKE and SH) can be included at up to 95% of the concentrate fed to pasture based cows without impacting on milk production or composition, pasture DMI, BW or BCS. Cows offered 6kg of concentrates produced more milk and milk fat yield than cows offered 3kg, however, this response is unlikely to yield an economic return.

Key Words: by-products, dairy cow, milk production.

1412 Evaluating the feeding value of field peas for growing and finishing cattle. H. L. Greenwell*[1], K. H. Jenkins[2], and J. C. MacDonald[1], [1]*University of Nebraska-Lincoln, Lincoln,* [2]*University of Nebraska, Scottsbluff.*

A two year experiment was conducted to determine the effects of field pea (FP) supplementation during grazing and finishing phases on animal performance and carcass characteristics. In year one, 110 steers (initial BW = 348 kg; SD = 22 kg) and in year 2, 113 heifers (initial BW = 249 kg; SD = 11 kg) were arranged in a 3 × 2 factorial. The first factor was supplementation during grazing, consisting of three treatments: 1) FP; 2) mixture of dry rolled corn (70.8%), solubles (24%), and urea (5.2%); (DRC); (mixture was used to ensure RDP was not limiting); 3) control group receiving no supplement (CON). The second factor was finishing treatment, cattle were fed a DRC-based finishing diet with or without 20% FP (DM basis). Cattle grazed crested wheatgrass pastures and were supplemented at a rate of 0.5% BW (DM basis). During the growing phase ending BW and ADG ($P < 0.01$) were greatest for calves supplemented DRC (413 ± 11 kg, 0.89 ± 0.05 kg, respectively) followed by FP (399 ± 11 kg, 0.78 ± 0.05 kg, respectively) and the CON treatment (379 ± 11 kg, 0.62 ± 0.05 kg, respectively). In the finishing phase there was an interaction between growing and finishing treatments for G:F ($P = 0.03$), a result of cattle supplemented with FP during the growing phase and with no FP in the finisher performing better than cattle supplemented with FP during growing and with FP also included in their finishing diet (0.142 ± 0.004 kg vs. 0.132 ± 0.004 kg, respectively). There were no other interactions of finishing and growing treatments on other variables ($P \geq 0.10$). Feedlot ADG was affected by growing treatment ($P < 0.01$), where cattle in the CON treatment had greater ADG (1.95 ± 0.04 kg) than cattle that were supplemented DRC (1.80 ± 0.04 kg) and FP (1.78 ± 0.04 kg), which were not different. Final BW and HCW tended ($P = 0.07$) to be affected by growing treatment in a similar manner to feedlot ADG. Inclusion of FP in the finishing diet had no impact on carcass characteristics. In conclusion, cattle supplemented DRC during grazing had greater ADG than cattle supplemented FP or CON. However, in the finishing phase CON cattle compensated in feedlot ADG. Inclusion of FP in grower supplement or finishing diets may be advantageous if appropriately priced.

Key Words: cattle, field peas, finishing, grazing

1413 Cotton burrs as alternative roughage to adapt beef steers to steam-flaked corn-based finisher diet. L. A. Ovinge*[1], J. O. Sarturi[1], P. R. B. Campanili[1], B. J. M. Lemos[2], B. C. Bernhard[1], and D. Pettit[1], [1]*Texas Tech University, Lubbock,* [2]*Universidade Federal de Goiás, Goiânia, Brazil.*

Effect of cotton burrs as a roughage source during the transition of beef cattle (hay to finisher diet) was evaluated on intake, ruminal characteristics, nutrient digestibility, and feeding behavior. Ruminally cannulated steers ($n = 6$; BW = 235 ± 81 kg) were assigned using a complete randomized design to 1 of 2 adaptation strategies: Alfalfa hay-based or cotton burrs-based. In both strategies, roughage sources decreased as steam-flaked corn gradually increased. Steers were fed ad libitum once daily, a series of six diets (7-d period each): wheat hay; 4 step-ups; and a finisher. In situtechnique was used to assess ruminal fiber degradability (substrate = wheat hay). Wireless rumen pH probes were used. A 3-d spot fecal collection (twice daily, last 3 d of each period) and AIA were used to estimate total tract apparent nutrient digestibility. Rumen fluid samples (0, 4, 8, and 16 h post-feeding) were taken (d-6 of each period) for VFA and NH_3. Data were analyzed using Glimmix procedure of SAS (wheat hay period used as a covariate). Intake was not affected by adaptation strategies ($P \geq 0.16$), except for a tendency ($P = 0.10$) for steers adapted with alfalfa-strategy to ruminate more per kg of NDF consumed during finisher diet, than those adapted with cotton burrs-strategy. Steers fed cotton burrs-strategy showed lower ruminal pH average on step-3 and finisher periods (5.62 and 5.51 vs. 6.04 and 5.83; $P < 0.01$ and $P = 0.05$, respectively) compared with alfalfa-strategy. A greater area of pH below 5.6 (200 vs. 15 min*pH; $P < 0.01$); lower ruminal NH_3 concentration (5.1 vs. 8.8 mg/L; $P < 0.01$); and lower digestibility (OM, ADF, and hemicellulose; $P \leq 0.02$) during step-3 were also observed for steers fed cotton burrs-strategy compared to alfalfa-strategy, respectively. However, cotton burrs-strategy steers showed greater ($P = 0.01$) NDF digestibility during step-4; greater ($P < 0.01$) OM digestibility during finisher diet; and lower acetate/propionate ratio ($P = 0.04$) with a tendency ($P = 0.08$) to have greater propionate molar proportion during step-2, compared to alfalfa-strategy steers. Ruminal fiber degradability was not affected by adaptation strategies ($P \geq 0.36$), neither was dietary starch digestibility during common

finisher ($P = 0.73$). Cotton burrs adaptation strategy induced an improved ruminal fermentation environment during finisher diet, although with riskier ruminal pH and rumination than alfalfa-strategy. Further evaluation must consider cattle growth performance and economic aspects.

Key Words: adaptation, cotton burrs, alfalfa

1414 Temporal effects of ruminal propionate infusion on feeding behavior of Holstein cows In the postpartum period.

1415 Evaluation of five cool season grasses and alfalfa-grass mixtures. J. Paulson*[1], D. Holen[2], D. Nicolai[3], and B. J. Heins[4], *[1]University of Minnesota Extension, Rochester, [2]University of Minnesota, Morris, [3]University of Minnesota, Farmington, [4]University of Minnesota West Central Research and Outreach Center, Morris.*

Our increased knowledge of NDF digestibility has shown a benefit to feeding grasses in ruminant diets. However, data on the yield and nutrient analysis of alfalfa/grass mixtures with modern grass varieties and harvest management are lacking. The objective of this study was to determine the yield and nutritional value of selected alfalfa-grass mixtures and grass monocultures. At 2 MN locations, plots of grasses alone, alfalfa alone, and alfalfa-grass mixtures were planted using a forage plot seeder. Four randomized replications were planted of all plot variables. Each location was seeded with 1 alfalfa (A) variety and each of 5 grass species. Grass species included smooth brome (SB), meadow brome (MB), orchard (OG), tall fescue (TF), and meadow fescue (MF). Forage samples were sent to Dairyland Laboratories, St. Cloud, MN and analyzed by NIRS for DM, CP, NDF, and TDN. Data were analyzed using the MIXED procedure of SAS. Independent variables for analyses were the fixed effects forage, and replicate was a random effect. Nutrient analysis for Otter Tail forage showed no significant differences for CP, NDF or $NDFD_{30}$ for any of the forage species or mixtures evaluated. However, at Lanesboro, the mixture of A × MF × MB was significantly higher ($P < 0.05$) in CP than the mixture of A x MF and A or MF in pure stands. NDF tended to be higher in pure grass but was significantly lower ($P < 0.05$) in the A × MF × MB mixed stand. In conclusion, high quality alfalfa/grass forage can compare favorably with alfalfa for both yield and nutrient analysis.

Key Words: alfalfa, grasses, meadow fescue, forage

1416 A novel bm3 corn silage hybrid with floury kernel genetics improves lactational performance and feed efficiency in Holstein cows. E. M. Remick*[1], S. M. Fredin[1], K. W. Cotanch[1], H. M. Dann[1], C. S. Ballard[1], J. P. Brouillette[2], and R. J. Grant[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Dow AgroSciences, Mycogen Seeds, Indianapolis, IN.*

Dry matter intake, lactation performance, feed efficiency and chewing behavior of multiparous Holstein cows ($n = 15$) fed diets containing a novel *bm3* corn silage (CS) hybrid with floury kernel genetics were compared to diets containing commercially available conventional and *bm3* hybrids using a replicated 3 × 3 Latin square design with 28-d periods. Cows were housed in tie-stalls, milked 3×/d, and fed a diet containing (DM basis) 49.0% of 1 of 3 CS hybrids (Mycogen Seeds, Dow AgroSciences, LLC): 1) a conventional CS hybrid (CON); 2) a brown midrib hybrid (BMR); and 3) a *bm3* hybrid with floury kernel genetics (BMRFL). All diets contained 6.3% hay crop silage and 44.7% concentrate. Diet nutrient composition averaged 14.8 ± 0.3% CP, 2.7 ± 0.5% NDF, and 26.3 ± 0.5% starch. Dry matter intake and milk yield were measured on d 22 to 28. Milk composition was measured on d 25 to 26. Cow behavior was monitored for 48 h over d 24 to 26. Data were analyzed by ANOVA using the MIXED procedure in SAS. Dry matter intake was increased ($P = 0.01$; SE = 0.5)

for cows fed BMR (28.0 kg/d) compared to CON (26.8 kg/d); DMI for cows fed BMRFL was intermediate (27.6 kg/d). Energy-corrected milk yield was increased ($P < 0.01$; SE = 1.5) for cows fed BMR (50.3 kg/d) and BMRFL (51.8 kg/d) compared to CON (47.2 kg/d). Milk fat yield was increased ($P \leq 0.05$; SE = 0.06) for cows fed BMRFL (1.87 kg/d) compared to CON (1.74 kg/d) and BMR (1.80 kg/d). Milk protein yield was increased ($P < 0.01$; SE = 0.06) for cows fed BMR (1.49 kg/d) and BMRFL (1.54 kg/d) compared to CON (1.36 kg/d). Milk urea-N was reduced ($P < 0.01$; SE = 0.3) for cows fed BMR (11.61 mg/dL) and BMRFL (11.16 mg/dL) compared to CON (13.60 mg/dL). Feed efficiency (Energy Corrected Milk/DMI) was increased ($P \leq 0.03$; SE = 0.04) for cows fed BMRFL (1.87) compared to CON (1.76) and BMR (1.79). Milk N efficiency ($P = 0.001$; SE = 1.2) was greatest for cows fed BMRFL (40.4%) followed by BMR (38.1%) and CON (35.3%). Cows fed CON chewed 5 min more per kg NDF consumed than cows consuming either *bm3* hybrid ($P < 0.01$). Lactational performance was increased for cows fed diets containing both *bm3* CS. Greater feed efficiency indicates that a *bm3* CS hybrid containing floury kernel genetics improves lactational performance and energy utilization compared to *bm3* and conventional CS. Additionally, improved milk N efficiency indicates greater ruminal carbohydrate fermentability can be achieved when feeding a BMRFL diet.

Key Words: brown midrib, floury corn, feed efficiency

1417 Alternative forage crops modify the composition and content of bovine milk fatty acids.

L. M. Cersosimo[*1], R. Tacoma[1], S. Greenwood[1], K. Juntwait[2], A. F. Brito[2], and J. Kraft[1], *[1]University of Vermont, Burlington, [2]University of New Hampshire, Durham.*

Bioactive fatty acids (FA) found in milk have been linked to human health benefits. Alternative forage crops (AFC) include small grains, warm-season grasses and legumes that can potentially enhance forage production. The objective of this study was to determine if traditional pasture strip-tilled with AFC (treatment, TRT) would alter the composition (g/100 g FA) and content (g/kg milk) of milk FA compared with traditional grass-legume pasture (control, CON). Two 21-d experiments, spring (SPR) and summer (SUM), were conducted using 16 lactating Jersey cows (SPR, 85 ± 46 DIM; SUM, 143 ± 58 DIM). Cows were divided into 2 groups and offered 60% TMR (DM basis) and 40% pasture as AFC or traditional. SPR AFC included barley, wheat, rye, triticale, and hairy vetch (2.4% diet DM), while SUM AFC included buckwheat, chickling vetch, and oat (10.0% diet DM). From d 19 to 21 of each experiment, milk samples were collected during four consecutive milkings. Forage and milk FA were analyzed via gas-liquid chromatography. Differences between least-squares means were evaluated using the student's *t* test (JMP Pro 12). SPR forage FA (% total) included CON (total n-3 FA: 30.1%; total n-6 FA: 35.2%) and TRT (total n-3 FA: 46.2%; total n-6 FA: 21.5%), whereas the SUM forage FA included CON (total n-3 FA: 44.4%; total n-6 FA: 22.6%) and TRT (total n-3 FA, 45.7%; total n-6 FA, 22.0%). No differences in the milk content of total PUFA, branched-chain FA, or biohydrogenation intermediates (e.g., *trans*-11 18:1) were observed in either experiment. Milk proportions of total odd-chain FA were higher ($P < 0.01$) in SPR TRT (2.07 g/100 g) than in SPR CON (1.96 g/100 g). Milk proportions of n-3 FA and *trans*-18:1 were respectively lower ($P < 0.01$) in SPR TRT (0.64 g/100 g; 20.5 g/100 g) than in SPR CON (0.71 g/100 g; 22.8 g/100 g), but the contents of these FA were not different between groups. Milk content of 12:0 was higher ($P < 0.05$) in SPR TRT (1.86 g/kg milk) than in SPR CON (1.56 g/kg milk) ($P < 0.05$). Total milk SFA content was higher ($P < 0.05$) in SUM TRT (33.7 g/kg) than in SUM CON (29.1 g/kg). Milk content of de novo FA (CON: 11.6 g/kg milk; TRT: 13.2 g/kg milk) and mixed FA (CON: 13.0 g/kg milk; TRT: 16.2 g/kg milk) were higher ($P < 0.01$) in SUM AFC-fed cows. In conclusion, AFC altered the composition and content of milk FA.

Key Words: dairy, organic, pasture

1418 Effects of post-ethanol extraction sorghum silage as an alternative forage in growing and finishing diets on steer performance, carcass characteristic and nutrient digestibility.

C. P. Blank[*1], D. D. Loy[2], and S. L. Hansen[1], *[1]Iowa State University, Ames, [2]Department of Animal Science, Iowa State University, Ames.*

Two experiments evaluated use of post-ethanol extraction sorghum silage as an alternative forage to hay in feedlot diets. In experiment one (Exp1), 72 crossbred steers (397 ± 23, SD) were used to evaluate growth and carcass characteristics. Steers were blocked by BW into pens of 6 steers and randomly assigned to growing diets containing 40% (DM basis) of sorghum silage (SS; 57.6% NDF) or grass hay (CON; 63.3% NDF) for 56d ($n = 6$ pens per treatment). Within each treatment steers transitioned to dry-rolled corn-based finishing diets (fed for 56d) containing 6% effective NDF contributed by the forage source, resulting in forage inclusions of 16% for SS and 13.1% for CON. Experiment two (Exp2), utilized a subsample of steers ($n = 12$ per treatment) housed in pens equipped with Growsafe bunks for determination of growing phase diet total tract digestibility. From d28- 42, steers received titanium dioxide at approximately 10 $g^{-1} \cdot steer^{-1} \cdot d^{-1}$. Fecal samples were collected on d 41 and 42. Fecal and total mixed ration samples were dried, and ground for analysis of DM, OM, NDF, ADF, CP, ether extract (EE), and starch. Data were analyzed using PROC MIXED of SAS with the fixed effects of treatment and block (Exp1) or treatment (Exp2); significance was determined at $P \leq 0.05$ and tendencies at $P \leq 0.10$. Growing phase DMI and ADG did not differ due to treatment ($P \geq 0.19$); however, SS-fed steers had improved

G:F compared to CON ($P = 0.04$). Finishing period ADG or G:F did not differ ($P \geq 0.15$), despite SS-fed steers having lesser ($P = 0.008$) DMI than CON-fed steers. No differences in DMI, ADG, or G:F over the whole trial were noted between treatments ($P \geq 0.12$), nor were any carcass traits affected ($P \geq 0.23$). Growing phase total tract apparent digestibility of DM and starch did not differ ($P \geq 0.19$), due to treatment; however, OM digestibility tended to be greater ($P = 0.09$) in SS-fed steers. During the digestibility assessment period DMI was lesser ($P = 0.003$) in SS-fed steers. Steers fed the SS diet had greater ($P \leq 0.03$) digestibility of EE, CP, NDF, hemicellulose, and cellulose than CON-fed steers. Interestingly, CON-fed steers had greater ($P < 0.0001$) ADF digestibility than SS-fed steers. These data suggest that post-extraction sorghum silage can be effectively utilized in feedlot diets as an alternative forage.

Key Words: sorghum silage, cattle performance, digestibility

1419 Effect of lactic acid bacterial inoculants on the fermentation parameters and aerobic stability of sorghum-sudangrass silage. X. Li[*1,2], Y. Zhu[2], D. Vyas[1], and A. T. Adesogan[1], [1]*Dep. of Animal Sciences, IFAS, University of Florida, Gainesville,* [2]*Institute of Grassland Science, China Agricultural University, Beijing, China.*

Sorghum-sudangrass (*Sorghum vulgare* × *Sorghum sudanense*) has great potential to be widely used for silage making because of its rapid growth, high yields and nutritional value, and acceptability to cattle. However, it is prone to aerobic spoilage, which reduces its nutritional value. The aim of this study was to examine the effect of lactic acid bacterial inoculants on fermentation quality and aerobic stability of sorghum-sudangrass silage. Sorghum-sudangrass was harvested at 20% DM, chopped to approximately 20-mm lengths and treated in triplicate with 10^6 cfu/g of fresh weight of *Lactobacillus buchneri* (LB), *L. plantarum* (LP), and *Enterococcus fecalis* (EF) or distilled water (Control). Samples were stored at room temperature (about 25°C) for 264 d in polyethylene bags. Silage chemical composition was analyzed, and aerobic stability was determined by measuring the number of hours the temperature in the silages remained stable before rising more than 2°C above room temperature. Data were analyzed using the General Linear Model procedure of SAS and means were separated using Duncan's test. Silage treated with LB had greater pH compared to Control, LP, and EF silages (3.78 vs. 3.75, 3.73, 3.75, respectively; $P \leq 0.05$). Similarly, acetic acid concentration was greater for the silage treated with LB compared to Control, LP and EF silages (2.59 vs. 2.05, 1.59, 2.20, % DM, respectively, $P \leq 0.05$); however, no effects were observed on butyric or propionic acid concentration. The NH_3–N/TN concentration was greater in EF silage and lower in LB silage compared to that of the Control silage (6.92, 5.13 vs. 5.90%, $P \leq 0.05$). The lactic acid concentrations were 15 and 13% greater in LP and EF silages, respectively compared to the Control silage (12.30, 12.04 vs. 10.70, % DM, $P \leq 0.05$). Silages treated with LB and EF took longer to heat than untreated silage when exposed to air (169, 166.5 vs. 133.5, h, $P \leq 0.05$). In contrast, silages inoculated with LP had lower aerobic stability compared to the Control silage (99.5 vs. 133.5, h, $P \leq 0.05$). Inoculating sorghum-sudangrass silage with LB and EF improved aerobic stability, whereas inoculating the silage with LP improved fermentation parameters.

Key Words: aerobic stability, fermentation, inoculants

1420 Effects of feeding triticale and wheat silages on feed intake, milk production and composition, and enteric methane production in lactating dairy cows. M. T. Harper*, J. Oh, F. Giallongo, G. Roth, and A. N. Hristov, *The Pennsylvania State University, University Park.*

The objective of this experiment was to evaluate the production effects of replacing corn silage (serving as the control) with either triticale or wheat silage in a total mixed ration fed to lactating dairy cows. Twelve Holstein cows (days in milk 38 ± 5.6, BW 632 ± 101.6kg) were used in a replicated 3 × 3 Latin square design experiment with 3, 28 d periods. Feeding was ad libitum for 5 to 10% refusals. The control diet consisted of (DM basis): 44% corn silage, 8% alfalfa haylage, 5% hay/straw mixture, 9% ground corn, 8% canola meal, 7.5% whole roasted soybeans, 7% SoyPLUS, 4.5% molasses, 4% cottonseed hulls, and 3% mineral premix. For the triticale diet, 22.7% (DM basis) of the corn silage was replaced with triticale silage. Similarly, 22.7% of the corn silage in the wheat diet was replaced with wheat silage. Diets met or exceeded the MP and NE_lrequirements of the cows. The triticale (Hyoctane) and wheat (Malabar) were harvested May 13 and 20, 2015, respectively, at the boot stage. The silages had DM of 30.7 and 40.7%, pH 4.48 and 4.46 and (DM basis): lactic acid, 7.03 and 6.43%; NDF, 51.1 and 51.0%; and CP, 17.3 and 14.6%, respectively. Diet did not affect DMI (27.5 kg/d; SEM = 1.8, $P = 0.37$), enteric methane emission (470 g/d; SEM = 23.4, $P = 0.16$), or milk fat yield (1.55 kg/d; SEM = 0.11, $P = 0.35$). Milk yield was higher in control versus triticale or wheat diets (42.7, 41.2, and 41.4 kg/d, respectively; SEM = 5.2, $P = 0.01$). Energy corrected milk yield was also higher ($P = 0.05$) in control (40.9 kg/d) versus triticale (38.6 kg/d) or wheat (38.5 kg/d) diets. Triticale and wheat diets increased ($P < 0.001$) milk urea nitrogen concentration compared with the control (12.7 and 13.1 vs. 10.8 mg/dL, respectively). Milk true protein and lactose yields were lower for both triticale and wheat diets compared with the control: 1.20, 1.20, and 1.27 kg/d (SEM = 0.096, $P = 0.02$) and 2.00, 1.98, and 2.14 kg/d (SEM = 0.173, $P = 0.01$), respectively. The results indicate that a 22.7% replacement of corn silage DM with either triticale or wheat silage in the diet of lactating dairy cows did not affect enteric methane emission

or DMI, but decreased milk yield.

Key Words: triticale, wheat, silage

1421 Effects of feeding sorghum and oat silages on feed intake, milk production and composition, and enteric methane production in lactating dairy cows. M. T. Harper*, J. Oh, F. Giallongo, J. C. Lopes, G. Roth, and A. N. Hristov, *The Pennsylvania State University, University Park.*

The objective of this experiment was to evaluate the production effects of replacing corn silage (serving as the control) with either sorghum or oat silage in the total mixed ration fed to lactating dairy cows. Twelve Holstein cows (days in milk 81 d ± 24; BW 615 kg ± 49.6) were used in a replicated 3 × 3 Latin square design experiment with 3, 28 d periods. Feeding was ad libitum for 5 to 10% refusals. The control diet consisted of (DM basis): 44% corn silage, 7.5% alfalfa haylage, 4% hay/straw mixture, 11% ground corn, 7.5% SoyPLUS (West Central Cooperative, Ralston, IA), 7.5% whole roasted soybeans, 7% canola meal, 4.5% molasses, 4% cottonseed hulls, and 3% mineral premix. For the sorghum diet, 22.7% (DM basis) of the corn silage in the diet was replaced with sorghum silage. Similarly, 22.7% of the corn silage in the oat diet was replaced with oat silage. The MP balance of the control, sorghum, and oat diets was 199, 238, and 290 g/d, respectively, whereas the balance of NE_l was 2.8, 2.4, and 2.8 Mcal/d. The forage sorghum (Alta AF 7202) was harvested on November 11, 2014 with the harvester set to 1 inch total chop length. The oats (Forage Plus) were mowed in a vegetative state and harvested on November 14, 2014. Sorghum and oat silages had DM of 30.5 and 30.8% and (DM basis): lactic acid, 2.89 and 7.27%; NDF, 62.7 and 54.7%; and CP, 9.5 and 11.7%, respectively. Enteric methane emission measurements were collected with the GreenFeed system. Control and oat diets resulted in higher DMI and milk yield than sorghum: 26.7, 27.1, vs. 26.0 kg/d (SEM = 1.68, $P = 0.02$) and 39.6, 40.2, vs. 38.7 kg/d (SEM = 3.57, $P < 0.01$), respectively. Methane emission (502 g/d; SEM = 26.7, $P = 0.59$) and milk fat yield (1.41 kg/d; SEM = 0.07, $P = 0.78$) were not affected by diet. The sorghum silage diet decreased milk true protein concentration ($P = 0.03$) compared with the control or oat silage (2.78 vs. 2.85 and 2.83%, respectively). Similarly, milk protein yield was decreased ($P = 0.05$) by the sorghum diet (1.04 vs. 1.13, and 1.13 kg/d, respectively). The results indicate that a 22.7% replacement of corn silage DM with oat silage is a viable alternative for dairy producers in the Northeast U.S.

Key Words: sorghum, oats, silage

1422 Effect of harvest method on digestibility of corn residue. T. M. King*[1], M. L. Jolly-Breithaupt[1], J. L. Gramkow[2], J. C. MacDonald[1], and T. J. Klopfenstein[2], *[1]University of Nebraska-Lincoln, Lincoln, [2]University of Nebraska, Lincoln.*

Advanced techniques of harvesting corn residue has led to improved residue quality by reducing proportion of stem in the bale. The objectives of this study were to determine 1) the effect of harvest method on the digestibility and quality of corn residue and 2) the effect of drying method used to process feces on digestibility estimates. An 85 d digestion study was conducted utilizing 9 crossbred wethers (initial BW = 42.4 kg; SD = 7 kg) blocked into 3 blocks based on initial BW. Residue based diets contained corn residue harvested with 1 of 3 methods (low-stem, high-stem, and conventional) at 70:27:3 residue: Sweet Bran®: bromegrass hay (DM basis). Five periods of 17 d provided 10 d for adaption and 7 d for total fecal collection. Sweet Bran® and bromegrass hay were fed at a 9:1 ratio in the fourth period for determination of residue digestibility by difference. Feces were collected twice daily, composited at the end of the period, and dried using 1 of 3 methods (60°C forced air oven, 100°C forced air oven, and freeze dry technique). No differences in DM intake, OM intake, or NDF intake were observed among residue type ($P > 0.05$). Low-stem had greater DM digestibility (DMD) than conventional ($P = 0.02$) and had a tendency to be greater than high-stem ($P = 0.06$). There were no differences in DMD ($P = 0.63$) or OM digestibility (OMD; $P = 0.86$) between high-stem and conventional. Low-stem had greatest OMD and NDF digestibility (NDFD, $P < 0.05$). High-stem had a NDFD which was greater than conventional ($P < 0.01$). Drying method had no effect on digestibility determination by lab assays for both OMD and NDFD ($P = 0.99$). Overall low-stem had the greatest digestibility with high-stem being intermediate and conventional having the lowest digestibility. Reducing the proportion of stem in the bale through changes in the harvest method can lead to an increased quality of corn residue.

Key Words: corn residue, digestibility, harvest method

1423 Supplementing Corn on Alfalfa Pasture to Alter Growth Performance, Carcass, and Quality Traits. Chloe Gresel, Cheryl Campbell, Lisa Duizer, Brian McBride, and Ira Mandell. *University of Guelph, Guelph, ON, Canada.*

Pasture finishing of beef cattle can be used to improve the fatty acid composition of beef (omega 3s and CLA) but at the possible expense of deleteriously affecting palatability traits. While pasture finished beef can command a premium in the marketplace, increased time on feed relative to finishing on a high grain diet can lead to production challenges due to much slower rates of gain for grass-fed beef. Supplementing corn on pasture may increase cattle gains and beef palatability attributes without necessarily deleteriously affecting beef fatty acid composition. The objective of this study was to examine how corn grain supplementation on alfalfa pasture alters carcass, meat quality, and fatty acid traits in an attempt to increase cattle performance and beef palatability. Fifty black Angus and Angus cross steers were randomly assigned to one of four management regimens: 1) 85.4% corn-based concentrate/14.6% forage diet fed in a drylot as a TMR (n = 12); 2) pastured cattle supplemented with corn at 1% BW (n = 13); 3) pastured cattle supplemented with corn at 0.5% BW (n = 12); 4) pastured cattle with no corn supplementation (n = 13). Pastured steers were rotationally grazed through 20 acres of predominantly alfalfa pasture while high concentrate-fed steers were housed in 2 drylot pens equipped with Calan gates to measure individual feed intakes. Cattle were fed for 111 d with BW taken every 14 d to track performance. Steers were harvested at a commercial packing plant where a rib section from each animal was shipped back to the University of Guelph Meat Lab for evaluation. Management regimen effects on performance, carcass, meat quality, trained taste panel and fatty acid data were evaluated using a Proc Mixed procedure in SAS. Average daily gain differed ($P < 0.0001$) across most management regimens. While grain feeding decreased ($P < 0.01$) dissectible lean, backfat and marbling were generally similar ($P > 0.14$) across management regimens. Grain feeding decreased ($P < 0.0001$) n-3 fatty acids without affecting ($P > 0.27$) CLA concentrations. Taste panel assessment of tenderness, juiciness, and beef flavor attributes were similar ($P > 0.30$) between beef from grain-fed cattle and beef from cattle that only consumed alfalfa pasture.

Key Words: beef cattle, grass-fed, fatty acids

1424 Effect of harvest method and ammoniation on apparent digestibility and intake of baled corn residue in lambs. A. C. Conway*, T. M. King, M. L. Jolly-Breithaupt, J. C. MacDonald, T. J. Klopfenstein, and M. E. Drewnoski, *University of Nebraska-Lincoln, Lincoln.*

The objective of this study was to assess the effect of three different harvest methods and ammonia treatment on the in vivo digestibility of baled corn residue. Nine wether lambs (49.2 ± 0.5 kg BW) were used in a 9 × 6 Latin Square design with a 3 × 2 factorial treatment structure; 3 harvest methods [conventional rake and bale (COV), New Holland Cornrower with 8 rows (high-stem; HS) or 2 rows (low-stem; LS) of corn stalks chopped into the windrow containing leaf, husk and upper stem] and ammoniation at 3% of DM of the resulting baled residue. Diets consisted of 64.2% corn residue, 29.8% Sweet Bran, 3.3% smooth-bromegrass hay, and 2.8% mineral mix (DM basis). Periods were 21 d (14 d adaptation and 7 d total fecal collection). Lambs were fed ad-libitum (110% of the previous day's DMI) during d 1 to 12 and reduced to 95% of ad-libitum intake for d 13 to 21. Treatment diets were fed over 6 periods, with the non-residue proportion of the diet (Sweet Bran, smooth-bromegrass hay, and mineral mix) fed alone in an additional period to determine the digestibility of the residue by difference. There was a harvest method by ammoniation interaction for ad-libitum DMI (d 7 to 12). Intake of non-ammoniated residue diets did not differ ($P \geq 0.92$) among harvest methods, however, ammoniation increased ($P \leq 0.05$) intake with LS having the greatest increase, COV

Table 1424.

Table 1. Effect of harvest method and ammoniation on *ad-libitum* DMI (% BW) and the DM and OM digestibility of the corn residue component of the diet.

	Non-ammoniated			Ammoniated			*P-value*			
	COV	LS	HS	COV	LS	HS	SEM	Harvest	Ammonia	Interaction
Diet DMI	2.6	2.6	2.6	3.6	4.1	3.1	0.15	<0.01	<0.01	<0.01
DMD,%	40.3	46.4	41.6	49.1	56.9	52.9	2.65	0.04	<0.01	0.89
OMD,%	45.9	50.6	45.6	55.1	60.1	57.4	2.43	0.12	<0.01	0.85

being intermediate and HS having the least increase. There was no harvest method by ammoniation interaction for DM or OM digestibility. Digestibility of DM (DMD) differed between harvest methods, with LS being greater than COV ($P = 0.01$) and tending ($P = 0.10$) to be greater than HS. Ammoniation increased DMD of the residues by 25% (10.2% units). Digestibility of OM (OMD) tended to be affected by harvest method with LS tending ($P = 0.06$) to be greater than COV. Ammoniation improved OMD of all harvest methods, resulting in a 22% (10.1% units) increase. Utilizing alternative harvesting technologies and ammoniation can improve the feeding value of baled corn residue.

Key Words: corn residue, digestibility, harvest method, ammoniation

1425 Effects of growing system and silage type on feedlot growth performance, carcass characteristics, and nutrient digestibility of beef steers. P. R. B. Campanili*[1], J. O. Sarturi[1], S. J. Trojan[1], M. A. Ballou[1], B. J. M. Lemos[2], L. A. Ovinge[1], and J. B. G. Mayorquin[3], *[1]Texas Tech University, Lubbock, [2]Universidade Federal de Goiás, Goiânia, Brazil, [3]Zamorano, Tegucigalpa, Honduras.*

The effects of beef cattle growing systems (grazing vs. bunk) and silage type (corn vs. sorghum) on finishing phase growth performance, carcass characteristics, and nutrient digestibilities were evaluated. Steers ($n = 128$; BW = 394 ± 21 kg) were backgrounded by either grazing (forage sorghum AF7401, 104 d) or bunk fed (65% concentrate diet, 85 d). Following the backgrouding period, animals were blocked by BW, and randomly allocated to one of the two dietary treatments, corn (BH8895) or sorghum (AF7401) silage at 20%, DM basis, in a randomized complete block design. During the finishing phase, steers were fed once daily at approximately 0800 h. A 5-d spot fecal collection (twice daily) and acid insoluble ash were used to estimate total tract apparent digestibility. Slaughter was performed on 132, 146, or 174 d on feed. Data were analyzed using the Glimmix procedure of SAS, using pen as the experimental unit. No interaction (growing system × silage type) was observed ($P > 0.16$), except for a tendency ($P = 0.06$) of bunk backgrounded steers to consume more sorghum than corn silage diet, compared with grazing backgrounded steers. Steers that grazed forage sorghum had greater ADG (25%), DMI (23%), and greater gain:feed (5%) during the finishing phase, compared with bunk backgrounded steers ($P < 0.01$). A greater HCW (7.8%), lower dressing percent (0.8% unit), and lower fat thickness (18%) were observed for steers grown under sorghum grazing conditions compared to backgrounded bunk fed steers ($P < 0.01$). Steers fed the corn silage diet had lower DMI (7%), greater ADG (5%), and consequently greater gain:feed (10%) compared with steers fed sorghum silage diet ($P < 0.01$). A 0.5% unit greater ($P = 0.03$) dressing percent and 0.1% unit greater ($P = 0.04$) KPH were observed for steers fed corn silage compared to those fed sorghum silage. Steers fed the corn silage diet also had greater ($P < 0.01$) DM (11%), CP (9%), EE (1.9%), and starch (8%) digestibilities compared to steers fed sorghum silage diet. Digestibility of fiber components were not affected ($P \geq 0.12$) by silage type or growing system. Sorghum grazing backgrounded steers positively affected finishing phase, but such strategies must be further be evaluated considering economical aspects and water use. Replacing corn silage with sorghum silage in beef finishing diets even at low roughage inclusion requires adjustments to balance dietary energy.

Key Words: grazing, silage, sorghum

1426 Effects of feeding green chopped winter forages on digestibility, ruminal fermentation and blood parameters in beef steers. T. M. Schulmeister*, M. Ruiz-Moreno, M. E. Garcia-Ascolani, F. M. Ciriaco, D. D. Henry, J. Benitez, J. C. B. Dubeux Jr., G. C. Lamb, and N. DiLorenzo, *University of Florida, North Florida Research and Education Center, Marianna.*

An experiment was conducted in the winter over 2 consecutive yr to evaluate the effects of feeding green chopped winter forages on digestibility and ruminal fermentation parameters in beef steers. Each yr, 9 ruminally cannulated Angus crossbred steers (yr 1: 359 ± 79 kg; yr 2: 481 ± 105 kg) received fresh chopped forage ad libitum, from pastures planted with one of the following mixtures: 1) FL401 cereal rye (*Secale cereale* L.)/Prine annual ryegrass (*Lolium multiflorum* Lam.) (RYE); 2) Horizon 201 oats (*Avena sativa* L.)/Prine annual ryegrass (OAT); 3) Trical 342 triticale (*X Triticosecale* spp.)/Prine annual ryegrass (TRIT). Intake was measured throughout the study using GrowSafe, and any unconsumed forage was discarded before the next d feeding. After a 14 d adaptation period, feed and fecal samples were collected twice daily for 4 d, to determine apparent total tract nutrient digestibility using indigestible NDF as a marker. On d 19, blood and ruminal fluid samples were collected every 3 h during a 24 h period, to analyze blood urea nitrogen (BUN) and glucose in the plasma, as well as NH_3–N, pH, and VFA concentrations in ruminal fluid. Data were analyzed as a generalized randomized block design with repeated measures, using the Mixed Procedure of SAS, with treatment as a fixed effect and animal and yr as random effects. Treatments did not affect ($P > 0.05$) intake of DM, OM, CP, NDF, or ADF; however, apparent total tract digestibility of DM, OM, CP, NDF, and ADF was greater ($P < 0.05$) for OAT and TRIT, when compared with RYE. Steers fed OAT had greater concentrations of plasma glucose ($P < 0.05$) compared with TRIT and RYE. An effect of sampling time ($P < 0.01$) was observed for ruminal pH; however no treatment or treatment × sampling time interactions were observed ($P > 0.05$). Steers fed RYE had greater ($P < 0.05$) concentrations of NH_3–N,

BUN, and the least concentrations of total VFA ($P < 0.05$). Molar proportion of acetate, branched-chain VFA and acetate:-propionate were greater ($P < 0.05$) for RYE when compared with OAT and TRIT. In conclusion, OAT and TRIT resulted in greater digestibility of nutrients, and ruminal fermentation and blood parameters that are conducive to enhanced growth performance when compared with RYE.

Key Words: fermentation, ruminants, winter forage

1427 Effects of feeding steers extruded flaxseed and hay together (total mixed ration) or sequentially (non-total mixed ration) on animal performance and erythrocyte vaccenic, rumenic, and α-linolenic acid content.

P. Vahmani*[1], D. C. Rolland[1], T. A. McAllister[2], H. C. Block[1], S. D. Proctor[3], L. L. Guan[3], N. Prieto[1], J. L. Aalhus[1], and M. E. R. Dugan[1], *[1]Agriculture and Agri-Food Canada, Lacombe, AB, Canada, [2]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, [3]University of Alberta, Edmonton, AB, Canada*.

Considerable research has been conducted to try and increase PUFA and their biohydrogenation intermediates (BHI) in beef, mainly vaccenic acid (VA; *trans*-11 18:1) and rumenic acid (RA; *cis*-9, *trans*-11 18:2), due to their purported health benefits. There is often large between-trial variation, and the objective of the present trial was to determine if feeding steers extruded flaxseed (Linpro-R; O&T Farms Ltd., SK, Canada) and hay (25 and 75%, respectively, DM basis) together as a total mixed ration (TMR) or sequentially (non-TMR) could help explain differences in PUFA BHI. Forty-eight Continental crossbred steers (325 kg [SD 16]) were stratified by weight to 6 pens of 8 steers and pens were randomized to either TMR or non-TMR. Steers were fed ad libitum for 240 d, feed intake was recorded daily, and steers were weighed every 28 d. Blood was collected on 0, 112, and 228 d, and erythrocyte fatty acid compositions were analyzed (i.e., erythrocyte composition correlates well with other tissues). Blood was centrifuged, and erythrocytes were direct methylated with methanolic HCl and analyzed by GC using a 100-m CPSil 88 capillary column. Data were analyzed using PROC MIXED of SAS. For animal performance, diet was the main effect and pen was the experimental unit. For erythrocyte fatty acids, the experimental model included diet as a main effect, days on test as a repeated measure and the diet × day interaction, with individual animal as the experimental unit. Dry matter intake was lower for non-TMR vs. TMR steers (10.56 vs. 11.42 kg/d; $P = 0.019$), but final weight (286 kg), ADG (1.18 kg/d), and feed efficiency (7.95) did not differ ($P > 0.05$). At 0 d, percentages of VA, RA, and α-linolenic acid (ALA) in erythrocytes (0.93, 0.29, and 0.07%, respectively) did not differ between TMR and non-TMR steers ($P > 0.05$). At 112 d, percentages of VA, RA, and ALA increased and non-TMR (2.82, 0.53, and 7.87%, respectively) were greater than TMR (1.71, 0.36, and 6.36%, respectively). At 228 d, the VA, RA, and ALA percentages were still greater than 0 d but were less than 112 d. The non-TMR (1.24, 0.20, and 5.90%) were still, however, greater than TMR (2.01, 0.25, and 6.78%). Our results suggest that the method of feeding management of supplementary sources of PUFA has minimal effects on animal performance but can profoundly affect the content of PUFA and their BHI in erythrocytes during the feeding period.

Key Words: α-linolenic acid, flaxseed, rumenic acid, total mixed ration, vaccenic acid

1428 Transcriptome responses to different forage allowance in the hypothalamus of grazing beef cows.

A. I. Trujillo*[1], F. Peñagaricano[2], A. Casal[1], J. Laporta[3], P. Soca[4], and M. Carriquiry[1], *[1]Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay, [2]University of Florida, Gainesville, [3]Department of Animal Sciences, University of Florida, Gainesville, [4]Facultad de Agronomia. Universidad de la Republica, Paysandu, Uruguay*.

The hypothalamus plays a major role in the response to changes in dietary nutrients supply. The aim of this study was to evaluate the effect of long-term nutrition at two different forage allowances (FA) of native pastures on the hypothalamic transcriptome of beef cows. Thirty-two multiparous cows (Angus, Hereford, and F_1 crossbreeds) were used, from May 2007 to May 2010, in a complete randomized block design with two FA throughout the year (4 vs. 2.5 kgDM/100 kg BW; HI vs. LO, respectively). At the end of the third experimental year and at 190 ± 10 d postpartum (45 d after calf weaning), cows were slaughtered and the hypothalami were collected. A subsample of 10 hypothalami ($n = 5$/treatment) from F_1 crossbreed cows was used. Total RNA extraction, amplification, library preparation, and sequencing were performed following the Illumina mRNA-Seq. Reads were mapped to the bovine reference genome using Tophat, and the resulting alignments were used to reconstruct transcript models using Cufflinks. Differential gene expression was evaluated using Cuffdiff. Additionally, gene set enrichment analysis was performed using goseq and meshr R packages. Overall, 217 genes were found to be differentially expressed at FDR < 0.05 and fold change ≥ 2 between HI vs. LO. Most differentially expressed genes were related to defense response and immune system, brain and neuronal development, neuronal regeneration and synaptic plasticity, neuronal communication, receptor and intracellular signaling, and metabolic hormone activity. The enrichment analysis using Gene Ontology (GO) and Medical Subject Headings (MeSH) databases revealed that GO biological process and MeSH terms related to defense response and immune system, negative regulation of proteolysis, chemotaxis, and regulation of JAK-STAT cascade were upregulated

in HI cows compared with LO cows. Meanwhile, GO biological processes and MeSH terms related to brain and neuronal development, synaptic plasticity, and neuronal communication were upregulated in LO cows compared with HI cows. These transcriptional changes in the hypothalamus would indicate a differential adaptation of grazing crossbreed cows to different nutritional environments. (This study was supported by CSIC Research Funds, UdelaR, Uruguay.)

Key Words: RNA-seq transcriptomic grazing

1429 Effects of feeding alfalfa stemlage or wheat straw for dietary energy dilution on growth performance and sorting behaviors of Holstein dairy heifers. H. Su*[1], N. M. Esser[2], W. K. Coblentz[3], K. F. Kalscheur[4], R. D. Hatfield[5], and M. Akins[1], *[1]University of Wisconsin, Madison, [2]University of Wisconsin, Marshfield, [3]U.S. Dairy Forage Research Center, Marshfield, WI, [4]USDA-ARS, U.S. Dairy Forage Research Center, Madison, WI, [5]U.S. Dairy Forage Research Center, USDA-ARS, Madison, WI*.

Feeding high-quality forage diets may lead to excessive weight gains and overconditioning for pregnant Holstein heifers. Restriction of energy density and DMI by heifers by using low-energy forages, such as straw, is a good approach for controlling this problem. Alfalfa stems containing high fiber and moderate protein content have the potential to be used to replace straw to reduce dietary energy. The objective of this study was to compare the growth performance and sorting behavior of dairy heifers offered an alfalfa silage/corn silage diet (CON; 13.1% CP, 67.4% TDN, and 39.7% NDF) with two energy-diluted diets replacing the corn silage and alfalfa silage with either alfalfa stemlage (STM; 12.6% CP, 60.1% TDN, and 46.4% NDF) or wheat straw (STW; 12.6% CP, 62.7% TDN, and 43.7% NDF) to get a similar diet composition. Seventy-two pregnant Holstein heifers (16.8 ± 1.3 mo) were stratified (24 heifers/block) by initial BW (light, 440 ± 18.0 kg; medium, 486 ± 18.6 kg; and heavy, 534 ± 25.1 kg) and then assigned to 1 of 9 identical pens (3 pens/block and 8 heifers/pen), where each of the 3 diets was randomly assigned to 1 pen within each block. Diets were offered in a 56-d feeding trial. Statistical analyses were performed using a MIXED procedure in SAS 9.3 with pen as the experimental unit. Daily DMI was greater for CON than for diluted diets (11.3 vs. 10.3 kg/d; $P = 0.01$), with no differences observed between STM and STW ($P = 0.61$). Average daily gains were greater for heifers offered the CON compared with heifers offered diluted diets (1.32 vs. 1.00 kg/d; $P = 0.02$). The feed:gain ratio tended to be less for heifers offered the CON relative to heifers offered diluted diets (8.6 vs. 10.7; $P = 0.08$). There were no differences detected across all growth measures within the diluted diets ($P > 0.05$). Physically effective fiber (pef) particle content was relatively static across sampling times for CON (overall sorting factor mean = 1.02), which indicates minimal sorting. Sorting against pef particles was observed for diluted diets and much more severely for the STM diet (overall sorting factor mean = 1.14 vs. 1.06; $P < 0.05$). These results indicate that diets diluted with low-energy forages (both STM and STW) were effective in reducing intakes of DM and energy and maintaining appropriate weight gains and body condition for pregnant Holstein heifers.

Key Words: alfalfa stemlage, dairy heifer, wheat straw

1430 Effect of partially replacing barley grain with liquid whey permeate in diets for finishing lambs on dry matter intake, average daily gain, and total tract digestibility. F. Joy* and G. B. Penner, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada*.

The objective of this study was to evaluate the effect of partially replacing barley grain with liquid whey permeate in diets for finishing lambs on DMI, ADG, and apparent total tract digestibility. Eighteen wether lambs were individually housed and randomly allocated to 1 of 3 dietary treatments in a completely randomized design. The control diet (CON) consisted of 67.7% barley grain, 20% barley silage, and 12.3% mineral and vitamin supplement on a DM basis. For the moderate-sugar (MOD) and high-sugar (HIGH) treatments, whey permeate was included in the diet at 5 and 10% on a DM basis, respectively, by replacing an equal proportion of barley grain. Water was added to equalize dietary DM content among diets with a targeted DM content of 53.5%. Lambs were provided with a 12-d dietary transition protocol (2 dietary steps) to gradually adapt them to the finishing diet. Subsequently, a 28-d treatment period was imposed with the final 4 d used for measurement of DMI and total fecal collection. Data were analyzed using the mixed model of SAS with the fixed effect of treatment. Addition of whey permeate did not affect DMI ($P = 0.96$) or ADG ($P = 0.43$) with average values of 1.22 ± 0.148 and 0.19 ± 0.026 kg/d, respectively. Total tract digestibility of sugar in the MOD treatment was greater (95.1 vs. 69.5 ± 6.32%; $P = 0.04$) than for CON whereas the HIGH treatment did not differ from CON or the MOD treatment. The apparent digestibility coefficients for DM (74.7 ± 2.74%), OM (76.8 ± 2.55%), starch (98.7 ± 1.32%), CP (65.5 ± 3.47%), NDF (36.43 ± 7.07%), and ether extract (74.34 ± 3.57%) did not differ among treatments ($P > 0.10$). The results of this study indicate that liquid whey permeate can partially replace barley grain without negative effects on DMI, ADG, or digestibility. In addition, our results show that a low inclusion rate (5% DM) may improve sugar digestibility.

Key Words: lamb, sugar, whey permeate

1431 Evaluation of the fermentation characteristics and glucosinolate content of cold-pressed or solvent-extracted carinata meal ensiled with corn forage. K. Rodriguez-Hernandez*[1,2], J. L. Anderson[1], M. A. Berhow[3], and A. Garcia[1], *[1]Dairy Science Department, South Dakota State University, Brookings, [2]CIRNOC-INIFAP, Matamoros, Mexico, [3]USDA, ARS, NCAUR, Peoria, IL.*

Carinata meal (CRM) is a quality protein source but contains high concentrations of sinigrin, a glucosinolate, which limits its use as a feedstuff. Previous research shows that CRM ensiled with forages reduces sinigrin content. Solvent extraction (SLV) or cold pressing (CPR) are methods used to extract oil from carinata seeds, leaving different residual oil content in the meals. We hypothesized that the oil content in CRM affects the fermentation when it is blended with forage for ensiling. The objectives were to determine the effects of CRM fat content when blended with corn forage on silage fermentation and sinigrin content. A micro-silo experiment was conducted with three treatments: 1) corn forage (CS), 2) CS and solvent-extracted CRM blend (CS:SLV), and 3) CS and cold-pressed CRM blend (CS:CPR). Both blends of CRM to forage were 25:75 on a DM basis. Micro-silos were packed at 86 kg of DM/m^3 in triplicate for 0, 7, 21, and 60 d of ensiling. Data were analyzed using MIXED procedures of SAS 9.4. The model included treatment, day, and treatment × day interaction, with significance declared at $P < 0.05$. The sinigrin content of CRM before blending was 15.3 vs. 16.2 mg/g for CPR and SLV meals, respectively. On d 0, within hours after mixing, the sinigrin content was reduced 94.8% in the CS:CPR blend but not in the CS:SLV blend. Compared with the original meal, by d 60, sinigrin content decreased 99.7% in CS:CPR and 99.4% in CS:SLV. Sinigrin was greater ($P < 0.01$) in CS:SLV compared with CS:CPR over time. Fat content as determined by ether extract was greater ($P < 0.01$) in the CS:CPR than in CS:SLV and CS. The pH decreased in all treatments over time but was greater in the blends. Acetic and lactic acids increased over time in all treatments. Acetic acid was less in the CS compared with the blends. Acetic acid was greater ($P < 0.01$) in CS:CPR than in CS:SLV. Lactic acid was less in CS:CPR. The CP was greater in both blends with CRM. Despite different fat contents, ensiling cold-pressed or solvent-extracted CRM with corn forage decreased sinigrin concentration without major detriment to silage fermentation.

Key Words: carinata meal, ensiling, glucosinolates

1432 Magnitude of difference in chemical and nutrient profiles, ruminal degradation kinetics, and intestinal digestion of three barley silages varieties in comparison with corn silage for dairy cattle. B. Refat*[1,2], W. Yang[3], J. J. McKinnon[4], J. Nair[1], A. D. Beattie[5], T. A. McAllister[6], D. A. Christensen[7], and P. Yu[1], *[1]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, SK, Canada, [2]Animal Production Department, Faculty of Agriculture, Zagazig University, Zagazig, Egypt, [3]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, [4]Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, SK, Canada, [5]Department of Plant Sciences, College of Agriculture and Bioresources, University of Saskatchewan, Saskatoon, SK, Canada, [6]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, [7]University of Saskatchewan, Saskatoon, SK, Canada.*

Whole-crop barley (*Hordeum vulgare* L.) silage is the main forage source for dairy producers in western Canada. There are many varieties that are constantly being developed. However, there is limited knowledge on their nutritional quality. The main objective of this study was to assess the magnitude of difference among barley silage varieties in comparison with corn silage in terms of their 1) chemical composition and energy values, 2) protein and carbohydrates fractions, 3) rumen degradation kinetics, and 4) intestinal absorbed true protein supply to dairy cattle. The experiment was a complete randomized design with four treatments: corn silage (P7213R), CDC Cowboy barley silage, CDC Copeland barley silage, and Xena barley silage. Five cannulated lactating dairy cows were used for measuring the in situ rumen degradation kinetics. Intestinal digestibility of rumen undegraded feed protein was estimated

using a 3-step in vitro procedure. This study showed no significance difference in total carbohydrates (CHO; % DM) among the three varieties of barley silage. Corn silage showed a higher CHO when compared with barley silage varieties (82.6 vs. 78% DM; $P < 0.05$). Corn silage had the highest total digestible nutrient TDN_{1x} (71% DM) and energy content NEL_{p3x} (1.5 Mcal/kg DM), whereas Cowboy barley silage had the lowest NEL_{p3x} (1.3 Mcal/kg DM; $P < 0.05$). Studying the CNCPS system, predicted values showed no significant difference among the three barely silage varieties on rumen degradable of NDF RDCB3 (averaged 14% DM; $P > 0.10$) but Cowboy barley silage was lower in total rumen degradable of carbohydrates (TRDC) when compared with other barley silages varieties (32 vs. 38% DM; $P < 0.05$). Corn silage had the highest TRDC compared with all barley silage varieties (42.5% DM; $P < 0.05$). In terms of the in situ rumen degradation kinetics, Cowboy barley silage showed a significant high degradation rate Kd (%/h; $P < 0.05$). Cowboy and Copeland barley silages had higher effective degradability of CP, whereas Xena had an intermediate level and corn silage showed the significant lowest values ($P < 0.05$). The corn silage had the highest intestinal digestible protein (IDP), whereas Xena barley silage had the lowest values of IDP. In conclusion, among the three barley silages, Cowboy barley silage had the highest degradation rate of fiber and more effective degradability of protein when compared with the other barley silage varieties. Corn silage has a potential to be used as a good forage source in western Canada compared with barley silage.

Key Words: energy, ruminal degradation kinetics, silage

1433 Production of high-quality and digestible forages to increase milk production and nutrient supply for lactating dairy cows. J. P. Pretz*[1], C. Ramsier[2], and D. P. Casper[1], *[1]Dairy Science Department, South Dakota State University, Brookings, [2]Ag Spectrum, Inc., De Witt, IA*.

Two forage production programs based on soil amendments and foliar nutrition were used to produce corn silage and alfalfa haylage followed by a feeding study to evaluate the lactational performance of Holstein dairy cows. Thirty peak-lactation (58 DIM ± 2.9 and 38.9 kg/d milk ± 7.6) Holstein dairy cows (8 primiparous and 22 multiparous) were blocked by milk yield, DIM, and parity and randomly assigned to 1 of 2 treatments using a randomized complete block design. Treatments were 1) CONTROL, which is a normal forage (65%) ration formulated using alfalfa haylage and corn silage produced via standard soil and agronomy programs, and 2) TEST, which is the same forage inclusion rates (65%) using alfalfa haylage and corn silage produced on an enhanced soil (base saturations) and agronomy program (foliar applications). Cows were fed the CONTROL ration during the covariate period of 7 d followed by 12 wk of data collection when CONTROL and TEST diets were fed. Milk production was increased ($P < 0.04$) for cows fed TEST compared with cows fed CONTROL forage (32.6 and 36.9 kg/d for CONTROL and TEST, respectively, throughout results). Dry matter intakes (23.9 and 22.8 kg/d) were similar ($P = 0.46$). Milk protein (0.98 and 1.09 kg/d; $P < 0.04$), lactose (1.62 and 1.88 kg/d; $P < 0.04$), and total solids (3.77 and 4.25 kg/d; $P < 0.05$) yields were increased for cows fed TEST forages compared with cows fed CONTROL forages. Fat-corrected milk (4%) tended ($P < 0.09$) to be higher (33.6 and 39.0 kg/d) for cows fed the TEST forages compared with cows fed CONTROL forages. Energy-corrected milk was increased ($P < 0.05$) for the TEST-fed cows (33.0 and 36.8 kg/d). A decrease ($P < 0.01$) in ruminal butyrate percentage was found for cows fed the TEST diet. Ruminal propionate concentration ($P < 0.10$) and percentage ($P < 0.10$) tended to increase when cows were fed TEST forages. There was a trend ($P < 0.06$) for an increase in total tract starch digestibility for cows fed TEST forage compared with CONTROL-fed cows (97.9 and 98.4% digestible). Digestibility of NDF (48.5 and 54.7%; $P < 0.03$) and ADF (48.3 and 54.4%; $P < 0.03$) were increased for the TEST-fed cows compared with cows fed CONTROL forages. Feeding higher-quality forages obtained from enhanced agronomy procedures increased milk production, milk composition, and fiber digestibility when lactating dairy cows are fed a high-forage ration.

Key Words: dairy cattle, forage quality, high-forage diet

1434 Increased forage neutral detergent fiber digestibility (in vitro or in situ) is positively related to dry matter intake and milk yield both across and within forage type. D. Sousa*, M. J. VandeHaar, and M. S. Allen, *Michigan State University, East Lansing*.

Effects of laboratory measures of forage NDF digestibility (fNDFD) on DMI and milk yield (MY) were determined by meta-analysis using a database of 135 treatment means from 52 trials reported in 47 peer-reviewed articles published from 1979 through 2015. Trials must have been conducted comparing divergent fNDFD (measured in vitro or in situ) within the same forage type in experimental diets with cows past peak lactation (>60 d postpartum). Meta-analyses were performed with all forages together and also separated by forage type: alfalfa ($n = 29$), grass ($n = 22$), corn silage without BMR ($n = 26$), brown midrib corn silage (BMR; $n = 47$), and sorghum silage ($n = 11$). Data were analyzed by ANOVA including the random effect of trial, fixed effect of fNDFD, diet forage NDF, and their interaction as continuous variables. Treatment means were weighted by the inverse of their variance. Statistical significance was declared at $P \leq 0.05$ and a trend at $P > 0.05$ to $P \leq 0.10$, and the interaction of fNDFD with fNDF was kept in the model if $P \leq 0.30$. Enhanced fNDFD increased DMI and MY; a one-unit increase in fNDFD in vitro or in situ was associated with a 0.07 kg/d increase in DMI ($P < 0.01$) and a 0.08 kg/d increase in MY ($P < 0.01$) for all forages, a

0.07 kg/d increase in DMI ($P = 0.02$) and no effect on MY for alfalfa, a tendency of 0.08 kg/d increase in DMI ($P = 0.06$) and a 0.23 kg/d increase in MY ($P < 0.01$) for grass, 0.09 kg/d increase in DMI ($P = 0.04$) and a 0.20 kg/d increase in MY ($P < 0.01$) for all corn silage, a tendency of 0.13 kg/d increase in DMI ($P = 0.06$) and a 0.27 kg/d increase in MY ($P < 0.01$) for BMR corn silage, and a tendency of 0.06 kg/d increase in DMI ($P = 0.09$) and a 0.19 kg/d increase in MY ($P < 0.01$) for corn silage excluding BMR corn. The sorghum data included only 11 treatment means from 5 trials that showed a tendency of 0.12 kg/d increase in DMI ($P = 0.09$) and no effect on MY but, when combined with corn silages, resulted in a 0.12 kg/d increase in DMI ($P < 0.01$) and a 0.21 kg/d increase in MY ($P < 0.01$). Forage NDF digestibility is an important parameter of forage quality that is positively related to DMI and MY within or across forage families.

Key Words: fiber digestibility, forage quality, intake

1435 Lactation performance, in situ degradability, and rumen fermentation of Holstein cows fed BMR-6 sorghum silage versus corn silage based diets.

K. K. Gautam, S. J. Trojan, J. O. Sarturi, and M. A. Ballou*, *Texas Tech University, Lubbock*.

The objectives of the study were to determine 1) the lactation performance, in situ degradability, and rumen fermentation of Holstein cows fed a bmr-6 sorghum silage (SS) vs. a leading non-bmr corn silage (CS) variety and 2) degradation kinetics of DM and starch from sorghum grain isolated from SS. In Experiment 1, four second lactation Holstein cows (578 ± 41 kg BW) in mid lactation, 101 to 113 DIM, were randomly assigned to diets containing SS or CS in a 2 × 2 crossover design with 14-d adaptation periods followed by 7-d collection periods. Cows were individually housed in open corrals (3.3 by 10 m) and fed once daily at 1000 h. Diets were formulated to supply 28% of the DM as each silage. Additionally, the diets were formulated to supply similar concentrations of NDF and total tract digestible starch, assuming 50% starch digestibility for SS. This was accomplished by replacing a portion of the steam-flaked corn (8% of diet DM) in the SS diet with 4% each of soy hull pellets and cottonseed hulls in the CS diet. All other dietary ingredients were similar between treatments. Milk production (32.6 vs. 31.4 ± 5.7 kg/d; $P > 0.725$) and percentages and yields of milk components did not differ ($P \geq 0.246$). In situ degradability of CS and SS were determined at 0, 6, 12, 18, 24, 36, 48, and 72 h. Cows fed CS had greater ($P \leq 0.001$) DM, OM, and NDF disappearances compared with cows fed SS at all incubation times. There was a treatment × time interaction ($P = 0.004$) for rumen pH recorded with greater pH at 1, 2, 3, 11, 12, 17, 23, and 24 h relative to feeding for SS. Total gas and methane produced from samples taken 3 h after feeding were greater ($P \leq 0.002$) for SS than for CS. The grain portion of SS was manually separated and ruminally incubated for 0, 3, 6, 12, 18, 24, 36, 48, and 72 h during Experiment 2. There were no differences ($P > 0.315$) between DM and starch disappearances of the sorghum grain until 18 h ($P \leq 0.001$). The DM disappearance continued to increase up to 72 h, but maximum starch disappearance, 55.7%, was reached at 18 h. Sorghum silage is an energy forage that may be used in lactating cow rations in areas where water availability may limit corn silage production; however, NDF and starch degradation should be improved.

Key Words: rumen, silage, sorghum

1436 Factors affecting methane production from ruminal fermentation of fiber isolated from dried distillers' grains and solubles.

O. R. Drehmel*[1], S. C. Fernando[1], J. L. Gramkow[1], J. V. Judy[1], J. C. MacDonald[2], H. A. Paz Manzano[1], and P. J. Kononoff[1], [1]*University of Nebraska, Lincoln,* [2]*University of Nebraska-Lincoln, Lincoln*.

Ruminants produce more methane (CH_4) than any other livestock animal. Consequently, focus has been placed on developing mitigation strategies for ruminants in both the dairy and the beef industries. The objective of this study was to determine the effect of addition of fat or cellulose to fiber from dried distillers' grains and solubles (DDGS) on ruminal CH_4 production. Three representative samples of DDGS were obtained from different commercial biorefineries and NDF residue was isolated. The purified NDF residue was fermented 1) alone (control), 2) with feed-grade corn oil, or 3) with microcrystalline cellulose powder using the in vitro gas production technique. Both cellulose and corn oil were added along with NDF residue at a 4:1 ratio (DM basis). Inoculum was obtained by collecting a mixture of rumen fluid from two steers (BW = 543.3 ± 20.6 kg) consuming a diet containing 30% concentrate and 70% roughage. For each treatment within each run, gas production was measured in real time over a 48-h period. Using a paired but separate bottle, the concentration of CH_4 gas produced was measured using a gas chromatograph at 0, 4, 8, 18, 24, and 48 h. The volume of methane produced at each time point was calculated by multiplying total gas produced by the concentration of CH_4. Three separate runs ($n = 3$) were conducted and data were analyzed as a randomized complete block in which run and source of DDGS were considered random effects and treatment was considered a fixed effect. Compared with the control (74.0 ± 6.06 mL/g), addition of corn oil tended ($P = 0.11$) to reduce total gas production (58.0 ± 6.04 mL/g) whereas addition of cellulose increased ($P = 0.02$) gas production (85.7 ± 6.06 mL/g). Similarly, compared with the control (0.075 ± 0.0125 mL/g), the addition of corn oil tended ($P = 0.12$) to reduce CH_4 production (0.043 ± 0.0125 mL/g) whereas the addition of cellulose increased ($P = 0.02$) CH_4 production (0.099 ± 0.0125 mL/g). In an in vitro setting, the addition of oil or cellulose to NDF resulted in the decrease or increase of methane production, which suggests that dietary components can be used to mitigate methane in

ruminant livestock.

Key Words: gas production, in vitro, methane

1437 Effect of native and hybrid varieties of whole-plant corn silage on digestion in diets for cattle. L. Corona-Gochi*, *Universidad Nacional Autonoma de Mexico, Mexico City, Mexico*.

Whole-plant corn silage (WPCS) in many production systems is the main component of forage in the diets of cattle, due to its yield, cost, and nutritional quality. The objective of this study was to evaluate two native varieties (red and white) and two commercial hybrids ("A" and "B") commonly planted in the valley of Mexico on DM yield and nutrient digestibility in cattle through a metabolism trial. The corn was planted at a density of 80,000 plants/ha and row spacing of 0.8 m, harvested 135 d after sowing with chop length 2.17 inches, and stored in plastic bag silos (70 kg). Four bulls (489 kg average BW) were used in a 4 × 4 Latin square design on a diet containing 55.4% (DM) WPCS, with the following treatments: T1-red native (RN), T2- white native (WN), T3-A hybrid (AH), and T4-B hybrid (BH). Data were analyzed with the MIXED procedure in SAS and comparison of means by the following contrasts: RN vs. WN, AH vs. BH, and natives vs. hybrids. Dry matter yield was higher ($P = 0.04$; 18.6%) for native varieties than for hybrids (25.5 vs. 2,145 ton DM/ha, respectively), and total tract digestion (%) of DM (76–84 ± 8), OM (78–85 ± 7), NDF (73 to 79 ± 6), FDA (73 to 84 ± 11), starch (91 to 86 ± 6), nitrogen (61 to 75 ± 14), and DE (57 to 71) was higher ($P < 0.01$) for native varieties than for commercial hybrids. No differences ($P > 0.05$) between natives and between hybrids were observed. Digestibility was higher for native varieties than for hybrids for DM (7.4%; $P = 0.002$), OM (6%; $P = 0.003$), NDF (8.3%; $P = 0.003$), FDA (12.9%; $P < 0.001$), starch (5.9%; $P = 0.031$), N (15.6%; $P = 0.002$), and DE (16.5%; $P = 0.005$). Because the native varieties of corn plant showed higher DM yield and nutrient digestibility compared with the hybrids, they are advisable for planting and use in cattle diets.

Key Words: cattle, corn varieties, digestibility

1438 Evaluation of brown midrib sudangrass silage in the diets of lactating dairy cows. K. F. Kalscheur* and B. Geoff, *USDA-ARS, U.S. Dairy Forage Research Center, Madison, WI*.

Forages that use less water but are high in digestibility are sought as alternatives to traditional forages such as corn silage. Brown midrib (BMR) sudangrass is a possible alternative that can provide high-quality forage as a replacement for corn silage. The objective of this study was to evaluate the replacement of corn silage and alfalfa silage with increasing concentrations of sudangrass silage in the diets of lactating dairy cows. Forty-eight Holstein cows in mid lactation were assigned to treatments in a randomized complete block design. Cows were fed a common covariate diet for 2 wk followed by 8 wk of experimental diets. Diets were formulated to contain 40% corn silage, 20% alfalfa silage, and 40% concentrate on a DM basis. Sudangrass silage was included in experimental diets at 0, 10, 20, and 30% of the diet DM. Proportionally, sudangrass silage replaced 2 parts corn silage and 1 part alfalfa silage. All other ingredients (high-moisture corn, canola meal, roasted soybeans, soyhulls, and minerals and vitamins) were included equally for all diets. Data were analyzed using MIXED procedures of SAS. Polynomial orthogonal contrasts were used to determine the effect of increasing BMR sudangrass silage in the diets of lactating dairy cows. Dry matter intake linearly decreased as sudangrass silage replaced corn silage and alfalfa silage ($P < 0.01$). Similarly, milk production decreased from 43.1 kg/d for cows fed 0% sudangrass silage to 39.2 kg/d for cows fed 30% sudangrass silage. Milk fat and lactose percentage were not affected by changes in forages; however, milk protein percentage was quadratically affected ($P = 0.02$). Yields of milk fat, protein, and lactose linearly decreased ($P < 0.05$) with increasing sudangrass silage. Similarly, energy-corrected milk (ECM) linearly decreased with increasing concentrations of sudangrass silage. Feed efficiency, defined as ECM/DMI, was not affected by changes in forage because milk production changes and DMI changes were the same. Although it was expected that increased digestibility of the BMR sudangrass silage would benefit the dairy cow, it is possible that the increased fiber in the sudangrass diets limited intake, resulting in a linear decrease in milk production.

Key Words: brown midrib sudangrass silage, dairy cows, forages

1439 Chemical composition and fermentation profile of corn silage ensiled for zero, thirty, ninety, or one hundred fifty days from corn treated with a foliar fungicide at different growing stages.

M. Weatherly*[1], C. Kalebich[1], K. Robinson[1], G. M. Fellows[2], and P. C. Cardoso[1], *[1]University of Illinois, Urbana, [2]BASF Corporation, Research Triangle Park, NC*.

Foliar fungicide application to the corn plant may reduce disease and provide developmental benefits to the crop. The objective of this study was to evaluate the effect of various applications of foliar fungicide on the nutrient composition and the energy and fermentation profile of corn silage ensiled for 0, 30, 90, or 150 d after harvest. Eight one-acre plots of corn were planted in April 2015. Treatments were replicated once and randomly assigned to one of the plots. Treatments were no foliar fungicide application (CON), one application of pyraclostrobin (Priaxor; BASF Corp.) foliar fungicide at corn vegetative growth stage V5 (V5), one application of pyraclostrobin and metconazole (Headline AMP; BASF Corp.) foliar fungicide at corn reproductive growth stage R1 (R1), and one application of pyraclostrobin foliar fungicide at V5 and one application of pyraclostrobin and metconazole foliar fungicide at R1 (V5/R1). At harvest, samples of the chopped corn silage were collected from each plot and immediately vacuum sealed. Corn silage ensiled for 0 d was frozen on the day of harvest, whereas corn silage ensiled for 30, 90, and 150 d was left in the vacuum-sealed bags for each respective time frame and frozen for later analysis. Statistical analysis was performed using the MIXED procedure of SAS. A treatment × time point interaction was observed for lignin ($P = 0.03$), water-soluble carbohydrate (WSC; $P = 0.02$) concentrations, and a tendency ($P = 0.07$) for VFA score. At 90 d of ensiling, R1 had lower lignin concentration (1.15 ± 0.21) than CON (2.55 ± 0.21), V5 (2.15 ± 0.21), and V5/R1 (2.55 ± 0.21) and higher concentrations of WSC (3.20 ± 0.49) than CON (2.45 ± 0.49), V5 (2.50 ± 0.49), and V5/R1 (2.60 ± 0.21). At 30 d of ensiling, CON tended to have a lower VFA score (8.18 ± 0.12) than V5 (8.92 ± 0.12), V5/R1 (8.73 ± 0.12), and R1 (9.05 ± 0.12). Corn silage from corn treated with foliar fungicide had improved chemical composition and fermentation and has the potential for increased milk production when fed to dairy cattle.

Key Words: corn silage, fermentation, foliar fungicide

1440 Chemical and energy profiles of value added pellet products based on combination of new coproducts from biofuel/bio-oil processing, low grade of peas, and lignosulfonate chemical compound at different levels for ruminants.

V. Guevara*, D. A. Christensen, J. J. McKinnon, and P. Yu, *Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, SK, Canada*.

The aim of this project was to test and develop eight high-value-added pellet products based on combination of coproducts from biofuel/bio-oil processing, low grade of peas, and lignosulfonate at different levels for ruminants. Statistical analyses were performed using PROC MIXED of SAS 9.3 with significance declared at $P < 0.05$. The results showed that BPP3 (high level of carinata meal, low level of peas, and no lignosulfonate), BPP4 (high level of carinata meal and low level of peas and lignosulfonate), and BPP7 (high level of canola meal, low level of peas, and no lignosulfonate) had the higher CP ($P < 0.05$), whereas both BPP3 and BPP4 also had the higher neutral detergent insoluble CP (NDICP; $P < 0.05$) and BPP6 (low level of canola meal and high level of peas and lignosulfonate) and BPP7 and BPP8 (high level of canola meal and low level of peas and lignosulfonate) had the higher acid detergent insoluble CP (ADICP; $P < 0.05$). BPP7 and BPP8 had the higher NDF, ADF, and ADL compared with the other blend pellet products ($P < 0.05$). Energy values using the NRC summative approach indicated that BPP1 (low level of carinata meal, high level of peas, and no lignosulfonate) and BPP6 (low level of canola meal and high level of peas and lignosulfonate) had the higher truly digestible nonfiber carbohydrate (tdNFC; $P < 0.05$); BPP3 and BPP4 had higher truly digestible CP (tdCP; $P < 0.05$); BPP1 was higher in truly digestible NDF (tdNDF; $P < 0.05$); and BPP7 and BPP5 (low level of canola meal, high level of peas, and no lignosulfonate) had the higher truly digestible fatty acids (tdFA; $P < 0.05$). However, BPP1 showed the higher level of total digestible nutrient (TDN; $P < 0.05$) and BPP1, BPP3, and BPP4 had the higher NE_L, NE_m, and NE_g ($P < 0.05$). In conclusion, carinata meal–based pellet products have more available protein (higher NDICP but lower ADICP) than canola meal–based blend pellet products. Canola meal–based blend pellet products have higher levels of NDF, ADF, and ADL than carinata meal–based pellet products. Pellet products based on carinata meal combined with peas has potential to be used as a good energy and good protein source compared with pellet products based on canola meal combined with peas.

Key Words: canola, carinata, lignosulfonate.

1441 Use of short-season hybrids may enable greater use of corn silage in western Canadian feedlot diets without decreasing animal performance.

G. E. Chibisa*[1] and K. A. Beauchemin[2], [1]*University of Idaho, Moscow,* [2]*Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada*.

As a result of the overall trend for an increase in corn heat units and growing season precipitation in western Canada, early maturing corn hybrids are currently being introduced where previously barley silage (BS) was the main forage used in feedlot cattle production. We hypothesized that early maturing corn silage (CS) could replace BS in backgrounding (BKGN) feedlot cattle diets, and because of its greater starch content, dietary proportion of CS could be increased and duration of the BKGN phase could be extended without compromising animal performance. A total of 160 steers (mean BW ± SD: 272 ± 22.4 kg) were assigned to 16 pens and fed BKGN diets containing either 60% (DM basis) BS (CON) or 60 (60CS), 75 (75CS), and 90% CS (90CS; 4 pens/treatment) until they reached an average pen BW of 380 (SBKGN; 2 pens/treatment) or 430 ± 15 kg (LBKGN; 2 pens/treatment) in a split-plot design. All steers were finished (FIN diet; 9% CS, 86% barley grain, and 5% supplement) to an equal-BW end point (700 ± 15 kg LW). During BKGN and FIN, DMI, ADG, and G:F were measured for all pens. Carcass data were also collected. There was no BKGN diet × duration interaction ($P > 0.05$) for most of the production measures. As dietary CS content increased during BKGN, DMI and ADG decreased (quadratic, $P \leq 0.003$) and there was also a tendency ($P = 0.078$) for a decrease in G:F at the highest level of CS. However, the BKGN diet had no effect ($P > 0.05$) on DMI, ADG, and G:F during the FIN phase. Similarly, the BKGN diet had no effect ($P > 0.05$) on carcass traits including dressing percentage and quality grade. As expected, compared with SBKGN steers, LBKGN steers took longer (105 vs. 71 d; $P = 0.001$) to reach the end of BKGN target weight. As a result of their heavier weight at the beginning of FIN, LBKGN steers also had a higher DMI (11.6 vs. 11.0 kg/d; $P = 0.045$) and reached the FIN end point earlier (116 vs. 146 d; $P < 0.001$) than SBKGN steers. However, the duration of BKGN had no effect ($P > 0.05$) on carcass traits. In summary, inclusion of up to 90% CS in cattle diets fed over a short or long BKGN phase did not compromise production performance during FIN.

Key Words: backgrounding duration, corn silage, production performance

1442 In vitro starch and neutral detergent fiber degradability of corn silage hybrids.

M. T. Harper*[1], G. Roth[1], H. L. Wells[1], C. Canale[2], A. Gallo[3], F. Masoero[3], and A. N. Hristov[1], [1]*The Pennsylvania State University, University Park,* [2]*Cargill Animal Nutrition, Shippensburg, PA,* [3]*Università Cattolica del Sacro Cuore, Piacenza, Italy*.

This study investigated in vitro starch and NDF rumen degradability of 5 corn silage hybrids: Hubner H5333RC3P, H6191RCSS, and H5222RC3P; Masters Choice MC 5250; and Healthy Herd Genetics 42HFC15. Three of these hybrids were rated as potentially high in starch degradability, whereas the other two, Hubner 5333 and Hubner 6191, were rated low to medium in starch degradability, respectively. Samples from a corn silage hybrid trial conducted in Centre County, PA, at The Pennsylvania State University's Russell Larson Research farm were ensiled (in triplicate) in sealed 2.5-kg-capacity plastic bags. Silages were moved to a −20°C freezer on d 0, 30, 60, 120, and 150 after ensiling and stored frozen for at least 30 d before analysis. Silage subsamples were dried at 65°C for 72 h, ground through a 4- (in vitro degradability) or 1-mm (NIR and chemical analyses) sieve, and analyzed for in vitro starch and NDF degradability in 2 commercial laboratories and one university laboratory. Seven-hour starch degradability was determined by in vitro incubation with ruminal inoculum (IVSD; 2 assays) and by NIR (2 assays). Silage samples were also analyzed for NDF degradability (NDFD) by 48-h in vitro incubation with ruminal inoculum (IVNDFD), for 30-h NDFD by NIR (NIRNDFD), and for total tract NDF digestibility by NIR (TTNDFD). IVSD varied from 65.1 to 68.3% and was not affected ($P \geq 0.50$) by hybrid. Starch degradability determined by NIR was higher than IVSD, 73 to 78%. IVSD clearly increased with increasing ensiling time ($P < 0.001$), from 58.3 and 66.0 (d 0) to 69.7 and 69.3% (d 150) for laboratories 1 and 2, respectively. The NIR analysis showed similar trends. Silage hybrids varied in NIRNDFD from 56.6 to 59.9% ($P = 0.001$), but there was no difference ($P = 0.15$) in IVNDFD due to hybrid. Hybrid also had no effect on TTNDFD. All procedures indicated decreased ($P \leq 0.002$) NDFD or TTNDFD with increasing ensiling time, particularly from d 0 (63.8%) to 30 (57.8%); for some hybrids, the decrease in NDFD reached 10 percentage units. In this study, IVSD was similar among corn hybrids and hybrid had no effect on IVNDFD. These data have to be confirmed in vivo. With all hybrids, IVSD clearly increased and NDFD decreased with ensiling time, particularly NDFD from d 0 to 30. The reason for the decrease in NDFD needs to be elucidated.

Key Words: corn silage, degradability, in vitro, neutral detergent fiber, starch

1443 Evaluation of use of heat-stable α-amylase for neutral detergent fiber contents by using cellulose standard in filter bags made from different textiles add starch in samples. T. N. P. Valente*[1], E. Detmann[2], and C. Batista Sampaio[3], *[1]IFGoiano, Posse, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil*.

The objective of this study was to evaluate the efficiency of using nylon textiles (50 μm), F57 (Ankom), and nonwoven textile (NWT; 100 g/m^2) on laboratory evaluation of NDF by using quantitative filter paper as purified cellulose standard (12.5 cm Ø; ashless with 0.0086% of ash and 96.53% of DM; code 050154; Vetec) by simulating composition of samples with additions of corn starch (Sigma S-5296; 91.62% DM). The quantitative filter paper was processed in a knife mill with a 1-mm screen sieve and the procedures for analyses of NDF contents were performed in a fiber analyzer (Ankom^{220}). The experiment was performed with additions of different ingredients into the filter paper: corn starch added at the levels of 15 or 50% of DM. The ratio 20 mg of DM/cm^2 of surface was followed. The treatment was based in the use or not of heat-stable α-amylase. The experiment was performed according to a completely random design using 3 textiles × 2 levels of starch × 2 using or not heat-stable α-amylase factorial arrangement. The recovery bias of NDF was NRF = (Mo − Me/Me) × 100, in which NRF = NDF recovery bias (%), Me = the expected mass of NDF or mass of cellulose standard (g), and Mo = the observed mass of NDF or the residue obtained after analysis (g). The bias estimates were obtained as described above based on assumption that the cellulose standard presents 100% of NDF. Statistical procedures were performed using by SAS. For type I error, 0.01 was adopted as the critical limit, using a Tukey–Kramer test. When heat-stable α-amylase was not used, the NDF contents were overestimated ($P < 0.01$) and presented similar biases for both starch levels. The biases varied from +3.89 to +9.88% observed for all types of filter bags. Such a pattern corroborates the interference of starch on laboratorial evaluation of NDF. The biases were generally lower for nylon than for F57 and NWT ($P < 0.01$) when 50% of starch was considered. The biases for both starch levels were not significant ($P > 0.01$) when α-amylase was used, which brings into evidence the removal of contaminant starch from insoluble residue. The use of F57 and NWT resulted in accurate estimates of NDF contents. For samples containing starch, use of heat-stable α-amylase is recommended in the evaluation of NDF contents. Thanks for financial support to IFGoiano, FAPEG, and CNPq.

Key Words: F57, nonwoven textile, nylon

1444 Production response of lactating cows to diets based on corn or forage sorghum silage harvested on two dates and supplemented with soybean meal or mechanically pressed cottonseed meal. J. K. Bernard*, S. Tao, and T. Smith, *University of Georgia, Tifton*.

A 6-wk randomized design trial with a 4 × 2 factorial arrangement of treatments was conducted to evaluate the production response of 48 lactating Holstein cows (140.9 ± 55.9 d in milk) to diets based on corn (CS) or forage sorghum silage (FS) harvested in the summer (S) or fall (F) and supplemented with either soybean meal (SBM) or mechanically pressed cottonseed meal (CSM). Corn was planted in April and harvested in July (CSS); a second crop was planted in August and harvested in November (CSF). Forage sorghum was planted in April, harvested in July (FSS), allowed to regrow, and harvested again in November (FSF). Ensiled forages provided 41.67% of the DM in the experimental diets. Approximately 19% of the total dietary N provided by SBM was replaced with CSM. Cows were fed a corn silage based diet for 2 wk before beginning the 4-wk experimental period. No differences ($P > 0.10$) were observed in DMI (23.6 ± 1.6 kg/d) or milk yield (35.0 ± 1.7 kg/d) among treatments. An interaction ($P = 0.03$) of forage source and protein supplement was observed for milk fat, which was lowest for CSF-CSM (3.09%) compared with the other treatments (3.64 ± 0.16%). Milk fat yield was greater ($P = 0.006$) for diets based on FS compared with diets based on CS (1.28 and 1.22 kg/d, respectively). No differences ($P > 0.10$) were observed in yield or concentration of milk protein, lactose, or SNF. An interaction ($P < 0.001$) was observed for efficiency of milk production, which was lowest for CSS-SBM (1.39) and CSF-CSM (1.39) compared with CSF-SBM, FSS-SBM, FSF-SBM, and FSF-CSM (1.54, 1.47, 1.48, and 1.58, respectively) but not different from CSS-CSM and FSS-CSM (1.44 and 1.44, respectively). Concentrations of milk urea N were lower for diets based on CS compared diets based on FS (8.50 and 11.50 mg/dL, respectively; $P < 0.001$) and for diets supplemented with CSM compared with diets supplemented with SBM (9.31 and 10.70 mg/dL, respectively; $P = 0.002$). Results of this trial indicate that diets based on CS or FS harvested in S or F can support similar performance and that CSM can be substituted for SBM without negatively affecting production.

Key Words: corn silage, forage sorghum, mechanically pressed cottonseed meal

1445 Commercial ground corn surface area is better related to rumen disappearance than geometric mean particle size. J. P. Goeser*[1,2], B. Beck[3], T. Koehler[4], D. Tanata[5], E. Reid[6], M. Kirk[7], and R. D. Shaver[8], *[1]University of Wisconsin, Madison, [2]Rock River Laboratory, Inc., Watertown, WI, [3]Witmers Feed and Grain, Columbiana, OH, [4]Landmark Cooperative, Cottage Grove, WI, [5]Medford Cooperative, Medford, WI, [6]Cooperative Feed Dealers, Conklin, NY, [7]Masters Choice, Anna, IL, [8]University of Wisconsin-Madison, Madison*.

Ground dry shelled corn is not uniform relative to animal performance. Geometric mean particle size (GMPS; μm) has been related to rumen digestion but research has evaluated only ground corns sized >700 μm GMPS. The industry has reduced GMPS to <400 μm in some cases. Furthermore, GMPS and standard deviation can be combined into a surface area measure (SA; cm^2). The objective of our work was to determine if GMPS or SA were related to rumen in situ starch disappearance (SD; % starch) for commercial dry ground shelled corns. Commercial dry, ground shelled corn ($n = 38$) samples were collected from feed mills in the Eastern and Midwestern United States. Samples were assessed for particle size by shaking eight sieves for 10 min, ranging from 2,000 μm to the pan, and determining percent weight retained on each. Geometric mean particle size and SA were determined using Kansas State University equations. Samples were assessed for starch (% DM) using the Hall 2008 AOAC procedure. Starch, GMPS, and SA mean and standard deviation were 70.6/3.2, 715/233, and 92.7/20.8, respectively. Three grams of corns were weighed into Ankom R510 bags (50-μm pores), soaked in warm water, and incubated for 0 or 7 h, in triplicate across three ruminally cannulated lactating dairy cows consuming a 60% forage, corn silage–based diet. After incubation, bags were rinsed in a commercial laundry machine, dried at 50°C for 24 h, and weighed to determine the DM disappearance. Residues were composited and starch was assessed. Corn SD at 0 (SD0) and 7 h (SD7) were determined as starch loss during incubation. The SD0 and SD7 (% starch) mean/standard deviation were 19.8/12.4 and 68.7/10.6, respectively, suggesting that a range in SD was achieved. Time point (class variable), starch, GMPS, and SA were related to SD using backward elimination and final model fit using Fit Model function within SAS JMP version 11.0. Geometric mean particle size and SA were not allowed within the same final model because GMPS is used within the SA calculation. The SA sum of squares was nearly 3 times that of GMPS (908 vs. 328), and hence only SA remained. Residual plots were assessed for normality. The final model exhibited $R^2 = 0.86$, SE = 10.3. Time, starch, and SA were ($P < 0.02$) related to SD, and time × starch showed a trend ($P < 0.06$). The parameter estimate for SA was 0.20 (SE 0.06). These observations suggest SA is better related to rumen starch disappearance than GMPS and should be considered by feed mills when evaluating ground corn and the top 15% SA here were >110 cm^2/g.

Key Words: corn, digestion, starch

1446 Effect of steam-flaked and ground corn with different particle size on dairy cow performance with high-concentrate diet. G. R. Ghorbani*, F. Ahmadi, and M. Haidary, *Isfahan University of Technology, Isfahan, the Islamic Republic of Iran*.

Eight midlactation Holstein cows were used to study the effect of steam-flaked and ground corn with different particle size on the performance of lactating cows with high concentrate. Cows were assigned to four treatments in a replicated 4 × 4 Latin square experiment. Cows were fed (ad libitum) a total mixed ration (36:64 forage:concentrate ratio, DM basis). The diets were different only in corn particle size. The treatments were ground corn with different particle size (mean particle size = 0.59, 0.68, and 0.82 mm, for treatments 1, 2, and 3, respectively) and steam-flaked corn for treatment 4 (density = 0.41 kg/L). Treatments had no effects on DMI, milk yield (MY), 3.5% fat-corrected milk (FCM 3.5%), milk protein, lactose, and SNF percentage. Milk fat percentage was significantly higher for cows receiving steam-flaked corn than for cows receiving treatment 1 and 2 diets (2.61, 2.48, and 2.70 vs. 2.75; $P = 0.003$). Rumen and urinary pH was greater for treatment 4 than for treatment 1, 2, and 3 (6.46 vs. 6.06, 5.92, and 6.05 [$P < 0.01$] and 8 vs. 7.93, 7.95, and 7.98, respectively). Feed efficiency (MY/DMI) was not affected by dietary treatments, whereas in treatment 4, 3.5% FCM/DMI was significantly ($P < 0.05$) higher than in treatment 1. Overall, these data indicate that ground corn with a mean particle size of 0.82 mm has effects similar to those of steam-flaked corn with 0.41 kg/L density.

Key Words: ground corn, Holstein dairy cows, particle size, performance, steam-flaked corn

1447 Effect of diastatic power and processing index on the feed value of barley grain for finishing feedlot cattle. G. O. Ribeiro Jr.*[1], M. L. Swift[2], and T. A. McAllister[1], *[1]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Hi-Pro Feeds, Okotoks, AB, Canada*.

The objective of this study was to assess the nutritional value of barley grain differing in diastatic power (DP; high vs. low, a malt trait) and processing index (PI; 75 vs. 85). One hundred sixty Angus × Hereford crossbred yearling steers (467 ± 38 kg; 144 intact; 16 rumen cannulated) were used in a complete randomized 2 × 2 factorial experiment. Steers were assigned to 16 pens, 8 of which were equipped with the GrowSafe system to measure individual feed intake. Cannulated steers (2 per pen) were randomly assigned to the 8 GrowSafe pens. Diets consisted of high- or low-DP barley grain (80.0% of diet DM) processed to an index of either 75 or 85% (PI). Ruminal pH in cannulated steers was measured over four 5-d periods using indwelling electrodes. Fecal samples were collected every 28 d from the rectum of each steer to assess digestibility using AIA as a marker. No differences ($P > 0.10$) in rumen pH were observed among cattle as measured by the indwelling pH meters. However, lower ($P < 0.05$) rumen pH was observed for steers fed low- as opposed to high-DP barley in rumen samples collected just before feeding and measured in the laboratory. Intake of DM and OM were not affected ($P \geq 0.24$) by DP but were lower ($P < 0.01$) with more severe processing (PI-75 vs. PI-85). Low-DP barley tended to exhibit higher ($P = 0.09$) total tract DM digestibility than high-DP barley. Steers fed PI-75 barley also had higher ($P = 0.06$) G:F and NE_g. Digestibility of DM, OM, CP, NDF, and starch was higher ($P < 0.05$) for PI-75 barley than for PI-85 barley. Low-DP barley increased ($P < 0.05$) carcass dressing percentage by 0.5% compared with high-DP barley, with a lower ($P = 0.06$) PI tending to increase rib eye area. Compared with high DP, steers fed low-DP diets had more ($P = 0.01$) total (41.7 vs. 19.4%) and severe liver abscesses (22.2 vs. 9.7%). Results suggest that although low-DP barley increased liver abscesses, differences in DP did not alter digestion or growth performance, but low-DP barley did improve dressing percentage. Barley with different DP responded similar to processing, with more intensive processing (PI-75) of barley improving starch digestion, feed efficiency, and NE_g without negatively affecting rumen pH.

Key Words: barley, beef cattle, malt traits, processing index

1448 Heating of ensiled high-moisture corn and aerobic loss of volatile organic compounds are delayed by inoculation with *Lactobacillus buchneri*. S. Qi, W. Rutherford, B. Smiley, B. Harman, and F. Owens*, *DuPont Pioneer, Johnston, IA*.

Volatile organic compounds (VOC) when combined with specific nitrous oxide air pollutants have been associated with smog. Volatile organic compounds are released from silage surfaces exposed for removal from storage and during feed mixing and delivery. Extent of loss of VOC depends on air exposure time and presumably is accelerated by silage heating. Inoculation of corn silage with *Lactobacillus buchneri* (LB) retards yeast growth and delays heating of corn silage exposed to air. This study was designed to measure effects of LB inoculation on heating and losses of VOC and DM from high-moisture corn (HMC). High-moisture corn from three different Pioneer hybrids was treated with 1×10^5 cfu LB/g wet material with a Pioneer brand LB inoculant or left untreated. Following treatment, samples were placed in triplicate PVC silos and allowed to ferment for 60 d. Following removal from storage, triplicate samples of each HMC were exposed to air in Honig adiabatic chambers with temperatures being continuously monitored. Wet silage samples were recovered after 24, 48, 72, 96, and 120 h of air exposure and a liquid extract was assayed for concentrations of specific VOC. Concentrations of ethanol, acetate, lactate, 2 propanediol (PD), and total VOC in fermented HMC were 0.5, 0.1, 0.8, 0.02, and 1.5% of DM for untreated HMC and 0.8, 0.5, 0.5, 0.04, and 2.0% of DM for LB-inoculated HMC, with LB silages being higher in total VOC and acetate ($P < 0.02$) but lower ($P < 0.02$) in lactate. Of the initial concentrations of total volatiles, ethanol, and lactate in fermented HMC, disappearance half-life during air exposure was shorter for control HMC (1.3, 1.4, and 1.1 d, respectively) than for LB-treated HMC (41, 11, and 300 d, respectively). Above and beyond this "hidden" loss of energy as volatiles, microbial metabolism during air exposure results in additional loss of DM. The DM lost during aerobic exposure was greater (4.92 vs. 0.3%; $P < 0.01$) for untreated HMC than for LB-treated HMC and time for silage temperature to increase by 1.7°C was shorter (55 vs. 150 h; $P < 0.01$) for control HMC than for LB-treated HMC. Results indicate that inoculation of HMC with LB postpones heating and retards release of VOC and DM from HMC. Through delaying the loss of VOC and increasing retention of DM during air exposure, inoculation of HMC with LB increased nutrient recovery from ensiled HMC.

Key Words: corn silage, *Lactobacillus buchneri*, volatile organic compounds recovery

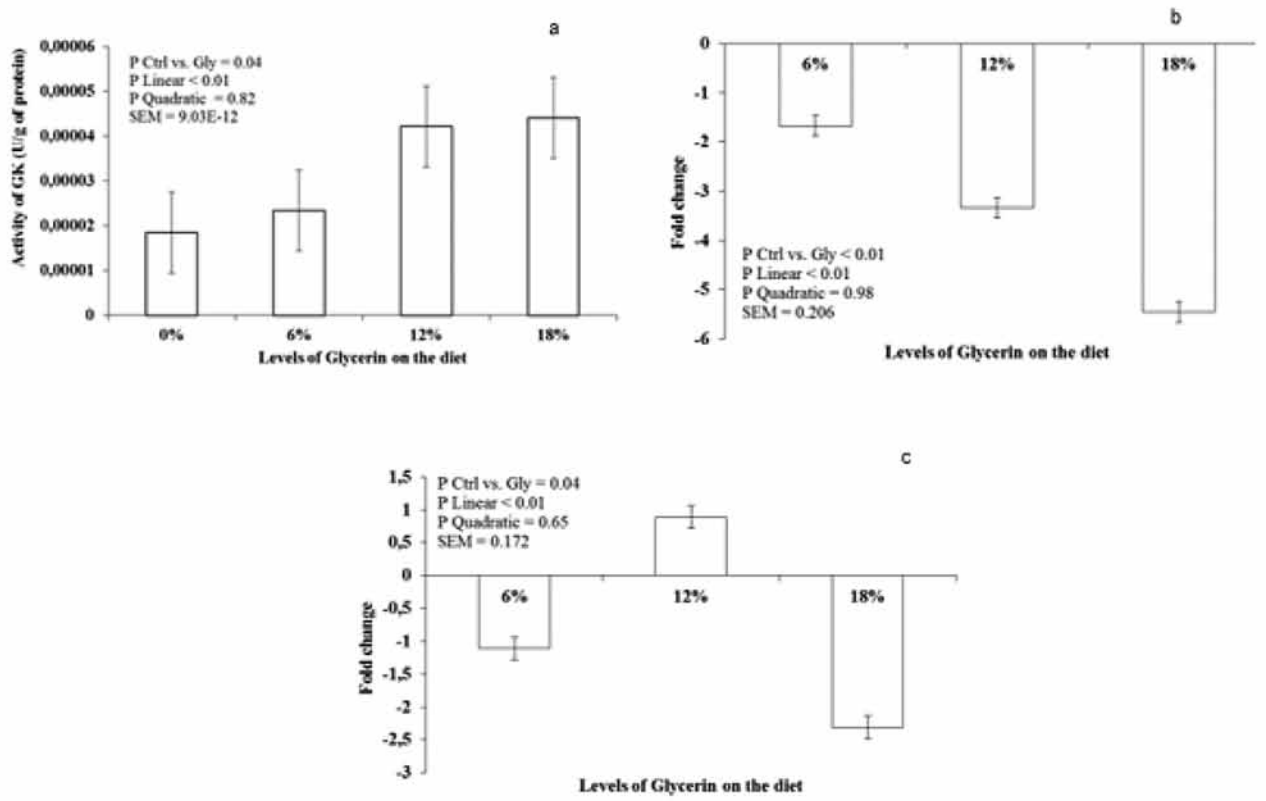

Figure 1449. Glycerol kinase activity (a), relative expression of *GK1* (b), and relative expression of *PCK1* (c) in the liver of young bulls fed with different crude glycerin concentrations.

1449 Liver gluconeogenesis in young bulls fed different levels of crude glycerin. M. M. Ladeira*[1], J. R. R. Carvalho[1], P. D. Teixeira[1], J. C. O. Dias[2], T. R. Gionbelli[1], A. C. Rodrigues[1], and D. M. Oliveira[3], *[1]Universidade Federal de Lavras, Lavras, Brazil, [2]IFNMG, Salinas, Brazil, [3]Universidade Estadual do Mato Grosso do Sul, Aquidauana, Brazil*.

This study aimed to evaluate gene expression of *glycerol kinase 1* (*GK1*) and *cytoplasmatic phosphoenolpyruvate carboxykinase* (*PCK1*) and glycerol kinase activity in the liver of young bulls fed different levels of crude glycerin. Forty-four crossbred young bulls (one-fourth Angus, one-fourth Nellore, one-fourth Senepol, and one-fourth Caracu), with initial BW of 368 ± 4 kg, were used in a completely randomized design, with four treatments (0, 6, 12, and 18% of crude glycerin in the diet, DM basis) and 11 replicates. Diets were formulated with corn silage as forage, and crude glycerin replaced ground corn. Corn gluten meal-21 was included in the diets with crude glycerin to provide similar levels of CP (13% CP). Immediately after slaughter of animals, liver samples were collected, frozen in liquid nitrogen, and stored in −80°C to analyze *GK1* and *PCK1* genes expression using RT-qPCR. In addition, same samples were used to measure glycerol kinase activity. Orthogonal contrasts were used to evaluate the linear and quadratic effects of glycerin and without-glycerin vs. glycerin diets. Liver glycerol kinase activity linearly increased ($P < 0.01$) following glycerin inclusion (Fig. 1a). On the other hand, the opposite results were detected on *GK1* and *PCK1* expressions (Fig. 1b and 1c, respectively). Expression of *GK1* in the liver was 1.61, 3.34, and 5.45 times lower when the animals were fed 6, 12, and 18% of crude glycerin, respectively, than in the liver of animals fed a diet without glycerin. Therefore, *GK1* expression was more affected by the diets than *PCK1*. In conclusion, the use of crude glycerin in feedlot diets downregulate the expression of *GK1* and *PCK1* and increases glycerol kinase activity in liver of young bulls.

Key Words: glycerol, glycerol kinase, *PCK1* gene

1450 Starch digestibility by lactating cows fed flint or dent corn silage stored two or six months before feeding. A. Laflotte[1], L. Aubry[2], B. Mahanna[3], and F. Owens*[3], *[1]U. Lorraine, Nancy, France, [2]DuPont Pioneer, Aussonne, France, [3]DuPont Pioneer, Johnston, IA*.

Starch availability from corn silage increases with duration of storage and is greater for grain from dent than from flint hybrids based on in situ or in vitro studies. This objective of this study was to determine the degree that starch digestibility by lactating cows changes during storage time from corn silages produced from one dent and one flint hybrid. Yields of DM for the dent and flint hybrid harvested and kernel processed from adjacent

1.1 ha plots in France on Oct 3 and Sep 26 at 41 and 37% DM were 16.1 and 15.1 t DM/ha, respectively; starch made up 32.5 and 27% of silage DM, respectively. Of ration DM, 53% was silage. Dietary energy levels were moderately low so that digestibility of starch from the silage could be accurately measured. Two groups of 10 lactating cows were fed each corn silage diet in a replicated crossover trial within periods that began 2 mo and again 6 mo after ensiling. Milk production and DMI were measured during 14-d periods of each segment. Fecal samples obtained from each cow on three nonconsecutive days during each segment were assayed for starch content. Milk yield, milk:intake ratio, and fecal starch concentrations all were greater ($P < 0.01$) 2 mo after ensiling, even though DMI was greater 6 mo after ensiling. Adjusted for differences in starch content of the diets, starch digestibility averaged 89 and 96% 2 mo after ensiling and 94 and 97% 6 mo after ensiling for the flint and the dent corn silages, respectively, increasing ($P < 0.05$) with silage storage time for the flint but not ($P = 0.66$) for the dent corn silage. After 6 mo of storage, starch digestibility was not different ($P = 0.17$) between the two corn silages. Averaged across periods, individual cows differed in starch digestibility being over 95.5% for 6 cows of the 20 cows but under 92% for 4 cows. Starch digestibility by individual cows was not correlated with parity, milk production, cow weight, or DM content of feces. In summary, when averaged across periods, total tract digestibility of starch was greater ($P < 0.02$) for this dent than this flint corn silage but tended to increase ($P < 0.07$) with duration of silage storage.

Key Words: corn silage, flint corn, starch digestion

1451 Ruminal in situ degradability and in vitro organic matter digestibility of peanut hulls under different incubation times with calcium oxide.

F. M. Ciriaco*[1], D. D. Henry[1], R. Beierbach[2], T. M. Schulmeister[1], M. Ruiz-Moreno[1], M. E. Garcia-Ascolani[1], N. Oosthuizen[1], P. L. P. Fontes[1], G. C. Lamb[1], and N. DiLorenzo[1], *[1]University of Florida, North Florida Research and Education Center, Marianna, [2]Instituto Nacional de Tecnología Agropecuaria (INTA), EEA Anguil, Anguil, Argentina*.

Two experiments were conducted to evaluate the effects of calcium oxide (CaO) and different DM contents on ruminal in situ degradability and on in vitro OM digestibility (IVOMD) of peanut hulls (PH). In Exp. 1, PH were incubated in duplicate (2 consecutive years) in 20-L buckets following the treatments 1) as is, 2) 50% DM for 7 d, 3) 50% DM for 14 d, 4) 50% DM + 5% CaO for 7 d, and 5) 50% DM + 5% CaO for 14 d. After 7 or 14 d of incubation, bucket contents were dried and ground to pass a 4-mm screen. Ruminal in situ degradability of DM, OM, NDF, and ADF of PH, either treated or not with CaO, was determined by incubating nylon bags for 24, 48, and 72 h in duplicate, in 9 ruminally cannulated steers consuming bahiagrass hay. In Exp. 2, PH were incubated in 20-L buckets (2/treatment) following the treatments 1) 70% DM, 2) 70% DM + 5% CaO, 3) 50% DM, and 4) 50% DM + 5% CaO. Buckets were opened after 3, 6, 9, 12, and 15 d of incubation, when a representative sample was collected, dried, ground (2 mm), and incubated for 48 h to determine IVOMD. For Exp. 1, data were analyzed as a randomized complete block design, using bucket as the experimental unit. The model included the fixed effect of treatment and random effect of year. For Exp. 2, data were analyzed as a completely randomized design with repeated measures and the model included the fixed effects of DM content, CaO, incubation days, and their interactions. For Exp. 1, at all ruminal incubation time points, no differences ($P > 0.05$) were observed on in situ degradability of DM, OM, NDF, and ADF. For Exp. 2, no effect of DM content ($P = 0.64$), CaO ($P = 0.27$), or their interaction ($P = 0.33$) were observed; however, there was a CaO × day of incubation interaction ($P = 0.07$) where when CaO was added, IVOMD was greatest at 6 d of incubation, and up to 15 d of incubation, it decreased significantly. We conclude that treating PH with CaO was not effective at improving in situ ruminal degradability of nutrients. Moreover, regardless of moisture content, when PH was treated with CaO and incubated for more than 6 d, IVOMD was negatively affected.

Key Words: calcium oxide, digestibility, peanut hulls

1452 A comparison of Lacto-Whey to soybean meal in continuous cultures fed corn- or wheat-based diets.

J. L. Firkins[1], B. K. Wagner*[1], J. E. Plank[1], B. A. Wenner[1], and G. Poppy[2], *[1]The Ohio State University, Columbus, [2]Fermented Nutrition Corporation, St, Luxemburg, WI*.

Lactate, a key intermediate in the fermentation of starch-based feeds, is either directly converted to propionate via acrylate by *Megasphaera elsdenii* or else is converted back to pyruvate and metabolized. In the latter process, more cellular carbon conversion into bacterial products should increase the assimilation of ammonia into bacterial nitrogen, primarily amino and nucleic acids. The effects of Lacto-Whey (LW), an ammonium lactate product, were investigated in dual-flow continuous culture systems ($n = 4$) using a 4 × 4 Latin square design. Lacto-Whey (+LW) was isonitrogenously dosed against soybean meal as a control (–LW) and factorialized with either a wheat- or a corn-based concentrate (formulated to have equal starch). Each individual continuous culture system was given 30 g of DM and their respective LW treatments in 2 equal feedings at 0800 and 2000 h (60 g/d). We hypothesized that the wheat +LW combination would increase propionate production while also increasing bacterial assimilation of ammonia. No differences ($P > 0.10$) were observed for total VFA or propionate production per day; however, the main effect of +LW tended ($P < 0.09$) to increase propionate at 1, 1.5, and 2 h after feeding. The main effect of corn increased

($P < 0.02$) the proportion of bacterial N derived from ammonia (as assessed using ^{15}N). No differences ($P > 0.10$) were observed in NDF or apparent OM digestibilities. Starch digestibility was moderately higher ($P = 0.09$) for corn than for wheat. To retain protozoa, the slower stirring speed probably sedimented grain and negated wheat starch from being more degradable than that from corn. An interaction between grain source and LW ($P < 0.05$) was explained by wheat without LW increasing lactate production but corn increasing lactate when combined with LW. Treatment × time interactions ($P < 0.05$) revealed higher lactate and total VFA concentrations in +LW treatments. Lactate in the LW dose disappeared by 1.5 h and was metabolized to propionate until 4 h. There were no treatment differences observed in the daily productions of methane and hydrogen, although the main effect of +LW numerically decreased methanogenesis. Under the conditions of this study, +LW supported microbial growth compared with soybean meal (–LW). Results are consistent with our expectation that Lacto-Whey should support lactate fermentation to propionate, thereby stabilizing ruminal fermentation.

Key Words: ammonium lactate, continuous cultures, starch source

---

1453 Glucose precursor supplementation in Holstein and Jersey cows as a preventative treatment for ketosis in the transition period. K. E. Mitchell*, *UC Davis, Davis, CA*.

Glucogenic substances can help treat subclinical or clinical ketosis by lowering β-hydroxybutrate (BHBA) levels and raising glucose (Glu) levels. Subclinical ketosis is defined as BHBA ≥ 1.0 mmol/L and Glu < 60 mg/dL and clinical ketosis is defined as BHBA > 1.2 mmol/L and Glu < 60 mg/dL. The objectives of this study are to determine if supplementation with a glucose precursor powdered product (GP; Glucose Booster; Stuhr Enterprises, LLC) during transition would decrease subclinical or clinical ketosis and have an effect on health and milk production of multiparous Jersey and Holstein dairy cows. Holstein ($n = 106$) and Jersey ($n = 105$) cows at a commercial dairy were systematically enrolled into either a control (C; odd-numbered ear tags) or GP (even-numbered ear tags) treatments. Glucose precursor was top-dressed on the prepartum pen (PreP) TMR and postpartum pen (PPost) TMR at a rate of 300 g/cow per day and mixed in using a pushup tractor. Cows were then allowed access to the TMR. Daily feed samples were pooled weekly and sent to Analab (Agri-King, Fulton, IL) for nutrient analyses. Weekly blood samples were analyzed for Glu (mg/dL) and BHBA (mmol/L) using NovaMax (Nova Diabetes Care, Inc., Billerica, MA). Weekly milk samples were taken to approximately 21 DIM followed by monthly tests. Holstein ($n_{GP} = 52$ and $n_C = 54$) and Jersey ($n_{GP} = 53$ and $n_C = 52$) data was analyzed using the MIXED procedure of SAS (version 9.4; SAS Institute 2015) with repeated measures by cow, parity as a random effect and fixed effects treatment, previous lactation milk fat and protein yield, period of lactation, and DIM. Jersey cows did not show a response to treatment. Holstein cows supplemented with GP increased production by 4.05 kg/d milk yield ($P = 0.0011$), 0.22 kg/d fat yield ($P = 0.0002$), and 0.12 kg/d protein yield ($P = 0.0042$) while on treatment. After treatment, GP Holsteins' production was still greater than that of C Holsteins by 2.45 kg/d milk ($P = 0.0487$), 0.08 kg/d fat ($P = 0.17$), and 0.08 kg/d protein ($P = 0.055$) until 120 DIM. Total number of health events in the first 60 DIM for GP Holstein cows decreased ($N_{GP} = 32$ and $N_C = 44$) and incidence of clinical and subclinical ketosis decreased by 15%. Holsteins and Jerseys responded differently to treatment; therefore, different breeds face different issues during early lactation. Holsteins tend to have a difficult transition period and are more likely to benefit from GP. For Holsteins, supplementation with GP prevented ketosis, decreased health events, and increased milk yield and milk component production.

Key Words: ketosis, β-hydroxybutyrate, glucose

1454 Manipulation of lactating dairy cows diets using reduced-fat distillers' grains, corn oil, and calcium sulfate to reduce methane production measured by indirect calorimetry. J. V. Judy*[1], T. M. Brown-Brandl[2], S. C. Fernando[1], and P. J. Kononoff[1], *[1]University of Nebraska, Lincoln, [2]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE*.

A study using 16 multiparous (8 Holstein and 8 Jersey) (78 ± 15 DIM, mean ± SD) lactating dairy cows, was conducted to determine the effects of dietary manipulation on methane mitigation in dairy cattle. A replicated 4 × 4 Latin square design with 35-d periods (28 d of adaption and 7 d of collections) used to compare four different dietary treatments. Treatments were composed of a control (CON) diet, which did not contain reduced-fat distillers' grain plus solubles (RFDDGS), and treatment diets containing 20% (DM basis) RFDDGS (DDGS), 20% RFDDGS with 1.38% (DM basis) added corn oil (OIL), and 20% RFDDGS with 0.93% (DM basis) added calcium sulfate (CaS). Methane sampling was performed using indirect calorimeters (head boxes). Compared with CON, DMI was greater ($P = 0.030$) for DDGS but was not affected ($P > 0.05$) by either OIL or CaS. Milk production was lowest in CON ($P < 0.001$) compared with DDGS, OIL, and CaS (26.3 vs. 27.5, 28.3, and 27.6 ± 0.67 kg/d for CON vs. DDGS, OIL, and CaS, respectively). Compared with CON, fat-corrected milk was greater ($P = 0.007$) in RFDDGS and OIL (30.7 vs. 32.1, 32.4, and 31.2 ± 0.67 kg/d for the CON, DDGS, OIL, and CaS, respectively). The addition of DDGS did not affect ($P = 0.690$) total methane produced compared with the CON diet. However, the addition of CaS reduced ($P = 0.020$) methane production whereas the addition of OIL tended ($P = 0.177$) to reduce methane production compared with the CON diet (421.6, 429.5, 394.7, and 381.4 ± 14.41

L/d for CON, DDGS, OIL, and CaS, respectively). When expressed as methane per unit of fat-corrected milk, cows consuming OIL and CaS produced less methane ($P = 0.009$) compared with CON and DDGS (13.9, 13.6, 12.3, and 12.1 ± 0.49 L/kg per day for CON, DDGS, OIL, and CaS, respectively). Similarly, when expressing methane per unit of DMI, cows consuming OIL and CaS produced less methane ($P = 0.015$) compared with those consuming the CON diet (22.3, 21.4, 19.9, and 19.6 ± 0.75 L/kg per day for CON, DDGS, OIL, and CaS, respectively). Results of this study indicate that methane production may be reduced by feeding rations containing RFDDGS with added corn oil or calcium sulfate without adversely affecting milk production.

Key Words: dairy cows, dried distillers' grains and solubles, methane

1455 Effect of particle size of a mash concentrate on behavior, rumen fermentation, and macroscopic and microscopic lesions of the digestive tract in Holstein bulls fed a high-concentrate diet.

M. Devant*[1], B. Quintana[2], A. Sole[2], and A. Bach[3,4], *[1]IRTA – Department of Ruminant Production, Caldes De Montbui, Spain, [2]IRTA, Caldes Montbui, Spain, [3]ICREA, Barcelona, Spain, [4]IRTA, Caldes de Montbui, Spain*.

Twenty-four individually housed Holstein bulls (456 ± 6.9 kg of BW and 292 ± 1.4 d of age) were exposed to a 2 × 2 factorial design (ingredients ground with a hammer mill using a sieve size of 2 [HM2] or 3 mm [HM3] vs. the same sieve size for all ingredients exception for corn, which was ground using at 10 mm [HM210 or HM310]) to evaluate the effect of mash particle size in finishing diets. Concentrate (36% corn, 19% barley, 15% corn gluten feed, and 8.4% wheat; 14% CP and 3.28 Mcal/kg) consumption were recorded daily, straw consumption was recorded weekly, and animals were filmed weekly to register behavior. Bulls were slaughtered after 56 d of exposure to treatments. Digestive tract and liver lesions were recorded, and tissue samples were collected. Data were analyzed using an ANOVA. Mean meal particle size was 0.85 ± 0.01, 1.26 ± 0.06, 1.05 ± 0.08, 1.26 ± 0.05 mm and percentage of particles between 0.5 and 1 mm was 68 ± 2.9, 46 ± 1,7, 46 ± 5.0, and 39 ± 3.3% for HM2, HM210, HM3, and HM310, respectively. When ingredients were ground at 2 vs. 3 mm, bulls tended ($P = 0.07$) to perform less social behaviors (128 vs. 155 ± 10.1 min/d, respectively), whereas rumen papillae fusion and the percentage of rumens classified as dark decreased ($P < 0.05$) and the number of rumen papillae increased ($P < 0.05$). In addition, reducing sieve size from 3 to 2 mm tended ($P = 0.08$) to increase cecum total VFA concentrations. Moreover, when corn was sieved at 10 mm, time spent eating concentrate was lesser ($P < 0.05$) than when all ingredients were ground at 2 or 3 mm (81 vs. 63 ± 5.0 min/d, respectively). In the cecum, grinding corn at 10 mm tended ($P = 0.09$) to decrease crypt depth and to increase the acetate-to-propionate ratio. Straw intake was greatest with the HM210 treatment. Moreover, in the jejunum, papillae length and crypt depth, molar percentage of acetate, and pH, and in the cecum, molar percentage of butyrate and acetate were affected by a significant interaction ($P < 0.05$) between the main factors. In conclusion, the particle size of a mash in bulls fed high-concentrate diets modifies behavior and affects digestive tract macroscopic and microscopic morphology.

Key Words: behavior, bulls, digestive tract morphology, particle size of mash

1456 Essential oils from three tropical *Citrus* species can reduce in vitro enteric methane production.

D. Kim*[1,2], I. M. Ogunade[1], K. G. Arriola[1], D. Vyas[1], and A. T. Adesogan[1], *[1]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [2]Division of Applied Life Science (BK21Plus, Institute of Agriculture and Life Science), Gyeongsang National University, Jinju, the Republic of Korea*.

The objective was to investigate the effects of essential oils from *Citrus sinensis* (SI), *Citrus limon* (LI), and *Citrus aurantifolia* (AU) on in vitro rumen fermentation, methane production, and digestibility of a total mixed ration (TMR). A TMR (0.5 g/sample) containing corn silage (28.5%), a ryegrass and triticale silage mixture (15.7%), and a corn–soybean–based grain mixture (55.8%) for dairy cows was treated with essential oils from SI, LI, or AU at doses of 0 (CON), 10 (Low), 20 (Med), and 30 mL/50 mL (High) of a rumen fluid–buffer inoculum (1:2 ratio) or with monensin (MON; 1.2 mg/g of TMR). Each treatment was incubated in triplicate in 120-mL gas-tight culture bottles at 39°C for 24 h. Each run was repeated thrice. Fermentation parameters, gas and methane production, and in vitro DM digestibility (IVDMD) were measured. Data for each essential oil were separately analyzed with the GLIMMIX procedure of SAS. Adding LI at Med and High doses increased IVDMD ($P < 0.05$) compared with MON (48.9 and 49.2 vs. 46.4% of DM, respectively) but had no effect compared with CON (48.9 and 49.2 vs. 48.1% of DM, respectively). All doses of SI and LI and Med and High doses of AU reduced ($P < 0.05$) methane production (mL/g of DMD). Compared with CON, gas volume (mL/g of DMD) was reduced ($P < 0.05$) by all doses of LI and by Med and High doses of AU. Ammonia N and total VFA concentrations and pH were unaffected by treatment. Compared with CON and MON, Med and High doses of LI and AU decreased ($P < 0.05$) molar proportion of acetate and increased ($P < 0.05$) that of propionate. Therefore, the acetate-to-propionate ratio was reduced ($P < 0.05$) by Med and High doses of LI (2.73 and 2.67 vs. 3.21 and 3.12, respectively) and AU (2.77 and 2.75 vs. 3.21 and 3.12, respectively) compared with CON and MON. Compared with CON, all doses of SI and LI as well as Med and High doses of AU reduced in vitro methane production

without reducing digestibility or total VFA concentration.

Key Words: citrus, essential oil, methane

1457 Enteric methane emissions from dairy cows fed a corn silage–based diet supplemented with increasing amounts of linseed oil.

C. Benchaar*, F. Hassanat, D. Warner, and H. Petit, *Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, QC, Canada*.

The objective of this study was to examine the effects of supplementing increasing amounts of linseed oil (LO) on intake, milk production, and enteric CH_4 emissions of dairy cows fed corn silage–based diets. Twelve lactating, multiparous Holstein cows (84 ± 28 d in milk and 42 ± 4.6 kg/d milk yield) were used in a replicated 4 × 4 Latin square design (35-d periods and 14 d of adaptation). Cows were fed ad libitum (5% orts, on an as-fed basis) a corn silage–based TMR (61:39 forage:concentrate ratio) not supplemented (control) or supplemented with 2, 3, or 4% LO (on a DM basis). Methane production was determined (3 consecutive days) using respiration chambers, and intake and milk yield were measured over 6 consecutive days. Data were analyzed using the MIXED procedure (SAS) and differences among treatments were declared significant at $P \leq 0.05$ using Dunnett's comparison test. Dry matter intake and energy-corrected milk (ECM) were not affected (23.5 and 33.1 kg/d, respectively) by supplementing LO at 2 and 3%, but they decreased (21.1 and 30.4 kg/d, respectively) when LO was added at 4%. Daily CH_4 emission averaged 515 g/d for cows fed the control diet and decreased by 8, 21, and 33% in cows fed 2, 3, and 4% LO, respectively. When adjusted for DMI, CH_4 emission averaged 21.7 g/kg for cows fed the control diet and declined in cows fed 2, 3, and 4% LO (19.7, 17.4, and 15.7 g/kg, respectively). When expressed per kilogram of ECM, CH_4 production was not affected by supplementing 2% LO (15.2 g/kg) but declined when LO was added at 3 and 4% (12.6 and 11.5 g/kg, respectively). Results of this study show that supplementing a corn silage–based diet with up to 3% of LO reduces enteric CH_4 production without adverse effects on DMI and milk production. However, a higher supplementation level (4%) impairs DMI and milk yield. These findings suggest that LO supplementation level should not exceed 3% (DM basis) in corn silage–based diets to mitigate enteric CH_4 without negatively affecting animal production.

Key Words: corn silage, linseed oil, methane

1458 Effect of different forages and concentrate levels on energy conversion, and enteric methane production of Holstein × Gyr heifers.

F. A. S. Silva*[1], S. C. Valadares Filho[2], E. Detmann[3], L. F. Costa e Silva[4], L. A. Godoi[1], B. C. Silva[3], J. M. V. Pereira[1], A. C. B. Menezes[1], P. Pucetti[1], and P. P. Rotta[4], *[1]Universidade Federal de Viçosa, Viçosa, Brazil, [2]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [4]Colorado State University, Fort Collins*.

The aim of this study was to evaluate the effect of diets containing corn silage (CS) or sugarcane (SC) with 30 or 50% of concentrate on energy conversion factors and methane production of Holstein × Gyr heifers. Sixteen Holstein × Gyr heifers with 12 ± 1.0 mo of age and average initial BW of 210 ± 20.2 kg were distributed in a completely randomized design using a 2 × 2 factorial scheme ($n = 4$), with two forages (CS or SC) and two levels of concentrate (30 or 50%) on a DM basis, during 112 d. For evaluation of energy losses, a digestibility assay was performed using the total collection of feces and urine over three consecutive days. The enteric CH_4 production was quantified by continuous analysis of regular samples of air excreted by the animals throughout the day, during six consecutive days. Greater ($P < 0.05$) CH_4 production as a function of DMI were observed for heifers fed SC-based diets. There was interaction ($P < 0.05$) between type of roughage and level of concentrate when CH_4 production was related to ADG and when expressed in relation to TDN, GE, and ME intakes. The increased level of concentrate in SC-based diets did not change ($P > 0.05$) CH_4 production in relation to TDN, GE, and ME intakes. Nevertheless, there was a reduction ($P < 0.05$) in CH_4 production related to ADG. The ratio between DE and TDN was influenced ($P < 0.05$) by type of roughage, and a greater ratio was observed for CS-based diets. The efficiency of the conversion from DE to ME was not influenced ($P > 0.05$) by variables analyzed in this study. However, the mean value observed in this study was above those proposed by the main systems of feed evaluation and nutrient requirements for ruminants. Therefore, we concluded that a greater inclusion of concentrate in SC-based diets can allow an improvement in CH_4 emissions per gain. The mean value suggested for the ME:DE ratio based on this study is 0.86.

Key Words: *Bos indicus*, calorimetry, methane

1459 Effects of duration of moderate increases in grain on bacterial diversity in the digestive tract of Holstein calves. S. Li[1], S. Moossavi[2], P. Azevedo[1], B. Schurmann[3], P. Gorka[4], G. B. Penner[5], J. C. Plaizier[1], and E. Khafipour*[1], *[1]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [2]Department of Medical Microbiology, University of Manitoba, Winnipeg, MB, Canada, [3]University of Saskatchewan,, Saskatoon, SK, Canada, [4]University of Agriculture, Krakow, Poland, [5]University of Saskatchewan, Saskatoon, SK, Canada*.

Feeding more grain to cattle alters the composition of digesta in the foregut and hindgut, including increasing its acidity, osmolality, and concentration of fermentable substrates. These changes may affect the composition and functionality of gut microbiota. In this study, effects of duration of grain feeding on the diversity of microbiota throughout the digestive tract were investigated in 25 Holstein steers (213 ± 23 kg; 5 to 7 mo of age). Animals received either a forage-based diet containing 92% hay and 8% of a mineral and vitamin pellet on a DM basis or a moderate-grain diet, obtained by replacing 41.5% percentage units of the hay in the forage-based diet with barley grain, for 7 or 21 d before slaughter. Immediately after slaughter, digesta samples were collected from the rumen, jejunum, ileum, cecum, colon, and rectum. Deoxyribonucleic acid was extracted from digesta samples and subjected to V4 sequencing of the 16S rRNA gene on an Illumina platform. Alpha-diversities of bacterial communities were calculated using various estimators. Differences in β-diversity of microbiota across treatments and time points were tested using permutational ANOVA. Across the digestive tract, the lowest α-diversity was observed in the ileum followed by the jejunum and rumen. The highest α-diversities were found in the cecum, colon, and rectum, with no differences among these three sites. Beta-diversity analyses showed that microbiota in the rumen, jejunum, and ileum were distinct ($P < 0.05$) and differed from those in the cecum, colon, and rectum ($P < 0.05$). Microbiota from the cecum, colon, and rectum were not distinct. Feeding the moderate-grain diet for 7 and 21 d reduced ($P < 0.05$) the richness of bacteria in rumen compared with feeding the forage-based diet during these periods. However, the moderate-grain diet did not affect these indices in the other sections of the digestive tract. Beta-diversity analysis indicated that the microbiota communities were altered in all sample sites on d 7 ($P < 0.05$) and did not change between d 7 and 21 of grain feeding. Overall, a moderate increase in the proportion of grain in the diet reduced bacteria diversity in the digestive tract of calves. The reduction occurred within 7 d after the increase in grain feeding and was maintained until 21 d after this change in diet.

Key Words: calf, grain, gut microbiome

1460 Muscle protein metabolism of growing Holstein × Gyr heifers. F. A. S. Silva*[1], S. C. Valadares Filho[2], L. N. Rennó[1], S. A. Santos[3], D. Zanetti[1], L. A. Godoi[1], M. V. C. Pacheco[1], H. M. Alhadas[1], P. P. Rotta[4], and L. F. Costa e Silva[4], *[1]Universidade Federal de Viçosa, Viçosa, Brazil, [2]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal da Bahia, Salvador, Brazil, [4]Colorado State University, Fort Collins*.

The aim of this study was to evaluate muscle protein metabolism of Holstein × Gyr heifers. Sixteen Holstein × Gyr heifers with an average age of 12 ± 1.0 mo and initial BW of 210 ± 20.2 kg were distributed in a completely randomized design using a 2 × 2 factorial scheme ($n = 4$), with two forages (corn silage or sugarcane) and two levels of concentrate (30 or 50%) on a DM basis, during 112 d. A total urine collection was performed from the 110th to the 112th day of the experimental period for quantification of 3-methylhistidine (3MH) excretion. Muscle protein metabolism was evaluated by the fractional synthesis rate (FSR), fractional degradation rate (FDR), and fractional accretion rate (FAR) of myofibril proteins. There was no interaction ($P > 0.05$) between type of forage and level of concentrate for any variable. Greater ($P < 0.05$) values for the daily excretion of 3MH, protein muscle gain, FSR, FDR, and FAR were observed for the animals fed 50% concentrate independent of forage type. Heifers fed sugarcane showed an increase in FSR and FDR with the increase in the concentrate level of approximately 54 and 53%, respectively. In the case of heifers fed corn silage–based diets, the increase in FSR and FDR was approximately 8 and 7%, respectively. This increase in concentrate level enabled animals consuming a sugarcane-based diet to reach protein turnover rates numerically similar to those animals consuming corn silage–based diets, even when it was associated with the inclusion of 50% concentrate. Therefore, the increase of 20% in concentrate levels using sugarcane-based diets is enough to raise the supply of nutrients and to provide a greater muscle growth in Holstein × Gyr heifers.

Key Words: dairy cattle, protein turnover, tissue deposition

1461 Effects of milk replacer feeding rate, egg yolk inclusion in milk replacer, and calf starter starch content on Holstein calf performance through four months of age. T. S. Dennis*, T. M. Hill, J. D. Quigley, F. X. Suarez-Mena, and R. L. Schlotterbeck, *Provimi North America, Brookville, OH*.

The objectives of this research were to evaluate milk replacer (MR) feeding rates, alternative protein sources in MR, and calf starter starch concentration and their effects on calf performance to 4 mo of age. Male Holstein calves (42.6 ± 1.2 kg BW; $n = 192$) were assigned at 3 d of age to 1 of 6 treatments in a randomized complete block design with a 2 × 2 × 2 factorial arrangement of treatments. Factors tested from d 0 to 56 (nursery) were low- or high-MR feeding rates, 0 or 10% inclusion of spray-dried egg yolks in MR, and low- or high-starch calf starter. Low MR rate was 0.66 kg DM fed for 39 d followed by 0.33 kg DM for 3 d. High MR rate was 0.87 kg DM fed for 5 d, 1.08 kg DM for 37 d, and 0.43 kg DM for 7 d. The MR contained 27.5% CP and 19.6% fat (DM basis) and starters contained 21.2% CP; low starch was a complete pellet with 10.2% starch and high starch was textured with whole corn and oats with 43.3% starch. From d 56 to 112 (grower), calves were randomly assigned to pens (4 calves/pen) maintaining MR rate and starch content while stratifying yolk treatments within pen. Starter was blended with chopped hay (5% of the diet) during the grower phase. Data were analyzed as repeated measures with calf (nursery) or pen (grower) as the experimental unit. Calf ADG, hip width, and BCS change were greater ($P < 0.05$) for calves fed high vs. low MR, 0 vs. 10% yolk, and high vs. low starch in the nursery. Starter intake was less ($P < 0.05$) for calves fed high vs. low MR, 10 vs. 0% yolk, and low vs. high starch. In the grower phase, calves fed low MR and high starch had the greatest ADG and hip width change compared with calves fed low MR and low starch, with other treatments intermediate ($P < 0.05$). Overall, calves fed high MR had 9% greater ADG and 4% greater hip width change than calves fed low MR, yet nutrient efficiency was similar, despite 80% more MR intake than calves fed low MR. Additionally, calves fed high-starch starter achieved 18% greater ADG and 17% greater hip width than calves fed low-starch starter overall, an over 2-fold greater response than the effect of MR feeding rate.

Key Words: calf, feeding rate, starch

1462 Effects of mineral and vitamin supplementation to pasteurized whole milk diets on growth and health of preruminant Holstein bull calves. D. Wood*[1], L. A. Krueger[2,3], M. Dehghan Banadaky[4], J. R. Stabel[5], M. A. Engstrom[6], D. C. Beitz[7], and R. Blome[1], *[1]Animix, Juneau, WI, [2]Agri-King, Inc., Fulton, IL, [3]Dep. of Animal Science, Iowa State University, Ames, [4]Department of Animal Science, Faculty of Agriculture, University of Tehran, Karaj, the Islamic Republic of Iran, [5]Infectious Bacterial Diseases Research Unit, National Animal Disease Center, Agricultural Research Service, USDA, Ames, IA, [6]DSM Nutritional Products, LLC, Parsippany, NJ, [7]Iowa State University, Ames*.

Our objective was to determine whether supplementation of vitamins and trace minerals (VTM), formulated to meet or exceed NRC requirements when added to pasteurized whole milk (PWM), increases challenge resolution and prevents intestinal macromolecular permeability after injection with bacterial lipopolysaccharide (LPS). Neonatal Holstein bull calves ($n = 24$) were randomly assigned to 1 of 4 dietary treatments. Calves were individually fed PWM diets for 15 d at a low (LM; 3.8 L) or high level (HM; 7.6 L) of daily intake and were supplemented (+) or not supplemented (–) with a commercial VTM premix (Animix, Inc.). No starter grain was offered. At d 13 of age, calves were subcutaneously injected with LPS of *Escherichia coli* (3 μg/kg of BW) and orally administered d-mannitol and lactulose to measure intestinal paracellular transport of macromolecules. Vitamins and trace mineral supplementation increased vitamin E in serum at d 7 compared with VTM(–) calves (2.22 ± 0.26 and 1.37 ± 0.17 μg/mL, respectively; $P < 0.05$), but vitamin E was not different among groups at the time of challenge. VTM(+) calves also demonstrated increased plasma Fe at 48 h after challenge compared with VTM(–) calves (1.11 ± 0.18 and 0.58 ± 0.08 μg/mL, respectively; $P < 0.05$). Copper (0.87 ± 0.06 and 0.72 ± 0.05 μg/mL; $P < 0.05$), Mg (19.1 ± 0.37 and 17.98 ± 0.41 μg/mL; $P < 0.05$), and P (82.7 ± 2.6 and 75.8 ± 2.4 μg/mL; $P < 0.1$) were greater in HM calves than in LM calves, respectively, throughout the study. Inflammatory acute phase protein haptoglobin was greatest in HM(–) calves ($P < 0.05$) on both d 13 and 15 (1,040.7 ± 305.4 and 782.6 ± 204.1, respectively), whereas differences in serum amyloid A and intestinal permeability were not detected. Average daily gain from d 1 to 13 was greater in HM calves than in LM calves (0.57 ± 0.03 and 0.45 ± 0.04 kg/d, respectively; $P < 0.05$) with no VTM effect. From d 13 to 15 (during LPS challenge), total gain was greater in HM(+) calves than in HM(–) calves (0.48 ± 0.04 and 0.39 ± 0.04 kg, respectively; $P < 0.1$). We conclude that VTM supplementation to PWM improved performance during challenge and affected Fe and vitamin E, whereas increased milk intake increased Cu, Mg, and P in plasma. Increased haptoglobin in HM(–) calves indicates decreased challenge resolution

when fed PWM not supplemented with VTM according to NRC guidelines.

Key Words: calf, pasteurized whole milk, vitamin E

1463 Effect of Axcelera-C on calf performance, intake, digestive development, and immune function during the first three months of life. M. Terré[1], F. Fàbregas[2], and A. Bach*[3], [1]*IRTA, Caldes de Montbui, Spain,* [2]*Department of Ruminant Production, IRTA, Caldes de Montbui, Spain,* [3]*ICREA, Barcelona, Spain*.

Ax Celera-C is a pellet based on whey concentrate and soybean meal (20% CP and 12% fat). Forty newborn Holstein female calves (40 ± 0.97 kg BW) were distributed in two feeding programs: 20 calves were offered Axcelera-C (AX) alone during the first 15 d of age and later on in combination (150 g/d Axcelera-C) with a concentrate until weaning, and 20 calves (CT) were fed the same concentrate throughout the study. Calves were fed the same milk replacer at the rate of 5 L/d at 12.5% DM concentration until 49 d age, when it was reduced to 2 L/d until weaning (56 d age). Chopped oat hay was offered ad libitum in a separated bucket. Animals were weighed weekly, and feed intake was recorded daily from 11 to 90 d of age. Humoral immunity was evaluated as the antibody response to a double injection of 0.5 mg of hen egg white lysozyme (HEWL) at 49 and 63 d of age. At weaning, rumen liquid samples and epithelium biopsies were obtained to determine pH and VFA concentration and to assess gene expression of *acat1*, *errfi1*, *hmgcs2*, *bpifa1*, and *trim40* as indicators of rumen epithelial growth, innate immunity, and inflammation. Data were analyzed using a mixed-effects model. Average daily gain was greater from 14 to 21 d of age in AX calves than in CT calves (0.50 and 0.35 kg/d ± 0.040, respectively). From 11 to 15 d of age, AX calves tended ($P = 0.10$) to have a greater DMI than CT calves (103 vs. 70 g/d ± 14.4, respectively), and as a result, the G:F was improved ($P < 0.05$) in AX calves in this period. When Axcelera-C was mixed with the starter feed, differences in DMI and performance disappeared for the remainder of the study. Primary and secondary responses to HEWL were similar in both treatments. Rumen pH and epithelium gene expression did not differ between treatments, but AX calves had greater ($P < 0.05$) rumen molar proportions of acetate and lower of propionate than CT calves at 56 d of age (60.1 and 19.5 vs. 55.5 and 24.1% ± 1.76, respectively). In conclusion, the use of Axcelera-C as a prestarter in young calves seems promising because it stimulates starter feed intake during the first 2 wk of life, but further research is needed to optimize the transition to a regular starter feed.

Key Words: calves, concentrate, performance

1464 Colostrum supplement feeding with a medium-quality bovine colostrum: Passive immunity transfer, health, and performance of dairy calves. M. R. De Paula, N. B. Rocha, E. Miqueo, F. L. M. Silva, T. Manzoni, S. Baldassin, and C. M. M. Bittar*, *University of Sao Paulo, Piracicaba, Brazil*.

The aim of this study was to evaluate the transfer of passive immunity, performance, and health of Holstein calves fed colostrum supplement associated with a medium-quality colostrum. After birth, 44 newborn male calves were blocked according to birth weight (BW) and date of birth and distributed in the following treatments: 1) 15% BW of high-quality colostrum (70.6 mg immunoglobulin/mL; $n = 15$; BW = 39.2 kg), 2) 15% BW of medium-quality colostrum (42.7 mg immunoglobulin/mL; $n = 14$; BW = 38.0 kg), and 3) medium-quality colostrum (41.7 mg immunoglobulin/mL; $n = 15$; BW = 39.1 kg) + colostrum supplement (Feedtech Colostrum Supplement; DeLaval, São Paulo, Brazil). Colostrum was fed within the first 12 h of life in two meals. For calves receiving the colostrum supplement, the product was supplied with the two colostrum meals in a dose of 15 mL each. Blood samples were taken every 12 h up to 48 h of life. Calves were individually housed, with free access to water and concentrate, and fed 6 L of milk replacer daily (12.5% solids, 21% CP, and 15% fat and 0700 and 1800 h), up to the sixth week of life, when they began to receive 4 L/d until weaned with 8 wk. Colostrum feeding protocol affected the total serum protein concentration at the first 48 h of life ($P < 0.05$), whereas the concentrations of albumin, γ-glutamyl transferase, and alkaline phosphatase were not affected during the same period ($P > 0.05$). Colostrum feeding protocol did not affect the fecal score, the number of days with diarrhea, days with fever, and days of needed rehydration ($P > 0.05$); however, animals that received high-quality colostrum were treated for a shorter number of days ($P < 0.05$). The concentrate intake and total DMI were not affected by colostrum supplement ($P > 0.05$) and increased over the weeks ($P < 0.0001$). Body weight, weight gain, feed efficiency, and growth measures were not affected by supplement ($P > 0.05$), although there was an age effect ($P < 0.0001$). The total serum protein concentration during the liquid-feeding phase was higher for animals receiving high-quality colostrum when compared with animals receiving medium-quality colostrum ($P < 0.05$). However, concentrations of albumin, glucose, and β-hydroxybutyrate were not affected ($P > 0.05$). Feeding the colostrum supplement associated with the medium-quality maternal colostrum did not affect the transfer of passive immunity, performance, or metabolism of animals during the liquid-feeding phase.

Key Words: blood parameters, colostrum supply, diarrhea, immunity, immunoglobulin Y

1465 Thermoregulation, performance, and blood metabolites in calves fed different amounts of colostrum. F. L. M. Silva*, M. D. Silva, E. Miqueo, N. B. Rocha, T. Manzoni, M. G. Coelho, and C. M. M. Bittar, *University of Sao Paulo, Piracicaba, Brazil*.

Colostrum is an important immunity supply that protects calves against infectious diseases. Additionally, colostrum is an excellent energy source for thermogenesis for the newborn calf. However, the amount of colostrum required to promote heat is not well established. The objective of this study was to evaluate the newborn thermoregulation, performance, and blood metabolites in calves fed different amounts of colostrum. Thirty newborn Holstein male calves were blocked by birth weight (BW) in a randomized experimental design and fed high-quality colostrum in 3 different volumes: 10, 15, and 20% of BW. The colostrum intake occurred immediately after birth and 6 h after the first colostrum feed, totaling the treatment. At 24 h of life, each calf was placed in a temperature-controlled chamber at 10°C, for 150 min. Rectal temperature, skin surfaces temperatures, heart and respiratory frequency, and shivering were measured every 15 min, and blood samples were taken every 30 min. After challenge, calves were individually housed, with free access to water and starter concentrate (20% CP and 80% TDN), and received 6 L/d of milk replacer (Sucelac; Agroceres; 21.6:15.5 and 12.5% solids) until the eighth week of life, when weaned. Data were analyzed as repeated measures over time by using the MIXED procedure (SAS Inst. Inc.). Feeding colostrum to newborn at 15 or 20% of their BW tended to increase ($P = 0.06$) the rectal temperature during cold challenge (37.7, 38.1, and 38.0°C). However, there were no effects on skin surfaces temperatures ($P > 0.05$). During challenge, feeding higher volumes of colostrum did not affect blood metabolites but tended to decrease ($P = 0.07$) plasma lactate concentration (46.7, 45.0, and 34.6 mg/dL). There was no difference ($P > 0.05$) among colostrum volume for shivering behavior. Concerning performance, there were no effects on growth ($P > 0.05$), but feeding colostrum at 15 or 20% of their BW increased ($P \leq 0.05$) heart girth (84.1, 86.9, and 86.6 cm). There were no effects ($P > 0.05$) on DMI and blood metabolites. As animals were growing, all parameters were significantly affected by age ($P \leq 0.05$); however, there were no treatment and age interaction effect ($P > 0.05$). Feeding newborn calves colostrum at 15 or 20% of their BW can increase thermoregulatory responses in newborns and improve some growing features during the liquid-feeding period. Supported by FAPESP.

Key Words: blood parameters, cold challenge, weight gain

1466 The effects of supplementing a ruminally protected B-vitamin complex on preweaning growth and performance of Holstein heifer calves. K. M. Wood*[1], E. Evans[2], C. L. Girard[3], H. Leclerc[4], L. Doepel[5], and G. B. Penner[6], *[1]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada, [2]Technical Advisory Services, Bowmanville, ON, Canada, [3]Agriculture & Agri-Food Canada, Sherbrooke, QC, Canada, [4]Jefo Nutrition, St. Hyacinthe, QC, Canada, [5]University of Calgary, Calgary, AB, Canada, [6]University of Saskatchewan, Saskatoon, SK, Canada*.

For preweaned dairy calves, incomplete rumen development may limit microbial B vitamin synthesis, resulting in a mild B-vitamin deficiency. Seventy Holstein heifer calves were used to evaluate the effect of providing a B-vitamin supplement in the starter on DMI, growth, and blood parameters. Calves were individually housed and fed in 1 of 3 rooms (block) until weaning at 9 wk of age. Dietary treatments were 13 g/d commercially available palmitic acid (CON; $n = 35$) or ruminally protected B vitamins (ProB; $n = 35$), in which 5 g of a B-vitamin supplement was blended with 8 g of palmitic acid. Treatments began at 1 wk of age. The 13 g of supplement was mixed with 50 g of calf starter and fed once per day. Once the calves consumed the supplement, they were offered calf starter ad libitum. Heifers were also fed 600 g of milk replacer (150 g/L water) divided into 2 feedings. After 7 wk, milk replacer was reduced to 300 g/d and calves were weaned at the end of wk 9. Calf BW and hip and rump height were measured on a weekly basis. Blood samples were collected on d 2 and 63 and analyzed for total protein concentration and platelet, white blood cell (WBC), and red blood cell (RBC) counts. Data were analyzed as a completely randomized block design with the mixed model using fixed effects of block, treatment, time, and their interaction. Regression was used to calculate growth traits. Calf ADG was 0.71 kg/d for both treatments (SEM = 0.017, $P = 0.84$). Hip and wither heights and ADG did not differ ($P \geq 0.77$) between treatments. There were no treatment differences ($P = 0.94$) for supplement intake or total DMI (CON = 933.8 kg/d and ProB = 967.2 kg/d; SEM = 40.5, $P = 0.56$). Final blood platelet count was 484.3×10^9/L for CON and 551.5×10^9/L for ProB (SEM = 22.5) and was greater in ProB than in CON ($P = 0.035$); however, final WBC and RBC did not differ ($P \geq 0.23$). These data indicate that supplemental ruminally protected B vitamins do not affect preweaning calf growth. However, supplementation may have implications on immune function, which may have implications for overall calf health.

Key Words: B vitamins, calf, preweaning

1467 RNaseq-based whole transcriptome analysis in the jejunum of preweaned calves under different milk feeding regimes. H. M. Hammon[1], D. Frieten[2], C. Gerbert[3], C. Koch[3], G. Dusel[2], R. Weikard[1], and C. Kühn*[1], *[1]Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [2]University of Applied Sciences, Bingen, Germany, [3]Educational and Research Centre for Animal Husbandry, Hofgut Neumuehle, Muenchweiler, Germany*.

An early dietary nutrition plan in calves is crucial for later appropriate heifer and cow performance. However, there is controversy about the appropriate milk supply during the first weeks of life. Currently, there is only limited knowledge about the genomewide expression pattern for the juvenile intestine. Therefore, we performed a next-generation-sequencing–based holistic whole transcriptome analysis of the jejunum in male German Holstein calves fed two different diets. Calves received colostrum for 3 d and then milk replacer (MR; 125 g powder/L). For one group of calves, MR was restricted to a volume of 6 L MR ($n = 6$), whereas the alternative group was fed on an ad libitum protocol for 8 wk ($n = 6$). Subsequently, MR intake for all calves was reduced to 2 L/d from wk 8 to 10 and maintained at this level until the end of the trial. During the entire experiment, both groups were provided hay and concentrate ad libitum. Eighty-one days after birth, the calves were euthanized, and epithelial sections of the jejunum were collected, snap frozen in liquid nitrogen, and stored at −80°C until further analyses. Total RNA was isolated with specific attention to avoid genomic DNA contamination. For each sample, an indexed, stranded sequencing library was prepared including a polyA bead-based selection step. Libraries were sequenced in a 2 × 80 bp paired-end protocol on an Illumina HiSeq2500. After demultiplexing, reads were trimmed for quality and adaptor sequences. The reads passing quality control were aligned to the bovine genome, and transcripts were assembled with an annotation-guided approach enabling discovery of yet-unannotated genes and transcripts. Differential expression between calf groups was analyzed based on expression normalized on total number of reads and length of the respective genes. On average, 56.8 million paired-end reads were obtained per sample, and the average percentage of reads mapping to the bovine genome was 88%. Between 18,395 and 20,904 genes per sample could be identified after applying a threshold of 10 read counts per gene. The number of novel transcripts amounted to 16,378. Applying a threshold of $q < 0.1$, which accounted for multiple testing, 99 genes showed a differential expression between groups. Among those, 22 were without previous annotation in the bovine genome. Our analyses provide the first comprehensive catalog of RNaseq-based whole transcriptome for the calf jejunum. Furthermore, our data prove persistent effects of differential milk diets on the jejunal gene expression pattern.

Key Words: calves, milk feeding, trancriptome

1468 Comparison of two calf-rearing programs on the performance and cost–benefit ratio. L. M. Gomez*, J. A. Henao, A. K. Amorocho, M. R. Valenzuela, C. Mesa, and P. Aguirre, *Nutri-Solla Group, Research and Development Unit, Solla S.A., Medellin, Colombia*.

There is a deep interest in assessing different kinds of calf rearing programs based on greater rates of liquid feeding to increase ADG and to decrease age at first calving. In a complete randomized design with repeated measures, two milk feeding plans (treatments) were evaluated in 57 Holstein female dairy calves (37.3 ± 3.7 kg BW and 3 d old) during 10 wk. Treatment 1 (T1) consisted of feeding 12% of weight at 3 d in whole milk and treatment 2 (T2) a consisted of a step-down program of 20 (from 0 d to 2 wk), 15 (3–4 wk), and 10% (5–10 wk) of weight at 3 d in whole milk. Calves were fed colostrum (IgG; 100 mg/mL) at 30 min of life and after that, they were left with the cow suckling ad libitum until 3 d of life without access to solid feed. Calves were housed in individual hutches with ad libitum access to T1 ($n = 28$) and T2 ($n = 29$). From the third day, calves were offered pelleted starter feed (173.1 g CP, 460.1 g NSC, and 201 g NDF per kilogram DM) in the morning at 0700 h. Water was offered ad libitum. The calves were weaned when the intake of the starter feed was over 1.000 g/d during three consecutive days, from Day 1 to 4 after weaning half of the milk amount was given and since 5 d without milk. Body weight, DMI, ADG, days to weaning (DW), feed:gain ratio, total protein and energy intake, chest girth (CG), height at withers (HW), height at sacrum (HS), and total cost of production were measured. No differences were found ($P > 0.05$) on BW, CG, and HW and HS changes during the 10 wk among treatments. At the end of the trial, no differences were detected ($P > 0.05$) in BW, ADG, DW, concentrate DMI and feed:gain ratio, CG, and HW and HS. Calves fed T2 tended ($P = 0.11$) to have greater total DMI and protein DMI (79.6 and 19 kg) than calves fed T1 (73.7 kg and 17.6 kg). Calves fed T2 had greater ($P < 0.05$) milk DMI, ME of DMI, and cost of production (33.3 kg, 341.5 Mcal, and 105.4 USD) than calves fed T1 (28.7 kg, 312.2 Mcal, and 93 USD). Feeding with a step-down program having more milk does not support improvements of performance and increases the average cost of production.

Key Words: calves, cost–benefit ratio, performance, weaning

AH – 100% alfalfa hay, OH – 66.7% alfalfa hay + 33.3% oat hay, WS – 66.7% alfalfa hay + 33.3% whole corn silage.

a, b – different superscript letters with the same row represent a significant difference between treatments (P<0.05).

1469 Effects of different forage combination on growth performance, ruminal fermentation, and digestibility of weaned calves. Y. Zou*, X. Zou, Z. J. Cao, Y. Wang, and S. L. Li, *State Key Laboratory of Animal Nutrition, Beijing Engineering Technology Research Center of Raw Milk Quality and Safety Control, College of Animal Science and Technology, China Agricultural University, Beijing, P. R. China*.

The effects of feeding different forage combinations on growth performance, ruminal fermentation, and digestibility were investigated in weaned calves for 35 d. Forty-five female calves weaned at 60 d with similar weight were randomly arranged into three treatments 1 wk after weaning with same pellet feed (60% of the diet); forage combinations were 1) 100% alfalfa hay (AH), 2) 66.7% alfalfa hay + 33.3% oat hay (OH), and 3) 66.7% alfalfa hay + 33.3% whole corn silage (WS). There was no significant difference (P > 0.05) among the three treatments with weaned calves in DMI. However, the BW and ADG of calves fed AH and OH were significantly higher (P < 0.05) than WS calves, with higher heart girth in OH calves (P < 0.05). Proportion of butyric acid, ratio of acetate to propionate, total VFA concentration, protozoal protein, bacterial protein, and microprotein in rumen were highest in OH (P < 0.05), AH was intermediate, and WS was lowest. Oat hay feeding increased CP and P digestibility (P < 0.05) and decreased diarrhea frequency, diarrhea rate, and feces index at the mean time. In conclusion, a forage combination of alfalfa hay and oat hay had certain advantages to promote the ruminal development of calves and reduce feed cost and diarrhea incidence. Based on this study, a feeding pattern of "26.67% alfalfa hay + 12.33% oat hay + 60% starter feed" is more suitable for 3-mo weaned calves.

Key Words: oat hay, ruminal fermentation, weaned calves

1470 Use of the Brix refractometer to evaluate milk replacer solutions for calves. H. K. Floren*[1], W. M. Sischo[1], C. Crudo[1], and D. A. Moore[2], *[1]Washington State University, Pullman, [2]Department of Veterinary Clinical Sciences, Washington State University, Pullman, WA*.

The Brix refractometer is used on dairy farms and calf ranches for several reasons including evaluation of colostrum quality (estimation of IgG concentration), estimation of serum IgG concentration in neonatal calves, and nonsalable milk evaluation of total solids for calf nutrition. Another potential use is to estimate the total solids concentrations of milk replacer mixes as an aid in monitoring feeding consistency. The purpose of this study was to evaluate the use of Brix refractometers to estimate total solids in milk replacer solutions. Five different milk replacer powders were mixed to achieve total solids concentrations from approximately 5.5 to 18%, for a total of 90 different solutions. Both digital and optical Brix refractometers were used to compare with total solids. The two types of refractometers' readings correlated well with one another (R^2 = 0.997). The Brix readings were highly correlated with the total solids percentage (R^2 = 0.94). A value of approximately 1.08 to 1.47 would need to be added to the Brix reading to estimate the total solids in the milk replacer mixes. Osmolality was correlated to the Brix reading but the relationship was different depending on the type of milk replacer. The Brix refractometer can be successfully used to estimate total solids concentration in milk replacer mixes to help monitor milk replacer feeding consistency.

Key Words: calf, milk replacer, refractometer

1471 Effect of corn wet distillers' grains inclusion in growing diets on backgrounded cattle performance. M. Arcieri*[1], P. Davies[2], D. Méndez[2], J. Elizalde[3], and I. Ceconi[2], *[1]Universidad Nacional de Córdoba, Córdoba, Argentina, [2]Instituto Nacional de Tecnología Agropecuaria, General Villegas, Argentina, [3]Private consultant, Rosario, Argentina*.

Distillers' grains (DG) can be used as energy as well as protein dietary sources. An experiment was conducted to evaluate the effect of partially replacing dry-rolled corn (DRC) and sunflower meal (SFM) with corn wet DG (WDG) in growing diets on cattle performance. One hundred ninety-two Angus calves (199 ± 3 kg initial BW) were assigned by weight to 1 of 3 blocks and group housed in 1 of 24 pens. Pens were randomly assigned to 1 of 4 diets containing (DM basis) 0% WDG, 19.4% DRC, and 20.4% SFM (CON); 10.0% WDG, 13.9% DRC, and 15.9% SFM (10-DG); 20.0% WDG, 8.0% DRC, and 11.8% SFM (20-DG); or 35.0% WDG, 0% DRC, and 4.8% SFM (35-DG). All diets contained 58.2% sorghum-sudangrass silage and 2.0% dry supplement. Diets were formulated to generate a RDP balance equal to zero and to meet or exceed MP requirements at expected ad libitum DMI and ADG. Dietary CP and lipid concentrations and IVDMD measured 12.0, 2.97, and 66.3%; 13.5, 4.00, and 66.8%; 15.1, 5.04, and 67.3%; and 17.3, 6.61, and 68.2% for CON, 10-DG, 20-DG, and 35-DG, respectively. Calves were fed once daily for 85 d and held off feed for 16 h to record initial and final individual BW. Data were analyzed as a generalized randomized complete block design. Cattle ADG was greater ($P < 0.01$) for calves fed the 20-DG diet (913 ± 20 g) compared with those fed the CON (682 ± 20 g) or 10-DG (829 ± 20 g) diets, although it was similar ($P = 0.93$) to those fed the 35-DG (915 ± 20 g) diet. Conversely, DMI was similar ($P > 0.65$) between cattle fed the CON (6.01 ± 0.27 kg/d), 10-DG (5.97 ± 0.27 kg/d), and 20-DG (5.93 kg/d) diets and smaller ($P < 0.01$) compared with cattle fed the 35-DG (5.41 ± 0.27 kg/d) diet. Consequently, G:F improved ($P < 0.01$) with increasing WDG dietary inclusion (114.4, 139.5, 154.2, and 169.6 ± 6.7 for CON, 10-DG, 20-DG, and 35-DG, respectively). Greatest lipid concentration in the 35-DG diet may have decreased fiber digestibility, which, in turn, could relate to reduced DMI. Additionally, ADG quadratic response ($P < 0.01$) may have resulted from greater NEg concentration and from DMI quadratic response ($P < 0.01$) with increasing WDG dietary inclusion. Including 35% WDG in a silage-based diet resulted in greatest G:F and growing-according ADG.

Key Words: backgrounding, cattle performance, distillers' grains

1472 Effects of *Saccharomyces cerevisiae* fermentation products on intestinal villi integrity in neonatal calves naturally infected with *Cryptosporidium* spp. S. Vázquez Flores[1], M. de Jesús Guerrero Carrillo[2], M. F. Scott[3], J. Hamann*[3], S. Barrera Almanza[1], C. Guizar Bravo[1], A. Patricia Baños Quintana[1], and P. Jazmin Aranda Vargasb[2], *[1]ESIABA-Tecnológico de Monterrey-Campus Querétaro, Querétaro, Mexico, [2]Facultad de Ciencias Naturales, Universidad Autónoma de Querétaro, Querétaro, Mexico, [3]Diamond V, Cedar Rapids, IA*.

The objective of this study was to characterize the integrity of intestinal villi in neonatal bull calves naturally infected with *Cryptosporidium* spp. This study took place on a commercial dairy near Querétaro, México (1,100 cows in production). At birth, all calves received a colostrum substitute and were randomly allocated to one of three treatments: maltodextrin (placebo control [C]), SmartCare + Original XPC (T1), or Biomos (T2). All calves showed satisfactory levels of serum IgG as determined by a commercial serum radio-diffusion kit (C = 1,367.5 ± 292.1, T1 = 1,492.3 ± 48.2, and T2 = 1,572.8 ± 106.5). Calves were then given UV-purified whole milk and calf starter until d 28. On d 28, all calves were humanely sacrificed within the university premises for postmortem analysis and intestinal sample collection (duodenum, jejunum, and ileum). All samples were formalin fixed, and the histopathological smears were stained with hematoxylin–eosin. Villi scores (length and width) were measured twice by 2 different trained analysts using 10 fields per smear with an optic microscope (40x). Oocyst concentration was made using a modified concentration technique (Arrowood, 1987), with Sheather's solution at 1.12 specific gravity, in fecal samples collected on d 0, 7, 10, 14, and 28. Villi integrity was characterized as normal, fragmented, atrophied, or blunt. Statistical analysis was performed using parametric (Hsu's MCB) and nonparametric (Wilcoxon) analyses in JMP 11.1.0. In general, the number of intestinal villi per field varied from 10.1 to 12.5. There were no differences in duodenal villi scores between treatments. Villi were less ($P < 0.05$) fragmented and atrophied for T1 compared with C and T2 in the jejunum and ileum. Compared with C, T1 and T2 had larger ($P < 0.001$) crypts present in the ileum. *Cryptosporidium* spp. was present in 100% of the bull calves and ranged in concentration from 8×10^4 to 4×10^9 oocysts/mL. The use of *Saccharomyces cerevisiae* fermentation products shows promising results in maintaining intestinal villi integrity in spite of the protozoan infection

Key Words: intestinal villi integrity, neonatal calves, *Saccharomyces cerevisiae* fermentation product

1473 Evaluation of Brix refractometer to assess immunoglobulin G concentration of first and second colostrum from Jersey cows. D. Rolle, S. Rodríguez, A. Valldecabres, and N. Silva-del-Rio*, *Veterinary Medicine Teaching and Research Center, University of California Davis, Tulare*.

The objective of this study was to evaluate if concentration of IgG in first and second colostrum from Jersey cows may be estimated using Brix refractometry on farm. Colostrum samples and total weight of first (n = 136) and second (n = 70) milking after calving were collected from multiparous Jersey cows on a 3,500-cow California herd. The first colostrum was collected at 9.4 ± 3.8 h after calving and the second colostrum at 21.0 ± 3.7 h after calving. Fresh colostrum samples were evaluated for Brix percentage by using a handheld electronic refractometer (Reichert Inc., Depew, NY). Colostrum samples were aliquoted in 2-mL vials and frozen before IgG analysis by radial immunodiffusion (RID). The association between Brix percentage and IgG concentration was evaluated with the CORR procedure of SAS. The GLM procedure of SAS was used to describe the regression equation between Brix percentage and IgG concentration. Observations above the maximum Brix reading (>32%) were removed. Concentration of IgG was higher (P < 0.001) for first colostrum, averaging 83.8 g/L (range: 23.7 to 172.9 g/L), than for second colostrum at 46.9 g/L (6.2 to 100 g/L). Similarly, Brix percentage was higher (P < 0.001) for first colostrum, with an average of 25.4% (range: 16.2 to 37.1%), than for second colostrum with an average of 18.4% (range: 13.1 to 29.1%). Readings of Brix percentage were highly correlated with concentration of IgG in first (r = 0.81) and second (r = 0.77) colostrum. Harvested colostrum weighed 3.9 ± 2.6 kg at first milking and 4.2 ± 2.1 kg at second milking. Based on the regression equation, the most adequate Brix percentage cut points to define colostrum quality (50 g of IgG/L) were 19.1 and 18.7% for first and second colostrum, respectively. For first colostrum, sensitivity of Brix refractometer was 96.1%, specificity was 60.0%, and positive and negative predictive values were 96.8 and 54.5%, respectively. For second colostrum, sensitivity of Brix refractometer was 78.6%, specificity was 79.5%, and positive and negative predictive values were 73.3 and 83.7%, respectively. Our results indicate that Brix measurements can be used to rapidly estimate IgG concentration on first and second milking colostrum from Jersey cows. To identify colostrum samples with >50 IgG g/L, the most adequate cut point was slightly inferior to the 21% Brix reading that previous studies suggested.

Key Words: Brix refractometer, colostrum immunoglobulin G, Jersey cow

1474 Effects of lactose inclusion in calf starters on starter intake, growth performance, and digestive organ development. K. Inouchi*[1], A. Saegusa[2], Y. Inabu[3], T. Sugino[3], and M. Oba[4], *[1]ZEN-RAKU-REN, Nishi-shirakawa, Japan, [2]ZEN-RAKU-REN, Fukushima, Japan, [3]Hiroshima University, Higashi-hiroshima, Japan, [4]University of Alberta, Edmonton, AB, Canada*.

The objective of this study was to evaluate the effects of lactose inclusion in calf starters on starter intake, growth performance, and digestive organ development. Sixty Holstein bull calves were raised on an intensified nursing program using milk replacer containing 28% CP and 15% fat and fed the texturized calf starter containing lactose at 0 (Control), 5.0 (LAC5), or 10.0% on a DM basis (LAC10; n = 20 for each treatment). All calf starters were formulated for 23.1% CP. As the pellet portion contained lactose and all adjusted ingredients, treatment calf starters differed only in the pellet. Ethanol soluble carbohydrate concentrations of Control, LAC5, and LAC10 were 7.3, 12.3, and 16.8% (DM), respectively. Starch concentrations of Control, LAC5, and LAC10 were 29.7, 27.0, and 21.4% (DM), respectively. All calves were fed treatment calf starters ad libitum, and their hay intake was limited to 150 g/d. Body weight, hip height, withers height, body length, hip width, and heart girth were measured weekly. Fifteen calves were killed at the age of 62 d, and 45 calves were killed at the age of 80 d. Digestive organs were harvested, emptied, rinsed and weighed. Starter DMI intake was 267 ± 45 (Control; mean ± SE), 216 ± 20 (LAC5), and 283 ± 31 g/d (LAC10) before weaning (d 7–56); 1,516 ± 156 (Control), 1,344 ± 105 (LAC5), and 1,622 ± 127 g/d (LAC10) during weaning transition (d 49–63); and 2,778 ± 164 (Control), 2,636 ± 109 (LAC5), and 2,812 ± 164 g/d (LAC10) after weaning (d 56–80). Average daily gain was 0.64 ± 0.03 (Control), 0.64 ± 0.03 (LAC5), and 0.71 ± 0.34 kg/d (LAC10) before weaning (d 7–56); 1.02 ± 0.76 (Control), 1.03 ± 0.08 (LAC5), and 1.17 ± 0.08 kg/d (LAC10) during weaning transition (d 49–63); and 1.41 ± 0.06 (Control), 1.40 ± 0.06 (LAC5), and 1.34 ± 0.06 kg/d (LAC10) after weaning (d 56–80). Wet mass of the reticulorumen was 1.37 ± 0.14 (Control), 1.49 ± 0.04 (LAC5), and 1.60 ± 0.09% BW (LAC10) at d 62 and 2.21 ± 0.08 (Control), 2.03 ± 0.07 (LAC5), and 1.97 ± 0.16% BW (LAC10) at d 80. None of the response variables above were significantly different (P > 0.05). In addition, treatments did not affect (P > 0.05) the other primary response variables including body height, body length, heart girth, and wet mass of the other digestive organs. These results indicate that inclusion of lactose in calf starters up to 10% of DM may not affect starter intake, growth performance, and digestive organ development.

Key Words: calf, lactose, starter

1475 Bioavailability of different sources of zinc using stable isotopes in male Holstein calves.

H. A. Tucker*, C. K. Foran, S. Bettis, P. Fisher, J. Xue, K. J. Wedekind, and M. Vázquez-Añón, *Novus International, Inc., St. Charles, MO*.

Trace minerals are an important component of ruminant nutrition. Furthermore, understanding the bioavailability of various trace mineral sources is essential for accurate dietary formulation. The objective of this trial was to determine bioavailability of Zn when provided in either an inorganic or an organic form. Sixteen weaned male Holstein calves (BW = 60 ± 2 kg [mean ± SE]) were used in a randomized compete block design. Calves were individually fed a common texturized starter formulated to meet NRC nutrient requirements. Calves were orally administered 4 or 8 mg of Zn from 2 sources: ^{67}Zn oxide and ^{70}Zn-methionine hydroxy analog chelate (^{70}Zn-MHAC). Blood was collected via catheters before isotope administration and 0.25, 0.5, 0.75, 1, 2, 4, 6, 8, 10, 12, 16, 20, 24, 36, 48, and 72 h after isotope administration for determination of isotope enrichment. Calves were euthanized 72 h after isotope administration, and target tissues were weighed and sampled for determination of isotope enrichment. Plasma area under the curve (AUC) for isotope enrichment was significantly ($P < 0.01$) greater with ^{70}Zn-MHAC (2.02 ± 0.12 ppm) compared with ^{67}Zn oxide (1.20 ± 0.12 ppm). When dose was considered, plasma AUC for isotope enrichment was significantly ($P < 0.01$) greater with 8 mg of labeled Zn (2.34 ± 0.12 ppm) compared with 4 mg (0.87 ± 0.12 ppm). Isotope enrichment was significantly ($P < 0.01$) greater with ^{70}Zn-MHAC compared with ^{67}Zn oxide for all tissues with the exception of omasal tissue, which tended ($P = 0.07$) to be greater. When dose was considered, isotope enrichment was significantly ($P < 0.01$) greater with 8 mg of labeled Zn compared with 4 mg for all tissues except muscle ($P = 0.17$) and tibia ($P = 0.42$). The slope for ^{70}Zn-MHAC was significantly ($P \leq 0.01$) higher compared with that of ^{67}Zn oxide for abomasal tissue (0.036 vs. 0.011; $r^2 = 0.88$), duodenal tissue (0.070 vs. 0.043; $r^2 = 0.90$), ileal tissue (0.069 vs. 0.028; $r^2 = 0.95$), jejunal tissue (0.072 vs. 0.024; $r^2 = 0.93$), liver (0.096 vs. 0.012; $r^2 = 0.83$), muscle (0.016 vs. −0.031; $r^2 = 0.89$), pancreas (0.076 vs. 0.003; $r^2 = 0.82$), thymus (0.023 vs. −0.003; $r^2 = 0.85$), and tibia (0.007 vs. −0.003; $r^2 = 0.86$). Together these data demonstrates using stable isotopes as a valid technique to measure bioavailability and greater bioavailability was observed from Zn-MHAC when compared with zinc oxide.

Key Words: bioavailability, stable isotopes, zinc

1476 Endocannabinoid concentrations in plasma associated with feed efficiency and carcass composition on crossbreed steers.

V. M. Artegoitia*[1], A. P. Foote[2], R. M. Lewis[3], D. A. King[2], S. D. Shackelford[2], T. L. Wheeler[2], and H. C. Freetly[2], *[1]University of Nebraska, Lincoln, [2]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [3]University of Nebraska-Lincoln, Lincoln*.

Endocannabinoids, including anandamide (AEA) and 2-arachidonoylglycerol (2-AG), are a class of endogenous lipid mediators that activate cannabinoids receptors and may be involved in the control of feed intake and energy metabolism. The objective of this study was to quantify AEA and 2-AG in plasma and identify possible associations with production traits and carcass composition in finishing beef steers. Individual DMI and BW gain was measured on 140 crossbred steers for 105 d on a finishing ration. Blood samples were collected on d 84 of the experiment, which was 40 d before slaughter. Variables were analyzed using Pearson CORR procedure of SAS. Mean endocannabinoid concentrations in plasma were 4.48 ± 1.82 and 0.43 ± 0.24 ng/mL for AEA and 2-AG, respectively. The AEA concentration was positively correlated with G:F ($r = 0.20$, $P = 0.02$), indicating that more efficient animals were correlated with higher AEA plasma concentration. Nevertheless, AEA concentration was negatively correlated with metabolic BW at the midpoint of the experiment ($r = −15$, $P = 0.07$) and initial BW ($r = −0.19$, $P = 0.03$). In addition, AEA concentration was negatively correlated with the 12th rib fat thickness ($r = 0.17$, $P = 0.07$), but no correlation was found with USDA-calculated yield grade ($r = −0.14$, $P = 0.11$) or marbling score ($r = 0.05$, $P = 0.54$). The concentration of 2-AG was positively correlated with AEA ($r = 0.21$, $P = 0.01$); however, 2-AG concentration was not correlated with parameters of feed efficiency or carcass composition. In summary, the present study is the first to report plasma concentration of endocannabinoids in steers. These results provide evidence that plasma concentration of a key endocannabinoid, AEA, was favorably correlated with feed efficiency and fat thickness on crossbred steers at finishing. The USDA is an equal opportunity provider and employer.

Key Words: anandamide, 2-arachidonoylglycerol, ultra-performance liquid chromatography tandem mass spectrometry

1477 The phenotypic relationship between residual feed intake and ultrasound carcass traits in Santa Gertrudis steers. C. R. Branton*, *Stephen F. Austin State University, Nacogdoches, TX*.

Numerous studies have been conducted characterizing phenotypic and genetic variation in RFI in beef cattle, but limited studies have examined effects of diet and/or stage of maturity on phenotypic reranking of cattle for feed efficiency traits. For this study, 2 trials were conducted with Santa Gertrudis steers (N = 233). Steers were fed a roughage-based diet (2.1 Mcal ME/kg DM) during the growing phase and a high-grain diet (3.0 Mcal ME/kg DM) during the finishing phase. Steers were weighed at 14-d intervals and DMI was measured (Calan gate or GrowSafe) for 70 d during both the growing and finishing phases, with ultrasound measurements obtained on Day 70 of each feeding phase. RFIp was calculated as the difference between actual DMI and expected DMI based on regression of DMI on ADG and mid-test $BW^{0.75}$. Stepwise regression revealed that final back fat depth (BF) accounted for additional variation in RFI in both the growing (R^2 = 0.43 vs. 0.46) and finishing (R^2 = 0.54 vs. 0.56) phases. Therefore, RFIc was computed for both phases based on regression of DMI on ADG, mid-test $BW^{0.75}$, and final BF depth. During the growing phase, RFI_p was positively correlated ($P < 0.01$) with DMI (0.75), feed:gain ratio (0.49), and final BF depth (0.13) but not with ADG or BW. Feed:gain ratio was negatively correlated ($P < 0.01$) with ADG (−0.70) but was not correlated with DMI. During the finishing phase, RFI_p was positively correlated ($P < 0.01$) with DMI (0.65), feed:gain ratio (0.51), and final BF depth (0.17) but not with ADG or BW. Feed:gain ratio was negatively correlated ($P < 0.01$) with ADG (−0.69) but was not correlated with DMI. Correlations between RFIp and RFIc were 0.91 and 0.92 during the growing and finishing phases, respectively. Spearman rank correlations revealed that ADG and feed:gain ratio measured during the growing phase were weakly associated with ADG (0.21) and feed:gain ratio (0.12) measured during the finishing phase, whereas rank correlations were moderate for DMI (0.47), RFIp (0.45), and RFIc (0.28) measured during the growing and finishing phases. Although these results indicate that a moderately positive rank correlation exists between RFI measured when steers are fed high-roughage vs. high-grain diets, these two feed efficiency traits may not be biologically similar. It is unclear as to whether the lack of a strong correlation between RFI measured during growing vs. finishing phases was due to influences of diet and/or stage of maturity.

Key Words: carcass composition, residual feed intake, Santa Gertrudis steer

1478 Using indigestible rare earth markers and internal markers to predict dry matter intake and residual feed intake. K. A. Weld* and L. E. Armentano, *University of Wisconsin – Madison, Madison*.

Residual feed intake (RFI) is a feed efficiency measure that requires multiple animal individual intakes. The objective of this trial was to determine the plausibility of using a known daily dose of a rare earth marker combined with an inherent, internal total mixed ration (TMR) indigestible component and spot fecal sampling to predict DMI and RFI of lactating dairy cattle. Fifteen lactating Holstein cows (107 ± 20 d in milk) were maintained on a single diet for 5 wk in tie stalls. Milk production and DMI were recorded daily, and milk samples and BW were taken weekly. Indigestible rare earth markers were administered orally by 3 methods: once daily by bolus (ytterbium), once daily by top-dressing TMR (samarium), or twice daily by bolus (lanthanum). Cows received all external rare earth markers the last 10 d of the trial with the final 3 d being used to collect 10 fecal samples. Fecal samples were composited and analyzed for concentrations of rare earths by inductively coupled plasma mass spectrometry (CV mean ± SD: 3.8 ± 1.7) and indigestible NDF (CV: 3.6 ± 4.3) and indigestible DM (CV: 5.4 ± 4.6) using a 288-h in situ incubation. Combining one of the three rare earth external markers with one of the two diet internal markers allows prediction of DMI and RFI as a 3 × 2 factorial. There was a significant correlation between measured DMI in the final week and DMI predicted using 1x bolusing ($r > 0.60$, $P < 0.02$) but not using top-dressing ($r > 0.42$, $P > 0.08$) or 2x bolusing ($r = 0.33$, $P = 0.22$). Phenotypic RFI was calculated as the difference between individual cow DMI and regression estimated DMI where the regression included $BW^{0.75}$, BW change (deltaBW; BW in kg), and milk energy (Mcal). Individual regressions were calculated for measured DMI and the 6 marker predicted DMI. The solutions from these regressions differed: (coefficient [±SE]; 5 wk of intakes: DMI = 0.50 (±0.10) × milk energy + 0.57 (±0.04) × $BW^{0.75}$ − 0.28 (±0.45) × deltaBW − 1.51 (±7.56); 1 wk intakes: DMI = 0.39 (±0.09) × milk energy + 0.11 (±0.03) × $BW^{0.75}$ − 0.37 (±0.39) × deltaBW − 11.47 (±6.51); and predicted DMI 1x/iNDF: DMI = 0.53 (±0.12) × milk energy − 0.07 (±0.05) − $BW^{0.75}$ + 1.48 (±0.55) × deltaBW + 23.57 (±9.27)).There was a correlation between the RFI calculated from the actual DMI in the last week and the RFI calculated from 5 wk of data ($r = 0.61$, $P < 0.05$).The actual RFI, from observed DMI of 5 wk or 7 d, were not correlated with the RFI calculated using the marker predicted DMI.

Key Words: digestibility marker, intake prediction, residual feed intake

Table 1479.

Item	Equation	R^2	P
DMVI	4.6733 (STIR) + 4.7374	.7011	<.0001
DMD	6.6871 (STIR) + 401.52	.1292	= .003
DDMI	2.6198 (STIR) - 0.7004	.5301	<.0001

1479 Short-term intake technique to predict dry matter intake and digestibility in forages.
F. M. Ingentron[1,2], B. C. Lentz[1], N. P. Stritzler[1], C. N. Rabotnikof[1], M. Menghini[3,4], and H. M. Arelovich*[3,4,5], *[1]Fac. Agronomia, Universidad Nacional de La Pampa, Santa Rosa, Argentina, [2]CONICET, Santa Rosa, Argentina, [3]CIC, Bahia Blanca, Argentina, [4]Dto. Agronomia, Universidad Nacional del Sur, Bahia Blanca, Argentina, [5]CERZOS, Bahia Blanca, Argentina*.

The objective of this study was to evaluate short-term intake rate (STIR) to predict DM voluntary intake (DMVI) and digestibility (DMD) in rams when offered different grass species usually grazed in semiarid Argentina. The evaluated forages were 3 warm-season grasses—fingergrass (F; *Digitaria eriantha eriantha* cv. Irene), kleingrass (K; *Panicum coloratum* cv. Verde), and switchgrass (S; *Panicum virgatum* cv. Alamo)—at vegetative (ve) and deferred (d) stages plus 4 small grains—wheat (W; *Triticum aestivum*) oats (O; *Avena sativa*), rye (R; *Secale cereale*), and triticale (T)—and alfalfa hay (AH; control forage for STIR). In separate experiments, 6 Pampinta rams (56 kg mean BW) were individually fed indoors ad libitum each forage in 2 daily meals (1000 and 1600 h) for 7 d of adaptation plus 7 d of DMVI observations and total fecal collection in bags. Simultaneously, a different group of 6 rams of similar BW were used to measure STIR. This group was fed once daily at maintenance level with AH. After 4 h of fasting, the animals were allowed active consumption of each forage for a 4-min period, controlled by an independent observer standing by each ram. Both DMVI and STIR were determined by subtracting refused from offered DM. Dry matter digestibility was calculated from DMVI and feces output, and digestible DMI (DDMI) was computed as well. The range of variable means and SE across grass species were 21.2 ± 2.3 (Sd) to 127.7 ± 7.2 (O), 34.3 ± 5.8 (Sd) to 69.1 ± 2.4 (AH), and 7.7 ± 1.5 (Sd) to 63.5 ± 3.3 (AH) for DMVI (g/kg $W^{0.75}$ per day), DMD (%), and DDMI (g/kg $W^{0.75}$ per day), respectively. The association between STIR and the variables DMVI, DMD, and DDMI (n = 6 for each forage) was studied by regression against the mean STIR value. Linear regression equations describing these relationships are shown in the table. There is strong positive association between STIR and DMVI; however, when a quality factor, such as DMD alone or linked to DMVI, is included, the STIR prediction potential seems to become weaker. Other factors such as palatability and leaf:stem ratio may have an influence not determined by this study.

Key Words: intake prediction, forages, sheep

1480 Effects of a blend of essential oils on milk yield and feed efficiency of lactating cows.
I. Guasch[1], G. Elcoso[1], B. Zweifel[2], and A. Bach*[3,4], *[1]Blanca, Lleida, Spain, [2]Agolin, Bière, Switzerland, [3]ICREA, Barcelona, Spain, [4]IRTA, Caldes de Montbui, Spain*.

The objective of this study was to assess the effect on milk yield and feed efficiency of a combination of essential oils for lactating dairy cows. A 56-d experiment was conducted involving 40 Holstein cows (688 ± 87 kg BW, yield 29.1 ± 73.0, and 220 ± 5.2 DIM) and 2 treatments. The study followed a randomized complete block design and lasted 8 wk. Treatments were either no supplementation (Control) or a supplementation of 1 g/d of Agolin Ruminant (Agolin, Switzerland) (AGR). Agolin Ruminant is combination of microencapsulated essential oil compounds (containing coriander oil, geranylacetate, and eugenol). All cows were fed a common TMR containing 15.3% CP, 34.6% NDF, and 1.53 Mcal of ENl/kg that was delivered twice daily. Treatments were applied in the milking parlor using a precision feeding system. The control cows received 300 g of soybean meal at each milking, and AGL cows received 300 g of soybean meal containing 1.66 g/kg of Agolin Ruminant at each milking (twice daily). Individual milk production, milk composition, and feed intake were recorded daily, and feed efficiency was then calculated (as kg of milk/kg of DMI). Treatment was individually applied, and cow was the experimental unit (n = 20). Data were analyzed with a mixed-effects model with repeated measures. Cows on AGL produced more (P < 0.05) milk (31.1 ± 1.02 kg/d) between 25 and 56 d of study than Control cows (29.7 ± 1.02 kg/d), but overall, there were no differences between treatments in milk yield. Milk fat (3.90 ± 0.08%) and milk protein (3.94 ± 0.08%) were not affected by treatment. There were, overall, no differences in DMI (24.8 ± 0.67 kg/d) between treatments, but AGL cows tended (P = 0.06) to consume less feed (24.2 ± 0.94 kg/d) than Control cows (24.8 ± 0.94 kg/d) in several days during the last 23 d of study. As a result, feed efficiency was greater (P < 0.01) in AGL cows (1.33 ± 0.05) for most days after 33 d of study than in Control cows (1.25 ± 0.05). It is concluded that Agolin Ruminant increases milk production after about 3 wk of treatment, and because feed intake does not change or even tends to decrease, feed efficiency increases.

Key Words: essential oil, milk efficiency, yield

1481 Repeatability of feed efficiency in beef cattle offered grass silage and zero-grazed grass.
S. Coyle*[1,2], C. Fitzsimons[1], D. A. Kenny[1], A. K. Kelly[2], and M. McGee[1], [1]*Teagasc Grange, Dunsany Co. Meath, Ireland,* [2]*University College Dublin, Dublin, Ireland*.

The objective of the study was to examine the within-animal repeatability of intake, growth, and feed efficiency between two consecutive feeding periods in beef cattle fed grass silage followed by zero-grazed grass. One hundred eighty-three steers comprising 94 Charolais (CH) and 89 Holstein-Friesian (HF) were used. Individual DMI and growth were measured over two consecutive 70-d feeding phases. Each feeding phase was preceded by a dietary adaptation period. For phase 1, steers were offered first-harvest grass silage (DM 290 g/kg and DM digestibility 700 g/kg) ad libitum, and for phase 2, they were offered zero-grazed grass (DM 196 g/kg) ad libitum. The grass herbage was harvested (without chopping) twice daily from *Lolium perenne* dominant swards using a "zero-grazer." The residuals of the regression of DMI on ADG and mid-test metabolic BW, within each breed, were used to compute individual residual feed intake (RFI) coefficients for each feeding phase. Repeatability between the two feeding phases for ADG, DMI, G:F, and RFI was estimated using Pearson correlation coefficients. Mean BW (SD) and age (SD) at the start of phase 1 were 485 kg (38.0) and 373 d (18.0) and 401 kg (43.3) and 399 d (7.6) for CH and HF, respectively. Corresponding BW at the start of phase 2 were 519 (38.3) and 441 (39.2) kg. During phase 1, overall ADG, DMI, G:F, and RFI (SD) for CH were 0.40 kg (0.17), 6.5 kg/d (0.57), 0.06 kg BW gain/kg DM (0.03), and −0.01 kg DM/d (0.35). Corresponding values for HF were 0.46 (0.17), 7.1 (0.60), 0.07 (0.02), and −0.02 (0.48). For phase 2, respective values were 1.31 (0.19), 9.1 (0.55), 0.14 (0.02), and −0.03 (0.34) and 1.25 (0.22), 9.5 (0.56), 0.13 (0.02), and −0.02 (0.43). For CH, correlations between the two feeding phases for ADG, DMI, G:F, and RFI were $r = 0.13$ ($P > 0.05$), $r = 0.70$ ($P < 0.001$), $r = 0.07$ ($P > 0.05$), and $r = 0.40$ ($P < 0.001$), respectively. Corresponding values for HF were −0.03 ($P > 0.05$), 0.51 ($P < 0.001$), 0.04 ($P > 0.05$), and 0.30 ($P < 0.01$). We conclude that DMI and, to a lesser extent, RFI are repeatable traits when cattle are offered grass silage and zero-grazed grass.

Key Words: beef cattle, feed efficiency, repeatability

1482 Repeatability of feed efficiency in steers offered a high-concentrate diet.
S. Coyle*[1,2], C. Fitzsimons[2], D. A. Kenny[2], A. K. Kelly[1], and M. McGee[2], [1]*University College Dublin, Dublin, Ireland,* [2]*Teagasc Grange, Dunsany Co. Meath, Ireland*.

The objective of the study was to examine the within-animal repeatability of intake, growth, and feed efficiency between the growing and finishing stages for beef cattle fed the same diet. One hundred sixty-seven steers comprising 90 Charolais (CH) and 77 Holstein-Friesian (HF) were used. Following a dietary adaptation period, individual DMI and growth were measured over two 71-d feeding phases 300 d apart. Mean BW (SD) and age (SD) at the start of phase 1 were 395 kg (37.8) and 283 d (18.3) and 294 kg (42.3) and 306 d (7.7) for CH and HF, respectively. Corresponding BW at the start of phase 2 were 675 (49.8) and 611 (49.3) kg. During both feeding phases, steers were individually offered the same concentrates (860 g/kg rolled barley, 60 g/kg soya bean meal, 60 g/kg molasses, and 20 g/kg minerals and vitamins) ad libitum plus a restricted allowance of grass silage daily. Throughout the interim period, they were all offered either grass silage or fresh grass herbage. The residuals of the regression of DMI on ADG and mid-test metabolic BW, within each breed, were used to compute individual residual feed intake (RFI) coefficients for each feeding phase. Repeatability between the two feeding phases for ADG, DMI, G:F, and RFI was estimated using Pearson correlation coefficients. During phase 1, overall ADG, DMI, G:F, and RFI (SD) for CH were 1.26 kg (0.26), 8.4 kg/d (0.82), 0.15 kg BW gain/kg DM (0.03), and −0.02 kg DM/d (0.51). Corresponding values for HF were 1.40 (0.22), 8.8 (0.84), 0.16 (0.02), and −0.05 (0.50). For phase 2, respective values were 1.39 (0.26), 11.5 (1.11), 0.12 (0.02), and −0.01 (0.69) and 1.31 (0.37), 12.5 (1.30), 0.11 (0.03), and −0.08 (0.95). For CH, correlations between the two feeding phases for ADG, DMI, G:F, and RFI were $r = 0.21$ ($P > 0.05$), $r = 0.63$ ($P < 0.001$), $r = 0.07$ ($P > 0.05$), and $r = 0.35$ ($P < 0.001$), respectively. Corresponding values for HF were 0.22 ($P = 0.06$), 0.56 ($P < 0.001$), 0.08 ($P > 0.05$), and 0.29 ($P < 0.05$). We conclude that DMI and, to a lesser extent, RFI are repeatable traits when cattle are offered a high-concentrate diet.

Key Words: beef cattle, feed efficiency, repeatability

1483 NADH dehydrogenase (ubiquinone) Fe-S protein-1 (NDUFS1), a core subunit of mitochondrial complex I, is not differentially expressed in peripheral blood mononuclear cells of beef steers with divergent residual feed intakes.
J. J. Michal[1], J. R. Russell[2], S. L. Hansen[2], J. F. Taylor[3], M. S. Kerley[4], U. S. Feed Efficiency Consortium[3], and K. A. Johnson*[1], [1]*Washington State University, Pullman,* [2]*Iowa State University, Ames,* [3]*University of Missouri, Columbia,* [4]*Division of Animal Sciences, University of Missouri, Columbia*.

Mitochondrial complex I (NADH:ubiquinone oxidoreductase) plays a crucial role in energy production and is intrinsically linked to animal bioenergetics. Several studies suggest mitochondrial protein complex subunits are differentially expressed in tissues and cells of chickens and cattle with divergent residual feed intake (RFI). The objective was to evaluate differences in mitochondrial complex I in peripheral blood mononuclear cells (PBMC) as a marker to identify different

RFI phenotypes. Crossbred steers fed corn- or roughage-based diets were RFI tested during the growing phase at the University of Missouri and shipped to Iowa State University where they were fed corn- or byproduct-based diets until harvest. Blood samples were collected on d 59 of the finishing phase from 37 steers that represented low and high extremes in growing phase RFI (n = 8 and 11 and mean RFI = −1.25 and 1.20 kg for corn-based diet and n = 10 and 8 and mean RFI = −1.67 and 1.25 kg for roughage-based diet, respectively). The PBMC were isolated and lysate proteins (50 μg total protein/lane) were separated by PAGE and blotted onto nitrocellulose membranes. A polyclonal antibody against NADH dehydrogenase (ubiquinone) Fe-S protein-1 (NDUFS1), a marker of complex I, was used to determine relative abundance of the protein in PBMC. Primary antibody binding specificity was confirmed with a commercially available bovine heart mitochondria lysate, which was also the positive control. Antibody binding was determined by chemiluminescence after blots were incubated with a horseradish peroxidase conjugated secondary antibody. The NDUFS1 band signal intensities were adjusted relative to the signal intensity of the positive control for each gel and normalized to total protein in the lane. There were no effects of diet (P = 0.50) or RFI phenotype (P = 0.45) on relative abundance of NDUFS1 protein in PBMC of steers. Examination of data from only steers with low RFI suggested a tendency, a slight positive relationship (r = 0.36, P = 0.14), between NDUFS1 protein abundance and low RFI, regardless of diet. A similar response was not evident in steers with high RFI (P = 0.79). Relative expression of the protein NDUFS1 is not clearly related to RFI of steers fed corn- or roughage-based diets and cannot be used as a marker for selection of efficient animals. This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2011-68004-30214 from the USDA National Institute of Food and Agriculture.

Key Words: NDUFS1 protein, residual feed intake, steer

1484 Dry matter intake prediction of heifers under tropical conditions. M. I. Marcondes*[1] and A. L. Silva[2], [1]*Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Brazil,* [2]*Universidade Federal de Vicosa, Vicosa, Brazil*.

The objective was to develop a model able to predict DMI of heifers raised under tropical conditions as well as to test the effect of breed (Holstein purebred vs. Holstein × Gyr crossbreed) on DMI. A database composed of 389 individual animal observations, from 14 experiments, was used to develop the model for DMI. Only experiments that had concurrent information about DMI, average BW, ADG, and breed were used. Animals that had ≥87.5% Holstein crosses were considered pure breeds and the others were considered crossbreeds. The data were analyzed following a meta-analysis procedure, where each experiment was considered a random sample for large populations. The model used to fit the DMI was $DMI = \beta_0 + \beta_1 \times BW + \beta_2 \times BW^2 + \beta_3 \times ADG + \beta_4 \times ADG^2$, in which DMI = dry matter intake (kg/d); BW = average body weight (kg); ADG = average daily gain (kg/d); and β_0, β_1, β_2, β_3, and β_4 are equation parameters. To test the random effects of independent variables on the intercept and slope, the variance components (VC), heterogeneous first-order autoregressive (ARH (1)), and unstructured (UN) matrices of (co)variance were tested. All statistical procedures were performed using the MIXED procedure of SAS and Akaike's information criteria was used to indicate the best (co)variance matrix. Breed effect was tested every equation parameter. Observations with Studentized residuals > |2.5| were considered outliers. For all statistical procedures, a significance level of 5% was adopted for fixed effects and a level of 20% was adopted for the random (study) effect. Heifer DMI values were linearly affected by BW and ADG and quadratically affected by ADG. Genetic group affected the BW and ADG coefficients, demonstrating that this is an important source of variation and that different models should be used to estimate the DMI of Holstein purebred and crossbred heifers. The fitted models were $DMI_{Holstein} = -0.2092 + 0.0169 \times BW + 2.5833 \times ADG - 0.5126 \times ADG^2$ and $DMI_{Crossbred} = -0.2092 + 0.0179 \times BW + 2.3048 \times ADG - 0.5126 \times ADG^2$, in which $DMI_{Holstein}$ = DMI of Holstein heifers (kg/d), $DMI_{Crossbred}$ = DMI of crossbred heifers (kg/d), BW = average body weight (kg), and ADG = average daily gain (kg/d). It can be concluded that DMI in heifers is affected by BW and ADG and different equations should be used to estimate DMI in Holstein purebreds and Holstein × Gyr crossbred dairy heifers raised under tropical conditions.

Key Words: dairy heifers, growing animals, Holstein × Gyr

1485 An improved model for predicting dry matter intake in prepartum dairy cows. F. A. Paiva*[1], F. Peñagaricano[1], J. K. Drackley[2], and J. E. P. Santos[1], [1]*University of Florida, Gainesville,* [2]*University of Illinois, Urbana*.

The objective was to develop a mathematical model to predict DMI in prepartum Holstein cows. Data on daily DMI, parity, BW, body condition (BCS), and chemical composition of diets fed ad libitum to 1,451 Holsteins during the final 21 d of gestation in 31 experiments were compiled. Cows were grouped according to parity prepartum as nulliparous (n = 290), primiparous (n = 510), or multiparous (n = 660) and BCS as thin (BCS < 3.00), moderate (3.00–3.50), or fat (BCS > 3.50). Body weight was used as percentage of the mean BW within parity for nulliparous (620 kg), primiparous (690 kg), and multiparous (760 kg) and day relative to calving (DRC) was used as a categorical variable. Dietary factors included NE for lactation, CP, ruminal degradable and undegradable protein, ash, fat, NDF, ADF, nonfibrous carbohydrates, percent dietary forage, forage NDF, Ca, P, Mg, and

Table 1485.

[1] Hayirli et al. (2003): J. Dairy Sci. 86:1771-1779.

[2] DMI, kg/d = 6.8591 + (BW% x 3.8748) + (NDF% x -0.1146) + (DCAD mEq/Kg x 0.006618) + Null (0) / Prim (2.5684) / Mult (2.2892) + Thin (0.4825) / Mod (0.3655) / Fat (0) + DRC (estimates)

dietary cation–anion difference (DCAD). Models were built with parameters entered in sequence using the MIXED procedures of SAS and R. Initial model included the random effects of study and cow nested within parity and study and the fixed effect of DRC. Each cow-level or diet-level factor was individually analyzed and fixed effects with $P < 0.05$ were used to build multivariable models. Multicollinearity among diet-level factors was assessed and parameters with high collinearity were individually evaluated in separate models. The final model was built using only significant variables and best fit assessed according to lowest Akaike's (AIC) and Bayesian (BIC) information criteria. The final model was DMI (kg/d) = intercept + [BW (% mean parity BW) × estimate] + [NDF (% of DM) × estimate] + [DCAD (mEq/kg) × estimate] + parity estimates + BCS category estimates + DRC estimates. The model was rerun 31 times excluding 1 of the 31 experiments each time, which was used to evaluate predictive ability using cross-validation (cross-validation model). Therefore, 31 different models were generated and the excluded experiment was used to evaluate the prediction of DMI. The final model was contrasted with other prediction models for DMI (Table 1). Of the total variance in DMI, the random effects accounted for 46.1%, the fixed effects accounted for 21.2%, and the residual accounted for 32.7%. The final model reduced the root of mean square of the predicted error by 0.46 to 0.56 kg/d, therefore more accurately predicting DMI of prepartum cows compared with currently used models.

Key Words: dry matter intake, model, prepartum

1486 The use of artificial neural network to estimate feed intake in lactating cows through milk mid-infrared spectra of individual cow milk samples.

J. R. R. Dórea*, G. J. M. Rosa, and L. E. Armentano, *University of Wisconsin – Madison, Madison, WI.*

Feed intake is one of the most important components of feed efficiency in dairy systems. It is, however, a difficult trait to measure in the field. The use of milk spectrum from mid-infrared (MIR) spectroscopy previously has been used to estimate milk traits and could be an alternative to direct measurement of DMI. The objective of this study was to develop a Fourier transform MIR-based milk analysis method coupled with artificial neural networks (ANN) to estimate DMI in lactating Holstein cows. Five hundred ninety-nine milk samples from 189 lactating cows housed at either the Emmons Blaine Dairy Cattle Research Center (Arlington, WI; $n = 129$ cows) or the Dairy Forage Research Center (USDA, Prairie Du Sac, WI; $n = 60$ cows) were analyzed for MIR spectra. Individual DMI was periodically recorded from cows housed in a free-stall barn equipped with 32 Insentec electronic feeding gates (Arlington) or directly measured on tie-stall barn (USDA). The spectra absorbance values were used as input variables to develop and optimize the ANN configuration. Wavelengths with less than 10% of CV among samples were not used. The ability of the resulting one-hidden-layer ANN model was compared with a linear predictive model developed through partial least squares (PLS) regression. Four ANN models were developed considering 5, 10, 15, and 20 neurons. A 7-fold cross-validation method was used to assess the predictive ability of the models. The r^2 of cross-validation increased as the number of neurons increased from 5 to 20 ($r^2 = 0.31$, 0.43, 0.45, and 0.48, respectively). The root mean square error (RMSE) decreased as the number of neurons increased up to 15 (RMSE = 4.13, 3.61, 3.30, and 3.38 kg/d, respectively). In contrast, the PLS model (7 factors) resulted in lower $r^2 = 0.14$ and greater RMSE = 4.41 kg/d. Compared with established statistical method (PLS), the proposed ANN model demonstrates the potential to provide improved prediction of DMI. Future research should be conducted to investigate alternative ANN architectures and to assess its performance using test validation in an independent data set.

Key Words: artificial neural network, intake, mid infrared

1487 Effects of supplementing lactating dairy cow ration with sodium sesquicarbonate on reticulorumen pH, rumination, and dry matter intake.

1488 Toxicity of antibiotics on rumen protozoan *Entodinium caudatum* and its associated microbes.
T. Park*, *The Ohio State University, Columbus*.

Rumen ciliate protozoa play important roles in rumen function. However, knowledge on the metabolism and physiology of rumen protozoa is limited, mostly because of lack of axenic cultures of rumen ciliate protozoa needed to generate direct evidence. Antibiotics alone and in combination with physical separation have been successfully used in generating axenic cultures of free-living aerobic ciliate protozoa, such as species of *Tetrahymena* and *Paramecium*. However, no effort has been successful in developing axenic cultures of rumen protozoa. Rumen protozoa have lived together with a high density of rumen bacteria and other groups of microbes for many millions of years, and killing of the associated bacteria and/or archaea resulted in loss of viability of rumen protozoa. The objective of this experiment was to evaluate the toxicity of different antibiotics to *Entodinium caudatum*, a major species of *Entodinium*, which, as a genus, accounts for more than 90% of the total rumen protozoa in cattle and sheep fed high-concentrate diets. Based on the mode of action, eight antibiotics were selected that each has a broad spectrum to kill or to inhibit bacteria. *Entodinium caudatum* cells grown in a culture were filtrated and washed to remove most of the free-living bacteria and methanogens. The washed *E. caudatum* cells were then fed a protozoal feed containing ground wheat, alfalfa, and grass and incubated for 72 h with 4 different concentrations and three replicates per antibiotic treatment. After incubation, *E. caudatum* cell counts, optical density, and electron microscopy (both scanning and transmission) were used to determine *E. caudatum* viability, growth of contaminating bacteria, and changes of intracellular structure of *E. caudatum* cells. Except ampicillin, all the tested antibiotics decreased *E. caudatum* growth in a concentration-dependent manner. Chloramphenicol appeared to be the most toxic to the viability of *E. caudatum*. Scanning electron microscopy and transmission electron microscopy revealed few ecto- or endosymbiotic microbes of the *E. caudatum* cells irrespective of the antibiotic treatments. Damages to the intracellular structures were detected by scanning electron microscopy, especially among the *E. caudatum* cells treated with chloramphenicol. Transmission electron microscopy is underway to further examine cellular damages, and several antibiotics cocktails are being evaluated for their usefulness to kill the associated microbes and generate an axenic *E. caudatum* culture.

Key Words: axenic culture, electron microscopy, *Entodinium caudatum*

1489 Effect of diets containing different levels of crude glycerol on nutrient intake in lambs.
M. A. Syperreck[1], M. Capelari*[2], I. Y. Mizubuti[1], and E. L. A. Ribeiro[1], [1]*Universidade Estadual de Londrina, Londrina, Brazil,* [2]*Michigan State University, East Lansing*.

Crude glycerin is a byproduct of biodiesel production that represents a potential ingredient for use in animal nutrition. The objective of this study was to evaluate the effect of diets containing different levels of crude glycerin on nutrient intake in male lambs. The experiment was conducted in the animal metabolism laboratory of Universidade Estadual de Londrina. Four castrated male lambs (25 ± 2.6 kg) were used in a 4 × 4 Latin square design. Animals were identified and individually allocated to metabolic cages containing a feeder and a water trough. The experiment was divided in 4 periods of 13 d, with the first 7 d for diet adaptation and 6 d of sample collection. A basal diet (50:50 forage to concentrate) consisting of chopped *Brachiaria dictyoneura* hay, ground corn, soybean meal, urea, and a mineral and vitamin premix was provided throughout the experiment. Crude glycerin was added to the basal diet at either 0, 5, 10 or 15% of diet DM. Diets were made isocaloric and isonitrogenous by the addition of ground corn and urea, respectively. Daily intake was measured based on individual orts. Samples of offered diets and orts were analyzed for DM, OM, CP, NDF, ADF, ether extract (EE) and total carbohydrates (TC). Data was submitted to ANOVA and regression with a 5% significance level. The inclusion of crude glycerin influenced the intake of nutrients ($P < 0.01$) when expressed as grams per day, percent BW, and grams per kilogram$^{0.75}$, with a quadratic response for all parameters evaluated. Overall, the highest theoretical nutrient intake in kilograms per day was between 3.81 and 5.14% glycerol inclusion. Only CP and EE, when expressed as percent BW and grams per day, resulted in higher theoretical intake for diets containing glycerin at 10.88 and 7.91% inclusion, respectively. Nutrient intake for all treatments was sufficient to meet the nutritional requirements and to keep the BCS within the desired to maintain the physiological status of the animals during the experimental period. Crude glycerin, when fed to lambs in a 50:50 forage-to-concentrate diet, can be included up to 5.14% of diet DM without negatively affect the intake of nutrients in grams per day and grams per kilogram$^{0.75}$.

Key Words: byproduct, energy, small ruminants

1490 Effects of corn particle size and neutral detergent fiber:starch ratio on in vitro neutral detergent fiber degradability.
S. Malan and E. Raffrenato*, *Department of Animal Sciences, Stellenbosch University, Stellenbosch, South Africa*.

Reducing particle size is the most common technique to increase starch digestibility, especially for corn, and both the

amount and the size of starch source may affect the rumen environment. The objective of our study was to verify the effects of specific ranges of corn particle size and NDF:starch ratios on starch and NDF degradability (NDFd). The same batch of corn was milled using a Wiley mill with either a 1- or a 2-mm screen. The corn was sieved and separated using the following sizes: <250, 250 to 500, 500 to 1,180, and 1,180 to 2,000 μm. All sizes were analyzed for starch, CP, EE, and NDF. Oat hay and alfalfa were used separately to evaluate the effects of particle size on NDFd using the NDF:starch ratios of 1:1 and 1:1.25. Ratios were adjusted for each size class based on actual starch and NDF contents of both corn and forages. Higher ratios were excluded because the buffering capacity of the medium avoided changes in pH and NDF digestibility. Residual starch and NDF of the fermented samples were obtained at 3, 6, 9, 12, 24, and 48 h. Rates of digestion (kdStarch and kdNDF) were calculated using a first-order decay model and estimated indigestible starch and NDF using the 48 and 240 h fermentation residuals, respectively. Indigestible starch was numerically different across sizes. Data were analyzed according to a randomized complete block design with a factorial arrangement of treatments. The main tested effects were size, ratio, forage, and their interactions. Fermentation run was considered a random effect. With increasing particle size, starch decreased from 79 to 55%, NDF increased from 3.4 to 33.1%, EE increased from 2.17 to 3.78%, and CP increased from 6.40 to 8.21%. Both forage type and NDF:starch ratio did not have any effect ($P > 0.45$) on ivSD and kdStarch. As expected, kdStarch linearly increased ($P < 0.01$) with smaller particle size with no interaction with either forage or NDF:starch ratio, from 0.14 to 0.47 h^{-1}. Interaction was present ($P < 0.01$) between forage and particle size for ivSD and kdStarch, with more starch degraded for the two smallest sizes and alfalfa. Particle size, and not amount, affected NDF digestibility for both forages ($P < 0.01$), with consistently higher NDFd and kdNDF for the largest size. Particle size affected NDF fermentation more than amount for corn, even if the medium might have decreased the effect of larger amount of starch.

Key Words: in vitro, neutral detergent fiber, particle size, starch

---

1491 Associations between residual feed intake and metabolite profiles and feeding behavior traits in feedlot cattle. M. D. Miller*[1], G. E. Carstens[1], J. M. Thomson[2], J. G. Berardinelli[2], M. R. Herrygers[2], J. White[2], L. O. Tedeschi[1], and P. K. Riggs[1], *[1]Texas A&M University, College Station, [2]Montana State University, Bozeman*.

Objectives of this study were to evaluate the effects of residual feed intake (RFI) classification on performance and feed efficiency in steers fed a high-grain diet and to examine associations between RFI and blood metabolite profiles and feeding behavior traits to identify RFI biomarkers. Performance, DMI, and feeding behavior traits were measured for 70 d in Angus crossbred steers ($N = 168$) using a GrowSafe system. Steers were classified into low- ($n = 52$), medium- ($n = 64$), and high- ($n = 52$) RFI groups based on ±0.5 SD from the mean RFI of 0.00 (SD = 0.82). Low-RFI steers consumed 17% less ($P < 0.0001$) DMI (9.05 vs. 10.89 ± 0.14 kg/d), had 18% lesser ($P < 0.0001$) feed:gain ratio (5.05 vs. 6.11 ± 0.10), and generated $95 per head more ($P < 0.001$) profit compared with high-RFI steers, even though ADG and carcass value were not affected by RFI classification. Blood samples were collected from steers with lowest RFI ($n = 25$) and highest RFI ($n = 24$) on Day 70 of the trial, and serum metabolite concentrations were analyzed using ^{1}H-NMR spectroscopy. Partial least squares (PLS; MetaboAnalyst) were used to examine associations between RFI and metabolites and feeding behavior traits. Of the 12 feeding behavior traits evaluated, 4 traits had variable of importance in projection (VIP) scores > 1.0, which included head-down (HD) duration, bunk visit (BV) duration, nonfeeding interval (NFI) duration, and head-down–to–meal duration ratio (HD:MD). The first 2 components of PLS accounted for 54% of between-animal variance in RFI. Steers with low RFI had longer ($P < 0.001$) NFI duration (less time at the bunk), 45% lower HD duration, 35% lower BV duration, and 32% lower HD:MD than high-RFI steers. Of the 44 metabolites detected by ^{1}H-NMR, 5 metabolites had VIP scores > 2, which included glycine, betaine, tyrosine, valine, and leucine. The first 2 components of PLS accounted for 34% of between-animal variance in RFI. Steers with low RFI had higher ($P < 0.001$) concentrations of glycine and lower ($P < 0.06$) concentrations of betaine, tyrosine, valine, and leucine than high-RFI steers. These preliminary results reveal that metabolomic profiling and feeding behavior traits may provide opportunities to identify biomarkers that are predictive of RFI in beef cattle.

Key Words: feedlot cattle, metabolites, residual feed intake

1492 Effects of acidity and silage type on lysine retention among two lipid-coated ruminally protected lysine products. J. N. Reiners* and D. W. Brake, *South Dakota State University, Brookings*.

Milk protein secretion among cattle consuming corn-based diets can be limited by metabolizable Lys. Therefore, ruminally protected AA (RPAA) are commonly included in cattle diets to increase metabolizable Lys intake. Previous data suggest that Lys associated with lipid-coated RPAA is reduced by greater diet moisture content. Effects of silage type and acidity on Lys associated with lipid-coated RPAA products (EB and EC) were evaluated over time. Crystalline Lys and Lys mixed with lipid in amounts equal to either EB or EC served as negative controls. Controls and each lipid-coated RPAA (4 g) were placed in mesh bags (10 by 20 cm; pore size = 50 mm) and mixed with

Table 1493. Effect of DIM on fecal composition and nutrient digestibility.

either alfalfa silage or corn silage at 2 different levels of acidity (pH = 4.6 or pH = 6.6) for 0, 6, 12, or 24 h. Silage pH was modified by mixing with 10% (wt/wt) NaOH. After removal, mesh bags were rinsed with cold water and contents of each bag were lyophilized. Lipid-associated Lys was subsequently determined by analyzing total free Lys content after removal of triacylglycerols and free fatty acids with hexane:methanol. Dissociation kinetics were calculated using the nonlinear procedure of SAS, and data were analyzed as a completely randomized design. As expected, the proportion of Lys that dissociated after initial contact (ID) from the negative controls was complete (100 ± 2.5%) and indicated that Lys analyses reflected measures of lipid-associated Lys. The ID from RPAA was less ($P = 0.02$) for EB (20.4 ± 2.8%) than for EC (31.3 ± 2.8%). Additionally, ID increased as acidity increased when RPAA was mixed with corn silage; however, ID was not affected by acidity when mixed with alfalfa silage (silage × pH ≤ 0.01). Amounts of Lys that slowly dissociated (SD) from RPAA during silage incubation were greater ($P = 0.01$) for EB (59.6 ± 4.8%) than for EC (38.4 ± 4.8%). Furthermore, SD increased with greater acidity in corn silage but did not differ among alfalfa silage with either greater or lesser acidity (silage × pH = 0.01). Rate of Lys dissociation was not different among either RPAA ($P = 0.40$; 10.9 ± 1.9%/h) and was not affected by acidity ($P = 0.73$) or silage type ($P = 0.62$). Lipid-associated Lys remaining at 24 h for EB (20.1 ± 5.7%) was not different ($P = 0.24$) compared with that for EC (30.3 ± 5.7%).

Key Words: amino acid, cattle, lysine

1493 Relationship of days in milk to nutrient digestibility in lactating multiparous cows.

A. M. Barnard*[1], H. Jensen[2], and T. F. Gressley[1], *[1]University of Delaware, Newark, [2]BioZyme, Wathena, KS.*

The objective was to determine if differences in days in milk (DIM) affect apparent nutrient digestibility in lactating multiparous cows fed the same ration. Of 136 cows in a multiparous, high-producing pen on a 1,000-cow commercial dairy, 24 were selected for sampling based on differences in DIM and milk yield (Low DIM: $n = 12$, milk = 64 ± 6 kg, and DIM = 85 ± 6; High DIM: $n = 12$, milk = 55 ± 4 kg, and DIM = 158 ± 15). Milk, fecal, and TMR samples were collected once daily for 10 consecutive days. Samples were collected in the morning on 6 d and the afternoon on 4 d. Individual cow milk and fecal samples were composited into one daily milk or fecal sample per DIM group and analyzed for nutrient composition. In addition, daily fecal composite and TMR samples were analyzed for apparent digestibility of potentially digestible NDF (PdNDFd), NDF (NDFd), protein (Protd), and starch (Starchd). Fecal nutrient composition and apparent digestibility data were analyzed using the Glimmix procedure of SAS. The model included fixed effects of group, sampling time, and their interaction. Day was included as a repeated measure. The CORR and REG procedures were used for comparing daily variations in digestibility with milk yield and composition. For fecal nutrient composition, DIM × sampling time was significant for ADF and NDF, due to sampling time differences in the low-DIM group (Table 1). There was a group effect on fecal DM in which DM was lower in low-DIM cows. Time effects were also observed, with CP being higher before noon and ADF, NDF, and ash being higher after noon. There was no effect of DIM on PdNDFd, NDFd, Protd, or Starchd. There was an effect of DIM × sampling time on Starchd ($P = 0.03$) due to higher Starchd at the before-noon sampling for high-DIM cows ($P = 0.03$). There were no significant correlations of digestibility measures with milk yield. A 1% increase in PdNDFd ($P = 0.02$) and NDFd ($P = 0.006$) was associated with a 0.04 and 0.05% increase, respectively, in milk fat percentage. A 1% increase in Starchd ($P = 0.003$) was associated with a 0.03% increase in milk protein percentage. Because DIM had minimal effects on digestibility measures, it is likely not necessary to consider DIM when selecting cows for estimation of nutrient digestibility within a high-producing pen.

Key Words: days in milk, fecal composition, nutrient digestibility

1494 Effects of animal and diet characteristics on digestibilities of dry matter, fiber, and starch in lactating cows. R. A. De Souza*[1], R. J. Tempelman[1], M. S. Allen[1], J. K. Bernard[2], B. Weiss[3], and M. J. VandeHaar[1], *[1]Michigan State University, East Lansing, [2]University of Georgia, Tifton, [3]The Ohio State University, Wooster*.

Our objective was to determine the effects of DMI, BW, and diet characteristics on total tract digestibilities of DM, NDF, and starch (DMD, NDFD, and StarchD, respectively) in high-producing cows. The database was constructed with individual observations of digestibilities, ingredients, and chemical composition of diets; BW and DMI; experimental design; and treatment arrangement. The data set contained 1,942 observations on 635 cows from 56 studies with >6 observations per treatment in Michigan, Ohio, and Georgia. Forage sources included corn, alfalfa, wheat straw, and orchardgrass. Nutrient digestibility means were 66 ± 6, 42 ± 11, and 93 ± 5% for DMD, NDFD, and StarchD, respectively. Diet nutrient contents (% DM) were 31 ± 5% NDF, 27 ± 6% starch, 2.6 ± 1.2% FA, and 17 ± 1.4% CP. Dry matter intake and BW were 23 ± 5 and 669 ± 79 kg, respectively. Data was analyzed using a mixed model with HPMIXED procedure of SAS. The full model included linear and quadratic effects of diets, $BW^{0.75}$, DMI, and all possible 2-way interactions between diet variables and DMI as fixed effects. Cow, block, period, and study were used as random effects. Best fitting reduced models were generated using backward and stepwise regression procedures. Interactions were not significant. A simplest model was generated using only DMI and the random effects. The backward, stepwise, and simplest models were cross-validated using five folds, and the resulting correlations coefficients across studies (CORR) were compared by *t* test. The model that resulted in the highest CORR and lowest number of variables was accepted as the best fitting model for each nutrient digestibility. The best fitting prediction equations were DMD = 69 − 0.20 × DMI (MSE = 8.5, r^2 = 0.68, CORR = 0.20); NDFD = 32 + 0.26 × grass + 0.46 × starch + 3.4 × FA + 0.83 × DMI − 0.020 × $starch^2$ − 0.34 × FA^2 − 0.030 × DMI^2 (MSE = 26, r^2 = 0.80, CORR = 0.41); and StarchD = 97 − 0.30 × DMI (MSE = 3.1, r^2 = 0.84, CORR = 0.22); grass, starch, and FA are expressed as percentage of DM and DMI is expressed as percentage of $BW^{0.75}$. Our results confirm that digestibility was reduced as DMI increased but at a lower rate than the previous equation used by NRC (2001). Digestibility of DM and StarchD can be predicted based on only DMI; however, NDFD required diet characteristics in addition to DMI. Starch levels > 25% and FA > 5% dramatically reduced NDFD.

Key Words: digestibility, intake, model, neutral detergent fiber, starch

1495 Effects of silage type and inclusion level on ruminal characteristics and feeding behavior of feedlot steers. P. R. B. Campanili*[1], J. O. Sarturi[1], S. J. Trojan[1], M. A. Ballou[1], L. A. Pellarin[1], J. D. Sugg[2], L. A. Ovinge[1], A. Alrumaih[1], and A. A. Hoffman[1], *[1]Texas Tech University, Lubbock, [2]Angelo State University, San Angelo, TX*.

Silage type and level of inclusion on beef cattle finishing diets ruminal fermentation and degradability, digestibility, and feeding behavior were evaluated. In Study 1, beef steers (*n* = 6; BW = 363 ± 23 kg) fitted with ruminal cannula were used (6 × 4 unbalanced Latin square design). Treatments (*n* = 4) consisted of silage type (corn = BH8895 and sorghum = AF7401) and silage inclusion (10 or 20%, DM basis). Each period consisted of 14 d for adaptation and 7 d for collections. Steers were individually fed ad libitum once daily. Silage degradability was studied by in situ technique. In Study 2, the same technique was used to study the degradability of intact ensiled sorghum grain (*n* = 10; 18.9-L units; 112 d of storage; 2 sites). Beef steers (*n* = 3; BW = 547 ± 56 kg) fed a growing diet were used. Data were analyzed using Glimmix procedure of SAS (day as repeated measure). Steers fed 20% sorghum silage had greater DMI (P = 0.03) and total VFA (P = 0.01) but tended (P = 0.07) to the least propionate molar proportion compared with other treatments. Steers fed 10% corn silage had the greatest (P = 0.04) ruminal butyrate and the least (P < 0.01) ruminal pH average compared with other treatments, which reached nadir at 5.62 (P < 0.01) 12 h after feeding. Additionally, the 10% corn silage treatment tended (P = 0.09) to have the least in vitro methane production. Starch digestibility tended (P = 0.08) to peak for steers fed 10 and 20% corn silage (98%) and bottom for steers fed 20% sorghum silage (92%). Steers fed corn silage had greater ($P \leq 0.01$) total tract apparent digestibility (11% DM and 32% NDF), lower (P < 0.01) acetate/propionate, and 34% greater (P < 0.01) silage ruminal degradation and tended (P = 0.07) to chew 1.1 h/d less compared with steers fed sorghum silage diets. Steers fed 20% silage chewed and ruminated more ($P \leq 0.04$), degraded more (P < 0.01) NDF, and had greater (P < 0.01) acetate/propionate but less DM digestibility than 10% silage-fed steers. Sorghum grain ruminal degradability reached 52% at 96 h. Replacement of corn silage with sorghum silage in beef finishing diets requires adjustments to balance dietary energy. Sorghum material induced a desirable roughage effect in feeding behavior but also offered potential to be improved regarding fiber digestibility and intact grain ruminal degradability.

Key Words: corn, silage, sorghum

1496 Identification of biological pathways involved in residual feed intake in Hereford cattle through gene set enrichment analysis. J. L. Mutch*[1], M. Neupane[1], C. M. Seabury[2], H. L. Neibergs[1], P. C. Tizioto[3], D. J. Garrick[4], M. S. Kerley[3], D. W. Shike[5], J. E. Beever[5], J. F. Taylor[3], U. S. Feed Efficiency Consortium[3], and K. A. Johnson[1], *[1]Department of Animal Sciences, Washington State University, Pullman, [2]College of Veterinary Medicine, Texas A&M University, College Station, [3]University of Missouri, Columbia, [4]Department of Animal Science, Iowa State University, Ames, [5]University of Illinois, Urbana*.

Understanding the biological differences between animals with different feed efficiency phenotypes enhances our understanding of the trait. The objective was to use gene set enrichment analysis-SNP (GSEA-SNP) to identify gene sets (GS) associated with the residual feed intake (RFI) phenotype in Hereford cattle. Feed intake and BW gain were measured on 847 steers and heifers at Olsen Ranches in Harrisburg, NE. Animals were genotyped using the Illumina BovineSNP50 (n = 358) or BovineHD BeadChips (n = 459). BovineSNP50 genotypes were imputed with Beagle 4.1 to the density of the Illumina BovineHD BeadChip using the BovineHD genotyped Herefords as a reference. Genomewide association analysis (GWAA) was performed using GRAMMAR mixed model software, and the most significant SNP for each of 19,723 genes from the UMD-3.1 reference assembly were selected as a proxy for that gene. Gene proxies were considered only for SNP that were located within 8.5 kb of a gene, as this is representative of the average haplotype block size in Herefords (determined by a haplotype block analysis). Following GWAA, GSEA-SNP was conducted with 4,389 GS from Gene Ontology (GO), Kyoto Encyclopedia of Genes and Genomes (KEGG), Reactome, Biocarta, and Panther. Significance was calculated using the null distribution estimated from 10,000 permutations for each GS using GenABEL in R. An enrichment score was calculated for each GS using a modified Kolmogorov–Smirnov statistic and normalized (NES) based on the size of each GS. The GS associated (NES > 3.0) with RFI were centrosome (37 leading edge genes [LEG]) and cytoskeleton (97 LEG) from GO and peroxisome from KEGG (30 LEG). The centrosome GS is involved in mitosis and cell cycle regulation and the peroxisome GS is involved in lipid homeostasis. The cytoskeleton organization GS contained four differentially expressed LEG: *Type I keratin 19* (*KRT19*), *α 1 actin I* (*ACTA1*), *α 1 actinin* (*ACTN1*), and *cysteine and glycine-rich protein 3* (*CSRP3*). These genes were previously found by this consortium to be differentially expressed between the high- and low-RFI groups of Herefords. In the low-RFI group, expression of *KRT19* in the liver was greater than in the high-RFI cattle. Low-RFI Herefords also had reduced expression of *ACTA1* in the liver and pituitary, *ACTN1* in the hypothalamus, and *CSRP3* in the liver. Alterations in lipid metabolism and cell cycle regulation are associated with the RFI phenotype. This project was supported by AFRI Competitive Grant no. 2011-68004-30214 from the USDA National Institute of Food and Agriculture.

Key Words: cattle, gene set enrichment analysis, residual feed intake

1497 Updating equations to estimate dry matter intake of Nellore and beef crossbred cattle. L. F. Costa e Silva*[1], S. C. Valadares Filho[2], P. P. Rotta[3], J. A. G. Azevedo[4], F. F. Silva[1], A. C. B. Menezes[1], and B. C. Silva[3], *[1]Universidade Federal de Viçosa, Viçosa, Brazil, [2]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [4]Universidade Estadual de Santa Cruz, Ilheus, Bahia, Brazil*.

Dry matter intake is the most important variable that affects animal performance, mainly in beef cattle due to economic impact and its complex gastrointestinal system with peculiar metabolic functions. A database with 1,459 animals, being 1,188 Nellore and 271 beef crossbred cattle, was developed to generate equations estimating DMI for animals raised on feedlot. Variables such as DMI, BW, metabolic BW (mBW), ADG, and level of concentrate (LC) were collected. First of all, a PROC CORR was used to evaluate which variables are significantly correlated with DMI. The variables mBW, LC, and ADG presented the highest correlation with DMI, and those were chosen to be part of the equations generated. The range of DMI in this database was from 2.96 to 12.3 kg/d whereas LC was from 0 to 100% and ADG was from −0.36 to 2.26. After all, statistical models were fitted by the cross-validation procedure. Also, differences between genetic group (Nellore and beef crossbred cattle) were evaluated, which allowed us to develop two different equations. Then, the following equations were developed to estimate DMI of Nellore and beef crossbred cattle, respectively: for Nelore cattle, DMI $= -2.406 + 0.064 \times LC - 0.00065 \times LC^2 + 0.070 \times BW^{0.75} + 4.384 \times ADG - 1.255 \times ADG^2$ ($R^2 = 0.797$), and for beef crossbred cattle, DMI $= -4.355 + 0.0598 \times LC - 0.00049 \times LC^2 + 0.128 \times BW^{0.75} + 3.974 \times ADG - 1.128 \times ADG^2$ ($R^2 = 0.717$). From this, if we derive these equations in function of level of concentrate, we can know at which amount of concentrate each genetic group is able to reach the maximum DMI. Therefore, Nellore cattle reach maximum DMI when 49.2% of concentrate is provided in diet whereas beef crossbred cattle reach this amount for 61.0% of concentrate. This statement proves that Nellore cattle are more sensible to high amounts of concentrate than beef crossbred cattle. Moreover, if we derive these equations in function of ADG, we are able to know at which ADG the animals reach maximum DMI. For Nellore and beef crossbred cattle, the maximum DMI is reached when

ADG is 1.75 and 1.76 kg/d, respectively. Therefore, Nellore cattle are more sensible when level of concentrate is increased in diet when compared with beef crossbred cattle.

Key Words: beef crossbred cattle, cross-validation, level of concentrate, Nellore

1498 Rumen bacterial species associate with residual feed intake in beef cattle.

A. A. Elolimy*[1], M. Abdelmegeid[1,2], J. C. McCann[1], D. W. Shike[1], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]Kafrelsheikh University, Kafrelsheikh, Egypt*.

Residual feed intake (RFI) describes an animal's feed conversion efficiency independent of phenotypic performance. The objective of this study was to quantify differences in ruminal bacteria between the most efficient animals and the most inefficient animals and any interaction with rumen sample fraction. One-hundred fifty Red Angus cattle were allocated to three groups according to sex and herd origin. Animals were fed in confinement for at least 78 d to determine the RFI category for each. Within each contemporary group, the two most efficient (n = 6) and least efficient animals (n = 6) were selected. Rumen solids and fluid were collected immediately after slaughter. Bacterial DNA extraction from the solid fraction included mechanical homogenization followed by enzymatic and bead beating lysis for all samples. Real-time quantitative PCR was used to examine the relative abundance of specific ruminal bacteria compared with the geometric mean of two universal 16S rRNA primers. Data were analyzed using the MIXED procedure of SAS 9.3. Fixed effects in the model included RFI category, rumen fraction, RFI × fraction, and sex. Individual animal was the experimental unit and incorporated into the statistical model as a random effect nested within group. Of the nine species evaluated, *Succinivibrio dextrinosolvens* was the most abundant, averaging 1.8% of 16S rRNA copy number. Results indicated most efficient cattle had a 6-fold decrease (P = 0.04) in relative abundance of *S. dextrinosolvens* and also had a 4-fold reduction (P = 0.02) in *Anaerovibrio lipolytica*. Although most efficient cattle tended (P = 0.09) to have greater relative abundance of *Eubacterium ruminantium*, a tendency (P = 0.10) for an RFI × fraction effect indicated the greatest differences were between the solid fraction of most efficient and least efficient cattle. Fraction effects were observed for *Butyrivibrio proteoclasticus* (P < 0.001) and *Selenomonas ruminantium* (P < 0.001) as each were increased within the solid fraction compared with the liquid. An RFI × fraction effect (P = 0.01) also was observed for *Fibrobacter succinogenes*, with a greater relative abundance in the liquid compared with the solid fraction for least efficient cattle. No effect of RFI or fraction was observed for *Megasphaera elsdenii* or *Prevotella bryantii*. These findings indicate large differences in RFI phenotypes in beef cattle are associated with bacterial species in the rumen, and they may have a role in conferring feed efficiency.

Key Words: bacteria, residual feed efficiency, rumen

1499 The association between body condition score, residual feed intake, and hyperketonemia.

F. M. Tiberio*[1], R. S. Pralle[1], C. A. Getschel[1], R. C. Oliveira[1], S. J. Bertics[1], K. A. Weigel[1], R. D. Shaver[1], L. E. Armentano[2], and H. M. White[1], *[1]Department of Dairy Science, University of Wisconsin, Madison, [2]University of Wisconsin – Madison, Madison*.

The transition period in dairy cows is associated with the onset of negative energy balance and body fat mobilization. Mobilized lipids can lead to excessive ketone production. The objective of this trial was to characterize the relationship between hyperketonemia (HYK) and milk production, BCS, and residual feed intake (RFI). Blood and milk samples were collected twice weekly from cows 5 to 18 d in milk (DIM) for a total of 4 samples. Hyperketonemia was diagnosed using the Precision Xtra Meter and defined as blood β-hydroxybutyrate (BHBA) ≥ 1.2 mmol/L. Cows were treated on diagnosis. Dry period (−28 DBCS), calving, and final blood sampling BCS was recorded. Previous midlactation production and DMI were used to calculate RFI by subtracting predicted energy intake from the observed energy intake. Effect of milk composition, milk yield, lactation number, BCS, and previous RFI on the observed maximum BHBA concentration (MAXBHBA) was determined using PROC MIXED of SAS 9.4. Least squares means ± SE are reported. Of the 570 cows sampled, 19.7% were diagnosed with HYK. Mean DIM at the first positive HYK test was 9 ± 0.9 d and the average BHBA concentration at the first positive HYK test was 1.53 ± 0.14 mmol/L. MAXBHBA was greater ($P \leq 0.05$) for multiparous cows compared with primiparous cows. Milk fat content was increased (4.33 vs. 4.69 ± 0.05%; $P < 0.0001$), milk protein content was decreased (3.60 vs. 3.40 ± 0.02%; $P < 0.0001$), somatic cell count was decreased, and milk yield was increased (44.02 vs. 47.47 ± 1.46 kg/d; $P < 0.0001$) in the first 30 DIM for cows positive for HYK compared with negative cows. Cows with a DBCS ≥ 4.0 had greater MAXBHBA (0.88 vs. 1.28 ± 0.08 mmol/L; $P \leq 0.05$) than cows with lower BCS. Cows that lost >0.75 BCS units after calving had greater ($P \leq 0.05$) MAXBHBA than cows that lost ≤0.75 BCS units. MAXBHBA was not significantly correlated to RFI. Prompt diagnosis and treatment of HYK appears to prevent HYK-associated decreases in milk production. Avoiding overconditioning of dry cows and excessive fat mobilization during the transition period may decrease HYK incidence; however, previous lactation RFI does not appear to be correlated to developing HYK.

Key Words: body condition score, hyperketonemia, residual feed intake

1500 Effects of arginine infusion through jugular vein on the milk performance and casein synthesis in midlactation cows. M. Z. Wang*, *Yangzhou University, Yangzhou, P. R. China*.

Previous studies show that milk protein yield increases with arginine infusion (Doepel and Lapierre, 2011). Our previous in vitro work by Chen et al. (2013) demonstrates that arginine increases casein protein synthesis in bovine mammary epithelial cells and that arginine plays an important role in the transcriptional regulation of casein genes and mTOR-related genes in bovine mammary epithelial cells (Wang et al., 2014). Subsequently, our Wistar rats feeding trail found that a 2x Arg group had significant effects on the mammary gland development and its casein protein synthesis (Hu et al., 2015). But whether arginine promotes the growth of the cow mammary tissue and casein expression is unknown. Therefore, this study was performed to investigate the responses of milk yield and milk composition for arginine infusion by midlactating Holstein cows. Six healthy lactating cows at similar lactation stages with similar weights, parities, milk yields, and body conditions were divided into 3 groups (2 for each group), casein model group (control group), arginine infusion group (37.66 g arginine contenting 12.10 g N/d), and alanine isonitrogen group (77.24 g alanine containing N 12.13 g N/d), respectively, in a 3 × 3 Latin square trail with a 7-d infusion plus a 15-d interval per period. The milk performance, casein content, and casein gene expression were detected. The results showed that at Day 5, the arginine infusion group was higher than the casein model group in the contents of milk protein and nonfat milk solids ($P < 0.05$), whereas at Day 6, the arginine infusion group was higher in milk fat content compared with the alanine isonitrogen group ($P < 0.05$). As for the milk casein contents, α-casein in the casein model group was lower than these in the other 2 groups ($P < 0.05$), β-casein had no difference between groups ($P > 0.05$), and κ-casein of the arginine infusion group was the highest among the groups ($P < 0.05$). In addition, arginine the infusion group had significantly higher expression in genes CSN1S1 and CSN1S2 ($P < 0.05$), and numerically higher expression in gene CSN3 compared with the other 2 groups. We therefore concluded that for the first time, arginine infusion increases the contents of α-casein and κ-casein in milk as well as their gene expressions in mammary tissue from dairy cows, which is contributed to the improvements of milk protein content and milk quality.

Key Words: arginine, casein, jugular infusion, milk performance

1501 Diet starch content and fermentability affects feed intake and milk yield of cows in the postpartum period. R. I. Albornoz*, *Michigan State University, East Lansing*.

The objective of this study was to evaluate the effects of diet starch content and fermentability fed during the postpartum (PP) period on DMI, yields of milk (MY) and milk components, and body reserves. Fifty-two multiparous Holstein cows were used in a randomized block design with a 2 × 2 factorial arrangement of treatments. Diets were formulated to 22 (LS) or 28% (HS) starch with dry ground corn (DGC) or high-moisture corn (HMC) as the primary starch source. Treatments were fed from 1 to 23 d PP and then switched to a common diet until 72 d PP to measure carryover (CO) effects. Treatment period (TP) diets were formulated for 22% forage NDF and 17% CP, and starch concentration was adjusted by substitution of corn grain for soyhulls. The diet for the CO period was formulated to 20% forage NDF, 17% CP, and 30% starch. Throughout the experiment, both DMI and MY were measured daily, and milk components, BCS, and back fat thickness (BFT) were measured weekly. During TP, DGC increased DMI by 2.2 kg/d compared with HMC ($P < 0.01$) but tended to increase DMI more with HS (3.4 kg/d) than LS (1 kg/d; interaction, $P = 0.12$). Treatments also interacted over time; DGC increased DMI throughout the TP for HS but only after the first week for LS compared with the HMC treatments ($P < 0.01$). There was no main effect of starch content on DMI. The effect of corn source diminished over time during the CO period ($P = 0.03$), with no main effects of treatment on DMI. Dry ground corn increased yields of milk by 2.6 kg/d ($P = 0.12$), 3.5% fat-corrected milk (FCM) by 4.3 kg/d ($P = 0.02$), fat by 165 g/d ($P = 0.03$), and protein by 165 g/d ($P = 0.01$) compared with HMC, with no effect of starch content throughout the TP. Starch source and content interacted ($P < 0.05$) to affect yields of fat and FCM during the CO period, which were greater for DGC-HS and HMC-LS (1.78 and 52.1 kg/d, respectively) than for DGC-LS and HMC-HS (1.62 and 48.6 kg/d, respectively). Dry ground corn tended to decrease BCS loss until the third week of TP ($P < 0.15$) compared with HMC but had no effect overall. No effects of treatment were detected for BFT during TP but HMC increased BFT 0.1 mm ($P = 0.04$) during the CO period. Ruminal fermentability of starch is an important consideration for diets of cows in the PP period.

Key Words: dry corn, fresh cows, high-moisture corn

1502 Effects of feeding a histidine-deficient diet on lactational performance of dairy cows.

F. Giallongo*[1], M. Harper[1], J. Oh[1], C. Parys[2], I. Shinzato[3], and A. N. Hristov[1], *[1]The Pennsylvania State University, University Park, [2]Evonik Nutrition & Care GmbH, Hanau, Germany, [3]Ajinomoto Co., Inc., Tokyo, Japan*.

A 10-wk randomized complete block design study with 24 Holstein cows (87 ± 22 days in milk and 630 ± 56 kg BW) was conducted to determine the effects of feeding a His-deficient diet on lactational performance of dairy cows. Following a 2-wk covariate period, cows were blocked by days in milk, milk yield, and parity and randomly assigned to one of the following 2 treatments: His-adequate diet (HAD; digestible His [dHis] supply of 75 g/d, or 2.8% of MP requirements) and His-deficient diet (HDD; dHis supply of 50 g/d, or 2.0% of MP requirements). Both HAD and HDD were supplemented with rumen-protected (RP) Met (Mepron; Evonik Nutrition & Care GmbH) and RP Lys (AjiPro-L; Ajinomoto Co., Inc.) supplying dMet and dLys at 2.5 and 2.4% and 7.5 and 7.2%, respectively, of MP requirements. At the end of the study, HDD was supplemented with RP His (an experimental product supplying 9.3 g/d of dHis; total dHis supply of 62 g/d, or 2.5% of MP requirements) for 9 d. The diets consisted of (DM basis) 45% corn and 20% alfalfa silages and 35% concentrates. Diets contained 16.3 and 16.2% CP, respectively, and supplied MP and NE_L in excess of cow requirements. Dry matter intake and yields of milk, energy-corrected milk, and milk protein were decreased ($P \leq 0.02$) by HDD (25.4, 37.6, 34.4, and 1.07 kg/d, respectively) compared with HAD (27.1, 40.5, 37.4, and 1.18 kg/d, respectively). Milk urea nitrogen was decreased ($P < 0.01$) by HDD vs. HAD. Feed and energy-corrected milk feed efficiencies, milk nitrogen efficiency, milk fat and protein concentrations, milk fat yield, and BW change of the cows were not affected by treatments ($P \geq 0.12$). Blood hemoglobin concentration was 5.4% lower ($P < 0.01$) in cows fed HDD compared with cows fed HAD, suggesting a provision of about 24 g of His from this endogenous depot during the 8-wk experimental period. Plasma His concentration was decreased ($P < 0.01$) by HDD vs. HAD. Supplementation of RP His increased DMI (26.6 vs. 25.1 kg/d; $P < 0.01$) but did not affect milk yield (36.0 vs. 34.8 kg/d; $P = 0.28$) compared with HDD during the last 9 d of the study. Overall, feeding a diet deficient in His but supplying adequate MP, Met, and Lys had negative effects on DMI and lactational performance of dairy cows. The effect on DMI was reversed when RP His was supplemented.

Key Words: dairy cow, dry matter intake, histidine

1503 The effect of metabolizable protein supply for dry Holstein dairy cows on periparturient feed intake, metabolism, and lactation performance.

K. M. Hultquist*[1], K. W. Cotanch[1], C. S. Ballard[1], H. A. Tucker[1], R. J. Grant[1], R. Suzuki[2], and H. M. Dann[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]ZEN-NOH National Federation of Agricultural Cooperative Associations, Tokyo, Japan*.

Some nutritionists increase MP supply for dry cows to improve subsequent lactation performance and health based on field observations. This study determined the effect of MP supply during the dry period on DMI, metabolism, and early lactation performance. Eighty Holstein cows that had completed ≥1 lactation were randomly assigned to treatments: 1) a 55-d dry period with approximately 84 g MP/kg DMI in the far-off (13.1% CP, 9.4% starch, and 51.7% NDF) and close-up (12.9% CP, 14.9% starch, and 47.0% NDF) diets (LMP55), 2) a 55-d dry period with approximately 84 g MP/kg DMI in the far-off diet (13.1% CP, 9.4% starch, and 51.7% NDF) and approximately 108 g MP/kg DMI in the close-up diet (14.5% CP, 15.1% starch, and 43.0% NDF; LHMP55), and 3) a 43-d dry period with approximately 108 g MP/kg DMI in a 1-group

diet (14.5% CP, 15.1% starch, and 43.0% NDF; HMP43). Close-up diets were fed for 3 wk before expected calving. Dry diets supplied ≥29 g Met/d and ≥91 g Lys/d. A fresh diet (15.6% CP, 21.7% starch, and 33.5% NDF) was fed for 2 wk and then a high diet (15.2% CP, 26.1% starch, and 30.2% NDF) was fed for 10 wk. Diets were modeled with CNCPS version 6.5. Cows were individually fed 1x/d, group housed, and milked 3x/d. Milk was sampled weekly. Coccygeal blood was collected −3 to 2 wk relative to calving. Data were analyzed as a completely randomized design by ANOVA with the MIXED procedure of SAS with model effects of treatment, time, and treatment × time. Metabolism and lactation performance were not improved by providing additional MP during the dry period compared with a lower MP diet that met the Met and Lys requirements.

Key Words: dry period, metabolizable protein, transition cow

1504 Meta-analysis to predict amino acids limiting dairy cattle performance. I. J. Lean*[1], M. B. De Ondarza[2], C. J. Sniffen[3], and K. E. Griswold[4], *[1]Scibus, Camden, Australia, [2]Paradox Nutrition, West Chazy, NY, [3]Fencrest, LLC, Holderness, NH, [4]Kemin Industries, Inc., Des Moines, IA*.

Meta-analytic methods were used to provide statistical relationships between estimated MP (EMP) AA supply (g or g/ME) and milk protein content, milk protein percentage, and milk yield in lactating dairy cows. Sixty-three research publications (258 individual observations) were identified through a search of published literature using 3 search engines and met the criteria for inclusion in the meta-analysis. An advanced nutrition model (CNCPS 6.5 with NDS platform; RUM&N Sas, Italy) was used to determine dietary nutrient parameters including EMP AA. Two approaches were used to analyze the data: 1) a mixed models weighted analysis with a random effect of study to determine whether the explanatory variables predicted cow responses and 2) a classical effect size meta-analytical evaluation of responses to treatment. Regardless of the analytical approach or method of expression (g or g/ME), EMP Met increased milk protein yield, milk protein percentage, or milk yield, confirming that it can be first limiting in lactating dairy cow diets. With a difference of 0.07 units EMP His (g/ME) (1.13 vs. 1.20 for control and treatment, respectively), effect size analysis determined that each additional unit of EMP His (g/ME) increased milk protein yield by 1.72 kg, identifying His as a possible limiting AA. Milk yield increased by 3.28 kg/unit of EMP Trp (g/ME) (0.60 vs. 0.616 for control vs. treatment, respectively). Milk true protein yield was improved by EMP Leu (g). Estimated MP Lys (g or g/ME) did not increase responses in production outcomes. However, mean EMP Lys supply was lower than typically recommended and the change with treatment was minimal (157 vs. 162 g; 6.36 vs. 6.38% MP). This meta-analysis supports other research indicating the positive impact of Met and His as limiting AA for protein synthesis and suggests Leu, Trp, and Lys be given greater consideration in future research.

Key Words: amino acids, meta-analysis, milk protein

1505 Influence of essential amino acid balancing postpartum on lactation performance by dairy cows through a meta-analysis. L. F. Ferraretto*[1], C. S. Ballard[1], C. J. Sniffen[2], and I. Shinzato[3], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Fencrest, LLC, Holderness, NH, [3]Ajinomoto Heartland Inc., Chicago, IL*.

A meta-analysis was performed to evaluate the impact of dietary individual essential AA concentration (g of AA/Mcal of ME) on lactation performance by dairy cows during the initial 4 wk of lactation. The data set comprised 20 unpublished feeding trials evaluating the effect of lysine or lysine/methionine supplementation. Diets were formulated with CPM/CNCPS, which provided a complete dietary AA profile. Data were analyzed using Proc Mixed of SAS with treatments as fixed effects and trial as a random effect. Positive relationships between methionine and milk and milk protein yields were observed ($P < 0.10$ and $P < 0.07$, respectively) during wk 1 to 4. Actual and energy-corrected milk (ECM) yields increased ($P < 0.04$ and $P < 0.08$, respectively) along with lysine concentration on wk 1, 2, and 4 whereas milk protein yield increased ($P < 0.03$) during the 4 initial weeks of lactation. Arginine and threonine were negatively related to milk fat content and yield ($P < 0.07$ and $P < 0.10$, respectively) on wk 3 and 4. Quadratic relationships between milk or milk protein yields and dietary concentrations of leucine and phenylalanine ($P < 0.06$ and $P < 0.09$, respectively) were observed during wk 1 to 4. Isoleucine concentration was negatively related to ECM and milk protein yields ($P < 0.09$ and $P < 0.07$, respectively) during wk 3 and 4 and to milk and milk fat yields ($P < 0.09$ and $P < 0.05$, respectively) on wk 3. Dietary valine was positively related to ECM ($P < 0.10$) and negatively related to milk protein concentration ($P < 0.08$) on wk 2 and 3. On wk 3 and 4, a positive relationship between milk yield and valine was observed ($P < 0.08$). Dietary histidine was positively related to milk yield ($P < 0.07$) but negatively related to milk protein content ($P < 0.06$) on wk 2 to 4. Concentration of tryptophan was negatively related to ECM ($P < 0.07$), milk fat content ($P < 0.03$), and yield ($P < 0.02$). Overall, benefits on lactation performance were observed with increased concentrations of methionine, lysine, valine, and histidine. In contrast, isoleucine and tryptophan were negatively related to lactation performance whereas arginine and threonine depressed milk fat. These results underscore the importance of AA balancing beyond lysine:methionine ratio when formulating diets for early lactation dairy cows.

Key Words: amino acids, lactation performance, postpartum

1506 Canola meal in dairy cow diets during early lactation increases production compared with soybean meal. S. A. E. Moore*[1] and K. F. Kalscheur[2], *[1]University of Wisconsin-Madison, Madison, [2]USDA-ARS, U.S. Dairy Forage Research Center, Madison, WI*.

Replacement of traditional protein sources such as soybean meal (SBM) with canola meal (CM) has resulted in increased milk yield for dairy cows in mid to late lactation. The objective was to determine performance of early lactation dairy cows fed diets formulated with CM or SBM as the main protein source at either a high (HI; 17.6%) or low (LO; 15.4%) CP concentration. Seventy-nine multiparous Holstein cows (mean ± SD, 2.76 ± 0.87 parity) received the treatment diet beginning at calving. Cows were blocked by calving date and maintained the same treatment assignment until the experiment ended at wk 16 of lactation. Diets were formulated to contain 39.6% corn silage, 15.4% alfalfa silage, and 45% concentrate mix on a DM basis. Canola meal was included at 19.4 and 11.9% DM, whereas SBM was included at 14.5 and 8.9% DM. Data were analyzed using the MIXED procedure of SAS. Body condition score and BW at calving and previous lactation mature equivalent 305 were used as covariates. Cows fed CM diets were has milk yield compared with cows fed SBM (mean ± SEM, 55.7 vs. 51.2 ± 0.97 kg/d; $P < 0.01$). Dry matter intake tended to be greater for cows fed CM diets (25.8 vs. 25.0 ± 0.34 kg/d; $P = 0.09$). The source of CP did not affect milk fat, protein, lactose, or total solids percentage. Decreasing dietary CP concentration increased milk fat (4.09 vs. 3.90 ± 0.07%; $P < 0.05$) and total solids (12.8 vs. 12.5 ± 0.95%; $P = 0.07$). Cows fed HI diets produced greater milk urea N (MUN) than cows fed LO diets (12.6 vs. 9.82 ± 0.22 mg/dL; $P < 0.01$). Milk urea N tended to be lower for cows fed CM compared with cows fed SBM (10.9 vs. 11.4 ± 0.22 mg/dL; $P = 0.10$). Milk fat, protein, lactose, and total solids were greater for cows fed CM in agreement with increased milk production. Dry matter intake, milk yield, milk protein percentage, and lactose percentage did not differ with varying CP concentration. Energy-corrected milk (ECM) was greater for cows fed CM compared with cows fed SBM (57.6 vs. 53.6 ± 0.95 kg/d; $P < 0.01$). Cows fed CM exhibited a trend in feed efficiency (ECM/DMI) compared with cows fed SBM (2.27 vs. 2.16 ± 0.38; $P = 0.06$). These data suggest milk yield and feed efficiency can be improved in early lactation with the inclusion of CM.

Key Words: canola meal, early lactation, transition period

1507 The effects of heat stress on protein metabolism in lactating Holstein cows. S. Gao[1], J. Guo[1], S. Quan[2], X. Nan[1], L. H. Baumgard[3], and D. Bu*[1,4,5], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, P. R. China, [2]The Animal Physiology and Biochemistry Laboratory of the Ministry of Agriculture in Nanjing Agriculture University, Nanjing, P. R. China, [3]Iowa State University, Ames, [4]Hunan Co-Innovation Center of Animal Production Safety, CICAPS, Changsha, P. R. China, [5]CAAS-ICRAF Joint Laboratory of Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, P. R. China*.

Independent of decreased feed intake, heat stress (HS) decreases the synthesis of milk protein, but the mechanisms responsible for the decrease are not clear. To research the direct (not mediated by feed intake) effect of HS on the synthesis of milk protein, four multiparous, lactating Holstein cows (101 ± 10 DIM, 574 ± 36 kg BW, and 38 ± 2.4 kg milk/d) were randomly assigned to four environmental chambers and divided into two groups, for two experimental periods of 18 d (a 9-d control period and a 9-d trail period). A crossover design was used and period 1 and 2 were separated by 30 d. Cows in the control period of both period 1 and 2 were exposed to constant thermal neutral (TN) conditions (20°C, 55% humidity, temperature–humidity index [THI] = 65.5, and 12 h light and dark cycles) and allowed to eat ad libitum for 9 d. The trial period of both period 1 and 2 included a HS ($n = 2$) group and a pair-fed TN (PFTN; $n = 2$) group and two groups exposed to HS (36°C from 0600 to 1800 h, 32°C from 1800 to 0600 h, 40% humidity, THI = 84.5, and 12-h light and dark cycles) and TN, respectively. The pattern and magnitude of reduced feed intake in the PFTN cows mirrored that of the HS cows. Compared with PFTN, HS decreased milk protein yield (17.7%) and content (4.1%) ($P < 0.05$). Heat stress increased before-feeding rumen liquid NH_3–N concentration compared with PFTN. Microbial CP, estimated by urinary excretion of purine derivatives, absorbed by intestine was not different between HS and PFTN cows. Heat stress decreased plasma AA (total AA and 5 specific of free AA) ($P < 0.05$) and plasma glucose ($P < 0.1$) and tended to increase BUN and increased urea nitrogen in urine and decreased NEFA. The decrease in plasma AA could have resulted from an increase in nonmammary AA oxidation or an increase in AA utilization for the synthesis of ligands involved with an acute phase protein response. Regardless, it appears blood AA utilization is reprioritized away from milk protein synthesis during HS.

Key Words: heat stress, milk protein, milk protein precursor, protein metabolism, restricted intake

1508 The effect of fructose infusion on dry matter intake in dairy cattle. R. Yair* and M. S. Allen, *Michigan State University, East Lansing*.

Loading of fructose or its analogs in mammals resulted in the accumulation of fructose 1-phosphate in the liver, sequestering organic phosphate (Pi), preventing ATP production, and most likely, as a consequence, increasing feed intake. The objectives of this work were to determine the effects of fructose and Pi infusions on feeding behavior of dairy cows to link hepatic ATP synthesis and feeding behavior and better understand the mechanisms controlling feed intake. Eight Holstein cows from 4 to 8 d postpartum (PP) were used in a duplicated 4 × 4 Latin square design experiment with one block each of multiparous and primiparous cows. Periods were 24 h, including a 2-h infusion and a 22-h recovery period. Treatments were arranged in a 2 × 2 factorial with fructose and Pi infusions as main effects. Cows were infused through a jugular catheter with 0.6 mol/h of fructose or glucose and 0.3 mol/h of NaCl or NaH_2PO_4. Effects of treatment on DMI were analyzed by ANOVA with repeated measures. Both fructose and Pi had hyperphagic effects; fructose increased DMI by 23.11% in the first 0.5 h of infusion compared with glucose (4.16 vs. 3.38 kg; $P < 0.01$) but the effect diminished over time with no effect detected by 1 h following the start of infusion. An interaction was detected between Pi and block ($P = 0.06$); NaH_2PO_4 increased DMI over the 2-h infusion period by 36.9% compared with NaCl for multiparous cows (8.41 vs. 6.14 kg; $P < 0.001$) but did not affect DMI for primiparous cows. Although effects of fructose on DMI hints at a connection between ATP synthesis and intake, Pi infusion was expected to reduce the effect of fructose by providing Pi for ATP synthesis rather than increasing intake. It is possible that the infused phosphate did not enter the liver and, therefore, did not have the expected effect. Reducing dietary P is essential to limit P excretion. Previous works showed that feeding P levels similar to this work (0.37% of DM) does not reduce DMI; however, such level might be insufficient specifically for cows in the PP period. Accordingly, further research to understand the hyperphagic effect of Pi might have implications for diet formulation for cows in the PP period. Better understanding the effects of Pi and fructose on hepatic ATP synthesis should provide insights on the connection between ATP synthesis and feeding behavior in dairy cows.

Key Words: dry matter intake, fructose, phosphate

1509 Effects of maternal nutrient restriction and melatonin supplementation on vascularity in ovine maternal and fetal jejunum. G. Jia*, *North Dakota State University, Fargo*.

Mounting evidence from previous studies suggests that melatonin, a neurohormone secreted by the pineal gland, likely plays a role in regulating nutrient delivery by regulating blood flow and improving vascular development. Therefore, this study was conducted to investigate the effect of maternal nutrient restriction and melatonin supplementation on vascular development of maternal and fetal small intestine in sheep. Thirty-one primiparous ewes were randomly assigned to receive 5 mg of melatonin/d (MEL) or no melatonin (CON) and 100 (adequate fed [ADQ]) or 60% (restricted [RES]) of nutrient recommendations from d 50 to 130 of gestation. At d 130 of gestation, ewes were euthanized and small intestinal (jejunal) tissues were collected from the dam and fetus. Intestinal capillaries were stained using Anti-CD31 (Abcam) followed by fluorescently labeled goat anti-rabbit secondary antibody (Alexa Fluor 633; Abcam). A DAPI stain was used to counterstain cell nuclei. Z-stacks of 15-μm-deep optical sections of jejunal tissues including intact villi were obtained using a confocal laser-scanning microscope (Zeiss AxioObserver Z1 with LSM700). Rendered 3D images were analyzed for capillary volume, which was expressed as a percentage of the total villous volume by using Imaris 7 software (Bitplane, South Windsor, CT). Data were analyzed as a completely randomized design, with a 2 × 2 factorial arrangement of treatments. In the maternal jejunum, there was no effect of maternal melatonin treatment or nutritional level on capillary volume density ($P > 0.59$); however, due to the large decrease in jejunal mass (RES only 0.69 of ADQ; $P < 0.001$), total jejunal vascularity was decreased ($P = 0.02$) in RES ewes vs. ADQ ewes. For the fetal intestine, neither capillary volume density nor total intestinal vascularity was affected by MEL supplementation or nutritional level, and a melatonin × nutrition interaction was not observed. Our data suggest that nutritional level affects maternal jejunal mass and total vascularity. However, neither melatonin supplementation nor nutritional level affected capillary volume density of maternal jejunum or capillary volume density or total vascularity of fetal intestine. Future research is needed to investigate whether maternal melatonin supplementation or nutritional level, or both, postnatally affect vascularity of the intestine.

Key Words: intestine, maternal melatonin treatment, vascularity

1510 Production level of dairy cows affects the extent of diet-induced milk fat depression. Y. Sun*, M. S. Allen, and A. L. Lock, *Michigan State University, East Lansing*.

The interaction between diet and milk production level on the risk of diet-induced milk fat depression (MFD) was evaluated in a crossover design experiment with a covariate period. Thirty-two mid- and late-lactation multiparous Holstein cows (14 rumen cannulated and 18 noncannulated), with a wide range and uniform distribution of milk yield (25 to 60 kg/d), were randomly assigned to treatment sequence within level of milk yield. Treatment diets and composition (% DM) were 1) control diet (CON), containing 24% starch, 33% NDF, 22% forage NDF, and 3% fatty acids, and 2) MFD-inducing diet (MFDI), containing 30% starch, 28% NDF, 17% forage NDF, and 4% fatty acids. Treatment periods were 28 d with the last 7 d for data and sample collection. The statistical model included the random effect of cow and fixed effects of period, treatment, cannulation block, and the interactions of cannulation block and treatment and of treatment and period. Linear and quadratic effects for the interaction between covariate milk yield and treatment were added to evaluate responses to treatment by level of milk yield. The MFDI decreased milk fat concentration (3.31 vs. 3.69%; $P < 0.01$) and tended to decrease milk fat yield (1.21 vs. 1.28 kg; $P < 0.10$) and 3.5% fat-corrected milk (35.6 vs. 37.0 kg; $P < 0.10$) compared with the CON. There was no main effect of treatment on DMI but treatments interacted with covariate milk yield ($P < 0.01$); MFDI decreased DMI for higher producing cows but increased DMI for lower producing cows. Linear interactions ($P < 0.10$) were detected between treatment and covariate milk yield for milk fat content and yields of milk fat and 3.5% fat-corrected milk; compared with CON, MFDI decreased content and yield of milk fat and 3.5% fat-corrected milk to a greater extent in higher producing cows than lower producing cows. The MFDI treatment decreased mean ruminal pH compared with CON (6.00 vs. 6.13; $P < 0.01$), and treatments interacted with covariate milk yield ($P < 0.10$), with less difference between CON and MFDI in higher producing cows than lower producing cows. Compared with CON, MFDI increased BCS change (0.18 vs. 0.11; $P < 0.01$) but response was not related to covariate milk yield. In conclusion, higher producing cows were at higher risk for milk fat depression induced by a high-starch, low-forage NDF diet containing supplemental fat.

Key Words: milk fat depression, production level, rumen pH

1511 Effect of production level and parity on responses of milk fat to supplementation with 2-hydroxy-4-(methylthio)butanoate. M. Baldin*[1], H. A. Tucker[2], and K. J. Harvatine[1], *[1]Penn State University, University Park, PA, [2]Novus International Inc., St. Charles, MO*.

We previously reported that high-producing cows are at higher risk of biohydrogenation-induced milk fat depression (MFD) and that 2-hydroxy-4-(methylthio)butanoate (HMTBa) reduced MFD in high-risk situations. The objective was to determine the relationship between production level and parity and responses of milk fat to supplementation with HMTBa (ALIMET; Novus International, Inc., St. Charles, MO). Twelve primiparous and 24 multiparous Holstein cows were used in a crossover design preceded by a 14-d pretrial period. The 35-d treatment periods included 28 d of a low-risk diet (31% NDF, 27% starch, and 4.2% EE) followed by 7 d of a moderate-risk diet (29% NDF, 30% starch, and 1% soybean oil). Treatments were control (corn carrier) and HMTBa (0.1% of diet DM). At the end of pretrial period, cows averaged 127 ± 33 DIM (mean ± SD) and 41 ± 9 kg milk/d (minimum 27 kg/d and maximum 61 kg/d). Milk yield and DMI were measured daily, and milk was sampled every 7 d and analyzed for fat and protein concentration. Data were analyzed using PROC MIXED with repeated measures, with cow by treatment as the subject, and the effect of treatment was tested at each time point. During the low-risk phase, no overall effect of treatment or treatment × time interactions were observed for DMI, milk yield, and milk fat and protein yield and concentration ($P > 0.2$ for all). Additionally, no treatment × parity or treatment × parity × time interactions were observed for milk fat concentration ($P = 0.2$) and yield ($P = 0.9$). During the moderate-risk phase, no overall effect of treatment or treatment × time interactions were observed for DMI, milk yield, and milk protein concentration and yield ($P > 0.4$ for all). 2-Hydroxy-4-(methylthio)butanoate supplementation maintained higher milk fat concentration (3.67 vs. 3.86; $P < 0.001$) and yield (1.37 vs. 1.47; $P < 0.001$) at the end of the moderate-risk phase. No treatment × parity or treatment × parity × time interactions were observed for milk fat variables ($P > 0.4$ for both). On d 35, responses (HMTBa; control) of milk fat concentration and yield correlated positively with pretrial milk yield (0.35 [$P = 0.03$] and 0.38 [$P = 0.02$], respectively). In conclusion, HMTBa maintained milk fat yield when cows were fed a diet with moderate risk of biohydrogenation-induced MFD and milk fat response to treatment was correlated with production level but not affected by parity.

Key Words: HMTBa, milk fat

1512 The timing of feed availability entrains the circadian rhythm of milk synthesis in dairy cattle. I. J. Salfer*, J. Y. Ying, and K. J. Harvatine, *Penn State University, State College, PA*.

Dairy cows have well-recognized natural daily rhythms of feed intake and milk synthesis. However, little is known about the regulation of these circadian rhythms. Variation in feed intake throughout the day results in a daily pattern of nutrient absorption, which may entrain the rhythm of milk synthesis. The objective of this study was to investigate the effect of the timing of feed availability on the daily rhythm of milk synthesis. Sixteen cows were randomly assigned to one of two treatment sequences in a crossover design. All cows were fed the same total mixed ration ad libitum for 16 h/d either during the day (DF) or the night (NF). Cows on the DF treatment had feed available from 0700 to 2300 h, whereas NF cows were offered feed from 1900 to 1100 h. Treatment periods were 17 d, and cows were milked every 6 h the last 7 d of each period. Milk samples were collected at each milking on the final 2 d of each period and analyzed for fat, protein, and milk urea nitrogen (MUN). Blood samples were collected on the final 3 d of each period to represent every 4 h over the day. Body temperature was monitored using vaginal temperature loggers. Data was analyzed as a crossover design in Proc Mixed and by cosine analysis to determine the phase (time at peak) and amplitude (peak to mean) of daily rhythms. Milk yield; fat and protein yield; and fat, protein, and MUN concentration displayed 24-h rhythms. Treatment modified the rhythm of milk yield, protein yield, and MUN, fat, and protein concentration ($P < 0.05$). Briefly, milk yield and lactose concentration were phase delayed by approximately 4 h in NF cows ($P < 0.05$). The daily rhythms of fat, protein, and MUN concentration of NF cows were phase advanced by 2, 10, and 3 h, respectively ($P < 0.05$). The rhythms of fat, protein, and MUN concentration exhibited a greater amplitude in NF compared with DF. Blood glucose followed a daily rhythm that was not affected by the timing of feed availability ($P > 0.10$). There was a daily rhythm of body temperature that was phase advanced 4 h by NF ($P < 0.05$). The timing of feed availability modified the rhythm of milk synthesis and body temperature in dairy cattle but did not modify the daily pattern of plasma glucose.

Key Words: circadian rhythm, food entrainment, milk synthesis

1513 Characterization of peripartum liver and skeletal muscle ceramide concentrations in lean and overweight Holstein dairy cows. S. Saed Samii*, J. E. Rico, and J. W. McFadden, *West Virginia University, Morgantown*.

Circulating sphingolipid ceramide is associated with the development of insulin resistance in overweight monogastrics. An increase in NEFA delivery to the liver can increase lipoprotein ceramide packaging and secretion. In turn, lipoprotein ceramide can antagonize insulin action in skeletal muscle. We recently discovered that ceramide concomitantly increases with hyperlipidemia in overweight cows transitioning from gestation to lactation. Considering evidence in monogastrics, our objective was to characterize the relationship between adiposity and liver and skeletal muscle ceramide concentrations. Multiparous Holstein cows were grouped by adiposity at d −28 prepartum as either lean (2.9 ± 0.1 BCS; $n = 7$; LEAN) or overweight (4.0 ± 0.2 BCS; $n = 7$; OVER). Diets were formulated to meet or exceed requirements. Blood samples were routinely collected from d −21 to 21, relative to calving, and liver and skeletal muscle biopsies were performed at d −21, −7, and 4. Liquid chromatography tandem mass spectrometry was used to quantify ceramide, monohexosylceramide (GlcCer), and lactosylceramide (LacCer). Data were analyzed as repeated measures using a mixed model with fixed effects of adiposity and time. Pearson's correlations were analyzed. Relative to LEAN, OVER experienced increased BCS loss, plasma NEFA, hepatic total lipid accumulation, and circulating ceramide (e.g., C24:0-ceramide) during the transition from gestation to lactation ($P < 0.05$). Comparable to plasma, C24:0-ceramide was the most abundant ceramide in the liver and muscle. To support a relationship between liver and plasma ceramides, plasma total ceramide and liver total ceramide were positively correlated during transition ($r = 0.39$, $P < 0.05$). Similarly, plasma C24:0-ceramide and liver C24:0-ceramide were positively correlated ($r = 0.41$, $P < 0.05$). Coinciding with an increase in circulating NEFA, hepatic total ceramide and C24:0-ceramide increased postpartum in OVER ($P < 0.05$). Liver total ceramide and C24:0-ceramide were positively correlated with plasma NEFA ($r = 0.44$ and 0.49, respectively; $P < 0.05$). Additionally, we observed an increase in postpartum hepatic C22:0-ceramide in OVER ($P < 0.05$). Hepatic total GlcCer tended to be increased postpartum for all cows ($P = 0.10$); however, hepatic total LacCer increased only in LEAN ($P < 0.05$). Muscle total ceramide and C24:0-ceramide levels were lower prepartum in OVER ($P < 0.05$). In contrast, postpartum muscle C16:0- and C24:0-ceramide were higher in OVER ($P < 0.05$). We conclude that enhanced lipolysis in overweight dairy cows increases hepatic ceramide synthesis to support ceramide accumulation in circulation. The ability of hepatic-derived ceramide to antagonize insulin action in extrahepatic tissues

during early lactation requires further investigation.

Key Words: ceramide, insulin resistance, peripartal dairy cow

1514 Variation in rumen epithelial fatty acid metabolism and cholesterol homeostasis contributes to different responses to the high-grain diet adaptation in beef cattle. K. Zhao*[1,2], Y. Chen[1], G. B. Penner[3], M. Oba[1], and L. L. Guan[1], *[1]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [2]College of Medicine, Xi'an Jiaotong University, Xi'an, P. R. China, [3]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada*.

Ruminal digestive disorders are common during high-grain diet transition. However, little is known about the mechanism regulating this process, especially at the transcriptional level. In this study, we conducted a genomewide transcriptome comparison of ruminal epithelia when cattle were exposed to a rapid high-grain transition. Transcriptome analysis of ruminal papillae, collected from 15 beef heifers when fed 3 different dietary steps during the transition (3, 75, and 92% grain), were performed using RNA-seq. Expression of 11,044, 11,322 and 11,282 genes were detected (with reads per million [RPM] > 1 in 15 heifers of each diet) under the 3, 75, and 92% grain diets, respectively. Principle component analysis showed that the transcriptome profile of rumen epithelia between the low-grain diet (LGD; 3%) and high-grain diets (HGD; 75 and 92%) were different. During the transition from 75 to 92% grain, the ruminal pH showed varied change patterns: decreased (DG; $n = 5$) or increased (UG; $n = 5$). When the ruminal tissue transcriptomes were compared between 75 and 92% grain diets (92 vs. 75%) in each group, the expression of some ketone body and cholesterol synthesis–related genes tended to be decreased in UG (*acetyl-CoA acetyl transferase 2* [*ACAT2*], *3-hydroxy, 3-methylglutaryl CoA synthase 1* [*HMGCS1*], *HMG-CoA reductase* [*HMGCR*], and *farnesyl diphosphate synthase* [*FDPs*]) ($P < 0.1$), whereas some other cholesterol biosynthesis- and ketogenesis-related genes tended to be increased in DG (*sterol regulatory element binding transcription factor 2* [*SREBF2*] and *HMG-CoA lyase* [*HMGCL*]) ($P < 0.1$). Furthermore, the proton and cholesterol efflux–related genes were increased (Na^+/H^+ *exchanger 3* [*NHE3*] and *ATP-binding cassette 1* [*ABCA1*]) in UG ($P < 0.05$), whereas *monocarboxylate transporter 4* (*MCT4*) showed a tendency to be decreased in DG ($P < 0.1$). These results suggest DG heifers may have greater intracellular cholesterol and a reduction in intracellular pH, which might imbalance the epithelial homeostatic status. Pathway analysis showed that the differentially expressed genes in DG were involved in the "T cell receptor signaling" and "complement and coagulation cascades" pathway, whereas UG might activate cell repair function through "p53 signaling pathway" and cell cycle arrest. Overall, the different gene networks controlling fatty acid metabolism and cholesterol homeostasis among individuals might account for the animal variation in ruminal responses during high-grain diet adaptation in beef cattle.

Key Words: beef cattle, high-grain diet, rumen transcriptome

1515 Dose response effect of acetate on milk fat synthesis in lactating dairy cows. N. L. Urrutia*[1], M. Baldin[1], J. Y. Ying[2], Y. Fan[1,3], K. J. Harvatine[1], and J. Carvalho[1], *[1]Penn State University, University Park, PA, [2]Penn State University, State College, PA, [3]China Agricultural University, Beijing, P. R. China*.

Acetate is the main source of energy and substrate for milk fat synthesis in the dairy cow; however, the effect of acetate supply on milk fat synthesis has not been investigated in high-producing cows. The objective was to investigate the dose-dependent effect of acetate on milk fat synthesis. Six ruminally cannulated multiparous lactating Holstein cows were randomly assigned to treatments in a 4 × 4 Latin square design. Treatments were 0 (control), 5, 10, and 15 mol/d of acetate. Acetate was neutralized to pH 6.1 with sodium hydroxide and continuously infused into the rumen in 5 L/d for 4 d with 7-d washout periods. Milk samples were collected daily. Blood and rumen samples were collected twice (before noon and after noon) on the last day of treatment. Time course data was analyzed as repeated measures in SAS and all other data was analyzed using JMP Pro. The model included the random effect of cow and period and the fixed effect of treatment. Rumen concentration of acetate ($P < 0.01$) and acetate:propionate ratio ($P < 0.001$) linearly increased before feeding (before noon) and rumen concentration of acetate ($P < 0.001$), butyrate ($P < 0.05$), and total VFA ($P < 0.01$) linearly increased after feeding (after noon) as acetate dose increased. Acetate infusions linearly increased rumen pH before feeding ($P < 0.005$). Dry matter intake, milk yield, and protein yield and concentration were not affected by treatments. Acetate dose had a quadratic effect on milk fat yield ($P < 0.001$) and a linear effect on milk fat concentration ($P < 0.001$). Fat yield increased 7, 16, and 14% and fat concentration increased 6, 9, and 11% at 5, 10, and 15 mol/d, respectively, compared with the control. Acetate linearly increased yield and concentration of palmitic acid and yield of de novo synthetized fatty acids (both $P < 0.001$). Acetate infusions had no effect on plasma NEFA, glucose, glucagon, or insulin but linearly increased plasma βHBA after feeding ($P < 0.01$). These results demonstrate that acetate supply has an impact on milk fat synthesis under normal dietary conditions and suggest that milk fat yield and concentration may be improved through dietary strategies that increase rumen acetate production.

Key Words: acetate, milk fat synthesis, rumen infusion

1516 Lipogenic gene network expression in mammary tissue in response to abomasal infusion of casein, glucose, and acetate into feed-restricted lactating cows. M. A. C. Danes*[1,2], F. Batistel[3], G. A. Broderick[4], M. A. Wattiaux[5], and J. J. Loor[3], *[1]Federal University of Lavras, Lavras, Brazil, [2]University of Wisconsin, Madison, [3]University of Illinois, Urbana, [4]Broderick Nutrition & Research, LLC, Madison, WI, [5]University of Wisconsin-Madison, Madison*.

Nutrients that are building blocks of the main milk components also can work as regulators of the synthesis of these products through cell signaling pathways regulated at the transcriptional level. Six Holstein multiparous cows, averaging 40 kg milk/d, were used in a 6 × 6 Latin square with 14-d periods. Cows were fed the same diet for 10 d in each period, after which they were feed restricted for 4 d to 85% of ad libitum intake and abomasally infused with 1 of 6 treatments: acetate (A) or glucose (G), each at 5% of ad libitum ME intake (Mcal/d); casein (C) at 15% of ad libitum MP intake (g/d); A + C (AC); G + C (GC); or a saline solution (S; negative control). The mean milk fat yield was 1.58, 1.55, 1.42, 1.65, 1.51, and 1.41 kg/d for A, G, C, AC, GC, and S, respectively. Mammary tissue was biopsied on the last day of each period. The expression of lipogenic gene networks was evaluated via quantitative RT-PCR of 11 genes. Data were log2 transformed and analyzed using the GLIMMIX procedure of SAS. Infusion of all nutrients upregulated ($P < 0.05$) *ACSS2*, *ACACA*, and *FASN*, which are involved in acetate activation and de novo fatty acid synthesis. Surprisingly, A alone did not cause a greater effect than C and G, but when AC was infused, the expression of these genes was the greatest (approximately 2- to 3-fold greater), suggesting a role of AA in regulating fatty acid synthesis. This was even more evident in the upregulation ($P < 0.05$) by AC of *FABP3*, encoding a cytosolic transport protein required for use of fatty acids in triacylglycerol synthesis. Acetate and AC upregulated *IDH1* (approximately 2- to 5-fold), which encodes the main enzyme responsible for NADPH synthesis in mammary cells. This response agreed with the gene data indicating an overall stimulation of fatty acid synthesis especially in the AC treatment. There was no treatment effect ($P > 0.05$) on *AGPAT6*, *DGAT1*, *LPIN1*, and *PPARG*. Unexpectedly, A downregulated ($P < 0.05$) the lipogenic transcription factor *SREBF1*, which previously has been associated with fatty acid synthesis regulation in mammary tissue during milk fat depression. However, the fact that AC induced a strong tendency ($P = 0.08$) for upregulation (2-fold) of the transcription regulator *RXRA* compared with S underscores a potentially important role in the nutritional regulation of milk fat synthesis. Results underscore the role of nutrients in regulating mammary fatty acid synthesis at the transcriptional level.

Key Words: milk fat synthesis, nutrigenomics

1517 The effects of feeding increasing concentrations of corn oil on energy metabolism and nutrient balance in finishing beef steers. K. E. Hales*, A. P. Foote, T. M. Brown-Brandl, and H. C. Freetly, *USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE*.

The use of added fat source is common in high-concentrate finishing diets. The objective of our experiment was to determine if feeding increasing concentrations of added dietary corn oil would decrease enteric methane production, increase the ME:DE ratio, and improve retained energy in finishing beef steers. Four treatments were used in a replicated 4 × 4 Latin square ($n = 8$; initial BW = 397 kg ± 3.89). Data were analyzed using a Mixed model with the fixed effects of period and dietary treatment and random effects of square and steer within square. Treatments consisted of 1) 0% added corn oil (Fat-0), 2) 2% added corn oil (Fat-2), 3) 4% added corn oil (Fat-4), and 4) 6% added corn oil (Fat-6). Dry matter intake or GE intake did not differ across diets ($P > 0.39$). As a proportion of GE intake, fecal energy loss and DE loss did not differ by treatment ($P > 0.27$); however, urinary energy loss tended to linearly decrease as corn oil increased in the diet ($P = 0.09$). Additionally, methane energy respired linearly decreased as corn oil increased in the diet ($P < 0.01$). No differences were detected in ME loss as a proportion of GE intake ($P > 0.98$); however, the ME:DE ratio linearly increased as corn oil increased in the diet ($P < 0.01$). No differences in retained energy or heat production as a proportion of GE intake were noted ($P > 0.59$). Dry matter digestibility did not differ across diets ($P > 0.36$). Digestibility of NDF as a proportion of intake quadratically responded, increasing from 0% corn to 4% corn oil and decreasing thereafter ($P = 0.02$). Furthermore, ether extract digestibility as a proportion of intake quadratically increased, increasing from 0 to 4% corn oil inclusion before reaching a plateau ($P < 0.01$). No differences were detected in OM digestibility across treatments ($P > 0.35$). From these data, we interpret that adding dietary fat decreases urinary energy loss and enteric methane production while decreasing NDF digestibility when included at more than 4% of dietary DM. Moreover, the ME:DE ratio linearly increases as dietary fat increases. The USDA is an equal opportunity provider and employer.

Key Words: dietary fat, energetics, finishing cattle

1518 Isolation and comparison of expression of novel glucose transporters, GLUT3 and GLUT14, in bovine uteroplacental tissues from days sixteen to fifty of gestation. M. S. Crouse*, J. S. Caton, K. J. McLean, P. P. Borowicz, L. P. Reynolds, C. R. Dahlen, and A. K. Ward, *Department of Animal Sciences, North Dakota State University, Fargo*.

Glucose transporters *GLUT3* and *GLUT14* previously have not been isolated in ruminant utero-placenta. The glucose transporter *GLUT14* is a duplicon of *GLUT3* with 95% shared homology. We hypothesized that maternal nutrition and day of gestation would impact mRNA expression of *GLUT3* and *GLUT14* in heifers and that there would be a difference in mRNA expression between the two transporters. Crossbred Angus heifers (n = 49) were synchronized, bred via AI, assigned to nutritional treatment (CON = 100% of requirements to gain 0.45 kg/d and RES = 60% of CON), and ovariohysterectomized on d 16, 34, or 50 of gestation (n = 6 to 9/d); nonpregnant (NP) controls were not bred and ovariohysterectomized on d 16 of the synchronized estrous cycle (n = 6). The resulting treatment arrangement was a 2 × 3 factorial + 1. Utero-placental tissues (caruncle [CAR], intercaruncular endometrium [ICAR], fetal membrane [chorioallantois] [FM], cotyledon [COT], intercotyledonary placenta [ICOT], and amnion [AMN]) were obtained from the pregnant uterine horn immediately after ovariohysterectomy. For NP controls, only CAR and ICAR were obtained. Comparison of expression across tissues was achieved by using NP CAR and ICAR tissues as the baseline. For FM, COT, ICOT, and AMN, NP endometrium served as the baseline. Expression of *GLUT3* was greater ($P < 0.05$) on d 50 in CAR compared with d 16 CAR. In FM, *GLUT3* was greater ($P < 0.05$) on d 16 compared with to d 50 FM. There also was a significant day × tissue interaction for *GLUT3*, which was greater ($P < 0.01$) in d 50 CAR compared with all other tissues and days. Expression of *GLUT14* in CAR was greater ($P < 0.05$) on d 50 compared with d 16 and 34. Direct comparison of the two genes showed that *GLUT14* expression was 5-fold greater ($P < 0.01$) than *GLUT3* expression across all days, tissues, and treatments. There was a significant gene × tissue interaction ($P < 0.01$), such that *GLUT14* was greater in ICAR and intermediate in CAR compared with FM and compared with *GLUT3* in all tissues. These data demonstrate that glucose transporters *GLUT3* and *GLUT14* are expressed in ruminant utero-placenta and also support our hypothesis that the magnitude of mRNA expression of *GLUT3* differs from that of *GLUT14*. There were no effects, however, of nutritional treatment or day of gestation within gene.

Key Words: early gestation, facilitated transporters, glucose

1519 Does microbial contamination affect in situ estimation of crude protein degradability of concentrate feedstuffs? A. C. B. Menezes*[1], S. C. Valadares Filho[2], P. P. Rotta[3], S. A. Santos[4], D. Zanetti[5], M. V. C. Pacheco[1], B. C. Silva[5], H. M. Alhadas[1], J. M. V. Pereira[1], and P. Pucetti[1], *[1]Universidade Federal de Viçosa, Viçosa, Brazil, [2]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [3]Colorado State University, Fort Collins, [4]Universidade Federal da Bahia, Salvador, Brazil, [5]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil*.

Microbial contamination (MC) is an important source of errors in in situ methods, thereby resulting in underestimation of CP degradability as well as overestimation of RUP content. The aim of this study was to use ^{15}N to estimate the MC of fractions soluble (a), potentially degradable (b), and the rate of digestion of the fraction b (kd) of CP as well as to estimate the necessary incubation time to estimate the RDP of energy and protein feeds considering two outflow rates (0.05 and 0.08 h^{-1}). Twelve concentrates were evaluated: six energy concentrates—wheat bran, rice meal, ground corn, ground sorghum, ground corn cob, and soybean hulls—and six protein concentrates—cottonseed meal 38% CP, soybean meal, ground bean, peanut meal, sunflower meal, and corn gluten meal. The feeds were divided into 4 groups and they were ruminally incubated in 4 crossbred bulls for 0, 2, 4, 8, 16, 24, 48, and 72 h. To estimate the MC of the incubated residues, ruminal bacteria were labeled with ^{15}N via continuous intraruminal infusion of $^{15}(NH_4)_2SO_4$. Ruminal digesta was collected for the isolation of bacteria before the first infusion of ^{15}N and after the infusion of ^{15}N during the collection period. There was no difference ($P = 0.74$) in the parameters a, b, and kd, corrected and uncorrected for MC. All the feeds followed an exponential model of degradation and the model fitted well to the data, except for corn gluten meal; probably, the maximum incubation time used here (72 h) was not long enough to allow an accurate estimation of degradation profile. The cluster analysis allowed ($R^2 = 0.944$) grouping feeds into three different groups according to the necessary incubation time to estimate RDP. The first was formed by the high-starch energy concentrates (15.4 ± 0.46 h), the second by the low-starch energy concentrates (6.8 ± 0.60 h), and the third by the protein concentrates (9.9 ± 0.41), considering kp 0.05 h^{-1}. In conclusion, the MC was low and nonsignificant, so correction of ruminal protein degradation is irrelevant for the concentrate studied. However, the chemical composition of these feeds resulted in different incubation times to estimate RDP content, and it needs to be considered in techniques used to estimate CP digestibility in the rumen and intestines.

Key Words: microbial contamination, protein, rumen degradable protein

1520 Effect of concentrate type (starch vs. fiber) and bicarbonate addition in grass silage–based diets on performance, diet digestibility, and enteric methane emissions in lactating dairy cows. A. Bougouin*, A. Ferlay, M. Doreau, Y. Rochette, S. Rudel, C. Lascoux, and C. Martin, *INRA-UMR1213 Herbivores, Saint-Genes-Champanelle, France*.

Cereals and corn silage diets are extensively used for high-yielding dairy cows and it is well established that altering dietary starch and fiber proportion results in methane (CH_4) emissions mitigation. With grass silage-based diets, quantitative evidence of CH_4 emissions reduction with high-starch concentrate is lacking. Therefore, the objective was to compare the effects of fiber-rich (F) or starch-rich (S) diets based on grass silage, supplemented or not with bicarbonate (Fb and Sb), on CH_4 emissions, diet digestibility and performance in dairy cows. Four multiparous lactating Holstein cows were used in a 4 × 4 Latin square design experiment of 4 periods of 4 wk each. Four dietary treatments were assigned based on grass silage 42%, hay 8%, and 50% F or S concentrate (DM basis), supplemented or not with sodium bicarbonate (1% DMI). Bicarbonate was used as a digestive regulator to lower the risk of ruminal acidosis appearance. Intake and milk production were measured daily and milk composition was measured weekly during the experiment. Methane production and diet digestibility were measured simultaneously for the last 5 d of each period when cows were in open respiration chambers. Feed efficiency (fat- and protein-corrected milk/DMI) was calculated using data from wk 4. Data were analyzed using mixed-effect models with cows as a random effect and period and treatments as fixed effects. Orthogonal contrasts were used to evaluate diet type or bicarbonate supplementation effects. The S and Sb diets induced less daily CH_4 emissions (417.5 and 393.9 g/d, respectively) than F and Fb diets (487.9 and 506.4 g/d, respectively) as well as a significant decrease in CH_4 intensity (−14% in g/DMI and −20% in g/FPCM). Dry matter intake was reduced by 3.5% with the starch diets compared with fiber diets ($P < 0.05$). Total tract digestibility of nutrients (DM, OM, and starch) and GE were lower ($P < 0.05$) for F and Fb diets than for S and Sb diets. Feed efficiency and milk yield and fat content were not different between starch and fiber diets ($P > 0.05$) but milk protein content was greater for the starch diets (+3%; $P < 0.05$). Bicarbonate had no effect on diet digestibility and CH_4 emissions ($P > 0.05$). However, milk fat content was higher ($P = 0.05$) with Sb than S, F and Fb diets. Feeding 50% starch-rich concentrate with grass silage diets, with or without bicarbonate, is an effective dietary approach for reducing methane emissions without altering diet digestibility and milk performance of dairy cows.

Key Words: concentrate type, dairy cow, methane emissions

1521 Validation of the GreenFeed system against model-predicted methane emissions. P. Huhtanen[1], M. Ramin[1], and A. N. Hristov*[2], *[1]Swedish University of Agricultural Sciences (SLU), Umeå, Sweden, [2]The Pennsylvania State University, University Park*.

The GreenFeed (GF) system (C-Lock Inc., Rapid City, SD) was introduced to estimate methane (CH_4) emission by measuring gas concentrations and flux when cattle visit a GF. The objective of the present study was to validate CH_4 measured with the GF system with model-predicted CH_4 emissions. Evaluation was based on 55 treatment means from dairy and beef cattle studies, in which CH_4 emission was measured by GF. Methane emission was predicted with the models of Yan et al. (2000; models Y1 and Y2), Ellis et al. (2007; E), Jentsch et al. (2007; J), and Ramin and Huhtanen (2013; R1 and R2). If the parameter values required in the models were not reported, tabulated values were used. A concentration of 18.5 MJ GE/kg DM was assumed for models based on GE intake. The evaluation was based on root mean squared prediction error (RMSPE) expressed as a proportion of observed mean. The RMSPE was divided into errors resulting from mean bias, slope bias, and random error across regression line. Observed mean (SD) CH_4 emission, DMI, and dietary concentrations of CP and NDF were 386 g/d (103), 18.4 kg/d (5.6), 172 g/kg DM (34), and 401 g/kg DM (81), respectively. Mean CH_4 emission estimated by GF was close to values predicted by models Y, J, and R that were developed from respiration chamber data (Table 1). However, observed CH_4 values were much higher than those predicted by model E, which was developed from

Table 1521. Predicted CH_4 emission (observed, 386 g/d).

					Distribution of MSE			P-value	
Model	Predicted CH4, g/d	R^2	RMSPE	% of mean	Mean bias	Slope bias	Random error	Mean bias	Slope bias
Y1	395	0.898	34.2	8.9	0.062	0.019	0.919	0.07	0.31
Y2	394	0.925	28.6	7.4	0.066	0.007	0.927	0.06	0.53
J	371	0.949	28.7	7.4	0.281	0.091	0.628	<0.01	<0.01
E	294	0.900	103.1	26.7	0.800	0.104	0.095	<0.01	<0.01
R1	382	0.952	23.2	6.0	0.034	0.037	0.929	0.18	0.15
R2	376	0.954	24.1	6.2	0.180	0.006	0.814	<0.01	0.55

data determined by different techniques. The RMSPE ranged from 6 to 9% of observed mean except model E, with most of the error due to random variation. The RMSPE was smaller when the effect of feeding level was taken into account compared with a model based only on intake (Y2 and J vs. Y1 and E). The RMSPE was further reduced when the effects of diet digestibility and composition were taken into account in addition to intake (R1 and R2 vs. the others). It is concluded that CH_4 emissions estimated by GF were consistent with values predicted by models derived from large data sets from respiration chamber studies.

Key Words: GreenFeed, methane, model

1522 Influence of colostrum on the microbiological diversity of the developing bovine intestinal tract.

S. L. Ishaq*[1], E. Bichi[2], S. K. Olivo[1], J. Lowe[2], C. J. Yeoman[1], and B. M. Alridge[2], *[1]Montana State University, Bozeman, [2]University of Illinois, Urbana-Champaign*.

The timely acquisition of high-quality colostrum is a proven factor in promoting intestinal health in young calves, including supporting epithelial function, host metabolism, immune development, and microbial colonization. Mucosal microbial colonization is influenced by the birth environment and local factors (e.g., temperature, pH, host epithelia types, etc.). We studied the impact of colostrum on the choreography of the neonatal calf microbiome. Twelve healthy, male Holstein calves were separated from their dams immediately following birth; fed 4 L of aseptically collected, high-quality colostrum; and housed, monitored, and fed separately for the remainder of the experiment. Postpartum maternal udder and vaginal scrapings were sampled. Fecal samples were collected throughout the experiment. Three animals were euthanized for necropsy, and intestinal samples were collected after colostrum administration (Day 1) and progressively during the trial (Days 3, 7, and 21). The V3 to V4 region of the microbial 16S rRNA gene was sequenced from digesta, mucosal scrapings, and feces. Mean diversity indices were highest in maternal udder (mean 217 OTU) and vaginal scrapings (mean 152 OTU) followed by colostrum samples. In calf samples, diversity increased over time in all locations; duodenal (mean 122 OTU) and proximal jejunal samples (mean 217 OTU) had the highest diversity. Calf duodenal, middle jejunal, and ileal (Day 7) digesta samples and fecal samples were most similar to maternal colostrum samples using Bray–Curtis dissimilarity. When clustering with multidimensional scaling (MDS) by OTU abundance, there was some clustering by location of sample: intestinal samples, stomach samples, and maternal samples clustered somewhat together, respectively. The proximal jejunum had the highest diversity at the phylum level and contained phyla Acidobacteria and Actinobacteria, which were not observed in abundance elsewhere. Firmicutes increased along the digestive tract (proximal to distal), along which Bacteroidetes and Proteobacteria decreased, the latter of which was much higher in mucosal scrapings ($P < 0.05$). Shifts in community diversity were observed in the first few days after birth, and neither digesta nor mucosal microbiota had distinguished themselves by 21 d (LDA, PERMANOVA, and ANOSIM). A large proportion of genera in colostrum, udder, vagina, and intestinal samples could not be classified. In combination, these results indicate that colostrum contributes significantly to the trajectory of the intestinal microbiome of the young calf. Further studies are needed to identify the mechanism and clinical significance of these results and to explore the identity and importance of the unknown taxa.

Key Words: host-associated microbiome

1523 Effects of starch feeding on lipopolysaccharide concentrations in rumen fluid and feces in fresh dairy cows.

J. Guo*[1], J. C. Plaizier[1], S. Li[2], S. E. William[3], E. Khafipour[1], and H. M. Dann[3], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [3]William H. Miner Agricultural Research Institute, Chazy, NY.*

The objectives of this study were to determine 1) the effect of dietary starch content on the concentrations of lipopolysaccharide (LPS) endotoxin in rumen fluid and feces of lactating dairy cows during 21 d after calving and 2) the correlation between rumen and fecal LPS concentrations. Multiparous ruminally cannulated Holstein cows ($n = 16$) were fed a close-up diet (44% NDF and 16% starch, DM basis) for 21 d before expected calving. For the first 21 d after calving, cows were fed either a low-starch diet (37% NDF and 21% starch, DM basis) or a high-starch diet (32% NDF and 27% starch, DM basis). Rumen and fecal samples were collected at 6 h after feeding on d −14, 1, 2, 3, 4, 5, 6, 7, 9, 13, 17, and 21. Data were analyzed as a completely randomized design by ANOVA with the MIXED procedure of SAS with model effects of treatment, day, and treatment × day, with day treated as a repeated measurement. Across days after calving, LPS concentrations in the rumen were higher (12,793 vs. 6,592 EU/mL; $P < 0.01$) for the cows on the high-starch diet compared with cows on the low-starch diet. Cows on the high-starch diet also had a higher LPS concentration in feces during this period (11,885 vs. 7,129 EU/mL; $P < 0.05$). Day after calving did not affect the LPS concentration in rumen fluid. However, days after calving affected this concentration in feces ($P < 0.01$) due to a relatively low fecal LPS concentration at Day 1 after calving. The concentrations of LPS in rumen fluid and in feces were positively correlated ($r = 0.35$, $P < 0.001$). Our results show that feeding higher starch during the first 3 wk of lactation increased LPS concentrations in rumen fluid and feces, indicating a greater risk for compromised rumen health and inflammation.

Key Words: fresh cows, lipopolysaccharide, starch

1524 Correlations between the abundance of specific ruminal bacteria with milk production and total tract digestibility of dairy cows fed live or killed yeast.

Y. Jiang*[1], R. M. Martins[2], I. M. Ogunade[1], M. A. Bamikole[3], F. Amaro[2], W. Rutherford[4], S. Qi[4], F. Owens[4], B. Smiley[4], K. G. Arriola[1], A. Oliveria[5], D. Vyas[1], C. R. Staples[6], and A. T. Adesogan[1], *[1]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [2]Federal University of Viçosa, Viçosa, Brazil, [3]Department of Animal Science, University of Benin, Benin, Nigeria, [4]DuPont Pioneer, Johnston, IA, [5]Department of Animal Sciences, IFAS, University of Florida, Gainesville, [6]Dep. of Animal Sciences, University of Florida, Gainesville*.

Ruminal nutrient metabolism and animal performance depend on the abundance and diversity of ruminal bacteria. The objective of this study was to examine the correlation between the abundance of different ruminal bacteria and total tract nutrient digestibility and milk production of dairy cows fed diets supplemented without or with live or killed *Saccharomyces cerevisiae*. Four ruminally cannulated lactating cows (284 + 18 DIM) were assigned to 4 treatments arranged in a 4 × 4 Latin square design with four 21-d periods. Cows were fed a nonacidotic total mixed ration (46.8% corn silage, 8.5% wet brewers' grain, and 44.7% concentrate, DM basis). The diet was not supplemented with yeast or supplemented with a low dose of live yeast (5.7×10^7 cfu/d), a high dose of live yeast (6.0×10^8 cfu/d), or a high dose of killed yeast (6.0×10^8 cfu/d before heating at 80°C). Ruminal fluid was collected 0, 2, 4, 6, 8, and 10 h after the morning feeding on d 21 and strained through cheese cloth to separate solid and liquid fractions. Microbial diversity was examined by Illumina MiSeq sequencing of the V4 region of the 16S rRNA gene. Data were analyzed using R (R Core Team, 2013). In the ruminal solid fraction, the *Fibrobacter* abundance was correlated ($r = 0.60$, $P < 0.05$) with milk fat concentration. Unknown genera in family Lachnospiraceae and RFP12 were negatively ($P < 0.05$) correlated with NDF digestibility ($r = -0.52$ and -0.56, respectively). An unknown genus (UT) in family Paraprevotellaceae was negatively ($P < 0.05$) correlated with milk fat and protein content ($r = -0.56$ and -0.52, respectively) and NDF digestibility ($r = -0.65$), whereas a UT in family Clostridiaceae was negatively correlated with CP digestibility ($r = -0.59$, $P < 0.05$). In the liquid fraction, *Prevotella* was negatively correlated with DMI and milk protein and fat content ($r = -0.64$, -0.59, and -0.53, respectively; $P < 0.05$). Unknown genera in families Succinivibrionaceae and Ruminococcaceae were positively correlated ($P < 0.05$) with ADF digestibility ($r = 0.63$) and milk yield ($r = 0.49$), respectively, whereas a UT in family Lachnospiraceae was negatively correlated with DM digestibility ($r = -0.56$, $P < 0.05$). This study revealed several uncultured or unknown ruminal bacteria that appear important as candidates for future studies because of their correlation with one or more indices of dairy cow performance.

Key Words: correlation, milk production, rumen bacteria

1525 Inhibiting the growth of *Escherichia coli* O157:H7 in alfalfa silage with silage additives.

I. M. Ogunade*[1], D. Kim[1], Y. Jiang[1], K. G. Arriola[1], A. A. P. Cervantes[1], D. Vyas[1], Z. G. Weinberg[2], and A. T. Adesogan[1], *[1]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [2]Department of Food Quality and Safety, Agricultural Research Organization, The Volcani Center, Rishon Le Zion, Israel*.

This study examined if adding microbial inoculants or propionic acid to alfalfa silages contaminated with *Escherichia coli* O157:H7 would inhibit the growth of the pathogen during or after ensiling. Alfalfa forage was harvested at the early bloom stage, wilted to a DM of 54%, chopped to 19-mm lengths, and ensiled after treatment with one of the following: 1) distilled water (Control), 2) 1×10^5 cfu/g of *E. coli* O157:H7 (EC), 3) EC and 1×10^6 cfu/g of *Lactobacillus plantarum* (EC+LP), 4) EC and 1×10^6 cfu/g of *Lactobacillus buchneri* (EC+LB), and 5) EC and 2.2 g/kg of propionic acid (EC+ACID). Each treatment was ensiled in quadruplicate in laboratory silos for 0, 3, 7, 16, and 100 d and analyzed for EC counts, pH, and organic acids. In addition, samples from d 100 were analyzed for counts of yeasts and molds and aerobic stability. Data were analyzed using the GLIMMIX procedure of SAS. The pathogen was detected in all silages until d 7, but by d 16, it was not detected in those treated with EC+LB and EC+LP, although it was still detected in EC and EC+ACID silages. However, by d 100, the pathogen was not detected in any silage. The rate of pH decrease to 5.0 was fastest for the EC+LP silage (7 d) followed by the EC+LB silage (16 d). Nevertheless, all silages had attained a pH less than 5.0 by d 100. The rapid decrease in pH in EC+LP and EC+LB silages was associated with higher ($P < 0.05$) lactate and acetate concentrations, respectively, relative to the other silages during the early fermentation phase (d 3 to 16). Propionic acid was detected only in the EC+ACID silage. Yeast counts were lowest ($P < 0.05$) in EC+LB and EC+ACID silages. Subsamples of all d -100 silages were reinoculated with 1×10^5 cfu/g of EC immediately after silo opening. When the pathogen was subsequently enumerated after 168 h of aerobic exposure, it was not detected in silages treated with EC+ACID, EC+LB, or EC+LP, which all had pH values less than 5.0, whereas the EC silage had a pH value of 5.4 and 2.3 log cfu/g of the pathogen. Certain bacterial inoculants can hasten the inhibition of *E. coli* O157:H7 during ensiling, and like propionic acid, they can also prevent its growth on silage contaminated with the pathogen after ensiling.

Key Words: alfalfa, *Escherichia coli* O157:H7, microbial inoculants

1526 Partial replacement of ground corn by citrus pulp or steam-flaked corn fed at two concentrate levels on rumen parameters and kinetics. V. B. Ferrari*, N. R. B. Cônsolo, F. Rodriguez, J. F. Penso, M. O. Frasseto, and L. F. P. Silva, *University of Sao Paulo, Pirassununga, Brazil*.

The objective of this study was to evaluate three nonstructural carbohydrate (NSC) sources and two levels of concentrate on rumen parameters and kinetic of beef steers, having sugarcane silage as roughage source. Six rumen-cannulated Nellore steers, 345.10 ± 14 kg initial BW and` 20 mo old, were individually fed and assigned to 2 noncontemporary 6 × 6 Latin squares (LS) in a 3 × 2 factorial arrangement of treatments. Treatments consisted of three sources of NSC—ground corn (GC) and 70% of GC replaced by pelleted citrus pulp (PCP) or by steam-flaked corn (SFC)—and 2 levels of concentrate in diet (CONC)—either 60 (60C) or 80% (80C) on a DM basis. The experiment had 6 periods of 14 d. Samples of ingredients, orts, and rumen contents were analyzed for chemical composition. Rumen fluid was collected for rumen pH, short-chain fatty acids (SCFA), and ammonia nitrogen ($N\text{-}NH_3$) analyses. Statistical analysis was conducted using PROC MIXED of SAS and the model included fixed effects of CONC, NSC, and interaction (CONC×NSC) as well as random effects of period, animal(LS), and LS. Treatment effects were considered significant at $P \leq 0.05$. Increasing concentrate from 60C to 80C decreased NDF turnover rate ($P < 0.01$) and rate of passage (k_p) ($P < 0.01$). It also decreased DM and NDF intake ($P < 0.01$). Partial replacement of GC by either SFC or PCP decreased DM and CP intake ($P < 0.01$). The PCP increased NDF turnover rate ($P = 0.02$) and decreased k_p ($P < 0.01$) compared with GC. There was a CONC × NSC effect ($P < 0.05$) on rumen mass of OM, DM, and FDN, where PCP with 60C decreased these parameters. Rumen mass of iNDF was not influenced by any treatment ($P > 0.05$). Pelleted citrus pulp increased rumen pH ($P < 0.01$) and acetic acid ($P < 0.01$), decreased propionic acid ($P < 0.01$), and, consequently, increased A:P ratio ($P < 0.01$). The PCP increased total tract digestibility of DM ($P = 0.01$) and NDF ($P < 0.01$) compared with GC. Partial replacement of GC by SFC decreased acetic acid ($P < 0.01$), increased starch digestibility ($P = 0.05$), and decreased rumen $N\text{-}NH_3$ ($P = 0.03$). In conclusion, replacing GC with PCP in sugarcane silage based diets reduced intake and rate of passage but increased rumen pH and digestibility. Replacing GC by SFC increased starch digestibility and reduced rumen $N\text{-}NH_3$.

Key Words: carbohydrate source, concentrate levels, sugarcane silage

1527 Recovering lactating dairy cows from diet-induced milk fat depression using corn with different starch degradabilities. B. M. Koch, L. E. Koch*, W. C. Bridges, and G. J. Lascano, *Clemson University, Clemson, SC*.

Milk fat depression (MFD) is a condition where milk fat synthesis is impeded by ruminal biohydrogenation intermediates and continues to be a problem in the dairy industry. The objective of this experiment was to determine the effects of feeding a high- or low–rumen degradable starch diet after diet-induced MFD. Six rumen cannulated Holstein cows (416.58 ± 25.23 kg $BW^{0.75}$ and184.33 ± 29.6 DIM) were used in a crossover design consisting of covariate, induction, and recovery periods. All cows were fed a high-fiber control diet for 10 d during the covariate period and then switched to a high-PUFA and low-fiber diet for 10 d to induce MFD. After induction, cows were switched to one of two recovery diets with the incorporation of low- or high–degradable starch corn sources (LDS: 35% and HDS: 75% 7-h starch degradability) for 18 d. Samples were collected every 3 d throughout the duration of the trial. All dependent variables were analyzed using PROC MIXED of SAS including the covariate period as a fixed effect and repeated measures. Starch level was similar (25%; $P = 0.76$) in all treatments; however, crude fat level was greater for the induction diet compared with HDS and LDS (9.89 vs. 4.47 HDS and 4.92 LDS). There was no treatment effect on DMI but the effect of day on DMI was significant across treatments ($P < 0.01$). No treatment differences were detected for CP, crude fat, ADF, starch, sugar, and ash intakes but there was a significant increase of all nutrient intakes on Days 16, 22, and 28 ($P \leq 0.01$). Milk yield, protein, lactose, and solids-not-fat were not affected by treatment but were markedly decreased by day ($P < 0.01$). Milk fat decreased during induction ($P < 0.01$) and was significantly reduced by Day 7 and 10 ($P \leq 0.01$). Total fatty acids less than C16:0 and *cis*-9, *trans*-11 CLA were not affected by treatment but increased on Days 4, 7, and 10 of induction ($P \leq 0.01$). *Trans*-10, *cis*-12 CLA was not different for HDS or LDS, yet there was a tendency of days to differ ($P = 0.09$), with Day 7 and 10 of induction having a greater concentration. Milk fatty acid profiles of the recovery diets were similar, milk yield was not affected, and DMI did not vary by treatment during this experiment. This suggests that using corn sources with starch degradability of up to 75% may be incorporated into rations to recover milk fat to normal levels.

Key Words: milk fat depression, polyunsaturated fatty acids, starch degradability

1528 Effects of field pea supplementation on digestibility and rumen volatile fatty acid concentration of diets containing high- and low-quality forages. H. L. Greenwell*[1], J. L. Gramkow[2], M. L. Jolly-Breithaupt[1], J. C. MacDonald[1], and K. H. Jenkins[3], *[1]University of Nebraska-Lincoln, Lincoln, [2]University of Nebraska, Lincoln, NE, [3]University of Nebraska, Scottsbluff, NE*.

Five ruminally fistulated steers (initial BW = 202 kg; SD = 20 kg) were used in a 5 × 6 Latin rectangle to evaluate the effects of supplementation on total tract digestibility of diets containing either high- or low-quality forages. Treatments were set up as a 2 × 3 factorial (forage quality × supplement type). The first factor was high-quality forage (HQ; 50% alfalfa and 50% sorghum silage, DM basis) or low-quality forage (LQ; 50% brome grass hay and 50% wheat straw, DM basis). The second factor was one of three supplements: control (CON), dry-rolled corn (DRC), or field peas (FP). Steers were supplemented at 0.43% of BW (DM basis). Periods lasted 14 d with a 9-d adaptation period and 4-d collection period. Data were analyzed using the mixed procedure of SAS and evaluating significance at $\alpha = 0.05$. There were no interactions between forage quality and supplement type on digestibility ($P \geq 0.25$). Dry matter intake, DM digestibility (DMD), OM intake (OMI), and OM digestibility (OMD; $P < 0.01$) were greater with HQ forage (6.13 kg/d, 63.1%, 4.96 kg/d, and 64.2%, respectively) than with diets containing LQ (4.71 kg/d, 49.1%, 3.60 kg/d, and 50.1%, respectively). The FP supplement ($P \leq 0.03$) increased DMI and OMD (6.14 ± 0.512 kg/d and 61.6 ± 1.94%, respectively) over steers receiving DRC (5.33 kg/d and 56.1%, respectively) or CON (4.80 kg/d and 53.8%, respectively); DRC and CON did not differ in intake or OMD. The acetate-to-propionate ratio (A:P) was affected by both forage and supplement where HQ was less than LQ (3.61 ± 0.05 and 4.09 ± 0.05, respectively) and DRC supplement produced lower A:P (3.58 ± 0.07) than FP and CON (3.99 and 3.97 ± 0.07, respectively), which were similar. Propionate proportions differed, with HQ tending ($P = 0.06$) to have greater concentrations than LQ. There was a supplement effect ($P = 0.01$) where DRC increased propionate proportion over CON and FP (18.88, 17.96, and 17.72 ± 0.27%, respectively). Acetate proportions ($P < 0.01$) were greater for the LQ forage (72.3 ± 0.58%) than for the HQ forage diet (64.8 ± 0.58%). A supplement effect was observed for acetate ($P < 0.01$), with CON and FP values greater than DRC. Supplementing FP in low- or high-quality diets increases DMI and OMD and may be an acceptable supplement for beef cattle.

Key Words: cattle, field peas, forage quality

1529 Effect of live yeast fed to natural-program beef steers during the finishing phase. L. A. Ovinge*, J. O. Sarturi, M. L. Galyean, P. R. B. Campanili, and L. A. Pellarin, *Texas Tech University, Lubbock*.

Growth performance, carcass characteristics, nutrient digestibility, and feeding behavior were evaluated in natural-program beef cattle fed steam-flaked corn–based finishing diets with 3 inclusion levels of live yeast (ABVista Inc., United Kingdom; 0, 25, and 50 g/steer daily). Steers ($n = 144$; 341 ± 20 kg) were blocked by BW and assigned to treatments in a randomized complete block experimental design. The natural program did not include the use of implants, ionophores, and antibiotics. Live yeast was included in a premix (cottonseed meal carrier) at 1% of the diet (DM basis). Data were analyzed using the GLIMMIX procedure of SAS with pen used as the experimental unit. Feed efficiency tended to be improved (quadratic, $P = 0.08$) between d 0 and 183, with steers fed 25 g/d of live yeast having a 4.3% greater G:F than the average of other treatments. Linear increases in premium Choice ($P < 0.01$) and Choice ($P = 0.05$) carcasses were observed as live yeast increased in the diet. Total tract nutrient digestibility increased (quadratic, $P < 0.01$) as live yeast increased, with steers fed 25 g/d having greater digestible DM (5.4%), OM (4.8%), NDF (22.1%), ADF (19.9%), hemicellulose (22.7%), CP (6.2%), and ether extract (2.5%) than the average of steers in the other treatments. Rumination (11%), eating time (8%), and chewing activity (20%) were not affected by treatments (% of 24-h evaluation). Live yeast included at 25 g/d in the finishing diet of natural-program beef steers improved dietary nutrient digestibility (except starch) and carcass quality grade and tended to improve gain efficiency, without affecting feeding behavior.

Key Words: digestibility, live yeast, natural program

1530 Effects of calcium–ammonium nitrate on in vitro fermentation of bahiagrass hay with supplemental molasses. D. D. Henry*[1], F. M. Ciriaco[1], R. C. Araujo[2], M. E. Garcia-Ascolani[1], P. L. P. Fontes[1], N. Oosthuizen[1], C. D. Sanford[1], T. M. Schulmeister[1], M. Ruiz-Moreno[1], G. C. Lamb[1], and N. DiLorenzo[1], *[1]University of Florida, North Florida Research and Education Center, Marianna, [2]GRASP Ind. & Com. LTDA, Curitiba, Brazil*.

A randomized complete block design was used to determine the effects of increasing amounts of calcium ammonium nitrate (CAN) on in vitro fermentation of bahiagrass hay (*Paspalum notatum*). In vitro fermentation consisted of 100 mL of a 4:1 buffer:ruminal fluid inoculum and 0.7 g of a substrate composed of 80:20 bahiagrass hay:molasses (DM basis) incubated for 48 h in 125-mL serum bottles. Three days (block) of incubation were performed. Duplicate bottles in each day were randomly inoculated and received 1 of 4 treatments: 1) negative control (no added NPN; NEG), 2) control (0.75% urea in

the substrate DM; CTL), 3) 1.2% CAN (0.38% urea and 1.2% CAN in the substrate DM; 1.2CAN), and 4) 2.4% CAN (2.4% CAN in the diet DM; 2.4CAN). Treatments CTL, 1.2CAN, and 2.4CAN were isonitrogenous. Two ruminally cannulated Angus crossbred steers (348 ± 29 kg BW) fed bahiagrass hay ad libitum and 2.27 kg (as is) of a 50:50 molasses:crude glycerol mixture, daily, were used as ruminal fluid donors. In vitro OM digestibility (IVOMD) was determined using the same amounts of substrate and inoculum from the in vitro batch culture. Data were analyzed using the mixed procedure of SAS with the fixed effect of treatment and the random effect of day. Means of duplicate bottles within day were considered the experimental unit. Contrasts were used to determine the effect of NPN (NEG vs. others), linear effects of CAN, and quadratic effects of CAN. Gas production increased ($P = 0.023$) when adding NPN (295 vs. 301 ± 2.0 mL/g of OM incubated for NEG vs. NPN, respectively) and linearly decreased ($P < 0.001$) as nitrate amounts increased. Adding NPN increased ($P = 0.015$) IVOMD, whereas a linear ($P = 0.001$) decrease occurred as nitrate increased; however, no difference ($P = 0.351$) was observed between CTL and 1.2CAN. Methane production linearly decreased ($P = 0.001$) with the addition of nitrate (4.81 vs. 0.65 ± 0.325 mmol/g substrate fermented for CTL vs. 2.4CAN, respectively). There was no effect ($P > 0.05$) of NPN or nitrate on total VFA (m*M*), acetate:propionate ratio, or molar proportions of any VFA analyzed. Added NPN improved the IVOMD of bahiagrass hay as expected in a CP-deficient forage. Inclusion of 2.4CAN reduces IVOMD and methane production, whereas 1.2CAN also reduces methane production without affecting IVOMD, implying a potential intervention to decrease methane emissions.

Key Words: fermentation, nitrate, nonprotein nitrogen

1531 A meta-analysis to estimate the net macromineral (calcium, phosphorus, magnesium, sodium, and potassium) requirements for maintenance in beef cattle. L. F. Costa e Silva*[1], S. C. Valadares Filho[2], P. P. Rotta[3], M. I. Marcondes[4], D. Zanetti[1], F. A. S. Silva[1], and M. V. C. Pacheco[1], *[1]Universidade Federal de Viçosa, Viçosa, Brazil, [2]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [4]Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Brazil*.

To predict mineral requirements for beef cattle, the factorial method has been the most used. A meta-analysis was used to estimate the net macromineral (Ca, P, Mg, Na, and K) requirements for maintenance and retention coefficient in Nellore cattle. A database composed by 278 animals from 8 studies conducted in tropical conditions was developed, being 134 bulls, 73 steers, and 71 heifers. Also, animals were from the following genetic groups: Nellore ($n = 196$), Zebu × Holstein ($n = 46$), Angus × Nellore ($n = 18$), and Simmental × Nellore ($n = 18$). Variables such as mineral intake and mineral excretion as feces and urine were collected where retained mineral was calculated by difference between mineral intake and mineral excretion. Therefore, the linear regression between retained mineral and mineral intake, as milligrams per kilogram BW, was performed to achieve the net mineral requirement for maintenance and retention coefficient where the intercept and slope were considered the net requirement for maintenance (NRM) and retention coefficient (RC) of each mineral, respectively. Then, the NRM for Ca, Na, and K were 9.85, 4.47, and 16.28 mg/kg BW, these values being below those recommended by the beef cattle NRC system of 15.4, 15.0, and 38 mg/kg BW. Considering a 300-kg animal, the NRM for Ca would be 2.95 and 4.62 g/d when estimated by this new proposal and the beef cattle NRC system. This shows that the Ca supply to meet endogenous losses is overestimated, which could reduce Ca excretion via feces to environment. Moreover, the NRM for P and Mg were 19.0 and 1.87 mg/kg BW, which are close to the recommendations of the beef cattle NRC system of 16.0 and 3.0 mg/kg BW. However, the RC for Ca, P, and Mg were 59.1, 79.6, and 23.5%, respectively, which are close to the recommendations of the beef cattle NRC system of 50, 68, and 17%, whereas the RC for Na and K were 34.2 and 48.8%, respectively, which are below those recommend by the beef cattle NRC system of 91 and 100%. Therefore, we believe that these values for the net macromineral requirement for maintenance and retention coefficient can improve the understanding of dietary mineral requirements of beef cattle.

Key Words: meta-analysis, mineral requirements, Nellore

1532 Effect of micronutrient source on mineral status and performance of steers fed low- or high-sulfur diets. S. J. Hartman*, O. N. Genther-Schroeder, and S. L. Hansen, *Iowa State University, Ames*.

The objective was to determine effects of hydroxy (HYD) or inorganic (ING) trace minerals within low- or high-S diets on mineral status and performance of beef steers. Forty-eight Angus-crossbred steers were blocked by BW (316 ± 2.8 kg) and assigned to a 2 × 2 factorial with low (0.25%; LS) and high S (0.53%; HS; additional S as $CaSO_4$). Trace minerals (TM) were supplemented as 10 mg Cu, 30 mg Zn, and 20 mg Mn per kilogram DM from ING (sulfates) or HYD (IntelliBond; Micronutrients USA LLC, Indianapolis, IN). Growing period (GP; 84 d) diets were corn silage based and finishing period (FP; 78 d) diets were corn based with 12% hay. Steers (6/pen) were fed via GrowSafe bunks, and the experimental unit was steer ($n = 12$/treatment). Plasma and liver mineral concentrations were determined at trial initiation and at the end of GP and FP. Data were analyzed as a 2 × 2 factorial using SAS; initial plasma and liver mineral concentrations were covariates in analysis.

High S decreased ($P < 0.01$) end of GP and FP liver Cu concentrations and tended ($P \leq 0.1$) to decrease plasma Cu at these times. At the end of GP, HS decreased ($P = 0.04$) plasma Zn concentrations and tended to decrease ($P = 0.1$) liver Zn concentrations. Final liver Cu concentrations were greater in ING steers than in HYD steers ($P < 0.01$). Liver Mn concentrations displayed S × TM effects ($P = 0.05$) at the end of GP and FP, where LS-HYD had greater Mn concentrations than HS-HYD, HS-ING, and LS-ING at the end of GP; however, HS-HYD final Mn concentrations tended to be greater than LS-HYD and LS-ING tended to be greater than HS-ING and LS-HYD. Growing period ADG and G:F displayed TM × S effects ($P \leq 0.06$) where LS-HYD had better efficiency and gain than LS-ING and HS-ING. Overall, HS-HYD was less efficient than HS-ING ($P = 0.02$) and LS-HYD ($P = 0.06$). Overall DMI, ADG, final BW, HCW, and marbling scores were not different ($P \geq 0.12$) due to treatment; however, steers consuming ING had larger REA ($P = 0.02$) than those fed HYD, and HS decreased ($P = 0.03$) back fat and yield grade compared with LS. In this study HS decreased markers of Cu and Zn status, and differential effects of ING vs. HYD minerals were noted, although all steers maintained adequate status.

Key Words: beef, sulfur, trace mineral

1533 Effect of anionic salts on rumen fermentation in a continuous culture system. A. L. Kenny*[1], J. L. Purdom[1], M. M. Masiero[1], J. P. Jarrett[2], T. J. Wistuba[2], and M. S. Kerley[1], *[1]University of Missouri, Columbia, [2]Phibro Animal Health Corporation, Quincy, IL*.

The objective was to determine if anionic salt products (AS), commonly used to lower dietary cation–anion difference (DCAD) in prefresh dairy cattle diets, altered ruminal digestion, microbial fermentation, or microbial yield in a single-flow continuous culture system. Two consecutive experiments were conducted using 24 fermenters inoculated with rumen fluid from two lactating Holstein cows. For Exp. 1, fermenters were fed a basal diet twice daily (47.12 g DM/d; 37% wheat hay, 26% corn silage, 12.5% soybean meal, 11% soy hulls, and 13.5% supplement on a DM basis). Treatments (0.19 g/d) were added directly to randomly assigned fermenters (4/treatment) and consisted of control (CON; basal diet only), soybean meal (SBM), urea (URE), chloride and sulfur containing AS blend (CSB), glutamic acid fermentation product (GAF), and hydrochloric acid based product (HCB). In Exp. 2, the same basal diet was used except CSB and GAF treatments were blended to the basal diet at 0.077 and 0.146 g/d, respectively, and other treatments were blended to achieve 0.19 g/d (representing approximate adjustments for equivalent DCAD content from respective AS). Diets were fed for 7 d with 4 d of adaptation and 3 d of sampling. Passage rate was 5.47% for Exp. 1 and 4.83% for Exp. 2. Fermenter samples for VFA and ammonia analysis were collected at 0 and 4 h after the morning feeding. Outflow was collected daily, and fermenter content was collected at the end of the experiment. Data were analyzed as a completely randomized design with fermenters as the experimental unit, using the MIXED procedure of SAS (version 9.3; Cary, NC). In Exp. 1, NDF digestibility (%) tended to be lower ($P = 0.088$) for GAF (31.9) and HCB (33.0) compared with the other treatments except SBM (37.4). Ammonia concentration (mg NH_3 N/dL) for URE was greater (22.2; $P < 0.01$) than for the other treatments, with CSB greater (19.5; $P < 0.04$) than SBM (18.3) and CON (18.5). These differences were not found in Exp. 2. In both experiments, there were no effects on OM, CP, or ADF digestibility; microbial efficiency; microbial flow; or VFA. Differences in NDF digestibility and ammonia concentration between Exp. 1 and Exp. 2 may be due to run-to-run variability. In conclusion, adding anionic salt products to a prefresh dairy cattle diet had no detrimental effects on ruminal digestibility or microbial fermentation and yield.

Key Words: anionic salts, continuous culture, rumen fermentation

1534 Effects of prepartum dietary cation–anion difference and source of vitamin D on dairy cows: Vitamin D, mineral, and bone metabolism. R. M. Rodney*[1,2], N. Martinez[3], E. Block[4], L. L. Hernandez[5], C. D. Nelson[6], P. Celi[7], J. E. P. Santos[6], and I. J. Lean[1,2], *[1]University of Sydney, Camden, Australia, [2]Scibus, Camden, Australia, [3]Department of Animal Sciences, University of Florida, Gainesville, [4]Church and Dwight Animal Nutrition, Ewing, NJ, [5]Department of Dairy Science, University of Wisconsin, Madison, [6]University of Florida, Gainesville, [7]Faculty of Veterinary and Agricultural Sciences, The University of Melbourne, Parkville, Australia*.

This 2 × 2 factorial study evaluated the effects of feeding dairy cows diets containing either calcidiol or cholecalciferol (3 mg/11 kg of diet DM) and positive (+130 mEq/kg) or negative (−130 mEq/kg) dietary cation–anion difference (DCAD) on vitamin D, mineral, and bone homeostasis during transition. Pregnant Holstein cows ($n = 79$) were blocked by parity and milk yield and randomly allocated to treatments from 255 d of gestation until calving. All groups of cows were then fed on identical lactating cow diets until 49 d after calving. Blood samples were taken thrice weekly prepartum and after calving until d 30 of lactation, with additional samples taken at 0, 1, and 2 d postpartum, for analysis. Milk yield and composition were recorded for the first 49 DIM. Feeding calcidiol increased concentrations of calcidiol pre- (235.1 ± 6.18 vs. 60.3 ± 6.25 ng/mL) and postpartum (214.8 ± 4.85 vs. 59.13 ± 4.90 ng/mL) and calcitriol prepartum (55.66 ± 1.62 vs. 51.05 ± 1.64 ng/mL) when compared with feeding cholecalciferol. Feeding negative vs. positive DCAD increased prepartum

concentrations of calcitriol (58.0 ± 1.61 vs. 48.3 ± 1.65 pg/mL) but decreased calcidiol (136.0 ± 6.17 vs. 160.4 ± 6.26 ng/mL) and cholecalciferol (6.8 ± 0.41 vs. 9.7 ± 0.42 ng/mL) prepartum and calcidiol, cholecalciferol and calcitriol postpartum (131.3 ± 4.84 vs. 144.4 ± 4.91 ng/mL, 3.7 ± 0.28 vs. 4.9 ± 0.28 ng/mL, and 98.0 ± 4.29 vs. 117.5 ± 4.34 pg/mL, respectively). After calving, calcitriol was higher in parous than nulliparous cows. Blood calcium increased in cows fed calcidiol (2.45 ± 0.02 vs. 2.34 ± 0.02 and 2.27 ± 0.01 vs. 2.25 ± 0.01 m*M* for pre- and postpartum, respectively). Calcium concentrations in the negative DCAD group were lower before calving, compared with the positive DCAD group (2.36 ± 0.2 vs. 2.43 ± 0.2 m*M*), but higher postpartum (2.29 ± 0.01 vs. 2.23 ± 0.01 m*M*). Feeding negative DCAD lowered blood pH (7.44 ± 0.01 vs. 7.49 ± 0.01) compared with positive DCAD prepartum but not postpartum. There was no effect of vitamin D or DCAD on blood osteocalcin, PTH, adiponectin, leptin, or serotonin concentrations. Nulliparous cows had higher blood concentrations of osteocalcin and crosslaps than parous cows. Cows fed calcidiol produced 3.70 ± 1.2 kg/d more 3.5% fat- and energy-corrected milk than those receiving cholecalciferol.

1535 The net macromineral (calcium, phosphorus, magnesium, sodium, and potassium) requirements for growth in beef cattle estimated by meta-analysis.

P. P. Rotta*[1], S. C. Valadares Filho[2], L. F. Costa e Silva[3], M. I. Marcondes[4], A. C. B. Menezes[3], M. V. C. Pacheco[3], T. E. Engle[5], and B. C. Silva[1], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Universidade Federal de Viçosa, Department of Animal Science, Viçosa, Minas Gerais, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Brazil, [4]Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Brazil, [5]Colorado State University, Fort Collins*.

To predict mineral requirements in beef cattle, the factorial method has been the most used. A meta-analysis was used to estimate the net macromineral (Ca, P, Mg, Na, and K) requirements for growth in Nellore cattle. A database composed by 873 animals from 21 studies conducted in tropical conditions was developed, being 411 bulls, 255 steers, and 157 heifers. Also, animals were from the following genetic groups: Nellore (n = 473), Zebu × Holstein (n = 149), and beef crossbred cattle × Nellore (n = 250). The net mineral requirement was calculated using the following allometric model: $Mi = a \times EBW^b$, in which Mi is the amount of each mineral in the body, EBW is the empty body weight, and a and b are parameters of the model. When differences were observed for sex (bulls, steers, and heifers) and genetic group (Zebu, dairy crossbred, and beef crossbred cattle), distinct equations were separately generated. For crossbreeding, differences between dairy crossbreeds and beef crossbreeds were not verified ($P > 0.05$) for any mineral, which allowed us to analyze genetic group such as Zebu and crossbred cattle. Moreover, the allometric plateau method was used to reach the empty body weight at which animals achieve maturity for mineral retention and, after this point, there are only mineral requirements for maintenance. Therefore, differences regarding sex were observed for Ca and Na, allowing us to generate different equations for bulls, steers, and heifers. Also, from the database used in this study, bulls establish their need for Ca and Na when they reach 432 and 424 kg of EBW, respectively, whereas for steers, the EBW to reach maturity of these minerals were 421 and 481 kg, respectively. For heifers, the EBW were 432 and 405 kg for Ca and Na, respectively. In the case of P, Mg, and K, differences were verified for genetic group where zebu cattle establish the need for P, Mg, and K for growth when the EBW is 522, 427, and 460 kg, respectively. Moreover, considering crossbred cattle, the estimate of EBW for reaching maturity of P, Mg, and K is 469, 433, and 492 kg, respectively. Therefore, we believe that the equations for the net macromineral requirement for growth can improve the understanding of dietary mineral requirements of beef cattle and contribute to correct supply of minerals in diet reducing losses and environment pollution.

Key Words: beef cattle, mineral, requirement

1536 The effect of decreasing dietary cation–anion difference in the prepartum diet on urine mineral excretion and blood energy metabolite concentrations in multiparous Holstein cows.

B. M. Leno*[1], C. M. Ryan[1], T. Stokol[2], K. Zanzalari[3], D. Kirk[4], J. D. Chapman[4], and T. R. Overton[1], *[1]Cornell University, Department of Animal Science, Ithaca, NY, [2]Cornell University College of Veterinary Medicine, Department of Population Medicine and Diagnostic Sciences, Ithaca, NY, [3]Phibro Animal Health Corp., Quincy, IL, [4]Phibro Animal Health Corporation, Quincy, IL*.

The objective of this study was to determine the effect of decreasing dietary cation–anion difference (DCAD) in the prepartum period on prepartum urine mineral excretion and concentrations of energy metabolites in plasma in the periparturn period. Multiparous Holstein cows (n = 89) were randomly allocated to one of three prepartum diets with decreasing DCAD, CON (+18.3 mEq/100 g DM), MED (+5.9 mEq/100 g DM), or LOW (−7.4 mEq/100 g DM), beginning at 24 d before expected parturition and individually fed. Cows were fed a common postpartum diet from parturition until 63 d in milk. Urine samples collected 1x before treatment assignment and 1x/wk prepartum were analyzed for mineral and creatinine concentrations. Blood samples were collected 1x before treatment assignment, 2x/wk prepartum, 2x/24 h postpartum, and 3x/wk through 21 d postpartum. Repeated

measures analysis was conducted using the MIXED procedure of SAS with linear and quadratic effects of decreasing prepartum DCAD as contrasts. Pearson's correlation coefficient for the association between urine pH and urine Ca-to-creatinine ratio was determined using the CORR procedure of SAS. Least squares means or geometric means and 95% confidence intervals are presented. No difference in prepartum or postpartum concentrations of NEFA or β-hydroxybutyrate was observed for the treatment groups. A trend for a quadratic effect on postpartum plasma glucose was observed (CON = 50.0 mg/dL [48.6–51.4], MED = 50.8 mg/dL [49.4–52.1], and LOW = 48.6 mg/dL [47.2–50.0]; $P = 0.09$). No effect of treatment on Mg excretion was observed; however, as calving approached, the ratio of urine Mg to creatinine decreased in all groups ($P < 0.01$). A quadratic effect on mean ratio of urine Ca to creatinine was observed (CON = 0.03 [0.02–0.04], MED = 0.07 [0.06–0.09], and LOW = 0.33 [0.27–0.44]; $P < 0.01$). A quadratic effect on estimated grams of Ca excreted, based on a creatinine excretion rate of 29 mg/kg of BW per day, also was observed (CON = 0.7 g/d [0.6–0.9], MED = 1.7 g/d [1.4–2.0], and LOW = 8.2 g/d [6.8–10.0]; $P < 0.01$). Urine pH and urine Ca-to-creatinine excretion ratio were highly correlated ($r = -0.81$, $P < 0.01$). Feeding decreasing DCAD prepartum did not significantly alter concentrations of energy metabolites in plasma in the peripartum period. Urine Ca excretion greatly increased when cows were fed the lowest DCAD, suggesting greater Ca flux prepartum, which likely contributed to improved Ca status postpartum.

Key Words: dietary cation–anion difference, energy metabolism, mineral excretion

---

1537 The effect of decreasing dietary cation–anion difference in the prepartum diet on plasma haptoglobin concentrations and incidence of cytological endometritis in multiparous Holstein cows. B. M. Leno*[1], C. M. Ryan[1], R. O. Gilbert[2], K. Zanzalari[3], D. Kirk[4], J. D. Chapman[4], and T. R. Overton[1], *[1]Cornell University, Department of Animal Science, Ithaca, NY, [2]Cornell University College of Veterinary Medicine, Department of Clinical Sciences, Ithaca, NY, [3]Phibro Animal Health Corp., Quincy, IL, [4]Phibro Animal Health Corporation, Quincy, IL*.

The objective of this study was to determine the effect of decreasing dietary cation–anion difference (DCAD) in the prepartum period on concentration of haptoglobin in plasma in the peripartum period and incidence of cytological endometritis. Multiparous Holstein cows ($n = 89$) were randomly allocated to one of three prepartum diets with decreasing DCAD, CON (+18.3 mEq/100 g DM), MED (+5.9 mEq/100 g DM), or LOW (−7.4 mEq/100 g DM), beginning at 24 d before expected parturition and individually fed. Cows were fed a common postpartum diet from parturition until 63 d in milk. Plasma samples were analyzed for haptoglobin concentrations at wk −1 and d 3, 5, 7, and 14. A low-volume uterine lavage was conducted at approximately 8 d in milk (range 4–12 d; first lavage) and again at approximately 50 d in milk (range 40–60 d; second lavage). Cytology slides were prepared and 200 cells (excluding erythrocytes) were counted per slide to determine the percent polymorphonuclear leukocytes (PMN). The MIXED procedure of SAS, with linear and quadratic effects of decreasing prepartum DCAD as contrasts, was used to analyze plasma haptoglobin as a repeated measure and percent neutrophils present at the first and second lavage. Geometric means and 95% confidence limits are presented. Fisher's exact test was conducted to determine associations of treatment with incidence of cytological endometritis (CE) at second lavage (>10% PMN) using the FREQ procedure of SAS. A linear trend for lower plasma haptoglobin with decreasing DCAD was observed (CON = 0.7 mg/mL [0.6–0.8], MED = 0.6 mg/mL [0.5–0.7], and LOW = 0.6 mg/mL [0.5–0.7]; $P = 0.12$). No effect of prepartum DCAD on percent PMN at first or second lavage was observed. Incidence of CE was not different between treatment groups (CON = 10/30, MED = 7/30, and LOW = 9/29; $P = 0.70$). Decreasing prepartum DCAD did not alter PMN presence in endometrial cytology or incidence of cytological endometritis but tended to reduce haptoglobin in the peripartum period, suggesting decreased inflammation in those cows.

Key Words: cytological endometritis, dietary cation–anion difference, haptoglobin

1538 Influence of molybdenum concentration, pH, and transit time on the in vitro bioaccessibility of sulfur. J. Hawley* and E. B. Kegley, *Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville*.

In vitro bioaccessibility (IVBA) methods are useful to provide knowledge on possible interactions between antagonists and the factors involved in digestion on the potential to influence the physiological solubility of minerals for absorption into the animal. This study was conducted to evaluate the influence of Mo concentration, pH, and transit time on the S IVBA of S sources frequently used in beef cattle rations. In vitro digestions ($n = 540$) were used in a 3 × 5 × 3 × 3 factorial arrangement of treatments (4 replicates/treatment) to determine the effects of Mo concentration (no additional Mo [No Mo], 1 [Low Mo] ppm Mo added, or 5 [High Mo] ppm Mo added) on the S IVBA of S sources (no S source [Control], corn gluten feed [CGF], dried distillers' grains [DDG], chemical grade sodium sulfate [Na_2SO_4–CG], or feed grade sodium sulfate [Na_2SO_4–FG]) using hydrochloric acid solutions (pH = 2, 4, or 6), transit times (0.5, 2, or 6 h), and agitation to simulate the physiologic conditions that occur in the gastrointestinal environment. Sulfur IVBA in the processed samples was estimated by dividing extractable S in the in vitro digestions by

the S concentration in the S source being assayed. Sulfur and Mo concentrations were determined by inductively coupled plasma spectroscopy. Sulfur IVBA differed ($P < 0.0001$) by S source (0.0, 44.7, 42.9, 106.1, and 102.9% S for Control, CGF, DDG, Na_2SO_4–CG, and Na_2SO_4–FG, respectively). A Mo concentration× S source interaction was observed for S IVBA ($P < 0.0001$). The addition of High Mo to CGF and DDG decreased S IVBA, whereas the S IVBA of Na_2SO_4–CG was not affected by Mo concentration. Increased transit time for No Mo and Low Mo increased S IVBA and was greatest for Low Mo at 6 h; however, High Mo was not affected by transit time ($P < 0.0001$; Mo concentration × transit time interaction). A S source × transit time interaction was observed for S IVBA ($P < 0.0001$). Increased transit time increased the S IVBA of CGF and DDG, whereas the S IVBA of Na_2SO_4–FG was not affected by transit time. These findings indicate a complex interrelationship exists between the physiochemical properties of S sources, Mo antagonism, and ruminal factors on S bioaccessibility.

Key Words: antagonism, in vitro bioaccessibility, sulfur

1539 Bovine hair mineral concentrations as potential indicators of mineral status. J. Hawley* and E. B. Kegley, *Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville*.

This study was designed to assess the efficacy of bovine hair mineral concentrations as an indicator of mineral status. Thirty-six primiparous beef heifers of predominantly Angus breeding were stratified by BW, BCS, and anticipated calving date and assigned to 12 pens (3 heifers/pen) for a 260-d maternal nutrition study. Pens were randomly assigned to 1 of 4 treatments (2 × 2 factorial): 1) 0.15% S and 6 mg Cu/kg, 2) 0.15% S and 12 to 14 mg Cu/kg (6 to 8 mg from $Cu_2[OH]_3Cl$), 3) 0.55% S (from Na_2SO_4) and 6 mg Cu/kg, or 4) 0.55% S (from Na_2SO_4) and 12 to 14 mg Cu/kg (6 to 8 mg from $Cu_2[OH]_3Cl$). A cracked corn and soybean meal basal ration delivered each treatment starting at 170 ± 16 d of gestation through 150 ± 16 d in lactation. Heifers had ad libitum access to mixed grass pasture. Heifer blood, hair, and liver samples were collected on d 55 and 112 ± 16 relative to parturition, and progeny blood, hair, and liver samples were collected on d 59 and 114 ± 6 relative to birth. Point-biserial correlation (r_{bp}) analysis was used to determine the correlation between hair mineral concentrations and age. Pearson's correlation (r) analysis was performed to determine the correlation between bovine hair mineral concentrations and traditional mineral status indices. Indices that showed significant correlation were analyzed by simple linear regression to determine the working relationship between indices. Age influenced hair mineral concentrations. Progeny exhibited greater hair Cu ($r_{pb} = 0.47$, $P < 0.0001$) and Zn ($r_{pb} = 0.38$, $P < 0.0001$) concentrations. Heifer hair Cu concentrations were positively correlated with plasma Cu ($r = 0.70$, $P < 0.0001$) and liver Cu ($r = 0.59$, $P < 0.0001$) concentrations. Progeny hair Cu concentrations were negatively correlated with plasma S ($r = -0.55$, $P < 0.0001$) and positively correlated with liver Cu ($r = 0.32$, $P < 0.05$) concentrations. Regression equations revealed heifer hair Cu concentrations accounted for 49 and 35% of the variability in plasma and liver Cu concentration, respectively. Progeny hair Cu concentrations accounted for 30 and 10% of the variability in plasma S and liver Cu concentrations, respectively. Results suggest that bovine hair mineral concentrations alone do not provide sufficient information to assess mineral status; however, they may be useful when combined with other traditional mineral status indices to assess mineral status with greater precision.

Key Words: beef cattle, hair, mineral concentrations

1540 Effects of diets containing either traditional anionic salts or a commercial anionic supplement on feed intake and energy balance of prepartum dairy cows. F. S. Strydom*[1], J. N. Nothnagel[1], and J. P. Swiegers[2], *[1]Nova Feeds, Malmesbury, South Africa, [2]Ruminant Nutrition Consultancy, Bethlehem, South Africa*.

Anionic supplements are fed to prepartum (PP) dairy cows to reduce dietary cation–anion difference (DCAD) and improve calcium status at calving. Traditional anionic salts (AS) can reduce DMI, presumably due to poor palatability. Commercial

Table 1540.

DMI, kg/d (LS Mean)	AS	SC	AS v SC (Adj P value)
3rd week PP	12.6	13.5	1.00
2nd week PP	11.4	13.2	0.622
1st week PP	9.7	11.7	0.053
3 week average	11.4	12.8	0.0004

anionic supplements purportedly are more readily consumed, but there is little research to support this assertion. Twenty-nine pregnant multiparous Holsteins were used to examine the effects of AS or a commercial anionic supplement (SoyChlor [SC]) on DMI and energy balance (EB) during the last 3 wk of pregnancy. The AS supplement consisted of 55% ammonium chloride, 29% magnesium sulfate, and 16% ammonium sulfate. At dry off, each cow entered a communal pen and was accustomed to a Calan gate feeder. The far-off dry period diet was a total mixed ration without anionic supplementation. At 21 d before expected calving date, cows were alternately assigned to a treatment. The AS or SC was incorporated into the diet to yield a calculated DCAD [(Na + K) − (Cl + S)] of −120 mEq/kg. Urine pH was monitored to ensure similar metabolic acidification among the two PP groups. Individual DMI was measured daily. Diet energy content (estimated using the CNCPS version. 6.5 model) and DMI allowed calculation of EB. Data were analyzed using the Mixed procedure of SAS. Post hoc testing of means was done using Bonferroni's procedure. Overall treatment and treatment by week effects for each of the three PP weeks were examined. Least squares means are in the table. Over the entire PP period, cows supplemented with SC had higher DMI ($P < 0.001$) and EB ($P < 0.004$) than cows supplemented with AS. Dry matter intake and EB declined for both groups as the PP period progressed toward calving.

Key Words: anionic supplement, dry matter intake, energy balance

1541 Effect of level of dietary cation–anion difference and duration of prepartum feeding on calcium and measures of acid–base status in transition cows. C. Lopera*[1], R. Zimpel[1], F. R. Lopes Jr.[1], W. G. Ortiz[1], B. N. Faria[1], M. R. Carvalho[1], A. Vieira Neto[1], M. L. Gambarini[2], E. Block[3], C. D. Nelson[1], and J. E. P. Santos[1], *[1]University of Florida, Gainesville, [2]Federal University of Goiás, Goiânia, Brazil, [3]Church and Dwight Animal Nutrition, Ewing, NJ.*

Objectives were to determine the effects of extending the feeding of acidogenic salts prepartum at two levels of negative dietary cation–anion difference (DCAD) on mineral metabolism and acid–base status in dairy cows. One hundred twelve Holstein cows at 230 d of gestation were blocked by lactation (1 vs. >1) and 305-d milk yield and, within each block, randomly assigned to one of four treatments arranged as 2 × 2 factorial with two levels of DCAD (−60 vs. −160 mEq/kg) and two durations (DUR) of feeding the negative DCAD, short (S; 21 d) or long (L; 42 d). Cows in S received an isonitrogenous and isocaloric diet with a DCAD of +130 mEq/kg from 233 to 254 d of gestation. Therefore, during the first 21 d of the experiment, cows were fed one of three DCAD diets, +130, −60, or −160 mEq/kg, whereas during the last 21 d of gestation, they were fed either −60 or −160 mEq/kg. Urine was collected twice weekly, and pH was measured. Cows were weighed and their BCS was assessed once weekly prepartum. Intake of dry matter (DMI) was measured daily. Blood was sampled from the jugular vein at 250, 269, and 272 d of gestation and on d 0, 1, 2, 3, and 4 postpartum and analyzed for concentrations of ionized Ca (iCa), blood gases, pH, base excess, and bicarbonate (HCO_3^-). Data were analyzed by ANOVA with repeated measures using the MIXED procedure of SAS. Intake of DM

in the first 21 d in the experiment decreased ($P < 0.01$) by reducing the DCAD and averaged 11.8, 10.9, and 10.4 kg/d for cows fed +130, −60, and −160 mEq/kg, respectively. Similarly, urinary pH decreased ($P < 0.01$) with a reduction in DCAD and averaged 8.11, 6.59, and 5.67 for cows fed +130, −60, and −160 mEq/kg, respectively. Results for the last 21 d of gestation and first 4 d postpartum are depicted in Table 1. Reducing the level of negative DCAD from −60 to −160 mEq/kg reduced DMI, induced a more exacerbated metabolic acidosis prepartum, and increased the concentration of iCa in blood. Extending the duration of negative DCAD had minor impacts on blood iCa and measures of acid–base status.

Key Words: acidogenic salts, dietary cation–anion difference, prepartum

1542 Effects of concentrate type and chromium propionate supplementation on insulin resistance parameters, milk production, and reproductive outcomes in lactating dairy cows consuming excessive energy.

T. Leiva[1], R. F. Cooke[2], A. P. Brandao[1,2], and J. L. M. Vasconcelos*[3], *[1]UNESP – FMVZ, Botucatu, Brazil, [2]Oregon State University – EOARC Burns, Burns, [3]Sao Paulo State University, Botucatu, Brazil*.

This experiment compared insulin resistance parameters, milk production, and reproductive outcomes in lactating dairy cows consuming excessive energy and receiving, in a 2 × 2 Latin square design, the following treatments: 1) concentrate based on ground corn (CRN; $n = 13$) or citrus pulp (PLP; $n = 13$) and 2) supplemented ($n = 14$) or not ($n = 12$) with 2.5 g/d of chromium propionate. Twenty-six multiparous, nonpregnant, lactating Gir × Holstein cows (average 80 d in milk on d 0) were offered corn silage for ad libitum consumption (d 0 to 180). Cows individually received concentrate formulated to allow diets to provide 160% of their daily NE_L requirements. Cow BW, BCS, and milk production were recorded weekly. Blood samples were collected weekly before the morning concentrate feeding. Glucose tolerance tests (GTT) were performed on d 0, 60, 120, and 180, by infusing cows with 0.5 g of glucose/kg of BW. Follicle aspiration for in vitro embryo production was performed on d 0, 80, and 160. No treatment differences were detected ($P \geq 0.25$) for BW and BCS during the experiment. Milk production and milk fat and solid concentrations were similar ($P \geq 0.24$) between treatments. However, CRN had greater ($P = 0.01$) milk protein compared with PLP cows (3.54 vs. 3.14%, respectively; SEM = 0.08). Within weekly samples, concentrations of serum insulin and glucose as well as revised quantitative insulin sensitivity check index and insulin:glucose ratio were similar among treatments ($P \geq 0.40$), whereas CRN had less serum NEFA concentrations compared with PLP cohorts (0.178 vs. 0.219 mmol/L; SEM = 0.008). No treatment differences were detected ($P \geq 0.35$) on number of viable oocytes collected and embryos produced within each aspiration. During the GTT, no treatment differences were detected ($P \geq 0.16$) for serum glucose concentration, glucose clearance rate, glucose half-life, and insulin:glucose ratio ($P \geq 0.16$). Serum insulin concentrations were less ($P = 0.05$) in CRN cows supplemented with chromium propionate compared with nonsupplemented CRN cohorts (9.01 vs. 13.61 ng/mL, respectively; SEM = 1.73), whereas chromium propionate supplementation did not impact serum insulin within PLP cows ($P = 0.68$). In summary, concentrate type altered milk protein content and serum NEFA concentrations in lactating dairy cows consuming excessive NE_L and impacted the effects of chromium propionate supplementation on serum insulin response to a GTT but did not influence milk yield or reproductive responses.

Key Words: chromium, dairy cows, energy intake, insulin resistance

---

1543 Regulatory effect of dietary intake of chromium propionate on function of monocyte-derived macrophages from Holstein cows in mid lactation.

M. Garcia*[1], Y. Qu[2], C. M. Scholte[2], D. O'Connor[3], P. W. Rounds[3], and K. M. Moyes[2], *[1]Kansas State University, Manhattan, [2]Department of Animal and Avian Sciences, University of Maryland, College Park, [3]Kemin Industries, Inc., Des Moines, IA*.

Chromium (Cr) has been reported to improve insulin sensitivity and cattle performance. However, its effect on bovine macrophage metabolic and inflammatory response is unknown. The objective was to characterize the effect of dietary Cr on cow performance and the immunometabolic response of polarized macrophages ex vivo. Twelve healthy primiparous and 16 multiparous Holstein cows (143 ± 37 DIM) were enrolled. Cows were fed a common diet once daily that was top-dressed with 200 g of ground corn containing no Cr (CTL) or chromium propionate (CrP; 8 mg of Cr/cow per day) for 35 d. Cows were weighed at 0, 17, and 35 d of supplementation. On the same days, blood monocytes were isolated and cultured to obtain 3 monocyte-derived macrophage phenotypes: M0 (nonstimulated), M1 (interferon-γ polarized), and M2 (interleukin-4 polarized). The experiment was set in a randomized complete block design. Neither DMI nor milk yield were affected by CrP or its interactions. Similarly, plasma concentrations of glucose, insulin, and NEFA were not affected by CrP or its interaction with parity. Across parities, CrP increased expression of *IGFI* (fold change [FC]: 1.7; $P = 0.03$) in M0 and increased expression of *CXCL11* (FC: 2.2; $P = 0.07$) and *SLC2A3* (FC: 2.1; $P = 0.06$, only at 17 d of feeding) in M2. For primiparous cows, CrP compared with CTL tended to reduce the production of nitrate in M2 (266 vs. 532 n*M*; $P = 0.14$) and to increase the expression of *IGFI* in M2 at 17 d of supplementation (FC: 3.4; $P = 0.06$). For cows supplemented with CrP but not with CTL, primiparous cows compared with multiparous cows tended to have greater BW gain (37.8 vs. 0.6 kg; $P = 0.07$), better efficiency of BW gain ($P = 0.08$), greater blood monocyte number

(1.31 vs. 0.85 × 10^3/μL; $P = 0.10$), greater glucose in media in M2 ($P = 0.11$), and lower tumor necrosis factor-α in media in M1 (24.6 vs. 61.1 pg/mL; $P = 0.12$). In addition, at 17 d of supplementation, *SLC2A5* expression tended to be greater in M1 (FC: 10.6; $P = 0.13$) and in M2 (FC: 8.8; $P = 0.07$) and IGFI tended to be greater in M2 (FC: 3.5; $P = 0.06$). Regardless of parity, the minor effects observed may indicate potential regulatory mechanisms of Cr on the immunometabolic response of monocyte-derived macrophages via regulation of insulin and IGF-I on glucose transporters.

Key Words: chromium, lactating cows, macrophage

1544 Influence of supplementary zinc- and chromium–amino acid complexes on growth performance and carcass characteristics of finishing cattle fed zilpaterol hydrochloride.

R. Barajas*[1], M. E. Branine[2], C. K. Larson[2], and B. J. Cervantes[3], *[1]FMVZ-Universidad Autónoma de Sinaloa, Culiacan, Mexico, [2]Zinpro Corporation, Eden Prairie, MN, [3]Ganadera los Migueles, S.A. de C.V., Culiacán, Mexico*.

Eighty bullocks (528.27 ± 26.81 kg) were used to determine the influence of supplementary chromium (Cr) and zinc (Zn) from AA complexes on growth performance and carcass characteristics of cattle during a finishing period, which included feeding zilpaterol hydrochloride (ZIL). Bullocks were individually weighed and blocked by weight at study initiation. Groups of five bullocks were placed in 16 dirt-floor pens (6 by 12 m). Pen was the experimental unit. Pens within a block were randomly assigned to treatments as follows: 1) basal diet (13.5% CP and 2.15 Mcal NE_m/kg DM) that provided 30 mg of inorganic Zn/kg DM from $ZnSO_4$ plus an additional 40 mg Zn/kg DM from $ZnSO_4$ provided through a hand-fed supplement (control; CTR), 2) basal diet plus 40 mg Zn/kg DM provided from Zn methionine complex (ZnM; ZINPRO 120; Zinpro Corp., Eden Prairie, MN), 3) CTR plus 0.40 mg Cr/kg DM provided from Cr methionine complex (CrM; Micróplex; Zinpro Corp., Eden Prairie, MN), and 4) basal diet plus 40 mg Zn/kg DM from ZnM and 0.40 mg Cr/kg DM from CrM (ZCM). Diets provided equivalent supplemental levels of 70 mg Zn/kg DM. All bullocks were supplemented with 0.15 mg ZIL/kg BW (Zilmax; Merck Animal Health, Summit, NJ) for 30 d with a 3-d withdrawal before harvest. Zilpaterol, ZnM, and CrM were top-dressed in the feed bunk. Data were analyzed by ANOVA as a mixed model, for a randomized complete block design with a 2 × 2 factorial arrangement of treatments. The model included the random effect of block and fixed effects of ZnM, CrM, and ZnM × CrM interaction. Bullocks receiving ZnM gained faster than CTR ($P = 0.04$; 1.87 vs. 1.55 kg/d, respectively) and exhibited an improved ($P = 0.05$) gain:DM feed efficiency ratio (0.21 vs. 0.16 kg). Dietary ZnM tended ($P = 0.06$) to improve the observed/expected ratio of NE_m (1.21 vs. 1.01) and NE_g (1.27 vs. 1.02) compared with CTR, respectively. Zinc source had no effect on DMI ($P = 0.97$). Feeding CRM had no effect on performance variables ($P > 0.15$). The HCW was similar for bullocks fed $ZnSO_4$ or ZnM (366 and 372 kg, respectively). Carcass dressing percentage tended ($P = 0.10$) to be increased by ZnM compared with CTR (64.5 vs. 63.7%, respectively). The results suggest that ZnM supplementation may contribute to an incremental improvement in growth performance of finishing beef cattle fed ZIL.

Key Words: feedlot performance, zilpaterol hydrochloride, zinc

1545 Effect of peripartum source of dietary calcium and magnesium and postpartum level of magnesium on dry matter intake, performance, and plasma minerals in multiparous Holstein cows.

B. M. Leno*[1], S. E. Williams[1], C. M. Ryan[1], D. Briggs[2], M. Crombie[3], and T. R. Overton[1], *[1]Cornell University, Department of Animal Science, Ithaca, NY, [2]Papillon Agricultural Company, Inc., Easton, MD, [3]MIN-AD, Inc., Winnemucca, NV*.

The objective of this study was to determine the effect of source of dietary Ca and Mg in the peripartum period and level of Mg postpartum on DMI, milk production and composition, and plasma macromineral concentrations. Multiparous Holstein cows ($n = 41$) were randomly assigned to one of two prepartum diets beginning at 21 d before expected parturition in which supplemental Ca and Mg were provided primarily from common sources (C; calcium carbonate and magnesium oxide) or MIN-AD (M; Papillon Agricultural Company, Inc., Easton, MD). At calving, cows remained on the same source assignment and were further randomized to receive Mg at 0.45 (C-HM, $n = 11$; M-HM, $n = 9$) or 0.30% of DM (C-LM, $n = 11$; M-LM, $n = 10$). Cows were fed individually through 42 d in milk (DIM), and blood samples were collected 2x/wk prepartum and daily from d 0 through 7 postpartum. Repeated measures data were analyzed with the MIXED procedure of SAS. Actual postpartum Mg intake, based on 21-d average DMI and diet analyses, were 84, 71, 103, and 71 g/d for C-HM, C-LM, M-HM, and M-LM, respectively. Prepartum, cows fed M had increased DMI (17.9 ± 0.3 vs. 17.0 ± 0.3 kg/d; $P = 0.05$) and energy balance (10.0 ± 0.4 vs. 8.7 ± 0.4 kg/d; $P = 0.03$). An interaction of source, level, and week was found for postpartum DMI in wk 1 to 6 ($P = 0.03$), reflecting increased DMI during wk 2 for cows fed M-HM. No effects on postpartum energy balance were observed. There was no effect on milk yield postpartum. A source × time interaction for fat yield ($P = 0.01$), 3.5% fat-corrected yield ($P = 0.03$), and energy-corrected yield ($P = 0.02$) was detected such that cows fed M had higher yield, especially in wk 1 postpartum. No effects of treatment on plasma Ca concentrations were observed. Cows fed higher Mg tended to have higher plasma Mg postpartum (1.71 ± 0.03 vs. 1.64 ± 0.03; $P = 0.09$) and cows

fed M tended to have higher plasma P postpartum (4.67 ± 0.14 vs. 4.35 ± 0.13; $P = 0.09$). Overall, cows fed M had increased DMI in parts of the transition period and increased fat- and energy-corrected yield. Plasma Ca was not influenced by dietary source and level of Mg; however, plasma Mg was increased by feeding higher Mg postpartum and plasma P was increased by feeding M in the transition period.

Key Words: magnesium, mineral source, transition cow

1546 Effects of mineral supplementation on pre- and postpartum primiparous beef heifer performance and progeny preweaning performance.

J. Hawley*, E. B. Kegley, and J. G. Powell, *Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville*.

A study was conducted to determine the effect of mineral supplementation on primiparous beef heifer pre- and postpartum and progeny preweaning performance. Thirty-six primiparous beef heifers (20 ± 0.5 mo of age) of predominantly Angus breeding were stratified by BW (398 ± 24.9 kg), BCS, and anticipated calving date and assigned to 12 pens (3 heifers/pen) for a 260-d study. Pens were randomly assigned to 1 of 4 treatments (2 × 2 factorial): 1) 0.15% S and 6 mg Cu/kg, 2) 0.15% S and 12 to 14 mg Cu/kg (6 to 8 mg from $Cu_2[OH]_3Cl$), 3) 0.55% S (from Na_2SO_4) and 6 mg Cu/kg, or 4) 0.55% S (from Na_2SO_4) and 12 to 14 mg Cu/kg (6 to 8 mg from $Cu_2[OH]_3Cl$). A cracked corn and soybean meal–based supplement delivered each treatment starting at 170 ± 16 d of gestation through 150 ± 16 d in lactation. Heifers grazed mixed grass pasture and were provided access to predominantly fescue hay in quantities sufficient to ensure ad libitum forage intake. A 7-d controlled internal drug release $PGF_{2\alpha}$ protocol was used to synchronize estrus. Heifer BW and BCS were collected on d −113, −112, −85, −57, −29, 1, 27, 56, 85, 113, 149, and 150 ± 16 relative to parturition. Calf BW was collected on 0, 31, 59, 86, 115, 141, and 150 ± 6 d relative to birth. Orthogonal contrasts were used to determine the effects of Cu vs. S supplementation. Gestation length was not influenced ($P = 0.52$) by mineral supplementation. Mineral supplementation did not influence ($P \geq 0.40$) heifer BW, ADG, or BCS. Synchronized estrus response was not influenced ($P \geq 0.68$) by mineral supplementation; however, reproductive tract scores (Cu main effect, $P = 0.09$) and synchronized conception rates (Cu main effect, $P = 0.07$) tended to be greater for heifers supplemented with Cu. For calf birth weight, progeny from heifers fed 0.15% S and supplemented with Cu tended to have greater birth weights; however, supplemental Cu decreased birth weights for progeny from heifers fed 0.55% S (Cu × S interaction, $P = 0.09$). Progeny ADG trended to be greater from heifers supplemented with Cu (Cu main effect, $P = 0.13$). Results of this study suggest mineral supplementation may influence primiparous beef heifer postpartum reproductive and progeny preweaning performance.

Key Words: beef heifers, mineral supplementation, progeny

1547 Effects of mineral supplementation on pre- and postpartum primiparous beef heifer mineral status and progeny preweaning mineral status.

J. Hawley*, E. B. Kegley, and J. G. Powell, *Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville*.

A study was conducted to determine the effect of mineral supplementation on primiparous beef heifer pre- and postpartum and progeny preweaning mineral status. Thirty-six primiparous beef heifers (20 ± 0.5 mo of age) of predominantly Angus breeding were stratified by BW (398 ± 24.9 kg), BCS, and anticipated calving date and assigned to 12 pens (3 heifers/pen) for a 260-d study. Pens were randomly assigned to 1 of 4 treatments (2 × 2 factorial): 1) 0.15% S and 6 mg Cu/kg, 2) 0.15% S and 12 to 14 mg Cu/kg (6 to 8 mg from $Cu_2[OH]_3Cl$), 3) 0.55% S (from Na_2SO_4) and 6 mg Cu/kg, or 4) 0.55% S (from Na_2SO_4) and 12 to 14 mg Cu/kg (6 to 8 mg from $Cu_2[OH]_3Cl$). A cracked corn and soybean meal–based supplement delivered each treatment starting at 170 ± 16 d of gestation through 150 ± 16 d in lactation. Heifers had ad libitum access to mixed grass pasture. Heifer mineral status was assessed in blood samples collected on d −113, −85, −57, −29, 1, 27, 56, 85, 113, and 150 ± 16; in liver biopsy samples collected on d −113, −57, 1, 56, and 113 ± 16; and in colostrum samples collected 24 h relative to parturition. Heifer Se status was assessed in blood samples collected on d −113 ± 16, −13 ± 13, and 150 ± 16 relative to parturition. Progeny mineral status was assessed in blood samples collected on d 0, 31, 59, 86, 115, 141, and 150 ± 6 and in liver biopsy samples collected on d 7, 59, and 115 ± 6 relative to birth. Progeny Se status was assessed in blood samples collected on d 150 ± 6. Orthogonal contrasts were used to determine the effects of Cu vs. S supplementation. Heifers supplemented 0.55% S exhibited lower plasma and liver Cu concentrations (S main effect, $P < 0.05$). At parturition, heifers supplemented with 0.55% S exhibited lower plasma Cu concentrations (S main effect, $P < 0.01$). Supplemental Cu tended to increase colostrum Cu concentrations in heifers fed 0.55% S but lower colostrum Cu concentrations in heifers fed 0.15% S (Cu × S interaction, $P = 0.08$). Progeny from heifers supplemented with 0.55% S exhibited lower plasma Fe, serum Se, and liver Cu concentrations (S main effect, $P < 0.05$). Results of this study suggest mineral supplementation may influence primiparous beef heifer pre- and postpartum and progeny mineral status.

Key Words: beef heifers, mineral status, progeny

1548 Relative bioavailability of selenium sources for beef cattle. M. A. Zanetti*[1], J. S. Silva[2], J. C. D. C. Balieiro[1], and J. A. Cunha[2], *[1]University of São Paulo – USP/FZEA, Pirassununga, Brazil, [2]FZEA-USP, Pirassununga, Brazil*.

Recent research conducted at FZEA-USP, Pirassununga, Brazil, demonstrated that it is possible to reduce the cholesterol in bovine meat using high levels of organic selenium (Zanetti et al., 2014). This study aimed to compare the bioavailability of high levels of organic and inorganic selenium using muscle concentration. The study used 63 Nellore cattle of approximately 24 mo of age and 350 kg live weight, in a feedlot during 84 d, in individual pens. The animals (9/treatment) were submitted to one of the seven diets: control diet without additional supplementation of selenium, control diet + 0.3 mg Se kg DM in the form of sodium selenite, control diet + 0.3 mg of Se kg DM in the form of organic selenium, control diet + 0.9 mg Se kg DM in the form of sodium selenite, control diet + 0.9 mg Se kg DM in the form of organic selenium, control diet + 2.7 mg Se kg DM in the form of sodium selenite, and control diet + 2.7 mg Se kg DM in the form of organic selenium. The organic selenium used was yeast selenium. Diets were formulated according to NRC (1996) recommendations, and the roughage:concentrate ratio was 30:70. Corn silage was used and the concentrate was a mixture of corn grain and soybean meal. The control diet had 0.065 mg of Se/kg of DM. Animals were weighed at the beginning of the experiment and every 28 d. Food intake was monitored daily and offered in amounts to leave 10% orts. At the end of the experiment (84 d), the animals were slaughtered and muscle samples were taken for selenium analysis, according to Whetter and Ullrey (1978). The bioavailability was calculated by the technique of slope ratio assay (Ammerman et al., 1995). Linear regression was performed with the general linear models procedure (Proc GLM) of SAS (2004) to characterize muscle Se concentrations. The slopes estimation with SE were 0.028 ± 0.005 for the sodium selenite and 0.123 ± 0.005 for the yeast source. The difference between the slopes was significant ($P < 0.0001$). The relative bioavailability estimated by muscle selenium concentration for the yeast selenium in relation to the sodium selenite was 4.39 or 439%, when using diets high in concentrate and with high selenium levels. Acknowledgments: FAPESP.

Key Words: feedlot, muscle selenium, sodium selenite, yeast selenium

1549 Hydroxy trace mineral supplementation lowers proportion of low-quality embryos in postpartum dairy cows. A. H. Souza*[1], C. D. Narciso[2], G. E. Higginbotham[3], E. Martinez[2], R. Ruggeri[2], and E. O. S. Batista[4], *[1]Ceva Animal Health, Libourne, France, [2]Sequoia Veterinary Services Inc., Tulare, CA, [3]Micronutrients, Indianapolis, IN, [4]University of Sao Paulo, Pirassununga, Brazil*.

Objectives of this study were to test whether type of mineral source fed after calving (0 to 70 DIM) could improve quality of in vivo produced embryos from superovulated dairy cows. Postpartum Holstein cows (n = 82) received the same basic TMR (NRC 2001) composed (DM kg/d) of alfalfa hay (3.6), corn silage (3.2), haylage (1.4), wheat silage (1.5), flaked corn (4.4), canola meal (2.7), distillers' (1.7), almond hulls (2.7), corn gluten feed (2.0), EnergII (0.1), and mineral source (0.6). Animals were blocked by parity and calving date and randomly assigned to 2 dietary treatments differing only in type of supplemented mineral source, as follows: 1) hydroxy (HYD) (hydroxyl sources of Cu, Mn, and Zn) and 2) combination (COM) (sulfate sources of Mn, hydroxyl sources of Cu, and 75% zinc sulfate/25% organic Zn). Data was analyzed with the PROC GLIMMIX of SAS and cows were treated as a random experimental unit. Cows were superovulated with a modified 5-d double Ovsynch protocol associated with 400 mg/cow of FSH (Folltropin), and uterine content was flushed 6 d after synchronized ovulations. A single batch of FSH and frozen semen from a single sire (15×10^6 sptz/straw from Select Sires Inc.) were used to minimize variation due to FSH batch and service sire. In addition, a single treatment-blinded technician graded all embryos. There were no overall differences between groups in CL number, fertilization efficiency, or production of transferable embryos. Surprisingly, HYD supplementation significantly reduced the proportion of degenerated embryos in relation to all structures (HYD = 27.3 ± 4.5 vs. COM = 44.4 ± 6.2; $P = 0.03$) or fertilized structures (HYD = 34.8 ± 5.7 vs. COM = 52.2 ± 6.9; $P = 0.04$). In addition, further analysis indicated that HYD increased the proportion of cows that yielded more than 80% of good quality, freezable embryos (HYD = 32.4% vs. COM = 16.6%; $P = 0.04$). These results were unrelated to level of milk production and/or parity number of the superovulated cow. Also, conception results after transferring HYD (59.2%; n = 71) or COM (56.4%; n = 55) embryos to Holstein recipient heifers did not differ (P = 0.72). In conclusion, these findings support the hypothesis that feeding hydroxy minerals can improve embryo quality in postpartum dairy cows. Future research is needed to explore a possible positive impact of hydroxy mineral supplementation on conception results of artificially inseminated cows.

Key Words: dairy cow, embryo quality, hydroxy mineral

1550 Effects of zinc amino acid complex on mammary epithelium and dairy food chemistry.

J. E. Shaffer*[1], K. Pandalaneni[1], L. Mamedova[1], J. DeFrain[2], J. K. Amamcharla[1], and B. J. Bradford[1], *[1]Kansas State University, Manhattan, [2]Zinpro Corporation, Eden Prairie, MN*.

Objectives of this study were to determine effects of supplemental zinc level and source on mammary epithelial barrier integrity and milk chemistry in dairy cattle. In a mouse model, moderate zinc deficiency was shown to dramatically impact milk secretion and mammary gland involution. In addition, through multiple pathways, zinc is known to impact apoptosis in mammary and other epithelial tissues. To test for similar effects in cattle, 12 multiparous Holstein cows in mid to late lactation (132 ± 21 DIM) were blocked by milk production and randomly assigned to treatment sequence in a replicated 3 × 3 Latin square experiment. Each treatment period lasted 21 d (17 d of acclimation and 4 d of sampling). Treatments consisted of 1) 0.97 g zinc/d provided as $ZnSO_4$ (approximately 30 mg zinc/kg diet DM; 30-ZS), 2) 1.64 g zinc/d as $ZnSO_4$ (60-ZS), and 3) 0.55 g zinc/d provided as $ZnSO_4$ plus 1.13 g zinc/d provided as a zinc methionine complex (60-ZM; Zinpro Corp., Eden Prairie, MN). Treatments were also balanced for metabolizable methionine using Smartamine M (Adisseo Inc., France). Cows were housed in individual tie stalls, given ad libitum access to water, and fed a balanced basal ration twice daily. Treatments were provided daily in an oral bolus and contained all supplemental trace minerals except for selenium, which was included in the grain mix. Measurements were analyzed with a mixed model using fixed effects of treatment, period, and their interaction and the random effect of cow. Significance was declared at $P < 0.05$ and tendencies at $P < 0.10$. Feed intake tended to increase for 60-ZS cows ($P = 0.06$) and 60-ZM cows tended to have increased milk fat percentage ($P = 0.08$) compared with 30-ZS cows. No other effects on milk composition, yield, or production efficiency were observed. No effects of treatments were observed on heat coagulation time or the percent of NPN in the milk. Plasma electrolyte, lactose, and α-lactalbumin levels as well as transcript abundance of genes implicated in zinc transport (ZnT2), tight junction formation (occludin), and apoptosis (clusterin) were also unaffected by treatment. In conclusion, zinc supplementation of dairy rations at 60 ppm as opposed to 30 ppm did not appear to impact the integrity of the blood milk barrier or dairy food properties of milk.

Key Words: epithelial integrity, trace mineral, zinc

1551 Effects of sulfur on the nutrition value of dried distillers' grains with solubles for beef cattle.

L. He*, *China Agricultural University, Beijing, P. R. China*.

To investigate the effects of sulfur levels and sources on the nutrition value of corn dried distillers' grains with solubles (DDGS) for beef cattle, in vitro cultivation setting three sulfur levels (0.346, 0.692, and 1.038%) and four sulfur sources (Na_2SO_4, Na_2SO_3, $Na_2S_2O_3$, and Na_2S) without regard of interactions was conducted for 72 h with rumen fluid collected from Simmental × Limousin steers in triplicate and monitoring the fermentation parameters (DM digestibility [DMD], gas production [GP], VFA, and ammonia nitrogen [NH_3–N]) and model predicted indicators (OM digestibility [OMD], ME, NE, microbial protein [MP], and gas yield [GY]). The results showed that the sulfur content of DDGS used in livestock ranged from 0.346 to 1.038% on a DM basis; high sulfur level (0.692 and 1.038%) only decreased ($P < 0.05$) asymptotic gas production (b). As to the effects of sulfur sources, Na_2SO_4 and Na_2S produced more GP ($P < 0.05$) along with a faster rate ($P < 0.01$) than those of Na_2SO_3 and $Na_2S_2O_3$, whereas Na_2SO_3 had the highest b and the inverse for Na_2SO_4 ($P < 0.01$); Na_2SO_4 and Na_2S also had a higher ($P < 0.01$) OMD, ME, NE (for maintenance and growth), and GY_{24} and a lower ($P < 0.01$) DMD_{24} and MCP than those of Na_2SO_3 and $Na_2S_2O_3$; no significant response of VFA and NH_3–N to sulfur levels and sources was found ($P > 0.05$). These results suggest that DDGS with different sulfur content ranging from 0.346 to 1.038% have a similar feed value and that dietary sulfur source exerts a great effect on its nutrition value for beef cattle.

Key Words: dried distillers' grains with solubles, in vitro fermentation, sulfur

1552 Effects of sulfur on the in vitro fermentation profile of dried distillers' grains with solubles.

L. He*, *China Agricultural University, Beijing, P. R. China*.

This study was conducted to investigate the effects of sulfur on the nutrition values of dried distillers' grains with solubles (DDGS) for beef cattle by in vitro rumen fermentation. In vitro cultivation was conducted in triplicate with the rumen fluid collected from 3 Simmental steers, and the gas production (GP) was recorded until 72 h of incubation, setting DDGS as the fermentation substrate with different sulfur levels (0.346, 0.692, and 1.038%, on a DM basis) and various sulfur sources (Na_2S, $Na_2S_2O_3$, Na_2SO_3, and Na_2SO_4). The filtrate of the fermentation fluid was used to determine ammonia nitrogen (NH_3–N), VFA, and DM digestibility (DMD), finally calculating OM digestibility (OMD), ME, NEm and NEg, and microbial CP production (MCP) with the monitored parameters. The results showed that in vitro gas production parameters (b and c) of DDGS were significantly influenced by its sulfur

source ($P < 0.01$) but not sulfur level ($P > 0.05$), being that the sulfur from Na_2SO_3 developed the slowest gas production rate (c) (0.018/h) with the highest asymptotic gas production (b) (60.20 mL/g) and the inverse for Na_2SO_4 (0.049/h and 42.77 mL/g). What is more, sulfur from Na_2SO_4 and Na_2S produced higher ($P < 0.05$) GP than those of Na_2SO_3 and $Na_2S_2O_3$ at 12, 24, and 48 h, whereas there was no difference ($P > 0.05$) found in different sulfur levels. Sulfur from Na_2SO_4 and Na_2S also had higher ($P < 0.01$) DMD, OMD, ME, NEm, and NEg than that of Na_2SO_3 and $Na_2S_2O_3$. As to the VFA profile, sulfur from Na_2SO_4 tended ($P = 0.09$) to produce a lower total VFA (29.10 mmol/L) than the others (37.34, 39.10 and 37.98 mmol/L), and there was no difference ($P > 0.05$) in the individual fatty acid proportion. These results suggest that DDGS with different sulfur concentration ranging from 0.346 to 1.038% have a similar in vitro rumen fermentation profile, whereas its sulfur source exerts a great effect on the fermentation, indicating that the valence state of sulfur in DDGS makes a big difference to its nutrition value for beef cattle.

Key Words: dried distillers' grains with solubles, in vitro fermentation, sulfur

1553 Supplementation with a blend of capsicum and artificial sweetener alters milk yield and nutrient partitioning in lactating dairy cows. E. H. Wall* and D. M. Bravo, *Pancosma, Geneva, Switzerland*.

Supplementation of lactating dairy cows with capsicum oleoresin (CAPS) or with SUCRAM (SUC; Pancosma, Geneva, Switzerland) increases milk and component yield; however, responses to the two additives fed in combination have not been described. Therefore, the objective of this experiment was to determine the effects of a CAPS-SUC blend on lactation performance of dairy cows. Primi- and multiparous lactating Holstein dairy cows were housed together in a free-stall pen and were milked using an automated milking system (AMS). During a 10-wk period, CAPS-SUC was blended with a carrier and was dispensed at the AMS for CAPS-SUC cows (n = 91) at a rate of 0.22 kg/d (doses of CAPS and SUC: 100 mg/d and 3.2 g/cow per day, respectively); control cows received no additive (n = 102). All cows were supplemented with 300 mg/d of monensin. Individual cow milk production and composition, milking frequency, and BW were recorded daily. Average DMI of the pen was monitored daily and did not change throughout the study. Supplementation with CAPS-SUC did not affect milking frequency (3.5 milkings/d; $P > 0.60$). There was a parity × treatment interaction for milk yield characterized by a decrease with CAPS-SUC in primiparous animals (34.7 vs. 32.1 kg/d; $P < 0.001$) but an increase in multiparous animals (41.4 vs. 44.6 kg/d; $P < 0.001$). Yield of milk fat (1.6 kg/d) and protein (1.2 kg/d) was not affected by treatment ($P > 0.10$). There was a treatment × parity × stage of lactation interaction for BW such that in cows less than 100 DIM, BW was increased with CAPS-SUC only in primiparous animals (590 vs. 616 kg; $P < 0.001$) whereas there was no effect in multiparous animals ($P > 0.30$). The prevalence of subclinical ketosis, indicated by milk fat-to-protein ratios, was decreased with CAPS-SUC (20 vs. 15%; $P < 0.01$). The decrease in milk yield of primiparous cows together with a corresponding increase in BW indicates that CAPS-SUC may have altered nutrient partitioning to support skeletal growth or accretion of tissue stores in those animals. This, taken together with the decreased incidence of ketosis and changes in milk production, reveals that CAPS-SUC can shift nutrient partitioning and consequent milk production performance of lactating dairy cows.

Key Words: feed additive, phytonutrient, SUCRAM

1554 Supplementation with rumen-protected capsicum oleoresin increases milk production and component yield in lactating dairy cows. E. H. Wall* and D. M. Bravo, *Pancosma, Geneva, Switzerland*.

Insulin responses in peripheral tissues of dairy cows are shifted so that availability of glucose is prioritized for milk synthesis during lactation. Supplementation of dairy cows with rumen-protected capsicum oleoresin decreased insulin responses and improved milk production performance. The objective of this experiment was to test the hypothesis that supplementation of rumen-protected capsicum oleoresin (RP-Caps; NexUlin; Pancosma) would increase milk production of dairy cows. Primi- and multiparous lactating Holstein cows were housed together in a free-stall pen and were milked using an automated milking system (AMS). During a 6-wk period, cows were blocked by stage of lactation (1–99 DIM, n = 67; 100–199 DIM, n = 63; and 200+ DIM, n = 66) and were randomly assigned to RP-Caps or control treatments. Rumen-protected capsicum oleoresin was blended with a carrier and was dispensed at the AMS for RP-Caps cows (n = 97) at a rate of 0.22 kg/d (100 mg/cow per day of RP-Caps); control cows (n = 99) received no additive. All cows were supplemented with 300 mg/d of monensin. Individual cow milk production and composition, milking frequency, and BW were recorded daily. Prevalence of subclinical ketosis was estimated by milk composition (fat/protein > 1.5). Average DMI of the pen was monitored daily and did not change throughout the study. Supplementation with RP-Caps did not affect milking frequency (3.6 milkings/d; $P > 0.50$). There were no parity × treatment interactions detected; however, there was an interaction between stage of lactation and treatment ($P < 0.001$) such that only cows in the 1 to 99 DIM group responded to RP-Caps whereas there was no effect of treatment in the other two groups ($P > 0.50$). In that group, milk production was increased in RP-Caps cows (40.7 vs. 44.4 kg/d; $P < 0.001$). Rumen-protected capsicum oleoresin had no effect on fat (4.5 vs. 4.4) or protein (3.09 vs. 3.10) percentages; therefore, the increase in milk production was accompanied with an increase in component and energy-corrected milk yield (46.2 vs. 50.0

kg/d; $P < 0.001$). The increase in milk and milk component yield was not accompanied by changes in BW (673 vs. 669 kg; $P > 0.30$) or prevalence of subclinical ketosis (22.1 vs. 23.9%; $P > 0.50$), indicating that metabolic status was maintained despite the increased nutrient output into milk. Responses to RP-Caps may be mediated by postruminal effects on insulin responses and augmented glucose sparing during early and peripeak lactation.

Key Words: feed additive, phytonutrient, postruminal effects

1555 WS Effects of increasing sugar beets on steer backgrounding performance. I. McGregor*, C. M. Page, W. C. Stewart, and M. Van Emon, *Montana State University, Bozeman*.

The objective of this study was to evaluate the effects of sugar beets on steer backgrounding performance. Forty-eight Angus steers (260.7 ± 3.43 kg) were used in a completely randomized design for a 50-d study. On d −1, steers were weighed and assigned to 1 of 8 pens (6 steers/pen) equipped with GrowSafe units and one of four dietary treatments on d 0 ($n = 12$ steers/treatment; 2 pens/treatment): 1) 0SB, a control diet with no sugar beets; 2) 15SB, 15% sugar beets substituted for barley on a DM basis; 3) 30SB, 30% sugar beets substituted for barley on a DM basis; and 4) 45SB, 45% sugar beets substituted for barley on a DM basis. Sugar beets directly replaced rolled barley on a DM basis. All dietary treatments were formulated to meet or exceed the nutrient requirements of a 295-kg steer gaining 0.91 kg/d. The MIXED procedure of SAS was used for statistical analysis. Initial BW, mid BW, final BW, period 1 and 2 ADG, and period 1 and 2 G:F were not different ($P \geq 0.33$) due to dietary treatment. There was a significant treatment × day interaction ($P < 0.001$) for DMI. On d 3, 19, 21, 23, 33, 44, and 45, 0SB DMI was reduced ($P \leq 0.05$) and increased ($P \leq 0.05$) on d 12, 20, and 47 compared with 15SB. On d 3, 19, 21, 33, 35, and 50, 0SB DMI was reduced ($P \leq 0.03$) and increased ($P \leq 0.01$) on d 9, 12, and 20 when compared with 30SB. On d 19, 21, 27, 33, 37, 38, and 45, 0SB DMI was reduced ($P \leq 0.05$) and increased ($P \leq 0.04$) on d 9, 24, and 35 when compared with 45SB. On d 35 and 37, 15SB DMI was reduced ($P \leq 0.002$) and increased ($P \leq 0.05$) on d 9 and 36 when compared with 30SB. On d 37 and 47, 15SB DMI was reduced ($P \leq 0.02$) and increased ($P \leq 0.03$) on d 1, 9, 44, and 46 when compared with 45SB. On d 45, 30SB DMI was reduced ($P \leq 0.03$) and increased ($P \leq 0.04$) on d 24 when compared with 45SB. These data suggest that backgrounding steers can be fed diets with up to 45% sugar beets on a DM basis without negatively impacting performance.

Key Words: backgrounding, steers, sugar beets

1556 Effects of red grape pomace to adapt beef cattle to finishing diets and spoilage mitigation strategies. L. A. Pellarin*[1], J. O. Sarturi[1], P. R. B. Campanili[1], L. A. Ovinge[1], B. C. Bernhard[1], B. J. Johnson[1], J. C. Brooks[1], and E. W. Hellman[2], *[1]Texas Tech University, Lubbock, [2]Texas A&M AgriLife Extension and Texas Tech University, Lubbock*.

The effects of red grape pomace to step-up beef steers to steam-flaked corn–based finishing diets on growth performance, carcass characteristics, nutrient digestibility, feeding behavior, and mitigation of pomace spoilage were evaluated. In Study 1, crossbred yearling steers ($n = 48$; 364 ± 41 kg) were blocked by BW and randomly assigned to 1 of 2 adaptation strategies, 1) traditional roughage sources (alfalfa hay/cottonseed hulls based) and 2) red grape pomace based, in a randomized complete block design. Both adaptation strategies decreased roughage as steam-flaked corn gradually increased in diets. Steers were fed once daily, following standard operations of the Burnett Center (Idalou, TX), a series of 5 diets consisting of four 7-d step-up diets and 1 common finishing diet (160 d), which did not contain pomace. In Study 2, red and white grape pomace were ensiled (18.9 L units; $n = 6$/treatment) following 1 of the 4 spoilage mitigation strategies: 1) control, 2) molasses, 3) inoculant (*Lactobacillus buchneri*), and 4) inoculant + molasses in a completely randomized design (2 × 4 factorial treatment arrangement). Data were analyzed using the GLIMMIX procedure of SAS. Intake, gain, and efficiency of steers during either adaptation or finishing phases were not ($P \geq 0.16$) negatively affected by red grape pomace when compared with a traditional adaptation strategy. Total tract apparent digestibility of DM, OM, EE, NDF, and ADF evaluated during the finishing phase was not ($P \geq 0.53$) affected by adaptation strategies, except by a subtle (99.46 vs. 99.03%) increase ($P = 0.01$) in starch digestibility for steers fed pomace when compared with a traditional adaptation strategy, respectively. Feeding behavior was not ($P \geq 0.21$) affected by adaptation strategies, except by steers fed the traditional strategy spending 17.3 and 18.4% more time ruminating and chewing on step-up diet 3 compared with the pomace strategy in the same phase ($P = 0.04$ and $P = 0.01$, respectively). After storage period (169 d), red grape pomace lost less DM compared with white pomace (7.87 and 11.37%, respectively; $P < 0.03$), whereas no differences among mitigation treatments were observed ($P = 0.52$). Red grape pomace strategy adapted beef steers to finishing diets without detrimental effects on growth performance and nutrient digestion when compared with a traditional alfalfa hay/cottonseed hulls approach. Grape pomace can be stored for long periods under anaerobic conditions with modest amount of DM losses; however, spoilage mitigation after silo opening must be further studied.

Key Words: adaptation, grape pomace, storage

1557 Effects of thyme (*Thymus vulgaris*) essential oil on feed intake and feeding behavior of Nellore steers. L. C. Roma Junior*[1], E. S. Castro Filho[2], |J. M. Bertocco Ezequiel[3], M. Almeida[4], and E. H. C. B. Van Cleef[2], *[1]Sao Paulo's Agency for Agribusiness Technology – APTA, Ribeirao Preto, Brazil, [2]Sao Paulo State University – UNESP, Jaboticabal, Brazil, [3]UNESP, São Paulo State University, Department of Animal Science, Jaboticabal, São Paulo, Brazil, [4]São Paulo State University, Jaboticabal, São Paulo, Brazil*.

The objective of this study was to evaluate the effects of increasing amounts of thyme (*Thymus vulgaris*) essential oil (TEO) on feed intake and feeding behavior of Nellore steers. Four ruminally cannulated steers (701 ± 37 kg BW) were assigned to a 4 × 4 Latin square design and were fed a total mixed ration containing 40% corn silage, 10% bermudagrass hay, and 50% commercial concentrate. Treatments consisted of a daily ruminal infusion of 0 (T0), 2 (T2), 4 (T4), or 8 (T8) g/animal per day of TEO. Each period lasted 21 d (13 d of adaptation and 8 d of data collection) and animals were fed once daily (0700 h). Feed delivered and feed refused were monitored every morning to calculate DMI. Feeding behavior observations were performed by 4 trained observers who recorded, each 5 min during 12 h (from 0600 to 1800 h), the following activities: interaction with feed bunk (IB), interaction with waterers (IW), ruminating standing (RS), ruminating laying (RL), standing still (SS), laying (LA), stereotypies (ST), and other activities (OA). The chewing activity was also evaluated with observations of number of chews per feed bolus, time spent chewing each feed bolus, and chews per time. Data were analyzed using the MIXED procedure and orthogonal contrasts were used to determine the linear, quadratic, and cubic effects of TEO and of T0 vs. TEO treatments. The infusion of TEO did not affect DMI of steers (average = 8.6 kg/d). Also, no effects of treatments were observed for IB, IW, RS, RL, LA, ST, and OA, and the averages were 183.3, 10.0, 37.5, 283.5, 92.5, and 112.5 min, respectively. The time spent on activity SS was linearly increased ($P = 0.03$) with increasing inclusion of TEO, showing a 20% increase from T0 to T8. Regarding the chewing activity, no alterations were observed, and the treatments' averages were 46 chews/feed bolus, 56 s/feed bolus, and 0.82 chews/s. Although TEO has known powerful antibacterial properties, it does not affect DMI, or most of the animal behavioral activities, when infused up to 8 g/d. (Financial support: FAPESP 2014/01212-4.)

Key Words: additive, medicinal plant, thymol

1558 Effects of functional oils or monensin on dry matter digestibility, milk yield, and composition of Holstein cows. F. P. Rennó*[1], E. F. Jesus[2], T. A. Del Valle[1], G. D. Calomeni[1], T. H. Silva[1], C. S. Takiya[1], T. H. A. Vendramini[1], P. G. D. Paiva[2], G. G. Silva[1], A. Saran Netto[3], and J. Torrent[4], *[1]School of Veterinary Medicine and Animal Science, University of São Paulo, Pirassununga, Brazil, [2]School of Agricultural and Veterinary Sciences of UNESP, Jaboticabal, Brazil, [3]School of Animal Science and Food Engineering, University of Sao Paulo, Pirassununga, Brazil, [4]Oligo Basics Agroindustry, Cascavel, Brazil*.

Cashew nut shell liquid (CNSL) and castor oil have been defined as functional oils (FO) due to their antimicrobial, anti-inflammatory, antioxidative, and gastroprotective properties. Twenty-four multiparous cows (150.24 ± 61.43 d in milk and 29.1 ± 4.01 kg/d of milk yield) were used in a replicated 3 × 3 Latin square experiment with 21-d periods to compare the effects of FO or monensin (MON) supplementation on DM total apparent digestibility and milk yield and composition. Cows were assigned to one of these treatments: no additive (CON), supplementation of 500 mg/kg DM of FO (CNSL and castor oil as active ingredients; Essential; Oligo Basics, Cascavel, Brazil), and supplementation of 22 mg/kg DM of MON (Rumensin; Elanco Animal Health, São Paulo, Brazil). Diet was offered as a total mixed ration twice daily. Orts were weighed daily to determine feed intake, and samples of ingredients, orts, and feces were collected on Days 16, 17, and 18 of each period. Feces were collected every 9 h. All samples were analyzed for DM and indigestible NDF (iNDF) content. To obtain iNDF content, samples of ingredients, orts, and feces were placed in bags of nonwoven textile, incubated during 288 h in the rumen of two cows, and submitted to neutral detergent treatment. Fecal excretion was calculated based on iNDF intake and its concentration in feces. Cows were milked twice daily. Milk samples were automatically collected on Days 15, 16, and 17 of each period and analyzed fresh for fat, protein, and lactose by infrared methodology (Lactoscan; Entelbra, São Paulo, Brazil). Data were analyzed using PROC MIXED of SAS, and when treatment effects were significant, the PDIFF test was applied. Treatments did not affect DM intake or digestibility. Functional oils and MON increased ($P < 0.01$) milk (25.92, 27.17, and 27.13 kg/d for CON, MON, and FO, respectively), protein (0.78, 0.81, and 0.81 kg/d for CON, MON, and FO, respectively), and lactose (1.17, 1.22, and 1.22 kg/d CON, MON, and FO, respectively) yields. Cows supplied MON showed lower milk fat percentage compared with CON and milk fat from FO cows was not different from any of treatments (3.66, 3.46, and 3.60% for CON, MON, and FO, respectively). Cows supplemented MON produced milk with lower lactose concentration compared with FO cows. Monensin increased milk production with a decrease in milk fat percentage and FO increased milk production without affecting

milk fat percentage.

Key Words: castor oil, functional oil, ionophore.

1559 Effect of rumen-protected *Capsicum* oleoresin on immune responses in lactating dairy cows experimentally challenged with lipopolysaccharide.

J. Oh*[1], M. Harper[1], F. Giallongo[1], E. H. Wall[2], D. M. Bravo[2], and A. N. Hristov[1], [1]*The Pennsylvania State University, University Park,* [2]*Pancosma, Geneva, Switzerland*.

The objective of this experiment was to investigate the effects of rumen-protected *Capsicum* oleoresin (RPC) on immune responses in lactating dairy cows experimentally challenged with lipopolysaccharide (LPS). Nine multiparous Holstein cows (100 ± 9.1 d in milk and 665 ± 83.3 kg BW) were used in a replicated 3 × 3 Latin square design experiment balanced for residual effects with three 28-d periods. Treatments were 0 (control), 100, and 200 mg RPC/cow per day. Rumen-protected *Capsicum* oleoresin was mixed with a small portion of the total mixed ration and top-dressed. The basal diet consisted of (DM basis) 44% corn silage, 12% alfalfa silages, and 41% concentrate feeds and contained 16.1% CP and 30.9% NDF, and the NE_L and MP of the basal diet met the requirements of the cows. Bacterial LPS was intravenously administered at 1.0 μg/kg BW and blood samples were collected at 0, 2, 4, 8, and 24 h after administration. Dry matter intake, milk yield, and white blood cells including neutrophils, lymphocytes, monocytes, and eosinophils were decreased ($P < 0.01$) and rectal temperature, hemoglobin, and serum concentration of cortisol and haptoglobin were increased ($P < 0.01$) by LPS. Plasma concentration of thiobarbituric acid reactive substances, red blood cells, and platelets were not affected ($P \geq 0.13$) by LPS. Dry matter intake (25.7 kg/d; SEM = 1.73), milk yield (35.7 kg/d; SEM = 2.44), and milk composition were not affected ($P \geq 0.25$) by RPC after LPS challenge. Rectal temperature, white blood cells, red blood cells, hemoglobin, and platelets were also not affected ($P \geq 0.20$) by RPC, except lymphocyte counts were quadratically increased ($P = 0.02$) by RPC at 0 h. Compared with the control, RPC decreased ($P \leq 0.04$) serum concentrations of cortisol and haptoglobin and increased ($P < 0.01$) concentration of thiobarbituric acid reactive substances in plasma following LPS challenge. Collectively, feed intake, milk yield, rectal temperature, white blood cells, and red blood cells were not affected by RPC in dairy cows challenged by LPS. However, RPC increased concentration of thiobarbituric acid reactive substances in plasma and decreased cortisol and haptoglobin concentrations in serum. Data suggest that dietary supplementation of RPC increased oxidative stress in plasma and alleviated acute phase responses induced by LPS in lactating dairy cows.

Key Words: acute phase response, capsicum, lipopolysacharride

1560 Effects of cinnamaldehyde on performance of postweaned Holstein dairy heifers.

C. E. Chapman*[1], D. Ziegler[2], H. Chester-Jones[2], J. A. Clapper[3], and P. S. Erickson[1], [1]*University of New Hampshire, Durham,* [2]*University of Minnesota Southern Research and Outreach Center, Waseca,* [3]*South Dakota State University, Brookings*.

Essential oils are secondary metabolites obtained from plants and are gaining interest because of their functions similar to ionophores. The objective of this 70-d study was to determine the effects of the essential oil cinnamaldehyde compared with the ionophore monensin sodium on performance of postweaned Holstein dairy heifers. Eighty-four 12-wk-old Holstein heifers (109 ± 7.50 kg) were housed in a naturally ventilated curtain side-wall barn in 12 pens with 7 heifers/pen (3.98 m^2/hd). Heifers were randomly assigned to 1 of 4 treatments in a completely randomized design: 1) control (CON; carrier, 908 g of ground corn), 2) monensin sodium (MON; 1 mg/kg of BW + carrier), 3) cinnamaldehyde (CIN1; 1 mg/kg of BW + carrier), or 4) cinnamaldehyde (CIN2; 2 mg/kg of BW + carrier). The treatments were mixed into a 20% CP whole shell corn and protein pellet mix fed daily at 2.27 kg/head per day. Heifers had access to free choice hay and water daily. Initial BW and hip heights (HH) were taken at the start of the study and biweekly thereafter until calves reached 22 wk of age. Blood samples were also taken on each weigh day to determine blood urea nitrogen, glucose, and insulin-like growth factor-1 (IGF-1) concentrations. Fecal samples were taken from 3 heifers/pen initially and then at wk 4, 8, and 10 of the study to determine coccidia count. There were no performance effects ($P > 0.05$) of cinnamaldehyde on growth, hay intake, HH, or blood metabolites compared with heifers offered MON or CON. Average daily gains were 0.98, 0.99, 1.01, and 1.03 kg/d and average hay intakes per pen were 17.08, 16.34, 18.11, and 17.60 kg/d for CON, MON, CIN1, and CIN2, respectively. Fecal samples by pens indicated the presence of viable coccidia, but the number of counts was low and not consistent across heifers within each pen. Feeding monensin sodium to postweaned dairy heifers did not affect any of the performance parameters measured when compared with the control. Under the conditions of this study, there were also no benefits of supplementing cinnamaldehyde into grain mixes for postweaned heifers. Increasing the dose of cinnamaldehyde or changing the way it was administered to feed may have resulted in a different outcome.

Key Words: cinnamaldehyde, heifer, monensin sodium

1561 Effects of essential oils and exogenous enzyme in feedlot finishing diets high in flint ground corn at different particle sizes during the adaptation period. M. A. P. Meschiatti[1], J. M. M. D. Moraes[1], T. S. Acedo[2], L. F. M. Tamassia[2], C. S. Cortinhas[2], V. N. D. Gouvea*[2], J. R. Dórea[3], and F. A. P. Santos[4], *[1]USP, Sao Paulo, Brazil, [2]DSM Nutritional Products SA, Sao Paulo, Brazil, [3]University of Wisconsin, Madson, [4]University of São Paulo, Piracicaba, Brazil*.

The objective of this study was to evaluate the interaction between two feed additives—MON (sodium monensin; Tortuga) vs. CRINA-RUM (the combination of essential oils: Crina Ruminants, DSM, and α-amylase; Ronozyme RumiStar)—and two different ground flint corn particle sizes—ground corn (GC = 1.82 mm average particle size) or coarsely ground corn (CGC = 2.53 mm average particle size)—on performance of finishing Nellore bulls during the adaptation period, the first 30 d. Two hundred fifty-six Nellore bulls (initial BW = 360 kg ± 38) were fed diets containing 82.5% ground corn (1.82 or 2.53 mm), 8.5% sugarcane bagasse, 5% soybean meal, 3% minerals and vitamin supplement, and 1% urea. Animals were blocked based on initial BW and randomly allocated in 48 pens. Treatments were GC + MON (1.82 mm ground corn and sodium monensin; 26 mg/kg DM), GC + CRINA-RUM (1.82 mm ground corn and the combination of essential oils [90 mg/kg DM] + α-amylase [560 mg/kg DM]), CGC + MON (2.53 mm ground corn and sodium monensin; 26 mg/kg DM), and CGC + CRINA-RUM (2.53 mm ground corn and the combination of essential oils [90 mg/kg DM] + α-amylase [560 mg/kg DM]). The DMI, ADG, and feed efficiency (G:F) were evaluated after 30 d of adaptation. The data were analyzed using PROC MIXED of SAS in a 2 × 2 factorial arrangement (2 ground corn particle sizes and 2 feed additives). Pen was considered the experimental unit. No interactions between feed additives and flint corn particle size were observed ($P > 0.05$). There was no effect ($P > 0.05$) of ground flint corn particle sizes on performance of the animals during the adaptation period. Animals fed with CRINA-RUM had 7.89% greater DMI (8.36 vs. 7.70 kg; $P < 0.05$) and 11.9% greater ADG (1.26 vs. 1.11 kg; $P = 0.08$) compared with animals fed MON, respectively. In conclusion, the use of essential oil combined with α-amylase improved animal performance during the adaptation period for animals fed ground flint corn grain.

Key Words: beef, Nellore, starch

1562 Effects of essential oils and exogenous enzymes on intake, digestibility, and rumen fermentation in finishing Nellore cattle. M. A. P. Meschiatti[1], L. A. Pellarin[1], C. D. A. Batalha[2], T. S. Acedo*[3], L. F. M. Tamassia[3], C. S. Cortinhas[3], V. N. D. Gouvea[3], F. A. P. Santos[2], and J. R. Dórea[4], *[1]USP, Sao Paulo, Brazil, [2]University of São Paulo, Piracicaba, Brazil, [3]DSM Nutritional Products SA, Sao Paulo, Brazil, [4]University of Wisconsin, Madson*.

The objective of this trial was to evaluate the combination of essential oils and exogenous enzymes on intake, digestibility, and ruminal fermentation in finishing Nellore cattle. Five Nellore steers (427 ± 52 kg BW) were fed isonitrogenous and isocaloric diets containing 82.5% corn, 8.5% sugarcane bagasse, 5% soybean meal, 3% mineral and vitamin supplement, and 1% urea. The treatments were MON (sodium monensin; Tortuga; 26 mg/kg DM), CRINA (essential oils; Crina Ruminants; DSM; 90 mg/kg DM), CRINA$^+$MON (90 and 26 mg/kg DM, respectively), CRINA$^+$RUM (CRINA + α-amylase; Ronozyme RumiStar; DSM; 90 and 560 mg/kg DM, respectively), and CRINA$^+$RUM+P (CRINA + RUM + protease; Ronozyme Proact; DSM; 90, 560, and 840 mg/kg DM, respectively). The experimental design used was a 5 × 5 Latin square. The 20-d experimental periods consisted of 15 d for adaptation followed by 5 d for collections. Data were analyzed using PROC MIXED of SAS and means were compared by Tukey test considering animal and period as random effects and treatments as fixed effects. Cattle fed CRINA$^+$RUM presented greater ($P < 0.01$) DM and total nutrient digestible (TND) intakes compared with MON (9.77 vs. 7.69 kg and 7.73 vs. 5.89 kg, respectively). CRINA increased ($P = 0.02$) total CP digestibility compared with MON (74.9 vs. 65.3%, respectively). The combination of CRINA$^+$RUM+P also increased ($P < 0.01$) total CP and the total carbohydrate digestibility in comparison with MON (75.0 vs. 65.3% and 91.0 vs. 84.8%, respectively). Total starch digested (kg) was greater ($P < 0.05$) for cattle fed CRINA$^+$RUM in comparison with MON (5.44 vs. 4.19 kg, respectively), although no difference ($P = 0.12$) in fecal starch was observed between the treatments. No difference in total NDF ($P = 0.73$) and EE ($P = 0.60$) digestibilities, ruminal pH ($P = 0.84$), and molar concentration of acetate ($P = 0.14$) were observed among the treatments. Animals fed CRINA$^+$RUM presented greater molar concentration of propionate ($P = 0.02$) and lower acetate-to-propionate ratio ($P = 0.04$), compared with CRINA$^+$RUM+P (41.5 vs. 27.7 m*M* and 1.48 vs. 2.2, respectively). Ruminal ammonia nitrogen was lower ($P = 0.05$) for animals fed CRINA$^+$RUM in comparison with animals fed CRINA$^+$MON (12.4 vs. 20.26 mg dL^{-1}). In conclusion, the use of essential oils and their combination with amylase increases the DM and TDN intakes and the amount of starch digested in the total tract compared with sodium monensin, presenting minor effects on fermentation parameters.

Key Words: amylase, protease, starch

1563 Effect of inclusion of *Acacia mearnsii* tannin extract on nitrogen and energy balance in growing beef cattle fed a low-protein corn silage diet.

S. Capa de Avila*[1], G. V. Kozloski[2], K. R. McLeod[1], and D. L. Harmon[1], [1]*University of Kentucky, Lexington,* [2]*Federal University of Santa Maria, Santa Maria, Brazil*.

The study of tannins in animal feeds has primarily focused on the effects on digestibility, intestinal nutrient flow, and/or performance of ruminant animals; however, the overall impact on energetic efficiency in growing animals is not known. Eight Holsteins steers (BW = 332 ± 32.3 kg) were used in a replicated 4 × 4 Latin square design experiment to evaluate the effect of *Acacia mearnsii* tannin extract on energy metabolism and nitrogen balance. The experimental diets consisted of corn silage plus concentrate (10%) at 2 levels of intake with and without *A. mearnsii* tannin extract (3.9 g/kg of total dietary DM). The basal diet (DM basis) was formulated to be 36.2% DM, 8.1% MP, and 12.4% CP. The treatment structure was a 2 × 2 factorial: intake, 1.2 vs. 1.8 × NEm, and tannin addition vs. control. Each experimental period was 21 d with fecal and urine collections occurring Days 15 to 21. Respiratory gasses were measured d 19 to 21 by replacing the feed bunk with a respiration hood. Measures of inspired O_2 and expired CO_2, and CH_4 were continuously collected with samples analyzed at 9-min intervals. Whole-body heat production (HP) was calculated using the equation proposed by Brouwer. Data were analyzed for effects of intake, presence of tannin, and the interaction of intake × tannin. Treatment effects were considered significant at $P \leq 0.05$. Tannin extract addition did not affect ($P > 0.10$) any measure of nitrogen or energy balance. Tannins bind proteins, which are recovered in the fiber fraction of feces as such, and usually shift the N excretory pattern from urine to feces, being positive from the environmental point of view; however, this effect was not observed in the present study. As designed, all variables were higher with high intake ($P < 0.001$). There was no interaction between intake and tannin extract. More studies are needed to evaluate the mode of action of this phenolic compound on the use of energy in growing animals.

Key Words: heat production, intake, phenolic compounds

1564 Effects of condensed tannins on the ensiling and aerobic stability of purple prairie clover (*Dalea purpurea* Vent.) silage.

K. Peng*[1,2], Q. Huang[3], T. A. McAllister[4], S. Wang[1], Z. Xu[2], S. Acharya[2], and Y. Wang[2], [1]*College of Engineering, China Agricultural University, Beijing, P. R. China,* [2]*Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada,* [3]*College of Animal Science and Technology, Northwest A&F University, Yangling, P. R. China,* [4]*Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, Lethbridge, AB, Canada*.

Effects of condensed tannins (CT) on ruminal fermentation have been well documented, whereas little information is available on the effects of CT on ensiling. The objective of this study was to assess the effects of CT on ensiling and aerobic stability of whole-plant purple prairie clover (PPC) silage. The PPC contained approximately 55 g CT/kg DM, was harvested from 3 plots at the flowering stage, and was wilted in the field to DM of 35%. Forage was chopped to a theoretical length of 5 cm, divided into 2 portions, and ensiled without (Control) or with polyethylene glycol (PEG) in PVC laboratory silos (5/treatment). The PEG specifically inactivates the biological activity of CT. The silos were opened after 76 d of ensiling and the silage was subsampled for chemical characterization as well as assessed for aerobic stability over 14 d. Compared with PEG treated silage, Control silage had higher ($P < 0.001$) pH (5.02 vs. 4.61) and water soluble carbohydrates (2.40 vs. 0.26 g/kg DM) but contained less lactic acid (52.6 vs. 79.9 g/kg DM; $P < 0.01$), propionic acid (0.17 vs. 0.85 g/kg DM; $P < 0.05$), soluble N (0.29 vs. 0.40 g/kg DM; $P < 0.01$), NPN (0.35 vs. 0.44 g/kg DM; $P < 0.01$), ammonia N (2.7 vs. 3.3 g/kg DM; $P < 0.01$), and ochratoxin A (10.0 vs. 40.0 μg/kg DM; $P < 0.01$). Both silages had similar ($P > 0.05$) concentrations of total VFA, acetic acid, and deoxynivalenol. These results indicate that CT in PPC reduced protein degradation and decreased the activity of both lactic acid– and ochratoxin A–producing microorganisms. After 14 d of aerobic exposure, internal temperature of PEG-treated silage started to rise 12 h earlier than that of Control silage. This suggests that CT decreased microbial activity and improved the aerobic stability of PPC silage. This study demonstrated that plant CT could be used to improve silage quality by decreasing protein degradation and the activity of mycotoxin-producing microorganisms while improving the aerobic stability of silage.

Key Words: aerobic stability, condensed tannin, purple prairie clover, silage

1565 Effect of purple prairie clover (*Dalea purpurea* Vent.) and its condensed tannins on nutrient intake, digestibility, and growth performance of lambs. K. Peng*[1,2], D. C. Shirley[3], Z. Xu[2], Q. Huang[2,4], T. A. McAllister[5], A. V. Chaves[3], S. Acharya[2], S. Wang[1], and Y. Wang[2], *[1]College of Engineering, China Agricultural University, Beijing, P. R. China, [2]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, [3]The University of Sydney, Faculty of Veterinary Science, School of Life and Environmental Sciences, Sydney, Australia, [4]College of Animal Science and Technology, Northwest A&F University, Yangling, P. R. China, [5]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, Lethbridge, AB, Canada*.

This study evaluated the effects of purple prairie clover (PPC; *Dalea purpurea* Vent.) hay and its condensed tannins (CT) on feed intake, nutrient digestibility, and growth performance of lambs. Alfalfa and PPC were harvested at full flower, sun cured to <12% moisture, baled, and stored in a shed for 120 d. Purple prairie clover contained about 5% CT at harvest. Thirty-six individually fed lambs were randomly allocated into three groups and fed TMR containing 40% (DM basis) of pelleted barley grain–based concentrate and 60% of alfalfa hay (Alf), PPC hay (PPC), or PPC hay along with polyethylene glycol (PPC-p) for 77 d. Polyethylene glycol (PEG) dissolved in water was sprayed onto TMR to neutralize PPC CT activity. Lambs were fed once daily, DMI was measured weekly, and ADG was determined biweekly. Fecal samples were collected in the fifth week for 5 d to estimate nutrients digestibility using AIA as a marker. The Mixed procedure of SAS was used to analyze the data with treatment as a fixed effect and lamb as a statistical unit. Alfalfa and PPC hay had similar DM, OM, N, NDF, and ADF content at feeding. Lambs fed the PPC-p diet exhibited greater DM (68.8 vs. 59.8 vs. 66.7%; $P < 0.01$), OM (71.2 vs. 60.8 vs. 66.9%; $P < 0.001$), and N (76.5 vs. 61.0 vs. 65.5; $P < 0.001$) digestibility than those fed the Alf or PPC diets and greater NDF (59.3 vs. 42.9; $P < 0.001$) and ADF (51.0 vs. 43.3; $P < 0.05$) digestibility than those fed the Alf diet. Digestibilities of OM and DM were greater ($P < 0.05$) for PPC than for the Alf diet, whereas N, NDF, and ADF digestibility were similar. Addition of PEG to the PPC diet increased ($P < 0.05$) N and NDF digestibility and tended ($P = 0.07$) to increase ADF digestibility but did not affect DM or OM digestibility. Although PPC hay had greater DM and OM digestibility than alfalfa hay, CT reduced the fiber digestibility of PPC hay. Lambs consuming Alf, PPC, and PPC-p diet had similar ($P > 0.05$) ADG (187.1 vs. 187.1 vs. 185.3 g/d) and feed efficiency (0.151 vs. 0.151 vs. 0.147) but lambs consuming PPC tended ($P = 0.093$) to eat less (1.10 vs. 1.18 vs. 1.18 kg DM/d). Purple prairie clover hay had superior nutritive value to alfalfa hay owing to its greater DM and OM digestibility but did not improve lamb growth performance, possible due to the detrimental impact of CT on N and fiber digestion.

Key Words: digestibility, growth performance, lamb, purple prairie clover

1566 Effect of dietary polyphenol, protected amino acid, and crude protein levels on in vitro rumen fermentation and crude protein digestibility. B. Choi*[1], J. Yang[1], C. Ryu[1], S. J. Shin[1], Y. Kim[1], J. Heo[2], S. Cho[3], and N. J. Choi[1], *[1]Chonbuk National University, Jeonju-si, the Republic of Korea, [2]Microbial Institute for Fermentation Industry, Sunchang-gun, the Republic of Korea, [3]CALS Co., Ltd., Seongnam-si, the Republic of Korea*.

The present study investigated the effect of polyphenol (PP), protected AA (PA), and CP levels on in vitro rumen fermentation to improve protein utilization efficiency of dairy cattle. Dietary polyphenol extracted from sweet chestnut and protected methionine and lysine were used. Two CP levels of basal diets were designed to 16 and 18%. A factorial experimental design ($2 \times 2 \times 4$) was used to evaluate the effect of PP, PA, CP, and their interactions on rumen fermentation. Four different levels of PP (0, 0.5, 1.0, and 1.5% in diet) and two levels of PA (0 and 2.5% in diet) were mixed with two basal diets. A total of 16 different experimental diets were prepared and subjected to in vitro rumen simulated fermentation. After 24 h of incubation, rumen fermentation parameters and CP digestibility were determined. Significant main effects of factors were detected ($P < 0.05$) in gas production parameters. Factors of CP level and PA elevated gas production, and gas production decreased as levels of PP increased. However, there was no significant interaction between these factors. The factors of CP level and PP showed significant main effects on methane production ($P < 0.05$). Methane production in 18% CP diets was greater than in 16% CP diets, and methane was decreased when PP levels increased. Total VFA (TVFA) production was affected ($P < 0.05$) by the levels of CP and PP. Higher CP levels showed greater TVFA production. Total VFA production was decreased when PP levels were increased. However, TVFA production was not changed until PP levels reached 0.5%. All factors showed significant main effects on in vitro DM digestibility (IVDMD) ($P < 0.05$), and significant interactions were detected between CP × PP and PA × PP ($P < 0.05$). In vitro DM disappearance was decreased when PP levels were increased. However, these decreasing patterns were altered by the levels of CP and PA. Increasing CP or PA levels slowed the decrement of IVDMD by PP, and CP digestibility showed patterns similar to those of IVDMD. Significant main effects were found for the levels of CP and PP ($P < 0.05$), and a significant interaction was detected between PA and PP ($P < 0.05$). When PP and PA were added in the diet together, they both decreased CP digestibility. These results indicate that polyphenol can alter the rumen fermentation, and 0.5% of polyphenol in a diet can increase

protein bypass to the intestine from the rumen without negative effects on rumen TVFA production.

Key Words: crude protein, in vitro, polyphenol, protected amino acid, rumen bypass

1567 The effect of addition of mulberry leaves silage in the diet of beef cattle on their growth and slaughter performance. H. Wu*, Q. Meng, L. Ren, and Z. Zhou, *China Agricultural University, Beijing, P. R. China*.

The objective of the present study was to evaluate the effect of adding different levels of ensiled mulberry leaves to the diet of beef cattle on their growth and slaughter performance. Eighty-eight beef cattle (44 Limousine crossbred cows and 44 local breed bulls) at the age of 30 ± 3.2 mo and with an initial BW of 468.0 ± 10.0 kg were divided into 4 groups (n = 22) in a randomized complete block design with sex as a block. Four levels of ensilaged mulberry (0, 7.5, 15.0, or 22.5% DM) were tested using the basal diets, with all the treatment groups being isonitrogenous and isoenergetic. The trial lasted for a total of 100 d including 10 d for adaptation and 90 d for data collection. At the end of the feeding trial, eight cattle from each treatment group were randomly selected and slaughtered for measurement of slaughter performance including HCW, bone weight, net meat weight, back fat thickness, and rib eye area. All statistical analyses were performed for a completely randomized block design using general linear models (GLM) procedures of SAS (2000). The differences between means were assessed by the Student–Newman–Keuls test and statistical significance was defined at $P < 0.05$. The results showed that the additions of ensilaged mulberry leaves at the tested levels did not results in significant ($P > 0.50$) difference in final BW, ADG, DMI, or feed conversion efficiency. The additions of ensilaged mulberry leaves were not accompanied by a significant ($P > 0.20$) change in carcass parameters except for increases in hot dressing percentage and rib eye area ($P < 0.01$), which were 54.0% and 62.2 cm^2, 57.1% and 75.5 cm^2, 56.8% and 75.4 cm^2, and 56.1% and 75.5 cm^2 for addition level from low to high, respectively. These results indicated that although ensiled mulberry silage may not significantly improve feed utilization, growth, or major carcass characteristics of beef cattle, it can be used as a resource of nutrients for beef cattle feeding.

Key Words: beef cattle, growth performance, mulberry leaves silage

1568 Supplementation of Korean honeysuckle (*Lonicera vesicaria*) extract in timothy hay on in vitro ruminal fermentation. I. D. Lee*[1], S. K. Lee[2], S. J. Lee[2], S. Y. Yang[3], S. S. Lee[1], and J. S. Eun[3], *[1]Division of Applied Life Science, Gyeongsang National University, Jinju, the Republic of Korea, [2]Institute of Agriculture and Life Science, Gyeongsang National University, Jinju, the Republic of Korea, [3]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan*.

Korean honeysuckle (*Lonicera vesicaria*; KH) is a traditional shrub and used as folk medicine in Korea. The KH is a rich source of ascorbic acid and phenolic components, particularly anthocyanins, flavonoids, and phenolic acids. These compounds reportedly have multiple biological activities, including strong antioxidant activity and antibiotic properties. Therefore, we performed an in vitro experiment to assess the effects of KH extract (KHE) on ruminal fermentation characteristics. Milled timothy hay (0.3 g DM) was incubated with buffer, ruminal fluid, and KHE at 0 (control) 3, 5, 7, or 9% DM. The experiment was conducted in a completely randomized design with 3 replications to test the 5 dose rates (DR) of KHE. Batch culture fermentation was conducted for 12, 24, and 48 h separately to measure gas production (GP), degradability of DM, methane (CH_4) production, and ammonia N (NH_3–N) concentration at the 3 predetermined time points. Degradability of DM linearly decreased (P = 0.02) with increasing DR of KHE at 24 h, with 2.5 percentage unit decreases at 7 and 9% KHE, but there was no effect of KHE on the DM degradability at 12 and 48 h. Production of GP was generally similar to the pattern of DM degradability, having a linear decrease (P = 0.01) mainly due to 9% KHE at 24 h. Concentration of NH_3–N linearly increased because of increasing KHE supplementation at 12 h, whereas it tended to decrease in a quadratic manner (P = 0.07) at 24 h. Supplementing KHE quadratically decreased ($P < 0.01$) CH_4 production at 12 h, and it elicited linear decreases ($P < 0.01$) on CH_4 production at 24 and 48 h. However, KHE supplementation greater than 5% did not further decrease CH_4 production. These collective results demonstrate that KHE supplementation affected in vitro ruminal fermentation in a dose-dependent manner and that KHE has a potential to function as a ruminal fermentation modifier to suppress CH_4 production with minimal effects on nutrient digestion in the rumen. The positive effects on NH_3–N and CH_4 may have been resulted from combined effects from condensed tannins and saponin in KHE.

Key Words: in vitro batch culture, Korean honeysuckle extract, methane

1569 Effects of an extract of plant flavonoids from *Citrus aurantium* on performance, eating and animal behavior, ruminal health, and carcass yield in Holstein bulls fed high-concentrate diets.
M. Devant*[1], F. J. Crespo[2], A. Bach[3,4], and M. Paniagua[5], *[1]IRTA – Department of Ruminant Production, Caldes De Montbui, Spain, [2]Interquim SA, Barcelona, Spain, [3]ICREA, Barcelona, Spain, [4]IRTA, Caldes de Montbui, Spain, [5]Quimidroga, Barcelona, Spain*.

This study evaluated the effects of an extract of plant flavonoids from *Citrus aurantium* (Bioflavex CA; 24% naringin) on performance, eating pattern, behavior, and carcass quality of Holstein bulls. Ninety-nine bulls (201.8 ± 3.30 kg BW and 154 ± 0.83 d of age) were randomly allocated to 1 of 6 pens and assigned to a control (C) or Bioflavex CA (BF; 0.4 kg/ton of Bioflavex CA added to the concentrate). Each pen (6 by 12 m) had one drinker, one separate straw feeder, and one single space feeder with lateral protections where concentrate (40% corn, 14% barley, 11% wheat, 23% corn gluten feed, 15% CP, and 2.88 Mcal of ME/kg) was offered. Concentrate intake was recorded daily, and BW and animal behavior by visual scan were registered fortnightly. Animals were slaughtered after 168 d of study (12 periods of 14 d), and HCW and carcass quality were recorded. Data were analyzed using a mixed-effects model with repeated measures. Throughout the study, 4 C and 1 BF bulls were removed, 2 of the 4 C bulls due to lameness. Concentrate intake (6.9 ± 0.12 kg/d for C and BF), concentrate efficiency (0.23 ± 0.031 kg/kg), and carcass weight (262 ± 2.3 kg for C and BF) were not affected by treatments. The ADG (1.67 and 1.63 ± 0.042 kg/d for C and BF, respectively) and final BW (487 and 478 ± 3.6 kg for C and BF, respectively) tended ($P = 0.07$) to be greater in C bulls than in BF bulls. An interaction between treatment and time was observed for most behavior parameters. During the growing phase (periods 1 to 8), C bulls performed more self-grooming and attempted less mounts ($P < 0.05$) compared with BF bulls. During finishing (periods 9 to 12), an interaction in meal duration ($P = 0.01$) was observed; meal duration was greater (periods 9 to 11) in BF bulls compared with C bulls. Moreover, during finishing, nonagonistic interactions, such as oral nonnutritive and social behaviors, were greater ($P < 0.05$) in C bulls than in BF bulls. In addition, agonistic interactions (fighting, butting, and chasing) and sexual behaviors (flehmen and complete mounts) were greater ($P < 0.05$) in C bulls than in BF bulls. In conclusion, when bulls were supplemented Bioflavex CA, meal duration increased and animals' agonistic and sexual interactions were less frequent compared with non-supplemented bulls during the finishing period.

Key Words: behavior, bulls, flavonoids, performance

1570 A blend of cinnamaldehyde, eugenol, and capsicum oleoresin improves milking performance in lactating dairy cows.
C. Oguey* and E. H. Wall, *Pancosma, Geneva, Switzerland*.

Supplementation with a blend of eugenol, cinnamaldehyde, and capsicum oleoresin (ECC; XTRACT Ruminant; Pancosma, Geneva, Switzerland) was previously shown to modulate rumen function and improve feed conversion efficiency in growing ruminants. This trial aimed to determine the productive implications of this response in dairy cows. Primi- and multiparous lactating Holstein dairy cows (mean parity = 2.43; mean DIM at trial start = 125 d) were housed together in a free-stall pen and were milked using an automated milking system (AMS). For 8 wk, ECC was blended with a carrier and was dispensed at the AMS for ECC cows ($n = 97$) at a rate of a rate of 0.22 kg/d (dose of ECC = 1,000 mg/cow per day); control cows ($n = 104$) received no additive. All cows were supplemented with 300 mg/d of monensin. Individual cow milk production and composition, milking frequency, and BW were recorded daily. Average DMI of the pen was monitored daily and did not change throughout the study. Data were analyzed using the mixed procedure of SAS with repeated measures. Regardless of parity, milk production was increased with ECC (35.5 vs. 37.5 kg/d; $P < 0.001$). There was a parity × treatment interaction for the effect of ECC on milk composition such that protein percent was decreased in primiparous animals (3.2 vs. 3.1%; $P < 0.001$) but not affected in multiparous animals ($P > 0.30$). Still, ECC increased protein yield (1.1 vs. 1.2 kg/d; $P < 0.001$) and did not affect fat yield (1.4 vs. 1.4 kg/d; $P > 0.50$). Therefore, there was an increase in energy-corrected milk with ECC (38.2 vs. 39.3 kg/d; $P < 0.001$). There was no effect of ECC on BW (673 vs. 674 kg; $P > 0.70$) or prevalence of subclinical ketosis (5.1 vs. 5.5%; $P > 060$). Interestingly, there was a parity × treatment interaction for number of milkings per day. In primiparous cows, ECC increased milking frequency (2.9 vs. 3.2; $P < 0.01$), whereas there was no effect in multiparous animals (3.5 vs. 3.6; $P > 0.30$). These findings reveal that supplementation with ECC, even on top of an ionophore, improves milk production performance of lactating dairy cows.

Key Words: automated milking system, performance, XTRACT

1571 Evaluation of a proprietary blend of essential oil and cobalt on a commercial dairy. O. J. Kuester*, *South Dakota State University, Brookings*.

A field trial was conducted for 7 mo on a commercial dairy equipped with two Lely robotic milking units to evaluate the response of feeding a proprietary essential oil and cobalt product (EOC) on the lactational performance of lactating Holstein dairy cows. Cows were divided between two pens (57 ± 2 cows and 59 ± 3 cows for treatment [EOC] and control [C] pens, respectively), based on cow parity (2.65 ± 1.52 and 2.33 ± 1.20), days in milk (DIM) (184 ± 103 and 154 ± 94.2), and milk production (35.4 ± 11.3 and 36.9 ± 11.3 kg/d) before study initiation. Cows were group fed either an EOC or C total mixed ration (TMR) 2x/d, and pen diets were switched after 4 mo of data collection. Production data was collected daily from Lely Time for Cows (T4C) robotic milking software and was reduced to weekly observations for each cow. Management level milk production was not different (P = 0.92) between EOC and C treatments (41.5 ± 1.91 and 41.4 ± 2.05 kg/d, respectively). Fat and protein percentages were not different between EOC and C treatments (P = 0.55 and 0.56, respectively) but were numerically higher for EOC-fed cows than for C-fed cows (3.39% fat and 2.99% protein vs. 3.36% fat and 2.97% protein, respectively). Total feed intake was not different between treatments (P = 0.16) but was numerically lower for EOC-fed cows (25.7 kg/d) than for C-fed cows (25.9 kg/d). Feed efficiency (FE) was not different between treatments (P = 0.73) but was numerically lower for cows fed EOC than for cows fed C (1.60 FE and 1.62 FE, respectively). Feeding the proprietary EOC product on a commercial dairy operation that used robotic milking units did not increase management level milk production or FE but numerically increased milk percentages of fat, protein, and total feed intake.

Key Words: cobalt, commercial dairy, essential oil, robotic milker

1572 Effects of feeding functional oils or monensin on feedlot performance and carcass traits of Nellore cattle. A. C. Melo*[1,2], M. C. Pereira[3], A. L. Rigueiro[1], D. H. M. Watanabe[1], M. M. Squizatti[1], L. A. Tomaz[1], J. V. Dellaqua[1], O. A. Souza[1], P. F. Santi[1], A. L. J. Lelis[1], A. F. Toledo[1], and D. D. Millen[1], *[1]São Paulo State University (UNESP), Dracena campus, Dracena, Brazil, [2]Grant provided by São Paulo State Foundation (FAPESP), São Paulo, Brazil, [3]São Paulo State University (UNESP), Botucatu campus, Botucatu, Brazil*.

This study, conducted at the São Paulo State University feedlot, Dracena campus, Brazil, was designed to test the effects of adding functional oils (Essential) or monensin (MON) on feedlot performance and carcass traits of Nellore cattle fed high-concentrate diets. Ninety-six 22-mo-old Nellore yearling bulls (377.9 ± 32.0 kg) were assigned to 24 pens (4 animals/pen) and used in a completely randomized block with 2 × 2 factorial arrangement of treatments, replicated 6 times. Factors were inclusion (DM basis) or not of functional oils or MON, at a dose of 500 or 27 ppm, respectively. Animals were adapted for 16 d to the high-concentrate diets fed. The finishing diet contained 68.5% cracked corn grain, 14.0% sugarcane bagasse, 14.1% cottonseed meal, 2.1% supplement, 0.8% urea, and 0.5% limestone (DM basis). Cattle were fed ad libitum three times daily for 105 d, and DMI was recorded daily. No significant (P > 0.10) functional oils main effect or interactions between functional oils and MON were observed for any of the feedlot performance and carcass traits variables evaluated: final BW (without functional oil = 503.6 kg and with functional oil = 505.1 kg), DMI (without functional oil = 9.6 kg and with functional oil = 9.6 kg), ADG (without functional oil = 1.2 kg and with functional oil = 1.2 kg), G:F (without functional oil = 0.126 kg/kg and with functional oil = 0.126 kg/kg), HCW (without functional oil = 280.9 kg and with functional oil = 281.0 kg), and dressing percentage (without functional oil = 55.8% and with functional oil = 55.5%). Also, no significant (P > 0.10) MON main effect was observed for final BW, ADG, HCW, and dressing percentage. However, the addition of MON reduced (P = 0.001) the DMI (without MON = 10.3 kg and with MON = 8.9 kg) and improved (P = 0.01) G:F (without MON = 0.117 kg/kg and with MON = 0.136 kg/kg). Cattle fed MON performed better than those animals not fed MON. On the other hand, feeding functional oils did not improve feedlot performance and carcass traits in this study.

Key Words: additives, feedlot, Nellore

1573 Influence of tannins extract and monensin supplementation on performance of feedlot heifers in Argentina. C. Cabral[1], A. Lopez Da SIlva[2,3], J. J. Couderc[3], D. Colombatto[4], and R. Barajas*[5], *[1]Indunor, S.A., Buenos Aires, Argentina, [2]Feedlot Don Corral de Corijunio S.A., Buenos Aires, Argentina, [3]Nowet S.A, Buenos Aires, Argentina, [4]Universidad de Buenos Aires, Buenos Aires, Argentina, [5]FMVZ-Universidad Autónoma de Sinaloa, Culiacan, Mexico*.

Tannins extract and monensin have activity against several rumen bacteria that participate in feed-protein degradation; it was hypothesized that its effects could be synergistic. Three hundred forty-eight Angus heifers (207 ± 13.4 kg) were used to determine the influence of tannins extract and monensin supplementation on performance of feedlot heifers. The heifers were individually weighed and blocked by weight at study initiation. Groups of 29 heifers were placed in 12 dirt-floor pens (50 by 70 m). Pen was the experimental unit. Pens within a block were randomly assigned to treatments as follows: 1)

Table 1574. Effect of corn processing and dietary protein level on nitrogen (N) metabolism.

Items, g/d	SFC[1]			FGC		SEM	Contrast[1]

[1]Contrasts for P (corn processing effect), CP (protein level effect), and interaction (P×CP).

basal diet (14.1% CP and 1.75 Mcal NE_m/kg DM) plus 3.1 g of tannins extract (TE)/kg DM provided by ByPro (Indunor-Silvafeed; Buenos Aires, Argentina), 2) basal diet plus 35 mg of monensin (MON)/kg DM from Rumensin 200 (Elanco Animal Health, Indianapolis, IN), and 3) basal diet plus 3 g of TE and 35 mg of MON/kg DM (TEMO). Tannins extract and MON were top-dressed in the feed bunk. Data were analyzed by ANOVA as a mixed model, for a randomized complete block design. The model included the random effect of block and fixed effects of treatments (TE, MON, and TE + MON). Possible influence of initial weight was explored by covariance analyses. Heifers receiving TE had higher final weight than those received MON (P = 0.05; 316 vs. 306 kg) and gained faster (P = 0.04; 1.41 vs. 1.22 kg/d). Dry matter intake was not affected by treatments (P = 0.43). The gain:DM feed efficiency was better in heifers fed TE than in MON-supplemented heifers (0.17 vs. 0.15 kg). The observed:expected diet NE ratio was higher (P = 0.05) in TE heifers than in MON heifers (NEm, 0.97 vs. 0.93, and NEg, 0.96 vs. 0.90, respectively). The mean values of final weight, daily gain, DMI, feed efficiency, and NE exhibit by TEMO heifers were intermediate and not significantly distinct (P > 0.10) from those obtained by TE and MON heifers. The results suggest that TE supplementation may contribute to an incremental improvement in growth performance of beef cattle.

Key Words: feedlot performance, monensin, tannins

1574 Effects of different protein levels and corn processing methods on nitrogen metabolism in dairy cows and environmental pollution.
G. R. Ghorbani*, H. Rafiee, and M. Alikhani, *Isfahan University of Technology, Isfahan, the Islamic Republic of Iran*.

Eight midlactation Holstein cows averaging 105 ± 9 d in milk and 47.2 ± 3 kg of milk/d were assigned to a replicated 4 × 4 Latin square design (2 × 2 factorial) to study the effects of corn processing and protein level on nitrogen metabolism. Experimental diets contained either finely ground corn (FGC) or steam-flaked corn (SFC) based on either a low protein (LP; 14.8%) or a high protein (HP; 16.2%) content. Diets consisted of 40% forage, including 15% alfalfa hay and 25% corn silage. The concentrate contained soybean meal and urea as protein sources. Cows fed diets with a greater protein concentration had 11.2% greater N intake (717.2 vs. 644.9 g/d; P < 0.01), 7.8% greater urinary N (169.3 vs. 157.0 g/d; P < 0.01), 13.3% greater absorbed N (438.6 vs. 387.1 g/d; P < 0.01), and 8% greater pollution N (447.9 vs. 414.5 g/d; P = 0.01). Cows fed HP diets had lower milk N efficiency (30.6 vs. 33.0%; P = 0.01). Cows fed FGC rather than SFC had 6.7% greater N intake (703.1 vs. 659.0 g/d; P < 0.01), tended to have 3.4% greater urinary N excretion (165.9 vs. 160.4 g/d; P = 0.06), and had lower milk N efficiency (30.7 vs. 33.0%; P = 0.02). Results indicate that cows fed LP diets and SFC diets had greater N efficiency and reduced N loss.

Key Words: ground corn, level of protein, steam-flaked corn

1575 Eelative availability for lactating dairy cattle of methionine from two sources of ruminally protected methionine.
M. Ardalan*[1], C. F. Vargas Rodriguez[1], G. I. Zanton[2], M. Vázquez-Añón[3], E. C. Titgemeyer[1], and B. J. Bradford[4], *[1]Department of Animal Sciences and Industry, Kansas State University, Manhattan, [2]USDA-ARS, U.S. Dairy Forage Research Center, Madison, WI, [3]Novus International, Inc., St. Charles, MO, [4]Kansas State University, Manhattan*.

Our objective was to evaluate lactational responses of dairy cows to methionine (Met) provided from 2 rumen-protected (RP) Met sources. Twenty-one Holstein dairy cows (11 primiparous [137 DIM, 634 kg BW, and 3.6 BCS] and 10 multiparous [parity 2, 142 DIM, 670 kg BW, and 3.2 BCS]) were assigned to a treatment sequence in 4 replicated 5 × 5 Latin squares with 14-d periods. Treatments included 1) control; 2) and 3) 7.5 and 15 g/d, respectively, of a RP product (NTP-1401; Novus International, Inc., St. Charles, MO); and 4) and 5) 7.5 and 15 g/d, respectively, of a rumen-protected dl-Met product (Smartamine; Adisseo, Alpharetta, GA). By evaluation with CNCPS 4.0, the diet met MP and energy requirements when DMI was 25.6 kg/d for lactating Holstein cows

producing 45 kg/d milk with 3.5% fat and 3.0% true protein. Diets contained 16.1% CP and were predicted to be deficient in metabolizable Met (1.85% of MP) but sufficient in lysine (6.8% of MP). Feed intake and milk production were measured on d 11 to 14. Blood was collected on d 14. Dry matter intake, milk yield, energy-corrected milk (ECM), milk fat yield and percentage, and efficiencies of milk and ECM production were not affected by treatment ($P \geq 0.14$). Milk protein percentage and milk protein yield linearly increased with supplementation ($P < 0.01$), without differences between Met sources or interactions between source and level. Linear regressions of milk protein percentage and milk protein yield against supplement amount within source led to slope ratios (NTP-1401/Smartamine) of 95% for protein percentage ($P = 0.65$ for difference from 100%) and 84% for protein yield ($P = 0.60$ for difference from 100%), suggesting no differences between sources for increasing milk protein. Plasma Met concentrations were linearly increased ($P < 0.001$) by Met supplementation, with the increase being greater for Smartamine than for NTP-1401 ($P < 0.001$). Plasma d-Met was increased only by Smartamine. Plasma 2-hydoxy-4-methylthio-butyric acid (HMTBA) was increased only by NTP-1401. The sum of plasma Met and plasma HMTBA was linearly increased by Met supplementation ($P < 0.01$) with no difference between sources ($P = 0.89$). Our data demonstrated that supplementation of Met can improve milk protein percentage and yield. The 2 methionine sources did not differ in their effect on lactation performance or milk composition.

Key Words: dairy, methionine, milk protein

1576 Effects of rumen undegradable protein supplementation and ambient temperature on growth performance and blood metabolites in Korean cattle steers. H. J. Kang*, M. Y. Piao, H. J. Kim, and M. Baik, *Department of Agricultural Biotechnology, College of Agriculture and Life Sciences, Seoul National University, Seoul, the Republic of Korea*.

Under heat stress, RUP can have positive effects on milk production of dairy cow. This study was performed to evaluate whether rumen RUP supplementation and ambient temperature affects growth and blood metabolic parameters in Korean cattle. In Exp. 1, 14 Korean cattle steers (average 20.5 mo of age and 231.3 kg of BW) were divided into a conventional control diet group ($n = 7$) and a 0.55% RUP supplementation group ($n = 7$). Steers were allowed to receive daily an early fattening stage concentrate diet with the amount of 1.5% of BW using an automatic feeding station for 4 mo from July through October 2015, and they were allowed to receive a tall fescue with the amount of 0.75% of BW. Temperature data were analyzed by using one-way ANOVA, and growth and blood data were analyzed by using repeated-measured two-way ANOVA. Maximum ambient temperature and maximum temperature–humidity index (THI) were higher in July (30.6°C and 81.8, respectively), August (32.9°C and 80.7, respectively), and September (28.8°C and 80.3, respectively) than in October (19.8°C and 63.7, respectively). Blood was collected at starting day and at every 4 wk after 8 h fasting. Ruminally undegradable protein supplementation did not affect total feed intake, ADG, and feed efficiency (FE), although ambient temperature or month affected feed intake, ADG, and FE. Ruminally undegradable protein supplementation tended ($P = 0.08$) to decrease serum glucose concentrations, but it increased ($P = 0.006$) serum high-density cholesterol (HDL) concentrations. Ambient temperature or month affected ($P < 0.001$) both glucose and HDL concentrations. In Exp. 2, six Korean cattle steers (average 20.6 mo of age and 230.7 kg of BW) were raised in metabolic cages in a temperature-controlled room with air conditioning and heating system. Animals were divided into a conventional control diet group ($n = 3$) and a 0.55% RUP supplementation group ($n = 3$). In Exp. 2, steers were allowed to receive a same amount of the concentrate and the hay as that of Exp. 1. Experimental period 1 (P1) was 8 d with high temperature and period 2 (P2) was 8 d with normal temperature. Blood was collected at d 1 and 8 after 8 h fasting. Maximum ambient temperature and THI (34.4°C and 86.0) of P1 was higher ($P < 0.001$) than that (19.6°C and 67.0) of P2, respectively. In Exp. 2, RUP supplementation did not affect feed intake, ADG, FE, and blood parameters at both P1 and P2. In conclusion, RUP supplementation and ambient temperature affected blood parameters, although they did not significantly influence growth performance of Korean cattle.

Key Words: ambient temperature, beef cattle, blood metabolites, growth, rumen undegradable protein

---

1577 Guanidinoacetic acid as a precursor for creatine in steers. M. Ardalan*[1], M. D. Miesner[2], C. D. Reinhardt[1], D. U. Thomson[3], C. K. Armendariz[1], and E. C. Titgemeyer[1], *[1]Department of Animal Sciences and Industry, Kansas State University, Manhattan, [2]Department of Clinical Sciences, Kansas State University, Manhattan, [3]Department of Diagnostic Medicine/Pathobiology, Kansas State University, Manhattan*.

Guanidinoacetic acid (GAA) can be methylated to produce creatine. Because GAA supplementation bypasses the regulatory step in creatine formation, it may increase creatine availability. However, unregulated consumption of methyl groups may be problematic. We studied GAA supplementation in 7 steers maintained under conditions where methionine (Met) supply was purposefully limiting. Steers were limit-fed a soyhull-based diet and received abomasal infusions of AA to make methionine the solely limiting AA. Ruminal infusions of VFA and abomasal infusions of glucose provided energy. Factorial treatments (abomasally infused) included 0, 7.5, and 15 g/d GAA and 0 and 6 g/d l-Met. The experimental design

Table 1578. Dairy and Beef TMR CP and TAA population statistics.

Type	Parameter	n	Mean	St.Dev.	Min.	Max.
Beef	CP	9	13.2	1.2	11.2	14.7
Beef	TAA	9	11.1	1.1	9.3	12.7
Dry	CP	47	15.3	1.9	11.5	19.4
Dry	TAA	47	11.9	1.4	9.2	15.8
Lactating	CP	76	17.3	1.6	13.7	22.3
Lactating	TAA	76	14.0	1.2	10.4	18.7

was a split-plot, with Met main-plot treatments assigned in three 2 × 2 Latin squares. Subplot treatment was GAA, with amounts assigned to three 10-d subplot periods within each main-plot cell. Two steers received the same treatment sequence. Steers were housed in metabolism crates for measuring N retention over d 5 to 10. Jugular blood was collected on d 6, 8, and 10. Plasma GAA concentrations were increased by GAA supplementation ($P < 0.01$) but unaffected by Met ($P = 0.84$). Plasma creatine concentrations were increased by GAA supplementation ($P < 0.01$) but decreased by Met ($P < 0.01$). Plasma creatinine concentrations were unaffected by treatments ($P > 0.32$). Nitrogen retention was increased by Met ($P < 0.01$) but was not affected ($P > 0.28$) by GAA. There was, however, a tendency ($P = 0.10$) for N retention to demonstrate a Met × GAA interaction, with GAA linearly increasing N retention when 6 g/d Met was provided but decreasing N retention when no Met was supplemented. Urinary excretions of creatine and GAA did not demonstrate main effects of Met or GAA; however, both tended ($P < 0.10$) to be increased by GAA supplementation in the absence of supplemental Met but not affected by GAA when 6 g/d Met was supplemented. Urinary excretion of creatinine tended ($P < 0.10$) to be increased by GAA supplementation but was unaffected by Met. These data demonstrate that GAA can serve as a precursor to creatine in cattle and that metabolism of GAA and creatine are affected by methionine status. Supplementation of GAA did not affect N retention of growing steers, suggesting that either endogenous GAA production was adequate or longer periods may be required before responses are established.

Key Words: creatine, guanidinoacetic acid, methionine

1578 Total amino acid content variation for a commercial total mixed ration and relationship to crude protein. J. P. Goeser*[1,2], D. Sawyer[2], and G. A. Broderick[3], [1]*University of Wisconsin, Madison,* [2]*Rock River Laboratory, Inc., Watertown, WI,* [3]*Broderick Nutrition & Research, LLC, Madison, WI.*

Dairy cattle AA nutrition has evolved with NRC, CPM, and CNCPS model improvements. Ingredients rich in AA are added to dairy diets in precise amounts to better meet nutrient needs; however, animal health and performance still varies relative to expected responses when balancing for AA. The objective of this project was to describe total AA (TAA) population statistics and to determine if TAA varied relative to CP, for commercial TMR. Commercial TMR, $n = 141$, were selected from samples submitted to Rock River Laboratory for further analyses. Samples represented by dry, lactating dairy, finishing beef, and unknown TMR were dried using a microwave oven technique and ground (1 mm). TMR CP was determined as N × 6.25 after assaying N by a combustion technique. Total AA were determined after acid hydrolysis using *o*-phtaldialdehyde colorimetry. Type of TMR (beef, lactating, dry, and unknown) and CP were related to TAA using Fit Model function within JMP version 11.0; TMR type was considered random. Interactions and quadratic effects were tested. Residuals were visually assessed for normality using a residual by predicted plot. Commercial TMR CP and TAA (% of DM) and population statistics for all TMR except unknown are described in Table 1. Linear and quadratic relationships between CP and TAA were detected ($P < 0.05$). The quadratic effect was unanticipated and suggests a nonlinear relationship between TAA and CP. The model $R^2 = 0.78$, SE = 0.83, and parameter estimates (and SE) are as follows: 3.48 + CP × 0.58 (SE 0.04) + CP^2 × −0.02 (SE 0.01). That the slope estimate was <1.0 may partly be due to non-AA nitrogen in the form of urea, NH_3–N, or amide N present as glutamine and asparagine, all of which contribute N to CP but not to TAA equivalence. Results presented here demonstrate the variation in TAA contents of commercial farm TMR and may be useful when considering future model development and validation parameters. Furthermore, knowing TMR TAA in addition to CP may help improve on farm nutrition and troubleshooting.

Key Words: amino acid, protein, total mixed ration

1579 Impact of a rumen-protected methionine prototype on dairy cow performance, milk composition, and milk casein. A. M. Barnard*[1], B. A. Barton[2], C. A. Zimmerman[2], R. S. Ordway[2], and T. F. Gressley[1], [1]*University of Delaware, Newark,* [2]*Balchem Corporation, New Hampton, NY.*

Differences in the formulation of the protective matrix of methionine products may impact rumen degradation and intestinal availability. The objective of this study was to determine the effect of a rumen-protected methionine prototype on milk, milk protein, and casein yields. The study was conducted as a replicated 5 × 5 Latin square design in which 10 lactating,

multiparous Holstein cows were assigned to either a methionine-deficient control ration (–Con), –Con supplemented with 0.09% Smartamine M (Adisseo, Antony, France; +Con), or the –Con supplemented with a rumen-protected methionine prototype (Balchem Corporation, New Hampton, NY) to provide either 1 (Met1), 1.5 (Met1.5), or 2 (Met2) times the amount of methionine supplied by Smartamine M. The ration was balanced with AMTS version 4.1.4 assuming 50.0 kg/d milk, 3.70% fat, 3.00% protein, and 740 kg BW. The –Con was formulated to have MP, MP methionine, and MP lysine balances of −32.5, −15.3, and +4.9 g/d, respectively. Supplementation of Smartamine M to the –Con resulted in formulated MP, MP methionine, and MP lysine balances of −16.2, +0.1, and +4.9 g/d, respectively. Periods were 14 d, and milk samples were collected on Days 11 to 14 of each period. Data collected during the last 4 d of each period were averaged by cow and analyzed using the Glimmix procedure of SAS. Data from two cows were removed before analysis due to illness. The model included a covariate (data collected during a 2-wk standardization period), fixed effects of treatment and period, and random effects of cow and cow within block. There were no treatment effects on DMI, milk yield, fat percentage, fat yield, lactose percentage, milk urea nitrogen (MUN), or somatic cell count (SCC) (Table 1). Treatment affected protein percentage ($P = 0.05$) and yield ($P = 0.04$) and tended to affect casein percentage ($P = 0.06$) and yield ($P = 0.06$). Relative to –Con, +Con and Met1.5 increased protein percentage by 0.06 ($P = 0.04$) and 0.08 ($P = 0.01$) units, respectively; protein yield by 0.04 kg/d for both treatments ($P = 0.01$); casein percentage by 0.05 ($P = 0.05$) and 0.06 ($P = 0.06$), respectively; and casein yield by 0.03 kg/d for both treatments ($P = 0.02$). The results suggest that Met1.5 was as effective at restoring methionine levels as +Con.

Key Words: bovine, methione, prototype

1580 Effects of feeding canola meal or wheat dried distillers' grains with solubles alone or in combination as the major protein sources on ruminal function and production in dairy cows.

S. Abeysekara*[1] and T. Mutsvangwa[2], *[1]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada, [2]University of Saskatchewan, Saskatoon, SK, Canada*.

Canola meal (CM) is a good-quality protein supplement that is readily available and is used extensively in dairy cow diets in Canada and the United States. On the other hand, major growth of the ethanol industry in western Canada has resulted in large quantities of wheat dried distillers' grains with solubles (WDDGS) being available as an alternative protein supplement for dairy cows. Canola meal is an excellent source of limiting essential AA (e.g., lysine, histidine), whereas WDDGS has a greater CP content but is a poorer source of lysine; therefore, it is reasonable to consider that a judicious combination of CM and WDDGS as protein supplements may provide an optimal profile of essential AA that would improve milk production. The objective of this study was to determine the effects of feeding CM or WDDGS alone or in combination as the major sources of protein on ruminal fermentation characteristics and production in dairy cows. Fifteen lactating dairy cows (697 ± 46 kg BW and 76 ± 16 d in milk at the beginning of the experiment) were used in a replicated 5 × 5 Latin square design with 28-d periods (20 d of dietary adaptation and 8 d of measurements). Five cows in one Latin square were ruminally cannulated to facilitate ruminal sampling. The dietary treatments were 1) 100% CM as the major protein supplement, 2) 75% CM and 25% WDDGS, 3) 50% CM and 50% WDDGS, 4) 25% CM and 75% WDDGS, and 5) 100% WDDGS. Diets were isonitrogenous (17.6% CP) and were fed as TMR containing 50% forage and 50% concentrate. Dry matter intake (mean = 30 kg/d) was unaffected by diet. Milk production (40.4, 41.0, 41.2, 40.4, and 40.2 kg/d for the 100, 75, 50, 25, and 0% CM diets, respectively) was unaffected by diet. Milk composition was unaffected by diet; however, milk urea nitrogen linearly decreased ($P = 0.05$) as the dietary

proportion of CM decreased. Ruminal pH and concentrations of total and individual VFA were unaffected by diet. These results show that when dairy diets are formulated to contain 17.6% CP, CM or WDDGS can be fed alone or in combination as the major sources of protein and can support similar levels of milk production.

Key Words: canola meal, dairy cow, milk production, wheat dried distillers' grains with solubles

1581 Relative bioavailability of l-carnitine delivered by ruminal or abomasal infusion or by encapsulation in dairy cattle. K. E. Olagaray*[1], J. E. Shaffer[1], C. K. Armendariz[2], A. Bellamine[3], S. Jacobs[3], E. C. Titgemeyer[1], and B. J. Bradford[1], *[1]Kansas State University, Manhattan, [2]Department of Animal Sciences and Industry, Kansas State University, Manhattan, [3]Lonza, Inc., Allendale, NJ.*

These studies evaluated the relative bioavailability of l-carnitine delivered by different methods in dairy cattle. In Experiment 1, 4 Holstein heifers were used in a split-plot design to compare ruminally or abomasally infused l-carnitine. The study included 2 main-plot periods, with infusion routes allocated in a crossover design. Within main-plot periods, each of 3 subplot periods consisted of 4-d infusions separated by 4-d rest periods. Subplot treatments were infusion of 1, 3, and 6 g l-carnitine/d. Doses increased within a period to minimize carryover. Treatments were delivered in two 10-h infusions daily. Blood was collected before the start of infusions and on d 4 of each infusion to obtain baseline and treatment l-carnitine concentrations. There was a dose × route interaction ($P < 0.05$) and route effect ($P < 0.01$) for increases in plasma carnitine above baseline, with increases above baseline being greater across all dose levels when abomasally infused compared with when ruminally infused. Results demonstrated superior bioavailability of l-carnitine when ruminal exposure was physically bypassed. In Experiment 2, 56 lactating Holstein cows (143 ± 72 DIM) were used in a randomized complete block design (blocked by parity and milk production) to evaluate 2 rumen-protected products compared with crystalline carnitine. Treatments were 1) control, 2) 3 g/d crystalline l-carnitine (crystalline), 3) 6 g/d crystalline, 4) 5 g/d 40COAT (40% coating and 60% l-carnitine), 5) 10 g/d 40COAT, 6) 7.5 g/d 60COAT (60% coating and 40% l-carnitine), and 7) 15 g/d 60COAT. Treatments were top-dressed to diets twice daily. The 14-d experiment included a 6-d baseline-measurement period with the final 2 d used for data and sample collection and an 8-d treatment period with the final 2 d used for data and sample collection. Plasma, urine, and milk samples were analyzed for l-carnitine. Crystalline ($P < 0.001$) and 40COAT ($P = 0.01$) linearly increased plasma l-carnitine, and 60COAT tended to linearly increase plasma l-carnitine ($P = 0.08$). Total daily excretion (milk + urine) of l-carnitine averaged 1.52 ± 0.04 g/d in controls, linearly increased with crystalline and 40COAT, and quadratically increased with 60COAT (all $P < 0.05$). Crystalline increased plasma l-carnitine and milk + urine l-carnitine more than 40COAT and 60COAT (all $P < 0.05$). In conclusion, preventing ruminal degradation of l-carnitine increased delivery of bioavailable carnitine to cattle, but effective ruminal protection and postruminal availability is challenging.

Key Words: bioavailability, dairy cow, l-carnitine

1582 Comparison of three levels of a rumen-protected methionine product on performance of lactating dairy cows. A. M. Barnard*[1], B. A. Barton[2], C. A. Zimmerman[2], R. S. Ordway[2], and T. F. Gressley[1], *[1]University of Delaware, Newark, [2]Balchem Corporation, New Hampton, NY.*

Because methionine is one of the limiting AA in the majority of dairy cow rations, rations are commonly supplemented with rumen-protected methionine products. The objective of this study was to evaluate the effect of a newly developed product, AminoShure-M (Balchem Corporation, New Hampton, NY), on performance of cows fed a methionine deficit ration. In a replicated 5 × 5 Latin square design, 19 multiparous cows were assigned to either a methionine-deficient control ration (–Con), the control ration supplemented with 0.09% Smartamine M (Adisseo, Antony, France) to serve as a positive control (+Con), or AminoShure-M to provide either 1.5 (ASM1.5), 1.75 (ASM1.75), or 2 (ASM2) times the amount of methionine supplied by Smartamine M. Periods were 14 d, and milk samples were collected on Days 11 to 14 of each period. Data collected during the last 4 d of each period were averaged by cow and analyzed using the Glimmix procedure of SAS. The model statement included a covariate (data collected during a 2-wk pretreatment period) and fixed effects of treatment and period. Cow and cow within block were included as random effects. There were no effects of treatments on milk yield, DMI, fat percentage, fat yield, lactose percentage, energy-corrected milk (ECM), ECM/DMI, fat-corrected milk (FCM), milk urea nitrogen (MUN) or somatic cell count (SCC). There was an effect of treatment on milk protein percentage ($P = 0.0001$) and protein yield ($P = 0.0001$). Compared with –Con, +Con increased protein percentage (2.77 vs. 2.66%; $P < 0.0001$) and yield (1.33 vs. 1.26 kg/d; $P < 0.0001$). ASM1.5 ($P = 0.003$), ASM1.75 ($P = 0.002$), and ASM2 ($P < 0.0001$) increased protein by 0.05, 0.06, and 0.08 percentage units, respectively, compared with –Con. ASM1.5 ($P = 0.001$), ASM1.75 ($P = 0.001$), and ASM2 ($P < 0.0001$) increased protein yield by 0.04, 0.04, and 0.05 kg/d, respectively, compared with –Con. +Con also increased protein by 0.06 and 0.05 percentage units compared with ASM1.5 ($P = 0.002$) and ASM1.75 ($P = 0.004$), respectively, but was not different from ASM2. +Con also increased protein yield by 0.03 kg/d compared with ASM1.5 ($P = 0.005$) and ASM1.75 ($P = 0.01$). Similar to protein percentage, ASM2 was not significantly different from +Con, suggesting that this ASM treatment was as

effective at restoring methionine levels as +Con.

Key Words: bovine, methionine, milk protein

1583 Evaluation of *Brassica carinata* meal as a protein supplement for growing beef heifers.

T. M. Schulmeister*, M. Ruiz-Moreno, J. Benitez, M. E. Garcia-Ascolani, F. M. Ciriaco, D. D. Henry, J. C. B. Dubeux Jr., G. C. Lamb, and N. DiLorenzo, *University of Florida, North Florida Research and Education Center, Marianna*.

Brassica carinata is a new oilseed crop in Florida with the potential of producing high-quality biodiesel for use as jet biofuel. A high-protein meal is obtained as a byproduct of oil extraction; however, this meal has not been tested as a potential supplement for growing beef cattle. The objective of this experiment was to determine the effect of supplementation with *B. carinata* meal (BCM) on animal performance, attainment of puberty, and blood profile in growing beef heifers consuming grass hay. Thirty-two Angus crossbred heifers (271 ± 42 kg initial BW) were stratified by initial BW and randomly allocated to a total of 10 pens in 2 BW blocks. Within block, pens were randomly assigned to one of two treatments: 0 (CTL) or 0.3% of BW/d (as fed) of BCM pellets. All heifers had ad libitum access to bahiagrass (*Paspalum notatum*) hay and water, and BCM pellets were supplemented daily in the pen. Body weight and blood samples were collected every 7 d for a duration of 70 d, before the daily supplementation. Plasma was collected for analysis of progesterone and blood urea nitrogen concentrations and glucose. Data were analyzed as a generalized randomized block design including block in the model as a random variable. Progesterone data were analyzed using the LIFETEST procedure of SAS to determine the effect of treatment on time to attainment of puberty. There was a difference ($P = 0.02$) in ADG between CTL (0.28 kg/d) and BCM (0.49 kg/d). Time to attainment of puberty did not differ between treatments ($P = 0.36$). Supplementing *B. carinata* meal at 0.3% of BW/d in growing heifers consuming bahiagrass hay is a viable option for increasing ADG without negatively affecting their interval to attainment of puberty.

Key Words: *Brassica carinata*, protein supplement, ruminants

1584 Effects of replacing soybean meal with canola meal or treated canola meal on nitrogen metabolism and total tract digestibility in lactating dairy cows.

E. Marostegan de Paula*[1], M. A. Camargo Danes[2], N. E Lobos[3], G. I. Zanton[4], G. A. Broderick[5], and A. Faciola[1], *[1]University of Nevada, Reno, [2]Federal University of Lavras, Lavras, Brazil, [3]Kemin Industries, Des Moines, IA, [4]USDA-ARS, U.S. Dairy Forage Research Center, Madison, WI, [5]Broderick Nutrition & Research, LLC, Madison, WI*.

Canola meal (CM) has been shown to improve N efficiency in dairy cows when compared with soybean meal (SBM). Treating CM may increase its RUP fraction with the goal of increasing AA availability for absorption in the small intestine. The objective of this study was to evaluate the effects of feeding treated CM (TCM) on N metabolism and total tract digestibility of dairy cows. Thirty multiparous Holstein cows, averaging (means ± SD) 660 ± 55 kg BW, 119 ± 23 DIM, and 44.1 ± 7 kg milk/d, and 15 primiparous cows, averaging 592 ± 34 kg BW, 121 ± 19 DIM, and 33.5 ± 6 kg milk/d, were blocked in a randomized complete block design. Cows were fed a control diet for a 2-wk covariate period and then switched to the experimental diets for a 12-wk study; cows were individually fed in tie-stalls and had free access to water. Treatments differed only in CP source, which were SBM, CM, or TCM. The CM was treated by extrusion, with added molasses to promote the

Table 1584.

Table 1. Effect of soybean meal (SBM), canola meal (CM), or treated canola meal (TCM) on nitrogen metabolism and digestibilities

	Diet				Contrasts *P*-value	
Item	SBM	CM	TCM	SEM	SBM vs. CM+TCM	CM vs. TCM
N intake, g/d	653.0	691.9	691.9	22.7	0.17	1.00
Milk, kg/d	40.0	41.3	40.5	1.01	0.48	0.62
MUN, mg/dL	13.7	12.8	12.5	0.25	<0.01	0.43
DM digestibility, %	68.4	70.9	69.7	0.44	<0.01	0.08
OM digestibility, %	70.2	72.4	71.3	0.42	<0.01	0.07
CP digestibility, %	64.7	68.9	67.3	0.68	<0.01	0.09
NDF digestibility, %	45.1	49.1	47.1	0.80	<0.01	0.08
Fecal-N, g/d	206.5	201.9	210.2	8.01	0.96	0.47
Fecal-N, % of intake	31.6	29.2	30.3	0.45	<0.01	0.08
Urinary total N, g/d	219.4	221.3	215.5	7.25	0.92	0.57
Urinary total N, % of N intake	34.0	32.5	31.5	1.01	0.12	0.46
Urinary urea N, g/d	157.1	152.2	146.6	5.04	0.22	0.44
Urinary urea N, % of total urinary N	72.2	69.2	68.4	0.90	<0.01	0.52

browning reaction. All diets contained (DM basis) 30% alfalfa silage, 30% corn silage, 4% soy hulls, 2.4% mineral–vitamin premix, and 16% CP. The SBM diet contained 25% high-moisture corn (HMC) and 8.6% SBM; the canola diets contained 22% HMC and 11.4% CM or TCM. On the last day of wk 4, 8, and 12, spot urine and fecal samples were collected at 6 and 18 h after feeding. Data were analyzed using the MIXED procedure of SAS. Orthogonal contrasts were used to compare effects of different protein sources (SBM vs. CM + TCM and CM vs. TCM). Partial data are presented in Table 1. Compared with SBM, apparent digestibility of DM, OM, CP, and NDF was greater on both CM and TCM diets and there were trends for improved digestibilities when CM was compared with TCM. There were no differences for N intake, milk yield, and total N excreted in urine and feces; however, both canola diets decreased urinary urea N (% of total urinary N) and fecal N (% of total N intake) and decreased MUN concentration. No differences were observed between CM and TCM with regards to N utilization. Results from this experiment indicate that replacing SBM with CM or TCM in lactation diets improved digestibility and minimized environmental impact but that extrusion did not improve CM utilization.

Key Words: dairy nutrition, digestibility, nitrogen utilization

1585 Impact of different diet crude protein levels and ruminally degradable protein:ruminally undegradable protein ratios on midlactation dairy cow performance: II. Dry matter intake, digestibility, and nitrogen balance.

C. R. Guimaraes[1], S. G. Coelho[2], A. M. Pedroso*[3], F. S. Machado[4], M. M. Campos[4], R. A. Azevedo[2], L. C. Rezende[2], T. R. Tomich[4], and L. G. R. Pereira[4], *[1]Cargill Amidos, Uberlandia, Brazil, [2]UFMG, B. Horizonte, Brazil, [3]Cargill Premix & Nutrition, Campinas, Brazil, [4]EMBRAPA, Juiz de Fora, Brazil*.

This study evaluated the impact of different CP levels and RDP:RUP ratios in the diets of 24 crossbred Holstein–Gir midlactating dairy cows. Animals were allotted for 60 d to 4 treatments on a complete random design ($n = 6$). Experimental diets were formulated using the CNCPS version 6.1 model to meet production requirements and to be isoenergetic and provide the same amount of MP. Crude protein concentrations were 12.4, 13.0, 13.6, and 15.4% on a DM basis. Ruminally degradable protein levels ranged from 5.6 to 9.7% DM and RUP ranged from 6.8 to 5.7 DM in relation to treatments with lower and higher CP levels, respectively. Soypass (Cargill) was used in substitution to soybean meal and urea to adjust RDP:RUP ratios. Parameters evaluated were DMI, CP intake (CPI), DM digestibility, nitrogen balance, microbial protein yield (MPY), and plasma urea nitrogen (PUN). Data were analyzed using PROC MIXED from SAS 9.0 on a split plot design. Dry matter intake did not differ among treatments and ranged from 20.0 to 21.6 kg/d, whereas CPI increased ($P < 0.01$) as diets' CP level increased (2.59–3.46 kg/d). Treatments did not affect DM digestibility (60.2–61.9%) but CP digestibility increased ($P < 0.04$) as RDP levels in the diets increased (58.2–67.2%). Treatments did not affect milk N (119–135 g/d) or N in feces (178–182 g/d). Urine N increased (116–247 g/d) as diets CP level increased ($P < 0.01$). Microbial protein yield was not affected by treatments. Plasma urea nitrogen values raised from 10.2 to 19.6 mg/dL as RDP levels increased ($P < 0.01$). Results show that formulating diets with more RUP sources can be an efficient tool to reduce N excretion and improve N balance. Reducing RDP and CP levels in the diets did not affect DMI and did not impair MPY.

Key Words: ruminally degradable protein, ruminally undegradable protein, nitrogen balance

1586 Evaluation of protein supplementation in low- to medium-quality forage diets on intake and ruminal fermentation in steers.

J. R. Pukrop*[1], S. Day[2], P. M. Fricke[3], J. S. Luther[1], A. L. Jones[4], J. T. Sylvester[2], and A. E. Radunz[1], *[1]University of Wisconsin-River Falls, River Falls, [2]BioZyme, Inc., St. Joseph, MO, [3]Department of Dairy Science, University of Wisconsin, Madison, [4]University of Wisconsin-Madison, Madison*.

Four ruminally and duodenally cannulated steers (469 ± 37 kg initial BW) were arranged in a 4 × 4 Latin square to evaluate the impact of protein supplementation in low- to medium-quality forage diets on intake and ruminal fermentation. Protein supplement treatments included 1) high-fat dried distillers' grains (HDG; 10.8% fat), 2) low-fat dried distillers' grains (LDG; 5.7% fat), and 3) cottonseed meal (CSM; 3.0% fat). The basal diet (CON) consisted of low- to medium-quality chopped grass hay (8.3% CP and 64.9% NDF) fed ad libitum twice daily at h 0 and 12. Treatments were formulated to provide similar CP intake and were supplemented once daily to the basal diet: HDG at 0.8%, LDG at 0.7%, and CSM at 0.4% of BW. Each 21-d experimental period had 16 d of adaptation and 5 d of data collection. Intake data was collected d 17 to 21, and rumen fluid samples were collected on d 20 at h −2, 0, 2, 4, 6, 8, 10, and 12. Hay DMI was lower with supplementation of HDG ($P < 0.01$) verses CON and CSM but similar to LDG. However, hay DMI for LDG was not different ($P > 0.05$) than that for CON but lower ($P \leq 0.01$) than that for CSM. As expected, CP intake was greater ($P \leq 0.0001$) with protein supplementation than CON but not different among protein supplements. Fat intake was greatest to least for HDG, LDG, CSM, and CON, respectively ($P \leq 0.001$). Protein supplementation resulted in lower ($P \leq 0.05$) overall ruminal pH and over 2-fold greater ($P \leq 0.05$) ammonia concentration compared with CON. Overall ruminal pH was lowest for HDG compared with LDG, CSM, and CON (6.88, 6.23, 6.54, and 6.64 ± 0.09, respectively; $P = 0.0001$);

however, LDG and CSM were not different ($P > 0.05$) but lower ($P \leq 0.0001$) than CON. Total VFA production did not differ ($P = 0.46$) among treatments. Acetate proportions from greatest to least were CON, CSM, LDG, and HDG ($P \leq 0.03$). Propionate proportions from greatest to least were HDG, LDG, CSM, and CON ($P \leq 0.03$), with the exception of butyrate, which was not different between CSM and CON ($P = 0.26$). Supplementation of HDG, LDG, and CSM decreased ruminal pH and increased propionate while decreasing acetate proportions compared with no protein supplementation. Protein supplementation decreased hay consumption and the greatest decrease was observed with HDG supplementation.

Key Words: forage intake, protein supplementation, ruminal fermentation

---

1587 The effect of increasing concentrations of different methionine forms and 2-hydroxy-4-(methylthio) butanoic acid on hepatic oxidative status and genes controlling methionine metabolism and transmethylation flux. Q. Zhang*[1], D. N. Luchini[2], and H. M. White[1], *[1]University of Wisconsin-Madison, Madison, [2]Adisseo S.A.S., Alpharetta, GA*.

The d-isomer of methionine (Met) cannot be directly utilized by the mammary gland in dairy cows; instead, it is transformed into l-Met, the proteogenic isomer, in the liver and other extramammary tissues. It remains unclear whether different Met forms and a Met hydroxy analog, 2-hydroxy-4-(methylthio) butanoic acid (HMB), are metabolized and function similarly in the liver. The objective of the present study was to examine the regulation of key genes in methionine regeneration, transulfuration, and transmethylation pathways and hepatic oxidative status in response to increasing doses of different Met forms. Hepatocytes isolated from 4 calves less than 7 d old were maintained as monolayer cultures for 24 h before addition of treatments. Treatments of (0, 10, 20, and 40 μM) d-Met, l-Met, dl-Met, dl-HMB, or a 1:1 mixture of dl-Met and dl-HMB were added to Met-free media in triplicate. After 24 h, cell lysates were collected for quantification of gene expression by quantitative PCR, and mRNA abundance was normalized to the mean of 3 reference genes. Cell culture media were collected for quantification of reactive oxygen species (ROS) by fluorometric assay. Data were analyzed with PROC MIXED of SAS 9.3. Analyses of covariance confirmed equivalent slopes of Met form and the final model included form, dose, and random effect of calf within form. Data are reported as least squares means ± SE. Neither Met form nor Met concentration affected ($P > 0.10$) ROS released from the cells. There was no main effect of Met form ($P > 0.10$) for any genes examined. The enzymes encoded by *betaine-homocysteine methyltransferase* (*BHMT*) and *5-methyltetrahydrofolate-homocysteine methyltransferase* (*MTR*) utilize betaine and 5-methyltetrahydrofolate, respectively, to regenerate Met from homocysteine. Increasing concentration of Met did not alter ($P > 0.10$) *MTR* expression (1.274, 1.269, 1.264, and 1.255 ± 0.257 arbitrary units [AU]) but decreased ($P < 0.05$) *BHMT* expression (1.308, 1.223, 1.138, and 0.968 ± 0.234 AU). Expression of glycine N-methyltransferase, the enzyme that controls transmethylation flux from S-adenosyl-methionine, was not affected (2.205, 2.157, 2.108, and 2.011 ± 0.735 AU; $P > 0.10$) by Met concentration. There was no effect ($P > 0.10$) of Met concentration on expression of cystathionine β-synthase (0.958, 0.972, 0.985, and 1.012 ± 0.168 AU), a key enzyme for the transulfuration pathway. The decrease in *BHMT* expression indicates decreased need for cellular Met regeneration with increasing Met concentration independent of Met form. The lack of differences among Met forms on regulating genes examined indicates that all Met forms were metabolized similarly within primary bovine hepatocytes and had similar sparing effects on Met regeneration in the liver.

Key Words: methionine isomer, methionine regeneration, 2-hydroxy-4-(methylthio) butanoic acid

---

1588 Heat stress alters glucose homeostasis, hepatic heat shock proteins, and the immune system in lactating dairy cows. S. Quan[1,2], D. Bu*[1,3,4], Y. Zhang[2], J. Guo[1], S. Gao[1], and L. H. Baumgard[5], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, P. R. China, [2]The Animal Physiology and Biochemistry Laboratory of the Ministry of Agriculture in Nanjing Agriculture University, Nanjing, P. R. China, [3]Hunan Co-Innovation Center of Animal Production Safety, CICAPS, Changsha, P. R. China, [4]CAAS-ICRAF Joint Laboratory of Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, P. R. China, [5]Iowa State University, Ames*.

Experimental goals were to investigate glucose homeostasis, hepatic heat shock protein profiles, and circulating immune parameters in lactating dairy cows during heat stress (HS). Holstein cows ($n = 4$; 101 ± 10 DIM, 574 ± 36 kg BW, and 38 ± 2 kg milk/d) were used in a 2 × 2 crossover design during two experimental periods (each period lasted 10 d and were separated by 30 d) while housed in environmentally controlled chambers. Pair-fed, thermal-neutral control cows (PF) were exposed to constant 20°C and 40% humidity whereas HS cows were exposed to 36°C and 60% humidity from 0800 to 2000 h and 32°C and 60% humidity from 2000 to 0800 h with 12 h light and 12 h dark cycles. Blood and milk samples were collected on d 1, 4, 7, and 10 during both periods. Glucose tolerance test (GTT) was performed on d 6 of each period. Liver tissue was collected on d 10 of each period. Heat stress reduced milk yield (21.5%; $P < 0.05$) and lactose yield ($P < 0.05$; 300 g/d) compared with PF controls. Basal serum glucose decreased (30.1%; $P < 0.05$) and the rate of glucose

disposal following the GTT increased during HS (21.4%; $P < 0.05$). Serum IgA and TNF were reduced (38.1 and 23.4%, respectively) in HS cows ($P < 0.05$) compared with the PF controls but IgG, IgM, and IL-6 were similar between environments ($P > 0.05$). Liver HSP27 mRNA increased in the HS cows (51.2%; $P < 0.05$), but HSP70, HSP90, and HSF-1 did not differ between environments ($P > 0.05$). Heat stress markedly reduced mammary carbohydrate output, and the increased whole-body glucose utilization may be indicative of both an activated immune response and fuel required to mount and sustain a heat shock response.

Key Words: heat stress, glucose disposal, heat shock protein, immune activation, lactating cow

1589 The effect of heat stress and jugular infusions of methionine, lysine, and branched-chain amino acids in lactating dairy cattle. K. Kassube*, J. Kaufman, K. G. Pohler, and A. G. Rius, *The University of Tennessee, Knoxville*.

Heat stress (HS) affects numerous physiological processes including nutrient partitioning and protein metabolism. Heat stress decreases production of milk and milk proteins and may benefit from supplementation of essential AA. The objective of this study was to determine the effect of jugular infusion of essential AA in lactating dairy cattle experiencing HS. Twelve multiparous lactating Holstein cows were used in a crossover design to evaluate the effect of two environments (thermoneutral [TN] and HS) and the absence or presence of AA infusion (NAA or AA [methionine {12 g}, lysine {21 g}, leucine {35 g}, isoleucine {15 g}, and valine {15 g} per day]). Thermal treatments were imposed from d 1 to 14 and jugular infusion of AA was from d 7 to 14. Temperature–humidity index values during TN never exceeded 66, whereas temperature–humidity index values during HS peaked at 76 and were above 68 for 14 h/d. Milk and blood samples were collected on d 5 to 7 and d 12 to 14. Data were analyzed using the Mixed procedure of SAS and reported as least squares means ± SEM. The HS treatment increased ($P < 0.05$) respiration rates and rectal temperatures (72.1 vs. 47.0 ± 3.9 breaths/min and 39.4 vs. 38.5 ± 0.017°C, respectively). Compared with TN treatment, HS decreased ($P < 0.05$) DMI (17.4 vs. 18.9 ± 0.41 kg/d), milk yield (29.3 vs. 32.1 ± 1.09 kg/d), milk protein yield (0.87 vs. 0.98 ± 0.05 kg/d), and lactose yield (1.41 vs. 1.55 ± 0.10 kg/d). Amino acid treatment decreased ($P < 0.001$) lactose yield (1.43 vs. 1.54 ± 0.10 kg/d) but had no effect on DMI and milk yield. Heat stress decreased ($P < 0.05$) milk protein percent (2.95 vs. 3.06 ± 0.06%). Amino acid treatment increased ($P < 0.001$) milk protein percent (3.04 vs. 2.96 ± 0.06%) and decreased ($P < 0.001$) lactose percent (4.82 vs. 4.87 ± 0.04%). Compared with the NAA treatment, AA did not affect milk fat yield in the TN treatment (1.33 vs. 1.33 ± 0.09 kg/d) but decreased milk fat yield in the HS treatment (1.18 vs. 1.32 ± 0.09 kg/d; interaction, $P < 0.05$). Compared with the NAA treatment, AA treatment increased milk urea nitrogen in the TN treatment (11.7 vs. 10.9 ± 0.77 mg/dL) but did not increase milk urea nitrogen in the HS treatment (12.3 vs. 12.8 ± 0.74 mg/dL; interaction, $P < 0.01$). Plasma glucose decreased 6.7% in the AA treatment (2.8 vs. 3.0 ± 0.05 mmol/L; $P < 0.001$). Insulin, NEFA, and β-hydroxybutyrate were not affected by treatments. In conclusion, HS elicited expected decreases in production; however, the infusion of essential AA did not improve milk yield and milk protein yield during HS.

Key Words: essential amino acids, heat stress

1590 Effect of experimental design on production responses in high-producing dairy cows fed two levels of metabolizable protein. G. I. Zanton*, *USDA-ARS, U.S. Dairy Forage Research Center, Madison, WI*.

Inferences about lactation responses to diet have been hypothesized to be affected by the use of changeover instead of continuous experimental designs; a direct test of this hypothesis has not been well studied. The objective of this study was to evaluate the effects of reducing MP on lactation performance when dairy cows are fed diets continuously or according to a changeover design. Forty-six multiparous, Holstein cows were fed a common diet for 14 d and then randomly assigned to a randomized completed block design (CONT; $n = 34$; initial mean ± SD: 2.9 ± 0.9 parity, 84 ± 30 d in milk, 720 ± 59 kg BW, and 58.1 ± 6.4 kg milk/d) or a balanced 2-treatment, 4-sequence, 4-period changeover design (CHANGE; $n = 12$; 2.7 ± 1.0 parity, 90 ± 32 d in milk, 709 ± 78 kg BW, and 56.7 ± 3.9 kg milk/d). Cows were fed once and milk thrice daily, received rBST every 14 d, and received a diet that was predicted to be either adequate (ADMP) or deficient (LOMP) in MP for 112 d or changing according to sequence for four 28-d periods. The base diet was formulated to contain (% DM) 37.5% BMR corn silage, 16% alfalfa silage, and 41% concentrate. Treatments differed by adding 5.5% expeller soybean meal to the base diet for ADMP or 5.5% soyhulls for LOMP. By design, chemical composition differed with 16.6 vs. 14.7% CP, 28.2 vs. 31.1% NDF, and 27.6 vs. 27.5% starch for ADMP vs. LOMP, respectively. Production data were analyzed for study d 22 to 28, 50 to 56, 78 to 84, and 106 to 112, corresponding to 21 d of adaptation and 7 d of measurement for cows in the changeover design. Statistical analysis was conducted using the mixed procedure of SAS as either a randomized complete block design or as a balanced changeover design where differences with $P < 0.05$ are considered significant. As shown in the table, response to dietary treatment was not different for BW, BW change, and DMI, irrespective of experimental design. Milk and protein yield and milk urea N concentration were reduced with LOMP compared with ADMP for both designs. Fat yield response to diet was not different for CONT whereas fat percent increased with LOMP. In contrast, fat yield was significantly reduced for cows fed LOMP in CHANGE with

Table 1590.

Table 1. Production responses for cows fed diets containing either adequate (ADMP) or low (LOMP) levels of MP either continuously for 112 d (CONT) or according to a 4-period changeover design (CHANGE)

[1] P_{MP}: *P*-value for the effect of dietary treatment; P_{CO}: *P*-value for carry-over of previous treatment

no significant difference in fat percent for this design; significant carryover effect differences were observed. Under the conditions of this experiment, inferences on the response to different levels of MP were affected by the experimental design and the production variable of interest.

Key Words: experimental design, lactation, protein

1591 Meta-analysis of postruminal microbial nitrogen flows in dairy cattle.

1592 Prediction of crude protein and neutral detergent fiber content in *Pennisetum clandestinum* by near-infrared spectroscopy. A. Rivera*, *Universidad Nacional de Colombia, Medellin, Colombia*.

The objective of this study was to predict the CP and NDF content of *Pennisetum clandestinum* using near-infrared spectroscopy (NIRS).Three hundred fifty-four ($n = 354$) grass samples were collected from different dairy herds from northern Antioquia-Colombia, during 2015 and earlier 2016, which varied in soil types and fertility and grass growth stage and were analyzed at the Chemical Analysis and Bromatological Laboratory (certificate for ISOMEC 17025-2005) of the Universidad Nacional de Colombia at Medellin. Samples were dried to constant weight in a forced-air oven at 60°C for 48 h and then ground in a Wiley mill (1-mm sieve). Crude protein (N × 6.25) and NDF were analyzed following official methods. Content of CP ranged between 14 and 30.5%, with a mean of 23.07 ± 3.73%, and that of NDF ranged from 46.60 to 65.90%, with a mean of 56.22 ± 4.70%. Samples were randomized divided in two groups, and the first group ($n = 301$) was used for calibration and the second group for cross-validation ($n = 40$) and external validation ($n = 13$). Samples for calibration and cross-validation were scanned in an NIRS DS 2500 F monochromator (Foss-NIRsystem, Denmark) in the range of 1,108 to 2,492 nm for CP and 858 to 2,492 nm for NDF, with reflectance data collected every 8 nm. Modified partial least squares (MPLS) regression was applied to scatter-corrected spectra (SNV and detrend) and mathematical treatment (equation generation) was performed in the software WinISI version 4.8. The equations were selected by evaluating the statistical parameters (R^2 higher than 0.80, a SE of cross-validation [SECV] close to the SE of calibration [SEC], and a SE of reference database:SE of cross-validation [RPD] ratio greater than 3). As a result, the equation selected for CP was mathematically treated with derivative, 1; gap, 4; smooth, 3; smooth 2, 1; the mean was 22.48; SD 2,91; SEC 03253; SECV 0.439; and RPD 6.62 and correlation coefficients of calibration, cross-validation, and external validation were 0.977, 0.920, and 0.982, respectively. The equation selected for NDF was mathematically treated with derivative 1; gap, 4; smooth, 3; smooth 2, 1; the mean was 56.18; SD 4.56; SEC 1.571; SECV 1.770; RPD 2.75 and correlation coefficients of calibration, cross-validation, and external validation were 0.847, 0.727, and 0.781, respectively. According to these preliminary results, it was possible to predict reliably the CP content of *P. clandestinum*, but for NDF, further work is still needed.

1593 Impact of metabolizable protein source on pancreatic enzyme activity in finishing cattle fed dry-rolled corn–based diets. E. J. Blom*[1], D. W. Brake[1], M. R. Fiene[1], J. A. Walker[1], F. E. Keomanivong[2], and K. C. Swanson[2], [1]*South Dakota State University, Brookings,* [2]*North Dakota State University, Fargo*.

Previous data indicate increases in MP flow from soybean meal can increase pancreatic amylase content in cattle fed corn-based diets. However, reports on effects of increased MP flows from different protein sources are limited. We evaluated effects of added MP from either dried distillers' grains or porcine blood meal and corn gluten meal to finishing cattle fed dry-rolled corn–based diets designed to meet CP requirements (CP = 13.7% DM) on pancreatic α-amylase and trypsin and duodenal maltase activity. Two hundred sixteen crossbred steers (362.3 ± 3.4 kg BW) were blocked by initial BW, randomly assigned to 18 pens, and adapted to 1 of 3 dietary treatments. Treatments were a dry-rolled corn–based diet with added urea to meet CP requirements (CON), a diet with supplemental dried distillers' grains (DGS) designed to provide an additional 200 g/d MP, and a diet designed to provide 100 g/d additional MP from blood meal and 100 g/d additional MP from corn gluten meal (BMCGM). Cattle were fed for 152 d and subsequently harvested in a commercial abattoir. At harvest, pancreata and duodenal tissues were collected from 2 steers randomly selected within each pen for enzyme analyses. Pancreatic protein concentration (114.2 ± 4.3 mg/g) was not affected (P = 0.26) by dietary treatment. Pancreatic α-amylase activity per gram tissue was less (P = 0.01) among cattle fed DGS compared with CON and BMCGM. Additionally, added MP from DGS tended (P = 0.07) to decrease pancreatic α-amylase activity per gram pancreatic protein. Greater MP flow from BMCGM increased (P = 0.02) pancreatic trypsin activity per gram tissue; however, increased MP from either BMCGM or DGS did not impact (P = 0.30) trypsin activity per gram pancreatic protein (120.9 ± 22.25 U/g). Additions of MP did not affect (P = 0.43) protein content in duodenal tissue (62.1 ± 2.67 mg/g). Similarly, duodenal maltase activity (227.6 ± 13.87 U/g duodenum and 4.30 ± 1.217 U/g duodenal protein) was not affected ($P \geq 0.29$) by additional MP from either BMCGM or DGS. These data indicate that pancreatic α-amylase and trypsin activity are impacted by amounts and source of MP in finishing cattle, which could potentially influence starch and protein digestion in the small intestine.

Key Words: cattle, metabolizable protein, pancreas

1594 Comparative effects of multiple sources of rumen-protected methionine on milk production and serum amino acid levels in midlactation dairy cows. Y. Zang[1], S. Saed Samii*[1], L. R. Tager[2], J. W. McFadden[1], and K. M. Krause[1], [1]*West Virginia University, Morgantown,* [2]*MarSyt, Elizabethtown, PA*.

Methionine (Met) and lysine (Lys) are limiting AA in dairy cow diets. Supplementation of rumen-protected (RP) Met and Lys can improve milk yield as well as yield and content of milk protein. Currently, multiple sources of RP-Met are available for supplementation; however, the comparative efficacy of these supplements to improve performance requires evaluation. Therefore, our objective was to characterize the production response of three RP-Met supplements in midlactation cows. Twelve multiparous Holstein cows (602 ± 46 kg BW and 174 ± 18 DIM) were used in a replicated 4 × 4 Latin square design with 21-d treatment periods. Dietary treatments included a corn silage and alfalfa haylage diet (control; no added Met) supplemented with one of three RP-Met sources (Novimet [Innovad], Smartamine M [Adisseo], and Mepron M85 [Evonik]). Treatments were designed to maintain a Lys:Met ratio of 2.9:1. For the control, Lys (RP-Lys; AjiPro) was added at 0.02% ration DM. For RP-Met supplementation, Met (RP-Met) was added at 0.03% ration DM. Cows fed RP-Met were provided Lys (RP-Lys) at 0.20% ration DM. Milk yields were recorded, and samples were collected during each period (d 19 to 21). Blood samples were collected on d 21 at 2, 4, and 6 h following feeding, and serum was pooled. Following solid-phase extraction, 21 serum AA were quantified using gas chromatography tandem mass spectrometry. Data were analyzed using a mixed model with repeated measures (fixed effects of treatment and period). Treatments had no effect on DMI or milk yield. Treatment did not modify milk fat, protein, or lactose yield; however, milk protein content was elevated with Smartamine M relative to control or Novimet (3.30 vs. 3.24 and 3.24% respectively; $P < 0.05$). Milk fat and lactose concentration were not modified with treatment. Treatment with RP-Met tended to increase milk urea nitrogen (P = 0.12). Smartamine M increased serum Met concentration (27.3 μ*M*) compared with the control (21.2 μ*M*), Novimet (22.7 μ*M*), or Mepron M85 (23.3 μ*M*) ($P < 0.001$). In a similar manner, Smartamine M lowered the serum Lys:Met ratio (4.5:1) compared with the control (5.2:1), Novimet (5.2:1), or Mepron M85 (5.1:1) ($P < 0.05$). Smartamine M was also able to enhance circulating glutamine relative to the control (320.8 vs. 289.5; P = 0.15). Treatment did not modify serum levels of all other AA, including Lys. We conclude that Smartamine M increased circulating Met and milk protein content more effectively than Novimet or Mepron M85.

Key Words: dairy cow, lysine, methionine

1595 Milk protein synthesis gene expression and mTOR phosphorylation in response to the "ideal" profile of Lys, Met, Thr, Phe, His, Val, Ile, and Leu in bovine mammary cells. X. Dong*[1,2], Z. Zhou[1], Z. Wang[2], B. Saremi[3], and J. J. Loor[1], *[1]University of Illinois, Urbana, [2]Sichuan Agricultural University, Ya'an, IL, [3]Evonik Industries AG, 63457 Hanau, Germany*.

Essential AA (EAA) are important for milk protein synthesis and potentially could alter phosphorylation of the key proteins in the mTOR pathway. We hypothesized that the EAA profile affects the mammary transcriptome and mTOR phosphorylation/total mTOR (PmTOR/TmTOR) in bovine MAC-T cells. The specific objective was to investigate how changing the ratio of Lys to Met, Thr, Phe, His, Val, Ile, or Leu affects mRNA expression of key milk protein synthesis genes and PmTOR/TmTOR. Experiment 1 consisted (n = 5 replicates/treatment) of a control medium (i.e., the "ideal" EAA ratio [IPAA; 2.9:1 Lys:Met, 1.8:1 Lys:Thr, 2.38:1 Lys:His, 1.23:1 Lys:Val, 1.45:1 Lys:Ile, 0.85:1 Lys:Leu, and 2.08:1 Lys:Arg]) or IPAA supplemented with Met to achieve a 2.5:1 Lys:Met ratio (LM2.5) and a 2.0:1 Lys:Met ratio (LM2.0). Data were analyzed using a MIXED model in SAS. Treatment means were generated using the LSMEANS option and separated when significant with the PDIFF option. Compared with IPAA, increasing exogenous Met (LM2.5 and LM2.0) led to greater ($P < 0.01$) *SLC3A2* (l-type AA transporter) but LM2.0 led to the lowest ($P = 0.05$) *MTOR* expression and a strong tendency ($P = 0.06$) for greater *EEF2* (translation elongation factor). Although *EIF4EBP1* (translation repressor) expression did not change ($P = 0.15$), PmTOR/TmTOR was lower ($P < 0.05$) with LM2.5 and LM2.0 compared with IPAA. Experiment 2 consisted (n = 5 replicates/treatment) of IPAA or IPAA supplemented with Thr, Ile, Val, and Leu to achieve a 1.3:1 Lys:Thr ratio (LT1.3), 1.29:1 Lys:Ile ratio (LI1.29), 1.12:1 Lys:Val ratio (LV1.12), and 0.78:1 Lys:Leu ratio (LL0.78). Compared with IPAA, an increase in Thr, Ile, Val, and Leu resulted in greater ($P < 0.01$) expression of *SLC3A2*, but only an increase in Ile upregulated ($P = 0.05$) *EIF4EBP1*. Expression of *MTOR* and *EEF2* did not change ($P > 0.10$) compared with IPAA. Only the increase in Ile (LI1.29) and Val (LV1.12) led to greater ($P < 0.01$) PmTOR/TmTOR, indicating the potential for enhancing protein synthesis compared with IPAA. Overall, the data from these experiments indicate that changes in EAA profile, particularly Lys:Met, Lys:Val, and Lys:Ile, may affect mammary epithelial cell protein synthesis at least in part through regulating AA transport and PmTOR/TmTOR.

Key Words: essential amino acid profile, protein synthesis, mammary cell

1596 Nitrogen excretion of lactating dairy cows fed an alfalfa hay– or birdsfoot trefoil hay–based high-forage diet. M. Ghelich Khan[1], S. Y. Yang[1], J. S. Eun*[1], and J. W. MacAdam[2], *[1]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, [2]Department of Plants, Soils, and Climate, Utah State University, Logan*.

Legumes that contain condensed tannins (CT) may have lower protein degradability than alfalfa. The present study investigated the effects of feeding birdsfoot trefoil (*Lotus corniculatus* L.) hay (BFTH) on lactation performance and N utilization. Eight multiparous Holstein cows in mid lactation (150 ± 10.3 d in milk) were randomly assigned to 1 of 2 rations (AH-based TMR [AHT] or BFTH-based TMR [BFTHT]) in a crossover design with 2 experimental periods. Each experimental period lasted 16 d (14 d of adaptation and 2 d of total collection), and the 2 experimental periods were separated by a 7-d washout period. On the experimental diets, AH or BFTH was included at 40% DM to AHT or BFTHT, respectively. There were no treatment effects on DMI (21.4 vs. 20.7 kg/d; $P = 0.46$), milk yield (29.4 vs. 28.1 kg/d; $P = 0.47$), milk fat concentration (3.20 vs. 3.21%; $P = 0.40$), and milk protein concentration (3.20 vs. 3.16%; $P = 0.13$) for AHT and BFTHT, respectively. In addition, dietary treatments did not affect milk yield/DMI ($P = 0.59$) and energy-corrected milk yield/DMI ($P = 0.49$). In contrast, CP digestibility increased in BFTHT compared with AHT (69.1 vs. 64.8%; $P < 0.01$). Concentration of milk urea nitrogen decreased by feeding BFTHT compared with feeding AHT (11.9 vs. 13.3 mg/100 mL; $P < 0.01$), whereas total N excretion was similar ($P = 0.54$) between the diets. However, cows fed BFTHT excreted more N in feces (194 vs. 168 g/d; $P < 0.01$), whereas urinary N excretion did not differ between the diets ($P = 0.39$), leading to a decrease in the UN:FN ratio ($P = 0.03$) in cows fed BFTHT relative to those fed AHT. Overall results in the current study suggest that feeding BFTH in a lactation high-forage diet did not affect overall lactational performance, whereas it shifted routes of N excretion evidenced by the decreased UN:FN ratio compared with feeding AH. The positive impact on environment may be attributed to a functional effect of CT as well as a unique cell wall structure of BFTH.

Key Words: alfalfa hay, birdsfoot trefoil hay, nitrogen excretion

1597 Determination of relative methionine bioavailability in lactating cows fed Smartamine M, Mepron, and AminoShure M using the plasma-free AA dose–response method.
N. L. Whitehouse*[1], C. G. Schwab[2], S. M. Fredin[3], and A. F. Brito[1], [1]*University of New Hampshire, Durham,* [2]*Schwab Consulting, LLC, Boscobel, WI,* [3]*Adisseo, Inc., Alpharetta, GA*.

In vivo measurements of bioavailability of Met in rumen-protected Met (RP-Met) products are critical to determine their contribution to metabolizable Met supply. The objective of this experiment was to use the plasma free AA dose–response method to compare the bioavailability of Met in Smartamine M (Adisseo, Antony, France) from the new (SM1) and original (SM2) production plants along with 2 additional commercially available RP-Met products, Mepron (MPN; Evonik Ind., Kennesaw, GA) and AminoShure-M (ASM; Balchem Corp., New Hampton, NY). Ten multiparous lactating Holstein cows, fed Met-deficient diets, were used in a replicated 5 × 5 Latin square design with 7-d periods. Treatments included a negative control with no added RP-Met (CON) or 30 g of Met supplied by the 4 RP-Met products. Milk samples were collected and DMI measurements were made on d 5, 6, and 7. Blood samples were collected 2, 4, 6, and 8 h after the morning feeding (0500 h) on d 5, 6, and 7. Plasma was pooled by cow per day for AA analysis by HPLC. Data were analyzed using the MIXED procedure in SAS. Milk yield (46.0 kg/d; SEM = 1.0; $P = 0.60$), DMI (27.4 kg/d; SEM = 0.6; $P = 0.93$), and milk fat content (3.60%; SEM = 0.11; $P = 0.95$) were unaffected by treatments. Milk protein content was greatest ($P = 0.002$; SEM = 0.04) for cows fed SM1 (2.98%) and SM2 (3.00%), intermediate for those fed MPN (2.93%), and least for ASM (2.89%) and CON (2.87%). Plasma total sulfur AA (TSAA) concentrations (μ*M*) were greatest for cows fed SM1 and SM2 and intermediate for cows fed MPN and ASM compared with cows fed CON (Table 1). Plasma TSAA concentrations were expressed as a percent of total AA; TSAA were regressed on the 0- and 30-g Met treatments. Slopes for SM1, SM2, MPN, and ASM were 0.070 (SE = 0.004), 0.070 (SE = 0.004), 0.020 (SE = 0.004), and 0.015 (SE = 0.005), respectively. The bioavailability of Met (% of total Met), calculated as the slope ratio relative to SM1, were 100, 28, and 22% for SM2, MPN, and ASM, respectively. Based on the published bioavailability of Met in SM2 (80%), the calculated bioavailabilities of Met in SM1, MPN, and ASM were 80, 23, and 17%. There was no difference in Met bioavailability between SM1 and SM2. Bioavailability of Met in MPN and ASM are less than previous estimates compared with Smartamine M.

Key Words: bioavailability, methionine

1598 Impact of three rumen-protected lysine prototypes on dairy cow performance, milk composition, and milk casein.
A. M. Barnard*[1], B. A. Barton[2], C. A. Zimmerman[2], R. S. Ordway[2], and T. F. Gressley[1], [1]*University of Delaware, Newark,* [2]*Balchem Corporation, New Hampton, NY*.

Differences in formulation of the protective matrix of lysine products may impact rumen degradation and intestinal availability. The objective was to determine the effect of different formulations of lysine products on milk, milk protein, and casein yields. The study was conducted as a replicated 5 × 5 Latin square design in which 10 lactating, multiparous Holstein cows were assigned to either a lysine-deficient control ration (–Con), lysine-sufficient ration (+Con), or the –Con supplemented with either 1 of 3 different lysine prototypes (Lys1, Lys2, and Lys3; Balchem Corporation, New Hampton, NY). Rations were balanced using AMTS version 4.1.4 assuming 50.0 kg/d milk, 3.70% fat, 3.00% protein, and 740 kg BW. The +Con ration contained 1.60% porcine blood meal and was formulated to have MP, MP methionine, and MP lysine balances of −16.2, +0.1, and +4.9 g/d, respectively. The –Con ration was identical to +Con except that porcine blood meal was reduced to 0.64% with additional soybean hulls being added in its place, and –Con was formulated to have MP, MP methionine, and MP lysine balances of −42.8, +0.1, and −14.5 g/d, respectively. The lysine prototypes were supplemented at 0.21% of ration DM and contained 38% lysine, which were predicted to increase the MP lysine balance to +0.3 g/d. Periods were 14 d, and milk samples were collected on Days 11 to 14 of each period. Data collected during the last 4 d of each period were averaged by cow and analyzed using the Glimmix procedure of SAS. The model included a covariate (data collected during the 2-wk standardization period), fixed effects of treatment and period, and random effects of cow and cow within block. There were no treatment effects on DMI, protein or casein percentage or yield, lactose percentage, milk urea nitrogen (MUN),

or somatic cell count (SCC) (Table 1). There was an effect of treatment on milk yield ($P = 0.02$) and fat yield ($P = 0.03$). Lys1 increased milk yield compared with all other treatments except +Con and Lys1 increased fat yield compared with Lys3 and +Con. The positive milk response for Lys1 compared with –Con suggests that the Lys1 prototype was effective in meeting the lysine deficit in the –Con ration.

Key Words: bovine, lysine, prototype

Table 1. Effect of lysine supplementation on production measures. NO Table provided for placement!

1599 Effects of soybean meal, Fermenten, or expeller soybean meal on milk performance and intake in lactating dairy cattle.

S. W. Fessenden*[1], D. A. Ross[1], E. Block[2], and M. E. Van Amburgh[1], *[1]Cornell University, Ithaca, NY, [2]Church and Dwight Animal Nutrition, Ewing, NJ.*

The objective of this study was to evaluate effects of three different dietary sources of protein on intake, milk performance, and temporal changes in BW and condition score in lactating dairy cattle. Primiparous ($n = 48$) and multiparous ($n = 144$) cows were stratified by milk production and randomly allocated into 12 pens containing 4 primiparous and 12 multiparous cows each. Cattle ranged from 60 to 180 DIM and averaged 712 kg of BW at trial start. Diets consisted of (DM basis) 42% corn silage, 13% alfalfa forage, 20% grain corn, and 25% protein premix containing either soybean meal (Diet A), Fermenten (Diet B), or a expeller soybean meal (Diet C), at a 3.5% inclusion rate. All 3 diets provided a similar level (DM basis) of aNDFom (31%), CP (14.7%), starch (26.2%), and ME (70 Mcal ME/d) as predicted by the CNCPS. The trial consisted of a 2-wk adaptation/covariate period where all cows were fed diet C and covariate measurements were taken. Pens were then randomly allocated to treatments and weekly measurements of milk production, intake, BW, and condition score were taken for 10 wk. All data were analyzed using Proc Mixed in SAS with pen as the experimental unit. In the first 6 wk of the experimental period, an increase in DMI was observed for cows fed diet B compared with cows fed diet A and C (28.1 vs. 26.8 and 26.2 kg/d, respectively; $P < 0.01$). Cows fed diet B made more energy-corrected milk (45.6 kg/d) compared with cows fed diets A and C (44.0 kg/d for both A and C; $P < 0.01$). Milk protein and fat yield was also increased in cows fed diet B. All cows gained condition score over the duration of the experiment; however, cows fed diet A gained 0.03 BCS/wk less than cows fed diets B and C ($P < 0.01$). The results from this experiment demonstrate beneficial milk performance responses to Fermenten when fed with a source of rumen available true protein. Responses are consistent with a potential decrease in ruminal CP degradation as demonstrated by previous research in our lab. Results also demonstrate the value of rumen-degradable protein vs. rumen-protected protein when fed in nitrogen-efficient diets in high-producing dairy cattle.

Key Words: Fermenten, milk performance, nitrogen, rumen degradable protein

1600 Effect of ruminal bypass lysine on amino acid status, performance, and carcass characteristics of steers fed corn product–based diets.

N. A. Lancaster*[1], J. A. Tekippe[2], M. C. Claeys[1], and J. P. Schoonmaker[1], *[1]Purdue University, West Lafayette, IN, [2]Ajinomoto Heartland LLC, Chicago, IL.*

Corn and corn coproducts are the predominant sources of protein for feedlot cattle today, making up nearly 100% of diets in the Midwest. However, corn protein is a poor source of lysine, and current NRC models predict that a 45% corn, 30% DDGS, and 20% corn silage diet with 5% mineral supplement is deficient in lysine, despite the fact that the CP content of the diet (15%) exceeds requirements. Therefore, 84 steers were allotted by BW (367 ± 5.6 kg) and breed composition to 3 treatments to determine the effect of ruminal bypass lysine on blood AA, performance, and carcass characteristics. Treatments included a control with no added lysine or urea (Con), a diet that contained 0.5% Lys (AjiPro-L; Ajinomoto Inc., Chicago, IL), and a diet that contained 0.5% urea (urea). The lysine treatment was formulated to deliver 50 g/d of AjiPro-L (10 g/d of lysine). Twenty-eight steers were fed each diet and steers were housed in pens of seven (4 pens/treatment) that were blocked by BW (heavy and light). Steers were implanted with Revalor-XS at feedlot entry and were fed 300 mg of Optaflexx daily during the last 42 d of the study. Steers were slaughtered at a common BW (622 ± 13.8 kg). Data were analyzed as a randomized complete block design using the MIXED procedure of SAS. The model included the random effects of block and pen and the fixed effects of supplement and day as well as the supplement × day interaction. Total plasma AA did not differ among treatments at slaughter ($P = 0.93$); however, tryptophan tended ($P = 0.10$) to be greater (95.9, 87.8, and 103.4 μg/mL for Con, Lys, and urea, respectively) and PUN was ($P = 0.05$) greater (12.4, 12.7, 14.4 mg/dL for Con, Lys, and urea, respectively) for steers fed urea. There was no difference in DMI ($P \geq 0.62$), BW ($P \geq 0.91$), gain ($P \geq 0.73$), or G:F ($P \geq 0.75$) at any time point during the study. Treatment had no effect on HCW ($P = 0.50$), LM area ($P = 0.80$), marbling ($P = 0.93$), or any other carcass parameter ($P \geq 0.43$). In conclusion, it appears that an all corn/corn product diet provides a sufficient amounts of lysine to finishing feedlot cattle and supplemental bypass lysine may not be needed.

Key Words: beef feedlot, bypass lysine, growth

1601 Determining ruminal lysine degradability of a bypass soybean meal product and an encapsulated lysine source. J. M. Prestegaard*[1], A. L. Kenny[1], M. M. Masiero[1], and M. S. Kerley[2], *[1]University of Missouri, Columbia, [2]Division of Animal Sciences, University of Missouri, Columbia*.

A single-flow, continuous culture system was used to evaluate microbial efficiency (MOEFF), CP digestibility, VFA concentration, NH_3 concentration, OM digestibility, and lysine digestibility of a bypass soybean meal product and an encapsulated lysine source. Inoculated fermenters were randomly assigned to 1 of 3 treatments in 2 consecutive replicates (n = 24): a lysine-deficient basal diet (CON) consisting of corn, soybean meal, and corn silage; a lysine-sufficient diet (RP-SBM) containing rumen-protected soybean meal in replacement of soybean meal in the basal diet; and a lysine-sufficient diet (RP-LYS) consisting of CON supplemented with rumen-protected lysine. All treatments were balanced for similar amounts of rumen degradable protein to supply sufficient peptides and NH_3 based on microbial requirements. Fermenters were individually fed at 0800 and 1700 h for 7 d, consisting of a 4-d acclimation period to stabilize the microbial population and a 3-d sampling period. Volatile fatty acid and ammonia concentrations were analyzed in samples taken 0 and 4 h after morning feeding. Effluent was collected, composited, and frozen on the final 3 d of each replicate. Fermenter contents were collected and frozen on the final day of each replicate for bacteria analysis. No differences were observed for OM digestibility, apparent and true CP digestibility, NH_3, acetate, or propionate. In replicate 1, butyrate (mM) was greater (P = 0.01) for CON (13.63) relative to RP-SBM (9.30) or RP-LYS (9.00); however, no differences were observed in replicate 2. For both replicates, MOEFF (g effluent bacterial N/kg OM truly digested) tended to be greater (P = 0.08) in RP-LYS (21.32) than RP-SBM (17.62) and CON (17.49). Dietary lysine (g) was measured to be 0.33, 0.3,4 and 0.43 for CON, RP-SBM, and RP-LYS, respectively. Bypass dietary lysine (g) was lesser (P < 0.01) in RP-LYS (0.06) relative to RP-SBM (0.13) and CON (0.11). Lysine digestibility (%) was greater (P < 0.001) for RP-LYS (85.84) relative to RP-SBM (60.15) or CON (65.73). However, total effluent lysine (g) was statistically similar (P = 0.11) for CON (0.33), RP-SBM (0.36), and RP-LYS (0.33). Bacterial lysine in effluent (g) tended to be higher (P = 0.09) in RPLYS (0.27) relative to RP-SBM (0.23) and CON (0.22). Although dietary lysine in RP-LYS was degraded to greater extent by rumen microbes than in RP-SBM or CON, it appears the rumen microbial population compensated for lysine loss.

Key Words: continuous culture, lysine, rumen fermentation

1602 Effects of rumen-protected lysine and methionine on milk yield and milk composition in lactating Holstein cows fed two different levels of crude protein. A. Ostrensky[1], G. Negro[2], A. M. D. Santos[1], A. Anater[1], D. R. Ribeiro[1], L. F. Greco[3], M. N. Pereira[4], and R. D. Almeida*[2], *[1]Pontifícia Universidade Católica do Paraná, Curitiba, Brazil, [2]Universidade Federal do Paraná, Curitiba, Brazil, [3]Kemin South America, Indaiatuba, Brazil, [4]Universidade Federal de Lavras, Lavras, Brazil*.

Experimental objectives were to evaluate the effects of rumen-protected lysine and rumen-protected methionine (RPLM) supplementation on milk yield and composition of dairy cows. Holstein cows (n = 35) were housed in a free-stall barn and milked twice daily, received bST injections every 10 d, and were paired blocked based on milk yield, days in milk, and lactation order. The treatments consisted on four groups: 1) lower CP without RPLM supplementation (LPXX), formulated to 15.8% CP, 6.63% Lys as percent of MP, and 1.82% Met as percent of MP; 2) lower CP with RPLM supplementation (LPAA), formulated to 15.9% CP, 6.90% Lys as percent of MP, and 2.31% Met as percent of MP; 3) higher CP without RPLM supplementation (HPXX), formulated to 17.4% CP, 6.56% Lys as percent of MP, and 1.80% Met as percent of MP; and 4) higher CP with RPLM supplementation (HPAA), formulated to 17.5% CP, 6.92% Lys as percent of MP, and 2.32% Met as percent of MP. Experimental cows were fed simultaneously twice a day the same basal diet in a TMR and they were supplemented with soybean meal and/or RPLM (Lysipearl and Metipearl; Kemin, Brazil). The experimental design was a 4 × 4 Latin square with 28-d periods. Milk yield and composition were determined in the last 6 d of each period and analyzed using the mixed procedure of SAS containing the effects of milk yield in the covariate period, period, treatments (CP level, AA supplementation, and their interaction), and cow as a random effect. Milk yields were 39.26, 40.16, 39.72, and 40.25 kg/d for LPXX, LPAA, APXX, and APAA, respectively (P = 0.69 for CP level and P = 0.30 for AA supplementation). Cows fed higher CP diets showed higher (P = 0.002) protein content (3.34 ± 0.04%) than animals fed lower CP diets (3.29 ± 0.04%). The HPAA group had a tendency (P = 0.10) to produce more protein yield (1.335 ± 0.03 kg/d) than LPXX (1.283 ± 0.03 kg/d). There were no differences among treatments for all the other parameters: 3.5% fat-corrected milk, energy-corrected milk, milk energy output, fat, lactose, and total solids contents and yields. Increasing CP in the diet resulted in higher protein content in milk.

Key Words: amino acids, crude protein, metabolizable protein

1603 Immunometabolic gene expression in blood neutrophils (PMN) in Holstein dairy cows supplemented with rumen-protected methionine or rumen-protected choline during the peripartal period. P. Montagner[1], Z. Zhou*[1], D. N. Luchini[2], J. J. Loor[1], and M. Nunes Corrêa[3], *[1]University of Illinois, Urbana, [2]Adisseo S.A.S., Alpharetta, GA, [3]Federal University of Pelotas, Pelotas, Brazil*.

Objectives of this study were to evaluate mRNA expression of 30 genes related to neutrophil adhesion, chemotaxis and migration, oxidative stress, Toll-like receptor pathway, methionine cycle, and glutathione metabolism in response to rumen-protected methionine (MET) and choline (CHO) supplementation during the peripartal period. Forty multiparous Holstein cows were used in a randomized complete block design with 2 × 2 factorial arrangement of MET and CHO level (with or without). Treatments were control (CON), no MET or CHO; CON + MET (SMA); CON + CHO (REA); and CON + MET + CHO (MIX). From −21 d (close-up) to 30 d after calving, cows received the same diet (1.52 Mcal NE_L/kg DM) from close-up to calving. From calving to 30 d, cows were on the same diet (1.71 Mcal NE_L/kg DM) and continued to receive the same treatments through 30 d. MET supplementation was adjusted daily at a rate of 0.08% (DM basis) of diet and CHO was supplemented at 60 g/cow per day. Blood neutrophils were isolated on −10, 8, and 29 d relative to calving for quantitative PCR analysis. Data were analyzed as a factorial design with repeated measures using PROC MIXED in SAS. As expected, regardless of treatments, highest expression of proinflammatory genes (*TNFα* and *BPI*) ($P < 0.05$) were observed on 8 d, suggesting more pronounced inflammatory status compared with −10 and 29 d relative to parturition. The main effect of CHO toward greater ($P = 0.01$) expression of *cell adhesion molecule 1* (*CADM1*) and interactions of CHOL × day for PMN adhesion–related genes (*SELL*, *CXCR2*, and *ICAM1*) suggest activation of PMN in CHOL cows. In contrast, MET supplementation led to lower ($P = 0.02$) expression of *ITGAB2*, suggesting less activated status of PMN in MET cows. CHO cows also tend to have greater ($P = 0.06$) *IL10* compared with other treatments. Although *IL-10* was not changed by MET, main effect of MET was observed for lower *IRAK1*, suggesting a less pronounced inflammation in MET cows. Both *MPO* and *SOD2* were greater in MET cows whereas the main effect of CHO was not detected for *SOD2*; such changes likely were associated with reactive oxygen production in PMN. However, PMN functional study is required to confirm the proposed relationship. Overall, data indicate neutrophil gene network respond differently to peripartal supplementation with MET or CHO. Additional studies to examine the methionine and choline mechanism of action in PMN appear warranted.

Key Words: choline, methionine, transition cow

1604 Estimation of microbial protein and blood urea of confined bulls fed with diets containing virginiamycin and monensin sodium. F. R. Camilo*[1], A. M. Mobiglia[1], J. J. D. R. Fernandes[2], V. R. M. Couto[3], F. D. D. Resende[4], G. R. Siqueira[4], and R. K. Grizotto[5], *[1]CAPES Foundation, Ministry of Education of Brazil, Brasilia, Brazil, [2]UFG, Goiania, Brazil, [3]Universidade Federal de Goiás, Goiânia, Brazil, [4]APTA – Agência Paulista de Tecnologia dos Agronegócios, Colina, Brazil, [5]APTA – Agência Paulista de Tecnologia dos Agronegócios (São Paulo Agency of Agribusiness Technology), Colina, Brazil*.

The propose of this trial was to evaluate the effects of diets containing isolated and combined levels of virginiamycin (VM) and monensin sodium (MON) on microbial protein and blood urea of confined Nellore bulls. Fifteen Nellore bulls (536 kg of BW) with ruminal cannula were used in a randomized complete block design with five treatments in three replicates. The blocks were defined by initial BW. Treatments were defined by levels of VM and MON (mg/kg of DM) as follows: 30MON, 15VM+30MON, 25VM+30MON, 34VM+30MON, and 34VM. Animals were fed ad libitum twice daily with isonitrogenous and isoenergetic diets, with a 88:12 concentrate:roughage (sugarcane bagasse) ratio. The animals were kept in feedlot in individual pens for 28 d. The blood was

collected from the jugular vein before feeding and 2 and 3 h after feeding on the Days 0, 7, 14, 21, and 28. Spot sampling technique was realized on 28 d to estimate the daily excretion urinary of purine derivatives and then estimate microbial protein production. Data are shown in Table 1. There were effects ($P < 0.10$) on blood urea concentration between treatments and grams per day microbial protein for 34VM+30MON and 34VM treatments. The association of VM and MON resulted in greater microbial protein syntheses and effect quadratic in blood urea. In conclusion, the use of 34VM+30MON may increase of production of microbial protein, and blood urea resulted in lower concentration using 25VM+30MON on diet. Supported by Phibro/Minerva/FAPEG.

Key Words: additives, feedlot, virginiamycin

1605 Rumen fluid metabolomics analysis associated with feed efficiency on crossbred steers.

V. M. Artegoitia*[1], A. P. Foote[2], R. M. Lewis[3], and H. C. Freetly[2], *[1]University of Nebraska, Lincoln, [2]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [3]University of Nebraska-Lincoln, Lincoln*.

The rumen plays a central role in the efficiency of digestion in ruminants. To identify potential differences in rumen function that lead to differences in feed efficiency, rumen metabolomic analysis by ultra-performance liquid chromatography/time-of-flight mass spectrometry and multivariate/univariate statistical analysis were used to identify differences in rumen metabolites. Individual feed intake and BW gain was measured on 144 crossbred steers for 105 d on a high-concentrate ration. Eight steers with the greatest ADG and 8 steers with the least ADG within 0.32 SD of the mean DMI were selected for the study. The DMI did not differ between ADG groups (10.10 ± 0.05 kg/d; $P = 0.41$); however, ADG was greater ($P < 0.01$) in the greatest ADG group (1.96 ± 0.02 kg/d) than the least ADG group (1.57 ± 0.02 kg/d). Rumen fluid was collected at slaughter. Metabolite identification was obtained through a mass-based bovine database search. Verification of the identities of selected metabolites was conducted by comparing tandem mass spectrometry fragmentation patterns with those from authentic compounds. Principal component analysis and *t* test on rumen fluid metabolic profile identified 90 metabolites ($P < 0.10$) that segregated with ADG group. These metabolites were primarily involved in linoleic and α-linolenic metabolism (impact value 1.0 and 0.75, respectively; $P < 0.05$); both pathways were downregulated in the greatest ADG group compared with least ADG group. Ruminal levels of four metabolites associated with ADG group were screened by receiver operating curve analysis to test their efficacy as biomarkers for ADG. Subsequently, a partial least square discriminate analysis was used to develop a predictive model to verify and optimize the exclusive biomarkers. The combination of pentadecanoic acid, eicosanoic acid, linoleic acid, and α-linolenic acid produced a good predictor of feed efficiency, AUC (95% CI) = 0.901 (0.67–1.0), representing 87.5% of sensitivity and 75% of specificity. All four metabolite levels decreased in greatest-ADG animals vs. least-ADG animals in the rumen fluid. As well, higher fold levels of small molecules in the rumen fluid were found in greatest ADG vs. least ADG ($P < 0.05$), such as folic acid (13%), malonyl-CoA (30%), pyroglutamic acid (57%), oleamide (13%), and alloxan (23%; glucose analog). This study indicates that metabolomics based on ruminal fluid can yield metabolites that can predict and classify feed efficiency. Furthermore, on the basis of the pathway analysis of biomarkers, ruminant fluid metabolomics profile give new insight into the physiology of feed efficiency. The USDA is an equal opportunity provider and employer.

Key Words: average daily gain, dry matter intake, ultra-performance liquid chromatography quadrupole time of flight tandem mass spectrometry

1606 Enrichment of cattle rumen with bison rumen contents improves nitrogen digestion.

G. O. Ribeiro Jr.*[1], D. B. Oss[2], Z. He[1], V. Bremer[3], R. J. Forster[1], W. Yang[1], K. A. Beauchemin[1], and T. A. McAllister[1], *[1]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Brazil, [3]Elanco Animal Health, Greenfield, IN*.

This study investigated if the transfer of rumen contents from bison to cattle enhances cattle total tract fiber digestion. The experiment was a repeated measures design with two rumen transfers using 16 rumen cannulated Angus × Hereford cross beef heifers (461 ± 21 kg BW). Heifers were adapted to a barley straw diet (70/30% of DM, forage/concentrate) for 28 d before the experiment. After 46 d, 70% of rumen contents were removed from each heifer and replaced with mixed rumen contents collected after slaughter from 36 bison. This procedure was repeated 14 d later. Intake, chewing activity, apparent total tract digestion, ruminal passage rate, VFA, ammonia N, and protozoa counts were measured before the first transfer and 2 wk after the second transfer. The DMI increased ($P = 0.04$) from 1.39 to 1.50% of BW after the rumen transfers. Total chewing time did not change ($P = 0.74$; 13.9 h/d) but the chewing time per kilogram DM and NDF intake was reduced ($P < 0.001$) after rumen transfers. The DM, OM, NDF, and ADF digestibility were not affected ($P \geq 0.44$) by rumen transfers, but the total N digestibility was improved ($P < 0.001$; 68.3 vs. 70.4%). Microbial N flow (g/d) increased ($P = 0.03$); however, the efficiency of microbial N synthesis (g/kg of digested OM) was not improved ($P = 0.77$). No differences ($P > 0.14$) were observed for the ruminal rate of passage of fluids and solids. Ruminal ammonia N (m*M*) was not affected ($P = 0.77$) before feeding by rumen transfers but was greater ($P = 0.05$) 6 h after feeding. Total VFA (m*M*) and the proportion of butyrate

Table 1607.

Effects of nitrate and monensin on rumen fermentation parameters.

[1] NS indicates P>0.10.

increased ($P < 0.001$); however, acetate and the C2:C3 ratio decreased ($P \leq 0.02$) before and 6 h after feeding as a result of rumen transfers. As a result of rumen transfer, total protozoa counts and the proportion of *Ostracodinium* increased ($P < 0.001$) whereas *Entodinium* decreased ($P < 0.001$) before and at 6 h after feeding. Overall, cattle rumen inoculation with bison rumen contents improved diet protein digestion; however, DM and NDF digestibility were not affected.

Key Words: bison, digestibility, rumen inoculum

1607 Effect of nitrate, monensin, and the combination of additives on rumen fermentation using a semicontinuous culture system. M. Capelari*[1], K. A. Johnson[2], B. Latack[1], J. Roth[1], and W . Powers[1], *[1]Michigan State University, East Lansing, [2]Washington State University, Pullman*.

A 37-d experiment was conducted to investigate the effect of nitrate (NIT) and monensin (MON) on rumen fermentation using a semicontinuous culture system. We hypothesized that the combination of additives would reduce CH_4 emissions beyond that of either additive alone, without affecting production parameters. Additives (0, 1.25, and 2.5% diet DM of NIT; 0 and 4 mg/L of MON) were tested alone and in combination (NIT+MON; 6 total treatments; 3 replicates/treatment). Buffer and water were added to eighteen 2.2-L vessels on d −8 (1.2 L of a 50:50 mixture). The first 7 d (d −7 to 0) served as a steady state phase. On d −7, rumen fluid was pooled from 5 nonadapted lactating cows fed a 50:50 forage to concentrate diet and filtered through 2 layers of cheesecloth, and 1 L was transferred to each vessel along with 30 g of solid rumen content and 20 g of a basal diet (50:50 forage to concentrate) in a 8 by 20 cm nylon bag (50 μm mesh size). On d −6, 20 g of the basal diet replaced the solid rumen content bag, and from this point onward, 2 bags, each containing 20 g of the treatment diet, were always present in the vessels for 48 h. Buffer was infused at a constant rate (70 mL/h) throughout the experiment with a peristaltic pump. Gas production was measured daily. Twice weekly, DM disappearance (DMD), pH, and ammonia nitrogen (NH_3–N) were measured. Treatment did not affect DMD (69.13 g/100 g DM; $P > 0.05$). Compared with the negative control treatment, addition of NIT reduced total gas production (2.84 vs. 3.03 L/d; $P = 0.02$), CH_4 production (28.65 vs. 40.9 m*M*/d; $P < 0.01$), and CO_2 production (87.57 vs. 97.36 m*M*/d; $P < 0.05$). Compared with the negative control, addition of MON reduced CH_4 production (29.4; $P < 0.01$). Further CH_4 reduction, compared with the negative control, was observed when NIT+MON was added (24.31 vs. 40.9 m*M*; $P = 0.04$). No treatment effects were observed for pH (7.1) or protozoa count (4.3×10^3). Addition of NIT reduced NH_3–N (16.65 vs. 23.5 mg/dL; $P < 0.01$). The combination of NIT+MON enhanced reduction of CH_4 production in a semicontinuous culture fed a 50:50 forage:concentrate diet, with no detriment to DMD.

China*.

Rumen ureolytic bacteria elaborates urease to break down urea to ammonia for the synthesis of microbial protein, yet little is known about the diversity and distribution of rumen ureolytic microorganisms. The urease *ureC* gene has been chosen as the target gene for analysis of the urea-degrading microorganisms in various environments. This research investigated the predominant *ureC* genes of the ureolytic bacteria in the rumen of dairy cows using high-throughput sequencing. Six dairy cows with rumen fistulas were assigned to a two-period crossover trial. One group (Ctrl; $n = 3$) were fed the diet without urea and the other (Urea; $n = 3$) were fed rations plus 180 g urea/cow per day at three separate times. Rumen bacterial samples from liquid, solid, and wall fractions were collected for *ureC* gene amplification and sequencing using Miseq. Results showed that supplementation of urea did not change the rumen *ureC* gene abundance, whereas the wall-adherent bacteria (WAB) revealed a distinct ureolytic bacterial profile compared with solid-adherent bacteria (SAB) and liquid-associated bacteria (LAB). The *ureC* gene diversity and richness of rumen WAB was lower than that in the SAB and LAB ($P < 0.05$). The rumen predominant *ureC* gene operational taxonomic units (OTU) were gathered in clusters II, IV, and VI. Operational taxonomic units 5, 6, 15, 18, 12, 27, and 25 in the WAB; OTU 3, 4, and 1 in the LAB; and OTU 13, 19, and 21 in the SAB were predominant in each fraction, respectively. Most of the predominant OTU showed low similarity (72–91%) to the known rumen bacteria. The results suggested that the rumen of dairy cows harbors plenty of unidentified ureolytic bacteria. This survey contributes new data to existing *ureC* gene information relating to the ureolytic microbial community in ruminants and provides a basis for obtaining the regulation targets of ureolytic bacteria to mitigate urea hydrolysis in the rumen.

Key Words: diversity, rumen, *ureC* genes

1609 Rumen bacterial communities continue to shift five weeks after switching diets from conserved forage to pasture.
M. L. Bainbridge*, L. K. Saldinger, J. W. Barlow, J. P. Alvez, J. Roman, and J. Kraft, *University of Vermont, Burlington*.

Bacterial community structure is known to shift as a result of diet changes, but it is not known how long it takes for the bacterial populations to stabilize. The objective of this study was to characterize the weekly dynamics of rumen bacterial community composition of cows transitioning from an indoor diet, comprising conserved forage (CF), to a pasture. Five lactating Holstein dairy cows, maintained on a CF diet during the winter season, were switched to a pasture and followed for 5 wk. Individual rumen digesta samples were collected via esophageal intubation on wk −1, 1, 2, 3, 4, and 5 relative to the diet switch. Microbial DNA was extracted and the V1 to V3 region of the 16S rRNA gene was amplified. Sequence reads were obtained using Illumina MiSeq (version 3) and sequences were analyzed using MOTHUR (version 1.36.1). Bacterial densities ($\log_{10}$ 16S rRNA gene copies/mL rumen digesta) were quantified by real-time PCR. Data were analyzed using a repeated measures ANOVA in SAS (version 9.4). By wk 3 on pasture, bacterial densities in rumen digesta were higher when compared with CF (8.9 vs. 9.4, 9.4, and 9.5 $\log_{10}$ copies/mL for wk −1, 3, 4, and 5, respectively; $P < 0.01$). Bacteroidetes was the predominant phylum, accounting for 48 to 81% of total bacteria, followed by Firmicutes (16–47%) and TM7 (0–4%). *Prevotella* was the predominant genus of the Bacteroidetes phylum. By wk 5 on pasture, a higher abundance was observed of both bacteria of the phylum Bacteroidetes (75.3%) and *Prevotella* species (72.7%) when compared with CF (65.4 and 58.3% for Bacteroidetes and *Prevotella*, respectively; $P < 0.05$). The genus *Ruminococcus* was more abundant during wk 1 and 2 after the diet switch (3.4% for both weeks), when compared with 2.0% on wk −1 of CF ($P < 0.01$). Similarly, bacteria in the family Lachnospiraceae were more abundant during wk 1 and 2 (8.4 and 8.2%) and then became less abundant by wk 5 of cows grazing pasture (3.1%) when compared with wk −1 of cows on a CF diet (5.4%; $P < 0.05$). *Butyrivibrio* species were more abundant on wk 4 after the diet switch (3.6 vs. 1.7% for wk 4 of pasture and wk −1 of CF, respectively; $P < 0.05$) and then, on wk 5, returned to an abundance similar to CF (1.5%). In conclusion, rumen bacterial communities are highly dynamic after a diet switch and did not stabilize within 5 wk of cows grazing pasture.

Key Words: bacterial diversity, dairy cow, Illumina MiSeq

1610 Metabolome and microbiome associations after a grain and sugar challenge. H. M. Golder*[1,2], S. Denman[3], C. McSweeney[3], and I. J. Lean[1,2], *[1]Scibus, Camden, Australia, [2]University of Sydney, Camden, Australia, [3]CSIRO Animal, Food and Health Services, Queensland Bioscience Precinct, St. Lucia, Australia*.

Holstein heifers ($n = 40$) were allocated to 5 groups: 1) control (no additives), 2) virginiamycin (10 g/head·d; VM), 3) monensin (2.2 g/head·d) + tylosin (0.44 g/head·d; MT), 4) monensin (2.5 g/head·d) + yeast (Levucell SC Direct; 25 g/head·d; MY), and 5) sodium bicarbonate (200 g/head·d) + magnesium oxide (30 g/head·d; BUF). Heifers were fed twice daily a 62% forage:38% concentrate total mixed ration at 1.25% of BW DM/d for a 20-d adaptation period with their additive or additives. Fructose (0.1% of BW/d) was added to the ration for the last 10 d of adaptation. On d 21, heifers were challenged with a ration consisting of 1.0% of BW DM wheat and 0.2% of BW fructose plus their additive or additives. Stomach tube rumen samples were collected 3.6 h after consumption of the challenge ration and analyzed for pH; ammonia, d- and l-lactate, and VFA; and histamine concentrations and total bacteria. The 16S rRNA gene spanning the V4 region was PCR amplified and sequenced using an Illumina MiSeq platform. Sequence data was analyzed using the Quantitative Insights into Microbial Ecology software package (QIIME). Coinertia analysis, including Monte Carlo estimations (Ade4 package, R software) was conducted using operational taxonomic units (OTU) and rumen fermentation data from each group. A linear model was fitted to the OTU data and pairwise comparisons were performed to examine the significantly different OTU between groups ($q < 0.1$). Coinertial analysis explained 31.9% of the total variation in the associations among rumen fermentation products, bacterial community composition, and groups. Histamine and valerate concentrations explained the most variation in the microbiome. Contrasts between the control vs. BUF and control vs. MT groups showed these groups had the lowest number of significantly different OTU (14 and 23 OTU, respectively), indicating they may have similar microbiomes. The MLY vs. BUF had the highest number of significantly different OTU (826 OTU), suggesting their microbiomes had the greatest difference. New reference OTU14997 from the *Streptococcus* genus was more abundant in the control vs. MLY, VM vs. MLY, and BUF vs. MLY groups. New reference OTU20477 from the *Lactobacillus* genus was more abundant in the control vs. VM, MLY vs. VM, and BUF vs. VM groups. *Lactobacillus ruminis* was also more abundant in the MLY vs. VM and BUF vs. VM groups. *Lactobacillus mucosae* was more abundant in the BUF vs. VM group. The feed additives appeared to influence different microbial populations after the challenge.

Key Words: coinertia, feed additives, ruminal acidosis

1611 Ruminal dosing with *Megasphaera elsdenii* and strain persistence are associated with milk fat depression in Holstein cows. F. Cacite[1] and P. J. Weimer*[2], *[1]Federal Univ. of Mato Grosso, Cuiabá, Brazil, [2]USDA-ARS, Madison, WI*.

The objectives of this study were 1) to examine the effects of ruminal dosing of cows with the bacterium *Megasphaera elsdenii* (ME) on milk fat production and 2) to examine the persistence of the dosed species in the rumen. Nine cows (51–201 d in milk [DIM]) were divided into 3 groups balanced for DIM, milk production, and milk fat content and were fed the same TMR that contained corn silage, finely ground high-moisture corn, alfalfa haylage, corn oil, and monensin. The three treatments included ruminal dosing with pure cultures of one of two strains of ME (4257 and 5045, at an average of 1.9×10^{12} cells/dose) recently isolated from milk fat-depressed cows and a control dosed with sterile culture medium. To encourage persistence of ME, approximately 40% of the ruminal contents from each cow were removed just before dosing, and 108 g of sodium lactate was added for all treatments, on each of the 3 dosing days spaced 48 h apart. Milk production and composition were determined from 3x-daily milk samples collected from 8 d before first dosing to 21 d after first dosing, and ruminal fluid samples were collected for bacterial community analysis via 16 S rRNA metagenomics on the Illumina MiSeq platform. The dosing procedures resulted in a transient ruminal lactate concentration of up to 46 m*M* and a subsequent decrease in acetate:propionate ratio ($P < 0.0001$) as the lactate was metabolized. Both milk fat percentage and yield substantially varied by cow ($P < 0.001$) and were decreased ($P < 0.01$) during the week of dosing, when ME abundance was high. Data analysis of 112 ruminal samples using PROC REG of SAS revealed a negative correlation between ME relative abundance and milk fat percentage in cows dosed with ME strain 4257 ($r^2 = 0.46$, $P < 0.0001$) but not in cows dosed with strain 5045 ($r^2 = 0.056$, $P = 0.146$). Control cows dosed with lactate but not an ME inoculum displayed weak negative correlation between milk fat percentage and ME abundance ($r^2 = 0.183$, $P = 0.007$), suggesting that the native ME populations were also associated with reduced fat content. Similar results were observed for fat yield. Neither *Propionibacterium acnes* nor *Eubacterium pyruvativorans* were detected in even the most highly fat-depressed cows. The data confirm previous reports of a strong relationship between ME abundance and milk fat depression but suggest that the effect may be ME strain dependent.

Key Words: *Megasphaera*, milk fat, ruminal microbiome

1612 Potential for live yeast culture to enhance nitrate mitigation of methanogenesis in Jersey dairy cattle. R. A. Meller[1], J. M. Ashworth[1], A. M. Gehman[2], and J. L. Firkins*[1], [1]*The Ohio State University, Columbus,* [2]*Alltech, Inc., Nicholasville, KY.*

Concern over the environmental impact of dairy production has stimulated research to decrease enteric CH_4 production. One approach is feeding the electron acceptor NO_3 to be reduced by bacteria such as the selenomonads, thus outcompeting methanogens for aqueous H_2. We hypothesized that a live yeast culture (Yea-Sacc [YS]; *Saccharomyces cerevisiae*; Alltech, Inc.) would stimulate the reduction of NO_3 completely to NH_3 and thereby improve the ratio of CH_4 emission:energy-corrected milk production while decreasing blood methemoglobin concentration. Twelve lactating Jersey cows (8 multiparous and noncannulated and 4 primiparous and ruminally cannulated) were used in a replicated 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments. Cattle were fed diets either containing 1.5% NO_3 (from calcium nitrate) after an adjustment period or a control diet (containing urea isonitrogenous to NO_3) and were given a top-dress of ground corn without or with YS. All noncannulated cows were spot measured for CH_4 emission by mouth using GreenFeed (C-Lock Inc., Rapid City, SD). The main effect of NO_3 decreased ($P < 0.01$) methane 17% but decreased ($P < 0.01$) DMI by 10% (from 19.8 to 17.8 kg/d) such that the CH_4:DMI ratio tended ($P = 0.14$) to decrease by 8%. Milk and milk fat production were not affected, but NO_3 decreased ($P < 0.01$) milk protein from 758 to 689 g/d. Ruminal pH was decreased more after feeding diets without NO_3, and the acetate:propionate ratio was greater for cows fed NO_3, especially when combined with YS (interaction, $P = 0.01$). Others have noted lower palatability and lower consumption per meal, which is consistent with our observations. Methemoglobin was higher ($P = 0.01$) for cattle fed NO_3 than those fed urea but were still low (1.5 vs. 0.5% and only once exceeded 5%), documenting minimal risk for NO_2 accumulation at our feeding levels of NO_3. Although neither apparent OM nor NDF digestibilities were affected ($P > 0.15$), apparent N digestibility had an interaction ($P = 0.06$) such that, compared with those fed either diet without NO_3, N absorption was slightly higher for those fed NO_3 without YS but slightly lower for those fed NO_3 with YS. Under the conditions of this study, NO_3 did mitigate ruminal methanogenesis but was not particularly effective after considering that it depressed DMI and milk protein. Based on few interactions detected, YS had a minimal role in attenuating either of these responses.

Key Words: live yeast culture, methane, nitrate

1613 Inhibition of methanogenesis by nitrate, with or without defaunation, in continuous culture. B. A. Wenner*, B. K. Wagner, Z. Yu, N. St. Pierre, and J. L. Firkins, *The Ohio State University, Columbus*.

With regard to the focus of methane (CH_4) mitigation in ruminant production systems, nitrate (NO_3) serves as an alternative sink for aqueous hydrogen [H_2(aq)] accumulating in the rumen, producing ammonium via NO_3 reduction pathways and thereby decreasing CH_4 production. Defaunation has also been correlated in meta-analyses with decreased methanogenesis. We hypothesized defaunation might increase the CH_4 mitigation effect of NO_3 by removal of a symbiotic source of substrate to methanogens. In the present study, we applied a 2 × 2 factorial treatment arrangement in a 4 × 4 Latin square design to continuous culture fermenters ($n = 4$). Treatments were control ($-NO_3$) vs. nitrate ($+NO_3$; 1.5% of diet DM), factorialized with control (faunated [FAUN]) vs. defaunated (DEF). Fermenters were fed once daily (40 g DM; 50:50 forage:concentrate diet); four periods lasted 11 d with 3 d of sample collection. Buffer dilution and solids passage rate were maintained at 7.0 and 5.0%/h, respectively. There were no main effects of DEF or interaction of faunation status with addition of NO_3 ($P > 0.05$). The main effect of $+NO_3$ increased ($P < 0.05$) H_2(aq) compared with $-NO_3$ by 11.0 μM. The main effect of $+NO_3$ also decreased ($P < 0.05$) daily CH_4 production compared with $-NO_3$ by 8.17 mmol CH_4/d. Because there were no treatment effects on NDF digestibility ($P > 0.10$), the main effect of $+NO_3$ also decreased ($P < 0.05$) CH_4 production compared with $-NO_3$ by 1.43 mmol CH_4/g NDF digested. There were no effects of treatment ($P > 0.10$) on other nutrient digestibilities, N flow, or microbial N flow per gram of nutrient digested. These data support the existing literature that NO_3 incorporation in the diet can decrease the methanogenesis by dairy cattle. More importantly, methanogens are not necessarily inhibited by defaunation in a highly reduced environment. However, practical considerations such as nitrite toxicity and on-farm dietary adaptation to NO_3 should be considered before implementing this practice in U.S. dairy production systems.

Key Words: defaunation, methane, nitrate

1614 Does weaning age affect the development of ruminal and fecal microbiomes in dairy calves?
S. J. Meale[1], S. Li[2], P. Azevedo[2], H. Derakhshani[2], J. C. Plaizier[2], M. Steele*[3], and E. Khafipour[2], *[1]UMR Herbivores, INRA, Vetagro Sup, Saint-Genès-Champanelle, France, [2]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [3]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada*.

Despite the advantages of feeding an elevated plane of nutrition to preweaned calves, this feeding strategy may increase a calf's susceptibility to depressed growth during weaning. We hypothesized that weaning at an earlier age would result in a more rapid shift in gut microbiota and consequently be the cause of this growth depression. Therefore, our study examined the effects of weaning age on ruminal and fecal microbiomes in Holstein calves fed an elevated plane of nutrition before weaning. Twenty female Holstein calves were randomly assigned at birth to be weaned at 6 (early [EW]) or 8 (late [LW]) wk. Milk replacer (150 g powder/L water) was offered at 1.2 kg/calf per day in 2 meals until a 1-wk step-down. Rumen fluid and feces were sampled at wk 5, 7, and 9, representing EW5, EW7, EW9, LW5, LW7, and LW9. Deoxyribonucleic acid was extracted, and the V4 region of the 16S rRNA bacterial gene was amplified and subjected to paired-end Illumina sequencing. The output paired-end reads were merged using the PANDASeq assembler, analyzed using QIIME, and aligned to the Greengenes database. Alpha-diversity of bacterial communities was calculated using different richness estimators. Differences in β-diversity of microbiota across treatments and age were tested using PERMANOVA. Alpha-diversity indices did not differ ($P > 0.05$) across weaning age × week in feces. However, differences ($P < 0.05$) between EW5 and EW7 calves were observed in the rumen for Shannon and inverse Simpson indices. Beta-diversity of both rumen and fecal microbiota differed ($P \leq 0.04$) between weaning age × week, indicating a more gradual shift in late-weaned calves toward a postweaned state, compared with an abrupt shift in early-weaned calves. Bacteroidetes was the dominant ruminal phyla in preweaned calves, decreasing in abundance ($P = 0.02$) after weaning, regardless of the age of weaning. A corresponding increase ($P \leq 0.09$) in Firmicutes at weaning resulted in it becoming the dominant ruminal phyla in postweaned calves. The opposite shift in dominance was observed in feces where Firmicutes was dominant before weaning and Bacteroidetes was dominant in postweaned calves. These two phyla accounted for an average 86% of total ruminal or fecal sequences regardless of age or treatment. These results indicate that late weaning at 8 wk facilitates a more gradual shift in microbiota toward a postweaned state compared with early weaning at wk 6. Hence, weaning later could reduce the adverse effects caused by feeding a high plane of nutrition before weaning.

1615 Analysis methods differ in recovery of microbial glycogen. M. B. Hall*, *U.S. Dairy Forage Research Center, USDA-ARS, Madison, WI.*

Microbial glycogen is an 1,4-,1,6-α-glucan produced from carbohydrates and stored within bacterial and protozoal cells. Enyzmatic analysis of glycogen in bacteria requires lysis of cells to make glycogen available to enzymatic attack. Lysis is typically performed with alkaline treatment. The objective of this study was to compare the detection of corn starch and of α-glucan in a fermentation pellet by 3 lysis methods from the research literature: 30% KOH boiled for 3 h (30%K), 0.2 *N* NaOH boiled 15 min (0.2N), and 0.31 *N* NaOH at room temperature for 15 min (0.31N). Fermentation pellets were prepared in an in vitro fermentation with mixed ruminal microbes in Goering and Van Soest medium, with 3 g/L of glucose, fermented for 2 h. Each fermentation vessel was quantitatively transferred into a centrifuge tube and centrifuged at 13,000 × *g* for 45 min at 5°C. Supernatants were discarded. Pellets were resuspended in 0.9% saline and recentrifuged. Supernatant was discarded and pellets were frozen at −20°C. As per individual protocols, 30%K and 0.2N were performed on undried pellets transferred into 50-mL beakers and 0.31N was performed on freeze-dried fermentation pellets. Samples were analyzed in duplicate in 2 analytical runs on 2 separate days in a randomized complete block design with fermentation pellet as the experimental unit. The statistical model for each substrate included method and fermentation run as a random variable. After incubation with alkali, all samples were neutralized with acid, and acetate buffer was added to bring the pH to 4.9 to 5.0. The 30%K and 0.2N samples received 0.1 mL of heat-stable α-amylase and 200 U of amyloglucosidase and were incubated for 2 h at 50°C. 0.31N received 0.25 mL Hazyme DCL enzyme preparation and was incubated for 16 h at 55°C. After bringing samples to volume with distilled water, samples were centrifuged to clarify and the supernatant was analyzed for glucose by a glucose oxidase–peroxidase assay. Alpha-glucan was expressed as glucose × 0.9. Recovery of corn starch was 96.7, 95.8, and 91.6% with 0.2N and 0.31N greater than 30%K, respectively ($P < 0.01$). Alpha-glucan in fermentation pellets was 29.6, 29.8, and 26.0 mg with 0.2N and 30%K greater than 0.31N, respectively ($P < 0.03$); 0.31N gave recoveries 87 to 88% of the other treatments. The pattern of starch recovery did not reflect that of microbial α-glucan recovery. With the alkaline lysis methods tested, a boiling treatment appears to be necessary for greatest microbial glycogen recovery.

Key Words: bacteria, glycogen, rumen, starch

Table 1616.

Measure	LoN-Glc	LoN-Lac	HiT-Lac	HiU-Lac
6 h Residual carbohydrate				
Glc or Lac, mg	8.28	31.0	18.9	34.3
Detected maxima				
Microbial N, mg	2.05	0.66	1.62	1.22
Glycogen, mg	18.5	0.77	1.30	1.22
Organic acid carbon, mg	19.6	16.3	19.5	11.9

1616 Utilization of lactose by mixed ruminal microbes is affected by nitrogen type and level and differs from utilization of glucose. M. B. Hall*, *U.S. Dairy Forage Research Center, USDA-ARS, Madison, WI*.

The objective of this study was to evaluate the effects of providing lactose (Lac) at differing nitrogen (N) levels and types and glucose (Glc) at a low N level on products formed and substrate utilized by mixed ruminal microbes. The 3 N treatments were applied via modification of Goering and Van Soest medium: LoN (60% of enzymic digest of casein removed; 300 mg N/L) and HiU or HiT with urea or an enzymic digest of casein, respectively, added to LoN to give 451 mg N/L. Glucose and Lac were added at 3 g/L (79.5 mg/fermentation vial). Two replicated in vitro fermentations with mixed ruminal microbes were performed. Inoculum donors were 2 ruminally cannulated cows individually provided with 200 g each of Lac and Glc per day via their diets for 14 d before the fermentations. Vials, the experimental units, were destructively sampled hourly from 0 through 6 h of fermentation. Data were analyzed as a randomized complete block design. Organic acid carbon is the sum of carbon in acetate, propionate, butyrate, valerate, and lactate. Detected maxima and endpoints were analyzed with the factors treatment and fermentation run (random variable) in the statistical model. Orthogonal contrasts of Glc vs. all Lac, Lac LoN vs. HiN, and Lac HiT vs. HiU were evaluated. Significance was declared at $P < 0.05$ and a tendency was declared at $0.05 < P < 0.10$. Glucose was utilized more rapidly than Lac, giving less residual Glc than Lac at 6 h ($P = 0.02$); HiT tended to have a lower value than HiU at 6 h ($P = 0.07$). Maximum detected glycogen was greater for Glc than for all Lac ($P < 0.01$), which did not differ from each other ($P > 0.66$). Maximum detected organic acid carbon values did not differ among treatments, except for a tendency for a greater amount with HiT than with HiU ($P = 0.06$). Maximum detected microbial N accumulation (a proxy for cell growth) was greater for Glc than for Lac ($P = 0.04$) and tended to be greater for Lac with HiN than with LoN ($P = 0.07$). Rumen microbes utilize Glc and Lac differently; N level and type alters utilization of Lac.

Key Words: fermentation, lactose, rumen

1617 Effect of dietary energy source and level on rumen bacteria community in lactating dairy cows. D. Bu*[1,2,3], S. Li[4], Z. Yu[5], S. Gao[1], L. Ma[1], X. Zhou[6], and J. Wang[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, P. R. China, [2]CAAS-ICRAF Joint Lab on Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, P. R. China, [3]Hunan Co-Innovation Center of Animal Production Safety, CICAPS, Changsha, P. R. China, [4]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [5]The Ohio State University, Columbus, [6]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, P. R. China*.

Increased dietary energy level and degradation rate are beneficial to rumen microbial protein synthesis and milk production by dairy cattle. This study aimed to examine the effects of dietary energy source and level on rumen bacterial community in lactating dairy cows. Eight primiparous Chinese Holstein cows were used in a replicated 4 × 4 Latin square design. Cows were allocated to four treatments arranged in a 2 × 2 factorial design with energy levels (NEL, 1.52 vs. 1.72 Mcal/kg of DM, referred to as LE vs. HE) and energy sources (steam-flaked corn or ground corn, SFC vs. GC). All cows were fed twice daily ad libitum. Each experimental period consisted of 14 d for adaptation and 7 d for sample collection. Rumen fluid was collected in the morning 3 h after feeding via stomach tubing at d 17. Total DNA was extracted from each rumen sample, and the V4 hypervariable region of 16S rRNA gene was amplified and subjected to paired-end Illumina sequencing. After merging of paired-end sequencing reads, the low-quality sequences were removed and the quality-checked sequences were clustered into operational units (OTU) using the UPARSE pipeline. The resulting OTU were taxonomically classified using the RDP classifier implemented in QIIME. The bacterial communities were profiled using α diversity measurements, whereas the effects of both energy sources and levels were evaluated based on UniFrac distance using a

permutational ANOVA method. The differences in bacterial community structure were examined using DESeq2 in R. The LE and the GC treatments decreased bacterial richness as indicated by lowered number of species detected and estimates of both Chao1 and ACE ($P < 0.05$). The lower Shannon diversity index also suggests that LE and GC treatments decreased evenness of the rumen bacterial communities ($P < 0.05$). The composition of the bacterial communities was similar at the phylum level between two types of corn, but the high-energy diet altered bacterial communities by increasing Cyanobacteria while reducing Firmicutes and Proteobacteria ($P < 0.05$). At the genus level, the SFC diet had lower relative abundance of *Papillibacter* but higher relative abundance of *Mitsuokella* than the GC diet ($P < 0.05$). In contrast, dietary energy levels affected bacterial communities more extensively, with 51 genera being affected. The results indicate that increase in dietary energy level can affect rumen bacterial community to a greater extent than energy source when provided as steam-flaked vs. ground corn ($P < 0.05$)

Key Words: energy (source and level), metagenomics, rumen bacterial community

1618 Effect of different microbial inoculants on fermentation characteristics of *Miscanthus* silage and their rumen fermentation and digestibility.

J. Yang*[1], C. Ryu[1], S. J. Shin[1], B. Choi[1], Y. Kim[1], M. Park[1], J. Heo[2], S. Cho[3], and N. J. Choi[1], *[1]Chonbuk National University, Jeonju-si, the Republic of Korea, [2]Microbial Institute for Fermentation Industry, Sunchang-gun, the Republic of Korea, [3]CALS Co., Ltd, Seongnam-si, the Republic of Korea*.

The present study investigated the effect of starter culture of different microbial strains on *Miscanthus* silage quality and its in vitro and in vivo digestibility. *Pediococcus pentosaceus* NJ19, *Pichia anomala* NJ22, and *Saccharomyces cerevisiae* NJ50 were used as starter culture strains. A total of 4 experimental groups including the control (without inoculation) and three treatments (with inoculation) were used. Treatment NJ19 was inoculated at 10^7 cfu/g and treatments NJ22 and NJ50 were inoculated at 10^5 cfu/g of fresh weight. Silage quality was evaluated after 30 d of fermentation. Rumen fermentation patterns were determined using in vitro rumen simulated fermentation system. The effect of starter culture on palatability of *Miscanthus* silage and apparent nutrient digestibility were estimated using 4 rumen cannulated Hanwoo steers. An in vivo trial was performed based on a replicated 4 × 4 Latin square design. Regarding silage quality, DM in NJ19 and NJ50 was significantly lower than the control ($P < 0.05$). Significantly higher CP was found in NJ19 in comparison to other strains ($P < 0.05$). All treatments showed significantly elevated lactic acid production when compared with the control ($P < 0.05$). The highest production was recorded in the NJ19 treatment ($P < 0.05$). Acetic acid in NJ19 was significantly higher than in the other treatments ($P < 0.05$), and NJ22 was significantly lower than the others ($P < 0.05$). Significant difference in in vitro DM digestibility (IVDMD) was detected at 24 h of incubation. *Miscanthus* silage with NJ19 showed a significantly higher IVDMD ($P < 0.05$). Total VFA production in NJ19 was significantly higher than that in the other treatments ($P < 0.05$). Feed intake and apparent DM digestibility of *Miscanthus* silage with NJ19 were significantly higher than in the other treatments ($P < 0.05$). No significant differences among treatments were detected in OM, NDF, and ADF digestibility. These results indicate that inoculation with *P. pentosaceus* in *Miscanthus* silage can improve its ruminal fermentation, feed intake, and DM digestibility without negatively affecting the rumen environment.

Key Words: digestibility, microbial inoculant, *Miscanthus* silage, ruminal fermentation

---

1619 The effects of varying undigested neutral detergent fiber and physically effective neutral detergent fiber content of fresh cow rations on dry matter intake, rumination, and milk yield in multiparous Holstein cows.

S. E. Williams*, B. M. Leno, C. M. Ryan, and T. R. Overton, *Cornell University, Department of Animal Science, Ithaca, NY*.

The objective of this study was to evaluate the effects of varying levels of undigested NDF ($uNDF_{240}$; NDF remaining after 240 h of in vitro fermentation) and physically effective NDF (peNDF) content of fresh cow rations on DMI, rumination, and milk yield. Previously unpublished data from our lab indicated that cows fed higher $uNDF_{240}$ (approximately 10.7% DM) had higher DMI and improved health status compared with cows fed lower $uNDF_{240}$ (approximately 8.3% DM) in the postpartum period. Multiparous Holstein cows ($n = 56$) were fed a common prepartum ration beginning 28 d before expected parturition and randomly assigned at calving to one of two postpartum diets differing in content of $uNDF_{240}$ and peNDF (Table 1). Treatment diets, high fiber (HF; $n = 27$) and low fiber (LF; $n = 29$), were formulated for equivalent MP and starch, with higher fiber levels achieved through the addition of straw in the HF diet. At 29 d in milk (DIM), HF cows were switched to the LF diet and all cows were fed the LF diet through 42 DIM. Repeated measures data were analyzed with the MIXED procedure of SAS with model effects of treatment, time, and treatment × time. A treatment × time interaction ($P < 0.01$) was observed for DMI when expressed as a percent of BW, such that DMI for cows fed HF was lower in wk 3 (3.05% ± 0.07 vs. 3.35% ± 0.07; $P < 0.01$) and 4 (3.13% ± 0.06 vs. 3.50% ± 0.06; $P < 0.01$) postpartum. Despite this difference in intake, total daily rumination was not different between treatments (overall mean 543.4 ± 3.5 min/d; $P > 0.10$) at any time point. A treatment × time interaction for average weekly milk yield was observed ($P < 0.01$), such

that cows fed HF had lower milk production in wk 4 (46.4 ± 1.1 vs. 50.1 ± 1.0 kg/d; $P < 0.01$). However, differences in energy-corrected milk were not different (overall mean 47.8 ± 1.4 kg/d; $P > 0.10$). Increasing $uNDF_{240}$ and peNDF content of fresh cow rations may limit intake starting in wk 2 postpartum; however, differences in milk yield were not observed until wk 4 postpartum and limiting effects were alleviated after switching to the LF diet. We speculate that the LF diet may have contributed adequate $uNDF_{240}$ in this scenario, resulting in optimal DMI, whereas the additional $uNDF_{240}$ in the HF diet may have had limiting effects.

Key Words: physically effective neutral detergent fiber, undigested neutral detergent fiber, transition cow

1620 Bacterial diversity in the feces of lambs fed purple prairie clover (*Dalea purpurea* Vent.) and alfalfa (*Medicago sativa*). Q. Huang[1,2], D. Holman[1], T. W. Alexander[3], T. Hu[2], L. Jin[1], Z. Xu[1], T. A. McAllister[4], S. Acharya[1], and Y. Wang*[1], *[1]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada, [2]College of Animal Science and Technology, Northwest A&F University, Yangling, P. R. China, [3]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [4]Lethbridge Research and Development Centre, AAFC, Lethbridge, AB, Canada*.

Our previous studies have shown that purple prairie clover (PPC) reduced the fecal shedding of *Escherichia coli* O157:H7 in lambs and generic *E. coli* in cattle, a response attributed to the presence of condensed tannins (CT). This study assessed the effect of PPC and PPC CT on the composition of the bacterial community in the feces of lambs using high-throughput 16S rRNA gene pyrosequencing. A total of 18 individually fed lambs were randomly divided into three groups and fed alfalfa (Alf), a 40:60 (DM basis; Mix) mixture of Alf and PPC, and Mix with polyethylene glycol (Mix-P) for 18 d. The Mix and Mix-P diets contained about 36 g CT/kg DM. Polyethylene glycol (PEG; MW6, 000) was sprayed onto the Mix-P diet to inactivate the biological activity of CT. Fecal samples were collected on Day 0, 13, and 18 through digital rectal retrieval. The samples were freeze-dried, DNA was extracted, and bacterial 16S rRNA gene amplicons were sequenced using the 454 pyrosequencing technology. Regardless of diet, bacterial communities were dominated by Firmicutes and Bacteroidetes, with a large proportion of OTU within these phyla remaining unclassified at the genus level after analysis. Diet had no effects on the fecal bacterial composition at the phylum level or on α-diversity metrics. Compared with the Alf diet, the Mix diet reduced the number of OTU associated with *Butyrivibrio* ($P = 0.01$), *Anaeroplasma* ($P = 0.02$), and unclassified bacteria within the families Peptococcaceae ($P = 0.03$), Christensenellaceae ($P = 0.01$), Erysipelotrichaceae ($P = 0.02$), S24-7 ($P = 0.02$), and Dehalobacteriaceae ($P = 0.03$). Similar reductions occurred within the orders RF39 ($P = 0.05$) and ML615J-28 ($P = 0.02$), but no difference was observed between Mix and Mix-P groups ($P > 0.05$). In contrast, a greater proportion of genus *Prevotella* ($P = 0.02$) was found in the Mix group compared with the Alf group. These results indicate that PPC CT up to 36 g/kg DM in the diet exert only minor effects on the composition of the fecal bacterial community of lambs.

Key Words: condensed tannins, 454 pyrosequencing, gut microbiota, purple prairie clover

1621 Comparisons of microbial populations found in the rumen and in a dual-flow continuous culture fermentation system using high-throughput 16S amplicon sequencing. I. J. Salfer*, H. E. Larson, and M. D. Stern, *University of Minnesota, St. Paul*.

Dual-flow continuous culture fermenters are commonly used to study rumen fermentation in vitro. Previous research has shown that certain microbial populations are maintained within continuous culture at concentrations similar to in vivo values. The development of high-throughput genetic sequencing allows us to gain a global understanding of the microbial population in the rumen. The objective of this study was to use 16S amplicon sequencing to study phylogenetic differences and similarities between microbial communities found in the rumen of dairy cattle with those found in a dual-flow continuous culture fermentation system. Samples were collected from a rumen fluid, fermenter inoculum, and effluent collected directly from fermenters during 10 d of operation. Deoxyribonucleic acid (DNA) was extracted from samples, amplified to generate cDNA libraries, and sequenced using the Illumina MiSeq platform. Sequences were aligned using Mothur version 1.34.0 software and data were compared based on sample type (rumen vs. inocula vs. fermenter), inoculum donor, and day of fermenter operation. Redundancy analysis (RDA) was performed to determine correlations between fermentation measurements based on microbial community. Community differences were assessed using UniFrac metrics, analysis of molecular variance (AMOVA), and analysis of similarity (ANOSIM) based on Bray–Curtis dissimilarity matrices. Differences in taxonomic composition of different sample types were analyzed for kingdom phylum, class, order, and family taxonomic levels. Functional inferences were made by matching taxonomic data to KEGG orthology terms using PICRUSt software and analyzed by sample type. Results showed that UniFrac, AMOVA, and ANOSIM metrics were different ($P < 0.05$) between fermenters and rumen and inoculum samples. The microbial community within fermenters appeared to stabilize by Day 7 of fermenter operation. Bacteroidetes and Firmicutes made up the two most abundant phyla in rumen, inoculum, and fermenters and did not differ ($P > 0.10$) between sample types. Proteobacteria, Tenericutes, Spirochaetes, and Verrucomicrobia were found in dissimilar abundances ($P <$

0.05) between different sample types. Prevotellaceae was the most abundant family in all three sample types and did not vary ($P > 0.10$) between rumen, inoculum, and fermenter samples. PICRUSt predictions showed that AA metabolism, membrane transport, energy metabolism, and cellular processes and signaling were affected ($P < 0.05$) by sample type but that metabolism of carbohydrates, cofactors and vitamins, and lipids were not ($P > 0.10$). The overall microbial community differs between natural rumens and fermenters, but the concentrations of several prominent taxa are maintained.

Key Words: continuous culture, rumen, 16S sequencing

1622 Evaluation of in vitro and in situ starch digestibility assays. S. E. Schuling*, D. Schimek, and B. Vander Wal, *Hubbard Feeds Inc., Mankato, MN*.

The objective of this experiment was to evaluate commercial in vitro and in situ starch digestibility assays to estimate ruminal starch digestibility (RSD) and rate of ruminal starch degradation (kd). Twelve commercial dairy herds located in Wisconsin, Pennsylvania, and Missouri were used (4 free-stall and 8 tie-stall housing). Fecal samples were collected from 5 high- and 5 low-producing cows from each herd, and samples of total mixed rations (TMR) were collected after feed delivery from each pen ($n = 8$) or directly in front of each cow ($n = 80$). Corn silage (CS; $n = 13$) and corn (dry, $n = 9$, and high-moisture, $n = 7$) samples were also collected from each farm. Feed samples were thoroughly mixed and split for analysis. Fecal and TMR samples were sent to Rock River lab for starch analysis. Total tract starch digestibility (TTSD) was calculated from TMR and fecal starch content. The following equation was used to estimate RSD from TTSD: $y = 82.224 + (0.185 \times \text{ruminal})$, in which y = TTSD (Ferraretto et al., 2013). Samples of TMR, corn, and CS were sent to Rock River for 7-h in situ starch digestibility and to Dairyland lab for analysis of nutrient composition and 7-h in vitro starch digestibility. All herds tested milk through Dairy Herd Improvement Association and individual milk yield, milk fat, and milk protein content data were collected from test day closest to day of sample collection. The REG procedure of SAS was used to determine the relationship between in situ, in vitro, and in vivo RSD. In situ starch digestibility was related to in vivo RSD ($R^2 = 0.19$, $P < 0.002$). There was no relationship between in vitro and in vivo RSD ($R^2 = 0.01$, $P = 0.45$). The Cornell Net Carbohydrate and Protein System (CNCPS) uses ruminal starch kd to predict microbial protein production. Actual milk yield was related to model-predicted milk yield using model default kd for RSD ($R^2 = 0.69$, $P < 0.0001$). Ruminal starch kd was calculated for CS and corn using in situ data and entered into the CNCPS model (version 6.5; AMTS, LLC). This relationship was improved when measured in situ starch kd was entered for corn and CS ($R^2 = 0.76$, $P < 0.0001$). In conclusion, in situ starch digestibility at 7 h is a good approach for estimating RSD in vivo and using kd from this method improves milk yield predictions from the CNCPS model.

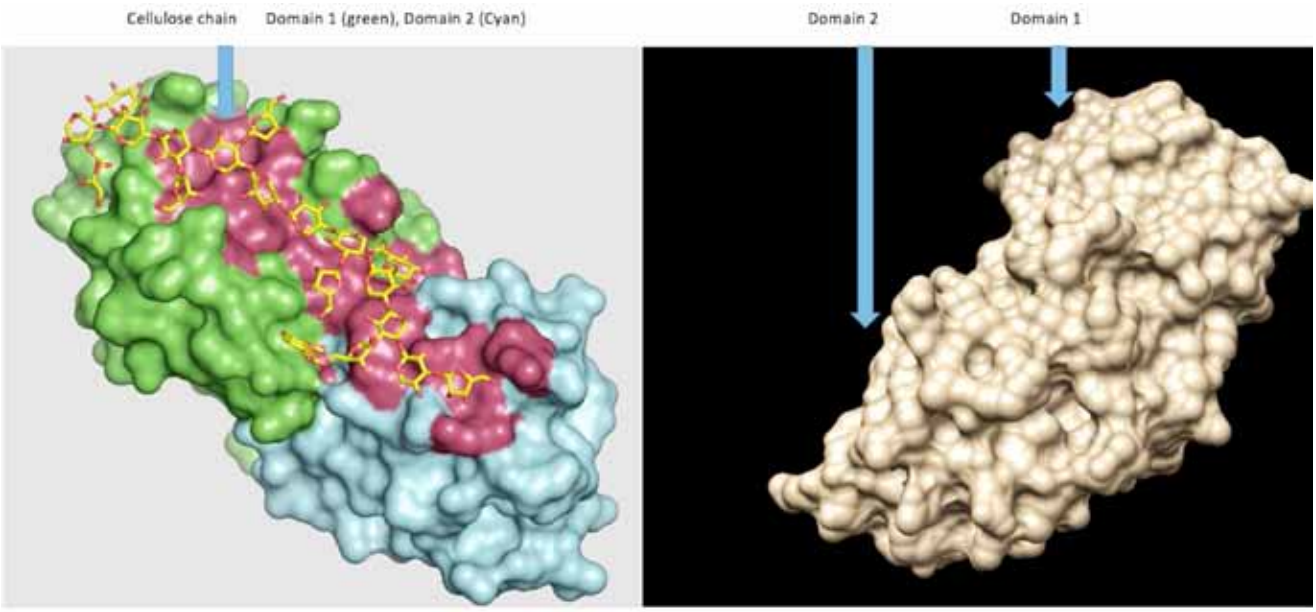
Key Words: in situ, in vitro, ruminal starch digestibility

1623 Effect of rumen acidosis and short-term feed restriction on messenger ribonucleic acid expression of genes relating to gut barrier function and immune response in Holstein steers. K. M. Wood*[1,2], R. L. A. Pederzolli[1], and G. B. Penner[1], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]University of Guelph, Guelph, ON, Canada*.

The objective of this study was to identify whether ruminal acidosis (ACID) or feed restriction (FR) affect genes influencing barrier function (claudin [CLDN], occludin [OCLN], tight-junction protein-1 [ZO-1], and tight-junction protein-2 [ZO-2]) and immune response (toll-like receptor-2 [TLR2], toll-like receptor-4 [TLR4], and Fc fragment of IgA receptor [FCAR]). Twenty-one Holstein steers were randomly blocked and assigned to 1 of 3 treatments: control (CON), ACID, and FR. Steers were fed a common diet with a 50:50 F:C ratio once daily at 0800 h for a 5-d baseline period followed by a challenge period. Rumen acidosis was induced by restricting feed to 25% DMI for 1 d and then offering pelleted barley (30% DMI:BW) the following day. Steers on the FR treatment were restricted to 25% DMI for 5 d. Steers were killed and tissues were collected from the rumen (RUM), jejunum (JEJ), and distal colon (DC) for measurement of mRNA expression using real-time PCR. Relative fold change was calculated by the ΔΔCt method, using pairs of endogenous controls (glyceraldehyde 3-phosphate dehydrogenase, large ribosomal protein P0, or β-actin) and then normalized to the mean of the CON. Data were analyzed as a randomized complete block design using treatment as a fixed effect and block as a random effect. In the rumen, CLDN and OCLN were increased in FR over others ($P \leq 0.02$) and TLR4 was increased by 1.62- and 1.98-fold over CON ($P \leq 0.05$) for ACID and FR, respectively. In the JEJ, expression of CLDN was greater in ACID than in CON and FR ($P = 0.01$) but both ACID and FR had greater expression of OCDN ($P < 0.01$), ZO1 ($P = 0.01$), and ZO2 ($P < 0.01$) than CON. In addition, there was greater mRNA expression for FCAR in FR steers ($P \leq 0.007$) than in ACID and CON steers and greater TLR4 in FR than in CON ($P = 0.04$). In the DC, genes relating to barrier function (CLDN, OCLN, and ZO2) were greater for FR than for CON ($P \leq 0.04$). These data demonstrate that mRNA expression of genes relating to barrier function and immune response in the gastrointestinal tract are differentially affected by nutritional stressors. Nutritional challenges affect the expression of genes related to barrier function in immune response in the gastrointestinal tract. This may have implications in identifying how cattle adapt to nutritional challenges and to identify strategies to improve gut barrier function.

Key Words: acidosis, cattle, gut barrier function

Fig 1625.



1624 Use of fecal starch as an indicator of starch digestibility and starter intake in preweaned dairy calves. T. S. Dennis*, W. Hu, F. X. Suarez-Mena, T. M. Hill, J. D. Quigley, and R. L. Schlotterbeck, *Provimi North America, Brookville, OH.*

Fecal starch (FS) has been used as a tool to evaluate starch digestibility in lactating dairy cows and feedlot steers. Some on-farm advisors are also using FS in a similar way to evaluate solid feed digestibility in preweaned dairy calves. Our objective was to evaluate the relationship of FS with starter intake and starch digestibility in preweaned dairy calves. Male Holstein calves initially 43 ± 2.9 kg BW from a single farm (N = 35) were fed different amounts of milk replacer ranging from 0.66 to 1.1 kg DM daily (27% CP and 17% fat) and weaned by 7 wk of age. Starters contained 37% whole corn, 20% whole oats, 35% protein pellet, and 3% molasses and contained 43% starch (first set) and 38% starch (second set). Fecal grab samples were taken from calves at 3 (n = 20), 6 (n = 20), and 8 wk (n = 35) of age. Twelve fecal samples per calf were taken via rectal palpation over a 5-d period each week, frozen daily, combined on an equal wet-weight basis, and subsampled for analysis. Chromic oxide was used as an external digestibility marker at 3 and 6 wk, whereas AIA was used as an internal marker at 8 wk. Milk replacer and starter intakes (offered and refused) were recorded daily during collection. Linear regression analysis of starch digestibility (%) and dry feed intake (kg/d) vs. fecal starch (%) were determined using PROC REG of SAS. At 3 wk of age, starch digestibility increased ($y = 0.69x + 40.80$; $R^2 = 0.53$, $P < 0.01$) and starter intake decreased ($y = -0.01x + 1.32$; $R^2 = 0.20$, $P = 0.05$) with increasing FS. At 6 wk of age, starch digestibility ($P = 0.11$) and starter intake ($P = 0.96$) were not related to FS. At 8 wk of age after calves were weaned, starch digestibility decreased as FS increased ($y = -0.62x + 99.7$; $R^2 = 0.86$, $P < 0.01$), whereas FS and starter intake were not related ($P = 0.17$), a relationship in contrast to the previously observed result in calves still consuming milk replacer. In the current study, results suggest that FS was not a good estimate of starch digestion or dry feed intake in the preweaned calf but has promise for evaluating starch digestibility in calves after weaning.

Key Words: dairy calf, digestion, fecal starch

1625 Expression and purification of a novel bacterial expansin from *Bacillus subtilis* that synergistically degrades cellulose with fibrolytic enzymes. A. A. P. Cervantes*[1], I. Muhammad[2], C. F. Gonzalez[3], D. Vyas[1], and A. T. Adesogan[1], *[1]Dep. of Animal Sciences, IFAS, University of Florida, Gainesville, [2]University of Florida, Gainesville, [3]University of Florida, Gainesville.*

Expansin-like proteins are a recently discovered group of proteins that can change the mechanical properties of plant cell walls. Many can synergistically improve cellulose degradation by fibrolytic enzymes. This study aimed to express and purify a novel bacterial expansin-like protein from *Bacillus subtillis*. Primers were constructed based on the Expansin-Yoaj protein sequence (accession number: WP_015383820.1) and tested using genomic DNA from *Bacillus subtillis* strain, UD1022. The plasmid p15TV-LdtR was used as template and transformed in *E. coli* DH5-α. Standard methods were used for chromosomal DNA isolation, restriction enzyme digestion, ligation, transformation, and agarose gel electrophoresis. The His-tagged fusion proteins in the plasmid were overexpressed in *E. coli* BL21-Star (DE3) cells. Then the cells were lysed

using a French Press and purified with a metal chelate affinity-column charged with Ni^{2+}. The remaining fraction was dialyzed, then protein concentration and molecular weight were determined. Protein identity was confirmed by sequencing and using Phyre[2] software. To examine the protein activity and synergism with cellulase, we examined if the expansin protein increased hydrolysis of carboxymethylcellulose (10 mg/ml) by *Trichoderma reesei* β 1- 4 endoglucanase EC (3.2.1.4) beyond the increase caused by the endoglucanase alone. The experiment had 5 (treatments: Control, enzyme, enzyme + expansin-like protein at doses of 100, 200, and 300 mg/ml) × 5 (incubation durations: 0,12, 24, 36, and 48 h) factorial treatment structure with 3 replicates per treatment combination. Additionally, all expansin doses were incubated by triplicate without cellulase for 48 h. Data were analyzed using the Generalized Linear Model of R. Protein concentration ranged from 0.130 to 0.345 mg/ml with an average molecular weight of 27 kDa. The Phyre[2] software revealed a two domain structure with polar residues typical in similar non-hydrolytic proteins. Synergistic increases in cellulose hydrolysis of 6 to 10% were detected ($P < 0.05$) by adding 100 but not 200 mg/ml of expansin-like protein. Whereas, adding 300 mg/ml of expansin-like protein decreased cellulose hydrolysis. Synergistic effects were more evident at 12 and 24 h (5 to 15%; $P < 0.05$) than at 36 and 48 h. On the other hand, using expansin alone did not exhibit hydrolytic activity after 48 h regardless of the dose. The newly expressed non-hydrolytic expansin-like protein synergistically increased cellulose hydrolysis by cellulase.

Key Words: expansin, synergistic effects, fibrolytic enzymes

1626 Annual rhythms of milk, fat, and protein production in U.S. dairy cattle. I. J. Salfer*, C. D. Dechow, and K. J. Harvatine, *Penn State University, State College.*

An annual pattern of milk composition has been well appreciated in dairy cattle with highest milk fat and protein observed during the winter and lowest in the summer. However, the rhythm has not been well quantified. The cosine function is commonly used to model repeating daily and seasonal rhythms and allows determination of the amplitude (mean to peak), phase (time at peak), and period (time between peaks) of the rhythm. The objective of this study was to use cosine analysis to characterize the annual rhythm of milk, fat, and protein production using both national milk production and herd-level data. First, 10 yr of monthly average milk butterfat and protein concentration by milk market were obtained from the USDA Agricultural Marketing service database. We first determined if the data fit a cosine function with a 12 mo period using the linear form of the cosine function by random regression in PROC Mixed. A zero amplitude test was used to determine significance of the rhythm. Fat and protein concentration fit a cosine function with a 12 mo period in all milk markets. There was an interaction between milk marketing order and milk fat and protein concentration ($P < 0.01$). The phase (time at peak) ranged from October 6 to January 6 for fat and from November 21 to December 12 for protein. The amplitude of the rhythm ranged from 0.07 to 0.14% for fat production and from 0.08 to 0.12% for protein production. The amplitude of milk fat rhythm generally was lower in southern markets and higher in northern markets. Second, the annual rhythm of milk yield and milk fat and protein yield and concentration were analyzed in monthly test day data from 1684 cows from 11 tie-stall herds in Pennsylvania. Milk, fat, and protein yield and fat and protein concentration followed yearly annual rhythms. Milk and protein yield were highest in May, fat yield and concentration were highest in February, and protein concentration was highest in November. There was an interaction of herd with the rhythm of milk yield, fat yield, and fat concentration. In conclusion, there is an annual rhythm of milk yield and milk fat and protein yield and concentration that fits a cosine function and varies by geographical location and herd.

Key Words: annual rhythms, milk synthesis, yearly pattern

1627 Molecular physiology of rumen papillae following an acidosis challenge. C. E. Kent-Dennis*, J. A. Pasternak, and G. B. Penner, *University of Saskatchewan, Saskatoon, Canada.*

The objective of this experiment was to evaluate the effect of ruminal acidosis on transcript abundance and localization of proteins regulated by local inflammation in the ruminal epithelium. Seven ruminally cannulated beef cows were used in a crossover design with two periods and two treatments (acidosis or control). Heifers were fed a baseline TMR with 50:50 forage to concentrate ratio and DMI was recorded daily. The acidosis induction consisted of feed restriction (25% of DMI for 1 d) followed by a grain challenge (30% of baseline DMI) and provision of the full TMR. Ruminal pH was monitored using indwelling probes and ruminal papillae biopsies were collected on d 2 and 6 following the induction of acidosis for RNA extraction and immuno-histofluorescence. Prostaglandin-endoperoxide synthase (PTGS1) and PTGS2 facilitate prostaglandin synthesis and were selected as targets because expression is thought to be regulated by inflammation. Gene expression was measured by quantitative real-time PCR, normalized to the geometric mean of three housekeeping genes within period. Immuno-histofluorescence of toll-like receptor (TLR)-9 and TLR-4 were used to evaluate localization in a subset of samples. Statistical analysis was performed using the MIXED procedure of SAS 9.4, with treatment and period as fixed effects. A pH threshold of 5.8 was used to define the occurrence of ruminal acidosis. During the day of the grain challenge, ruminal pH for acidosis cows was below pH 5.8 for 543 min, whereas pH of controls did not fall below the threshold at any time ($P = 0.02$). Minimum and mean pH were less on the

challenge day (min: 5.4 vs. 6.2 ± 0.17 and mean: 5.9 vs. 6.6 ± 0.14, respectively; $P < 0.01$) for acidosis than control cows. Two days after acidosis induction, transcriptional abundance of PTGS1 and PTGS2 in ruminal papillae were decreased by 1.37 ($P = 0.02$) and 2.08 ($P < 0.01$) fold, respectively, relative to controls. When evaluated at d 6, no differences were observed. TLR-9 was not ubiquitously expressed, but rather was concentrated in small areas within regions of the ruminal epithelium. TLR4 was intracellularly expressed in the stratum basale, stratum spinosum, and stratum granulosum regardless of treatment. The results of this study suggest a potential acute anti-inflammatory response following acidosis, which was also tightly regulated. However, the downregulation of PTGS2 was unexpected; related transcripts are being studied to elucidate these effects.

Key Words: acidosis, inflammation, rumen papillae

1628 Endocannabinoid and lipid metabolism gene network expression in adipose tissue of peripartal cows with low or high body condition score at calving. A. S. Alharthi*[1], Z. Zhou[1], D. N. Luchini[2], and J. J. Loor[1], [1]*University of Illinois, Urbana,* [2]*Adisseo S.A.S., Alpharetta, GA.*

Our previous research revealed a strong inflammatory response within adipose tissue during the transition into lactation. Whether this localized effect is a result of oxidative stress induced by lipolysis and fatty acid oxidation or via the production of endocannabinoids remains to be determined. The objective of this study was to investigate the expression of genes composing the endocannabinoid signaling system and lipid metabolism in adipose tissue during the transition period in dairy cows. Twenty multiparous Holstein cows were retrospectively divided by prepartum body condition score (BCS) into two groups (10 cows/group): BCS $\leq$ 3.25 (LoBCS) and BCS $\geq$ 3.75 (HiBCS). Adipose tissue was biopsied at d −10, 7, and 20 relative to parturition. Tissue RNA was used to evaluate 17 target genes via quantitative real time RT-PCR. Data were log2 transformed and analyzed by the MIXED procedure of SAS. Among the endocannabinoid-related genes, a BCS × day was observed for *NAPEPLD*, *CNR2*, and *FAAH*. Expression of *NAPEPLD* and *CNR2* was greater at d 7 in LoBCS than HiBCS cows, while *FAAH* was upregulated at d 7 and 20 LoBCS than HiBCS cows. Expression of monoglyceride lipase (*MGLL*), which inactivates 2-Arachidonoylglycerol, was overall greater ($P < 0.05$) across time in LoBCS than HiBCS. In addition, LoBCS than HiBCS cows had a strong tendency ($P = 0.06$) for greater overall expression of *POMC* across time. Regarding the genes related with lipid metabolism, a BCS × day ($P = 0.04$) was observed for the mitochondrial enzyme *SOD2*, important for clearing reactive-oxygen species that cause cellular stress and inflammation, because of greater expression at d 7 in LoBCS than HiBCS. Similarly, a strong tendency ($P = 0.07$) for a BCS × day was observed for *LIPE* due to greater expression at d 7 and 20 in LoBCS than HiBCS. Among genes associated with lipolysis, LoBCS compared with HiBCS cows had overall greater expression of *ABDH5* ($P = 0.04$) and *ATGL* ($P = 0.02$), indicating a greater state of basal lipolysis over time. Although no BCS effect was detected for *CPT1A*, its expression increased sevenfold on d 20 versus −10, indicating a robust capacity of adipose for fatty acid oxidation. Overall, data indicated that cows with prepartum BCS below 3.25 experienced greater alterations in lipid metabolism and endocannabinoid signaling. A potential linkage between those pathways and risk of disorders postpartum remains to be determined.

Key Words: body condition score, endocannabinoid, lipid mobilization

---

1629 Endocannabinoid network and proopiomelanocortin gene expression in peripartal bovine liver in response to rumen-protected methionine supplementation. A. S. Alharthi*[1], Z. Zhou[1], D. N. Luchini[2], and J. J. Loor[1], [1]*University of Illinois, Urbana,* [2]*Adisseo S.A.S., Alpharetta, GA.*

Results from our previous work revealed a beneficial effect of rumen-protected Met (MET) supplementation during the transition period on postpartal immune function, inflammation, and cow performance. Endocannabinoids (EC; 2-Arachidonoylglycerol, oleoylethanolamide, and anandamide) are produced on stimulation of EC receptors expressed in central nervous system and peripheral tissues. These compounds have orexigenic, anorexigenic or pro- and anti-inflammatory properties. Because MET-fed cows had a better immune and liver function postpartum, we sought to determine any changes in the EC gene network and the hormone precursor proopiomelanocortin (POMC). Twenty-two multiparous Holstein cows were fed experimental treatments consisting of a basal control diet (CON; $n = 11$) and CON plus Met (Smartamine M, Adisseo NA) (MET; $n = 11$). All cows received the same far-off diet from −50 to −22 d before expected calving, close-up diet from −21 d to expected calving, and lactation diet from calving through 30 d in milk (DIM). MET supplementation was adjusted daily from −21 d to 30 DIM at a rate of 0.08% (DM basis) of diet DM. The liver was biopsied at −10, 7, 20, and 30 d relative to parturition. RNA was extracted and used for quantitative real-time RT-PCR. Expression of each target gene was normalized by the geometric mean of three internal control genes. Data were log2 transformed and analyzed using the MIXED procedure of SAS. A strong tendency for a treatment × day effect was observed for the EC receptor *CNR2* ($P = 0.06$), the lipase *MGLL* ($P = 0.08$), the amidase *NAAA* ($P = 0.08$) and *POMC* ($P = 0.07$). These results were associated with greater expression of *MGLL* and *POMC*in MET compared with control cows on d 7, while the expression of *NAAA* was greater in MET compared with control cows on d −10 and 7. In contrast, the interaction for *CRN2* was associated

with lower expression in MET compared with control cows on d −10. There was an overall greater ($P < 0.05$) expression of the fatty acid amide hydrolase *FAAH* and the EC-synthesizing enzyme *NAPEPLD* in MET compared with control cows. Overall, results indicate that alterations in the hepatic EC signaling network in response to MET might be involved in the positive effect on performance and liver function. Additional studies to investigate the mechanism of action of MET on the hepatic endocannabinoid system appear warranted.

Key Words: endocannabinoid, liver, methionine, transition period

1630 Substrate utilization by *Megasphaera elsdenii* strain NCIMB 41125. A. M. Mobiglia*[1], F. R. Camilo[1], and J. S. Drouillard[2], [1]*CAPES Foundation, Ministry of Education of Brazil, Brasilia, Brazil,* [2]*Kansas State University, Manhattan.*

Megasphaera elsdenii (ME) is a key lactate-utilizer in grain-fed cattle, but less is known of its competitiveness in the rumen when administered as a probiotic before feeding grains. Our objective was to evaluate capacity for ME to utilize a wide range of alternative substrates, including glucose, fructose, galactose, arabinose, xylose, maltose, sucrose, lactose, trehalose, raffinose, fructo-oligosaccaride (FOS), potato starch, soy protein, and succinate. A basal medium (NC) was prepared with yeast extract, soy peptone, minerals, vitamins, and cysteine, and used alone or amended with sodium lactate or one of the above carbon sources. Lactate medium was adjusted to pH 5.6 and all other media were adjusted to pH 6.0. Hungate tubes containing sterile media were inoculated with 2% of a fresh culture containing approximately 9.6×10^8 CFU/mL ME strain NCIMB 41125 and incubated at 39ºC for 12 h. Changes in VFA concentrations were measured by gas chromatography using a capillary column (DB-WAX; J&W Columns) and flame ionization detector. Optical density (OD), measured as absorbance at $\lambda = 600$ nm, and pH were quantified, and cultures were enumerated on agar plates to determine viable cell counts. The study was a randomized complete block with individual cell culture as the experimental unit. Data were analyzed as mixed models with substrate as the fixed effect and block as a random effect. OD readings of cultures with arabinose, galactose, lactose, trehalose, and potato starch were comparable ($P > 0.05$) to NC, indicating limited capacity for metabolism of these carbon sources. Growth was greater with fructose compared to other substrates ($P < 0.05$), followed by glucose, lactate, and maltose, all of which were greater than NC ($P < 0.05$). Growth in media with FOS, raffinose, xylose, sucrose, and soy protein were marginally greater than NC ($P < 0.05$), while succinate inhibited growth ($P < 0.05$). Changes in culture pH and VFA concentrations were consistent with changes in OD measurements. Viable cell counts were lowest ($P < 0.05$) for succinate (6.8 versus 7.9 log CFU/mL for succinate and NC, respectively), again indicating an inhibitory effect of succinate on ME. Cultures with fructose, maltose, and glucose all had low terminal pH (4.31, 4.82, and 4.85, respectively), which may have adversely affected viable cell counts (8.15, 8.27, and 8.84 log CFU/mL, respectively). This study provides evidence for metabolism of a broad range of carbon sources by *Megasphaera elsdenii* strain NCIMB 41125.

1631 16S rRNA Bacterial sequences suggest dietary intervention can be used to change microbial community structure to reduce methane emission in Holstein dairy cattle. W. Tom*, J. V. Judy, P. J. Kononoff, and S. C. Fernando, *University of Nebraska-Lincoln, Lincoln.*

The rumen microbiome plays a critical role in host nutrient acquisition, and diet has been shown to alter the composition and function of the rumen microbiome. Most microbes in in the rumen resist in vitro culturing, remaining largely uncharacterized. Recent advances in next generation sequencing (NGS) methodologies provide an excellent opportunity to better understand changes in the structure of the rumen microbiome, which may lead to novel strategies to increase animal productivity and reduce livestock greenhouse gas emissions. This study utilizes high throughput sequencing of the 16S rRNA gene to compare bacterial community structure and abundance under different dietary conditions to evaluate the effect of the rumen microbial community on methane production in Holstein dairy cows. The experiment follows a randomized row by column design (8 x 4). Eight different Holstein cows were fed four different diets; reduced fat distillers grain (RFDDGS) mix, corn oil grain mix, calcium sulfate grain mix, and a standard corn and soybean meal control. Each diet was fed for 28 d and methane emissions were measured using indirect calorimetry (headboxes). Additionally, rumen samples were collected on Day 28 via esophageal tubing for microbial community analysis. Before receiving the first treatment diet, all cows were maintained on the same common diet to reduce animal to animal variation. DNA sequencing was performed using the Illumina MiSeq™ platform. Comparisons of rumen 16S rRNA bacterial communities show a significant difference in microbiome composition both by animal and by diet (PERMANOVA, $p < 0.001$). Pairwise comparison of all diets was performed using a Wilcoxon rank-sum test revealing significant differences between corn oil and RFDDGS ($p < 0.001$), calcium sulfate and RFDDGS ($p < 0.001$), corn oil and control ($p < 0.001$), and calcium sulfate and control ($p < 0.01$). Upon examining differences in operational taxonomic unit (OTU) abundances we identified multiple OTUs showing log fold changes between diets, supporting that bacterial community composition differs based on diet. This data suggests that dietary intervention can be used to mitigate methane emission by

controlling the microbial population within the rumen.

Key Words: bacterial community, microbiome, next generation sequencing, 16S rRNA

1632 Inulin as prebiotic for *Lactobacillus salivarius* and *Enterococcus faecium* with probiotic potential in ruminants.

D. Hernández-Sánchez[*1], J. L. Gómez–Hernández[2], M. M. Crosby–Galván[1], A. M. Hernández-Anguiano[1], J. E. Ramirez-Bribiesca[3], E. Aranda–Ibañez[1], S. S. Gonzalez-Muñoz[4], and R. Pinto-Ruiz[1], *[1]Colegio de Postgraduados, Montecillo Texcoco, Mexico, [2]Colegio de Postgraduados, Montecillo, Mexico, [3]Colegio de Postgraduados, Montecillo, Mexico, [4]Colegio de Postgraduados, Montecillo Estado de Mexico, Mexico.*

Milk production in Mexico is deficient and there are diarrhea problems in nursing calves. Lactic acid bacteria (LAB) are found in the digestive tract and show an antagonistic effect against enteric pathogens. Addition of prebiotics such as inulin to diets of calves might control gastrointestinal flora. Therefore, the aim of this research was to evaluate the influence of inulin on in vitro growth performance of *Lactobacillus casei* (*Lc*), *Lactobacillus salivarius* (*Ls*), and *Enterococcus faecium* (*Ef*). In vitro incubations were performed at 37°C, replacing the MRS glucose for inulin. The experimental design was complete randomized and treatments (T) were: T1 = MRS-glucose + Ls; T2 = MRS-glucose + Ef; T3 = MRS-glucose + Lc; T4 = MRS-inulin + Ls; T5 = MRS-inulin + Ef; T6 = MRS-inulin + Lc; T7 = MRS-inulin + Ls + Ef; T8 = MRS-inulin + Ls + Lc; T9 = MRS-inulin + Ef + Lc; and T10 = MRS-inulin + Ls + Ef + Lc. Variables were growth curve, pH, lactic acid production, ammonium, strains resistance to hydrochloric acid and bile salts, and antagonism against *Escherichia coli* and *Salmonella typhimurium*. Data were statistically analyzed with PROC GLM of SAS, and Tukey test ($P < 0.05$) was used to compare treatments means. Analysis of results showed a positive effect of inulin on the growth of strains, higher absorbance readings in MRS-inulin as compared to MRS-glucose (2.35^{d}, 2.28^{d}, 2.30^{d}, 2.83^{abc}, 2.67^{c}, 2.64^{c}, 2.75^{abc}, 2.93^{a}, 2.72^{bc}, and 2.88^{ab}, from T1 to T10, respectively; $P < 0.05$) and higher bacterial count at the end of the growth curve (10.98^{d}, 10.76^{d}, 11.29^{d}, 13.11^{c}, 13.63^{b}, 13.77^{a}, 12.93^{c}, 12.74^{c}, 12.43^{c}, and 12.92^{c} Log_{10} UFC mL^{-1} from T1 to T10, respectively; $P < 0.05$), whereas no changes were found for the other variables. We conclude that LAB *Ls* and *Ef* fermented inulin with a positive effect on strains growth, without affecting their probiotic potential.

Key Words: *Enterococcus faecium*, inulin, *Lactobacillus salivarius*

1633 Moisture content influences ensiling characteristics, in situ disappearance, and in vitro digestion characteristics of reconstituted corn grain.

F. R. Camilo[*1], A. M. Mobiglia[1], C. L. Van Bibber-Krueger[2], H. C. Muller[2], T. J. Ellerman[2], S. Katulski[2], and J. S. Drouillard[2], *[1]CAPES Foundation, Ministry of Education of Brazil, Brasilia, Brazil, [2]Kansas State University, Manhattan.*

Grain processing is a key factor influencing efficiency of feed utilization in feedlot cattle. Reconstitution of corn grain followed by ensiling modifies structural characteristics of grain, thereby improving starch availability and animal performance. The objective of this experiment was to evaluate changes in ensiling characteristics of corn grain reconstituted to different moisture levels, and to determine impact on in situ and in vitro digestion. Corn grain was ground to 4000 µ and subsequently mixed with water to final moisture concentrations of 27, 30, 33, and 36%. Grains were packed into 12 concrete silos (2-m dia. x 2-m height), each containing approximately 2650 kg of grain (3 silos per moisture level). Grains were allowed to ensile for 90 d, then sampled by drilling two 3-cm cores to a depth of 60 cm, which were composited to form one sample for each silo. Ensiled grains and a dry-rolled corn control (DRC) were characterized with respect to pH, moisture content, 16-hour in situ disappearance, and in vitro fermentation by mixed ruminal microbes. Grain pH was determined after steeping 25 g of grain in 100 mL deionized water for 1 h at room temperature. For in vitro fermentations, 3 g of grain (DM basis) were added to 250-mL screw-top bottles, mixed with 140 mL of artificial saliva and 10 mL of strained ruminal fluid, flushed with nitrogen, capped with Ankom gas pressure monitors, and placed into a shaking incubator at 39ºC for 16 h. Terminal pH was measured for each culture, and samples of supernatant were mixed 4:1 with 25% w/v metaphosphoric acid solution for determination of VFA profiles by gas chromatography using a flame ionization detector. In situ dry matter disappearance (ISDMD) of grains was measured over a 16-h ruminal incubation. The pH of ensiled grains was 6.3, 4.42, 4.23, and 4.15 for 27, 30, 33, and 36% moisture, respectively (linear and quadratic effects, $P < 0.01$). ISDMD were 36, 46, 43, 47, and 57% for DRC and ensiled grains with 27, 30, 33, and 36% moisture, respectively (linear, $P < 0.01$), in vitro gas production amounts were 89, 161, 163, 221, and 284 mL, respectively (linear, $P < 0.01$), and total VFA concentrations of cultures were 41, 58, 69, 86, and 100 mM, respectively (linear, $P < 0.01$). Moisture content of reconstituted, ensiled grain has a large impact on in situ and in vitro fermentation characteristics.

Key Words: corn, reconstitution, starch

1634 On the way to optimize the two stage Tilley and Terry technique for a more accurate in vitro assessment of rumen modifiers. A. Russouw[*1], E. Raffrenato[1], F. Chaucheyras-Durand[2], and E. Chevaux[2], [1]*Department of Animal Sciences, Stellenbosch University, Stellenbosch, South Africa,* [2]*Lallemand SAS, Blagnac, France.*

In vitro techniques using rumen inocula are routinely used to estimate NDF rumen and total tract digestibility values. By controlling the micro-environment of the test flask, the technique does not represent the dynamic environment of the rumen, often resulting in higher digestibility values when compared to in vivo values. Furthermore, because of the stability of the system, testing rumen modifiers in vitro may result in biased conclusions. Among the possible parameters, our objective was to assess the effects of using different buffers, NDF levels and doses of a live yeast assumed to stimulate fiber digestion, on rumen NDF and total tract OM in vitro digestibility (NDFd and TTOMd) using a modified Tilley and Terry procedure. Three buffers (Kansas State-KS; McDougall-MD; Goering and Van Soest-GV), two forages (wheat straw-WS, 83% NDF; oat hay-OH, 60% NDF) and 4 doses of yeast (0, 10^5, 10^6, 10^7 cfu/ml) were tested. Residual NDF of the fermented samples were obtained at 12, 24, and 48 h. The fermented samples followed also 48 h acid pepsin treatment for OMd estimation. NDF rate of digestion (kd) was calculated using a first order decay model and estimated iNDF using the 240 h fermentation residual. Data were analyzed according to a randomized complete block design with a factorial arrangement of treatments. The main tested effects were buffer, NDF level, and yeast dose. Run was considered random effect and response variables were NDFd and kd. The buffers resulted in different NDFd and kd ($P < 0.01$) with the KS resulting in the lowest and MD in the highest NDFd and TTOMd, for both WS and OH. Yeast interacted with both NDF level and buffer ($P < 0.01$), resulting in more effective action (higher kd) with higher NDF and GV and KS buffers. The most effective yeast dose was the 10^6 cfu/ml, when compared to the others across NDF levels and buffers, increasing kd on average 0.025 to 0.035 and 0.038 to 0.044 h^{-1} for WS and OH, respectively. Therefore, all parameters tested affected conclusions on the effectiveness of the rumen modifier tested.

Key Words: buffers, live yeast, NDF digestibility, Tilley and Terry

1635 Effect of feeding different flaxseed-based products on the rumen microbial community of dairy cows evaluated by high-throughput DNA sequencing. E. Castillo-Lopez[*1], J. Moats[1], N. D. Aluthge[2], H. A. Ramirez Ramirez[3], T. A. McAllister[4], C. L. Anderson[2], D. A. Christensen[1], T. Mutsvangwa[1], H. Lee-Rangel[5], G. B. Penner[1], and S. C. Fernando[2], [1]*University of Saskatchewan, Saskatoon, Canada,* [2]*University of Nebraska, Lincoln,* [3]*Iowa State University, Ames,* [4]*Lethbridge Research and Development Centre, AAFC, Lethbridge, Canada, Lethbridge, Canada,* [5]*Universidad Autonoma de San Luis Potosi, San Luis Potosi, Mexico.*

Four ruminally-cannulated lactating Holstein cows (mean and SD, 116.5 ± 17.5 DIM; 712.7 ± 92.3 kg BW) were used in a 4 × 4 Latin square with 28-d experimental periods to evaluate the effect of feeding flaxseed-based products on the rumen microbial population. Treatments (DM basis) were: 1) CONT, a control diet containing 51.9% of a barley-based concentrate, 20.0% alfalfa hay, and 28.2% barley silage; 2) FLAX, inclusion of 11.4% of a non-extruded flaxseed-based product which contained 55% flaxseed, 37% field peas, and 6.8% dehydrated alfalfa; 3) EF, inclusion of 11.4% of an extruded flaxseed-based product which contained 55% flaxseed, 37% field peas, and 6.8% dehydrated alfalfa; and 4) EFT, inclusion of 11.4% of an extruded flaxseed-based product which contained 55% flaxseed, 37% high-tannin faba beans (*Vicia faba*), and 6.8% dehydrated alfalfa. The flaxseed-based products used in FLAX, EF, and EFT were included (3 kg/d) by partially replacing 3 kg/d of the barley-based concentrate. At the end of each period, samples of ruminal contents were collected and DNA was extracted from samples. The V3 hypervariable region of the 16S rRNA bacterial gene was amplified and sequenced. Sequenced reads were subjected to phylogenetic classification using the pipelines UPARSE and QIIME. Data for the abundance of bacterial taxa were analyzed using the MIXED procedure of SAS. Major bacterial phyla were not affected ($P \geq 0.34$) by diet and included *Bacteroidetes* (48.8 ± 3.66%), *Firmicutes* (46.0 ± 3.92%), and *Proteobacteria* (1.3 ± 0.30%). Major bacterial families were similar ($P \geq 0.71$) across diets and were represented by *Prevotellaceae* (20.2 ± 2.82%) and *Veillonellaceae* (16.3 ± 6.19%). In addition, major genera remained unaffected ($P \geq 0.38$) and included *Prevotella* (19.3 ± 2.47%) and *Succiniclasticum* (14.5 ± 6.12%). However, compared to CONT, there were shifts in some bacterial families and genera for EF and EFT. The biohydrogenating bacteria, *Clostridium*, decreased ($P < 0.01$) resulting in 0.4, 0.1, 0.1, and 0.2 ± 0.05% for CONT, FLAX, EF, and EFT, respectively. Flaxseed extrusion and high-tannin faba beans did not affect predominant bacterial taxa; however, there were shifts in less abundant taxa including a decrease in

the biohydrogenating genus *Clostridium*.

Key Words: biohydrogenation, extruded flaxseed, rumen microbiome, tannin

1636 Effects of inoculum source and ammoniation on in vitro gas production kinetics of barley straw.

L. Xu[1,2], Z. X. He[1], P. X. Jiao[1,3], G. O. Ribeiro Jr.[1], V. Bremer[4], K. A. Beauchemin[1], T. A. McAllister[1], and W. Z. Yang[*1], [1]*Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, Canada,* [2]*Light Industry Vocational Technical College, Baotou, China,* [3]*Northwest Agriculture and Forestry University, Yangling, China,* [4]*Elanco Animal Health, Greenfield, IN.*

A batch culture was conducted to assess the effects of inoculum source and ammoniation on in vitro gas production (GP) and DM digestion (DMD) kinetics of barley straw (BS). The experiment was a 2 × 2 × 2 factorial with low- vs. high-fiber digesting rumen inoculum; ammoniated vs. untreated BS; and with and without the replacement of forage with concentrate. All substrates were ground through a 2-mm screen. Inoculum was collected from two low- and two high-fiber digesting beef heifers as defined by the rate of digestion (0.021 to 0.026/h) and effective degradability (ED) of DM of BS. For the concentrate treatment (BSC), 30% BS was replaced by an equal amount of concentrate. Additional vials containing only concentrate were used to correct for its contribution to GP. The GP was recorded at 3, 6, 9, 12, 24, 36, 48, and 72 h and DMD was measured after 6, 12, 24, 48, and 72 h. The experiment was repeated three times on different days. Data were fitted to exponential models: $GP = b(1-e^{-c(t-L)})$ and $DMD = a+b(1-e^{-c\,(t-L)})$. The GP parameters were not affected by inoculum source, but lag time decreased ($P < 0.01$) with ammoniation (0.6 h) vs. untreated (1.5 h) or with BSC (0.7 h) vs. BS (1.4 h). Initial GP (ml/g OM) increased ($P < 0.01$) with ammoniation (8.1) vs. untreated (7.1) or with BSC (8.2) vs. BS (7.0). For DMD, the high- vs. low-fiber digesting inoculum decreased ($P < 0.01$) the soluble fraction, lag time and ED of DM without affecting the potentially digestible fraction or rate of disappearance of the potentially digestible fraction. Ammoniation improved ($P < 0.01$) DMD kinetics (soluble, 11 vs. 15%; potentially digestible, 50 vs. 59%; rate, 5.4 vs. 6.2%/h; lag time, 2.8 vs. 2.0 h) and ED (30 vs. 36%) of BS. The BSC compared with BS had greater ($P < 0.01$) ED (36 vs. 31%) without altering other DMD parameters. Although both inoculum source (soluble, $P < 0.05$; lag time, $P < 0.01$; and ED, $P < 0.10$) and BSC (potential digestible fraction, lag time, and ED; $P < 0.01$) exhibited an interaction with ammoniation, kinetic parameters tended to be improved by ammoniation. These results suggest that inoculum from high-fiber digesting cattle did not improve in vitro GP or DMD of BS. In addition, the study confirmed that ammoniation improved the ruminal digestion of BS.

Key Words: ammoniated straw, batch culture, inoculum source

1637 Feeding ground flaxseed to lactating dairy cows decreases the ruminal proportion of *Archaea*, but does not change the major species of cellulolytic bacteria.

A. B. D. Pereira[*1], A. F. Brito[1], T. L. Resende[2], D. H. Woitschach[3], R. B. Reis[2], and K. J. Soder[4], [1]*University of New Hampshire, Durham,* [2]*Universidade Federal de Minas Gerais, Belo Horizonte, Brazil,* [3]*Universidade Federal de Viçosa, Viçosa, Brazil,* [4]*USDA-Agricultural Research Service, University Park, PA.*

The objective of this study was to investigate the impact of incremental amounts of ground flaxseed (GFX) on ruminal microbiota of lactating Jersey cows. Twelve lactating organically-certified Jersey cows (76 ± 23 DIM and 431 ± 25 kg of BW), part of a larger feeding trial, were used in a replicated 4 × 4 Latin square design with 21-d periods (14 d for diet adaptation and 7 d for sample collection). Cows were randomly assigned to 1 of 4 treatments (DM basis) consisted of 55% mixed-mostly grass silage, 8% mixed-mostly grass hay, 2% roasted soybean and: 1) 0% GFX, 6% soybean meal (SBM), and 27% corn meal (CM), 2) 5% GFX, 4.8% SBM, and 23.2% CM, 3) 10% GFX, 3.5% SBM, and 19.5% CM, and 4) 15% GFX, 2% SBM, and 16% CM. Ruminal fluid was sampled using an esophageal tube 7 h after the morning feeding on d 17 to 19 of each experimental period, pooled, and frozen at −80°C until analysis. After DNA extraction, the 16S rRNA gene V4 variable region PCR primers 515/806 were used. Following amplification, PCR products were pooled in equal proportions based on their molecular weight and DNA concentration, purified using calibrated Ampure XP beads, and then used to prepare the DNA library for Illumina TruSeq DNA analysis (Mr. DNA Molecular Research Laboratory, Shallowater, TX). Sequencing was performed on a MiSeq and data were processed using a proprietary analysis pipeline. Final operational taxonomical units were classified using BLASTn against a curated database derived from GreenGenes, RDPII, and NCBI. Orthogonal polynomial contrasts were used to test linear and quadratic effects. Results are shown in Table 1. The ruminal proportion of archaea responded quadratically to feeding GFX. Specifically, the proportion of *Methanobrevibacter* sp. and *Methanosphaera* sp. responded quadratically, whereas that of *Methanomicrobium* sp. decreased linearly with the greatest level of GFX resulting in the lowest values. Quadratic effects were also observed for *Fibrobacter* sp. and *Prevotella* sp. with feeding GFX. Whereas the 3 major ruminal cellulolytic species (*Fibrobacter succinogenes*, *Ruminococcus albus*, and *Ruminococcus flavefasciens*) were not affected by GFX supplementation, the ruminal proportion of *Prevotella ruminicola* and *Prevotella briantii* responded quadratically

Table 1637.

Table 1. Effect of ground flaxseed (GFX) on ruminal microbiota.

	Diets (% GFX)					$P < 0.05$	
% of total	0%	5%	10%	15%	SEM	Linear	Quadratic
Archaea	5.70	4.17	4.39	3.20	0.66	<0.01	0.01
Methanobrevibacter sp.	5.49	3.99	4.21	3.04	0.67	<0.01	0.02
Methanomicrobium sp.	0.06	0.05	0.05	0.04	0.01	0.04	0.15
Methanosphaera sp.	0.14	0.12	0.12	0.11	0.01	0.04	0.04
Butyrivibrio fibrisolvens	0.14	0.15	0.13	0.14	0.02	0.82	0.62
Prevotella sp.	11.3	12.7	14.1	17.7	0.87	<0.001	<0.001

Prevotella bryantii	0.01	0.02	0.02	0.03	0.004	<0.001	<0.001
Fibrobacter sp.	2.10	2.11	2.02	1.77	0.14	<0.01	<0.01
Fibrobacter succinogenes	0.21	0.22	0.21	0.27	0.08	0.31	0.37
Ruminococcus sp.	5.86	5.68	5.26	4.64	0.21	<0.001	<0.001
Ruminococcus flavefaciens	0.46	0.45	0.44	0.46	0.03	0.76	0.78
Ruminococcus albus	0.02	0.03	0.03	0.03	0.03	0.43	0.48

with greatest values found when feeding 15% GFX. Overall, feeding incremental amounts of GFX to lactating dairy cows decreased the ruminal proportion of methanogens, but did not affect the 3 major species of ruminal cellulolytic bacteria.

Key Words: dairy cows, ground flaxseed, ruminal microbiota

1638 Data acquisition settings of the Ankom RF system and inocula donors affect in vitro gas production.

D. R. Mertens[*1], N. Schlau[2], and D. M. Taysom[2], [1]*Mertens Innovation & Research LLC, Belleville, WI,* [2]*Dairyland Laboratories, Inc., Arcadia, WI.*

In vitro gas production (IVGP) provides information about the fermentation of feeds. The Ankom RF is a gas-release system that electronically acquires gas pressures. Objectives were to determine the effects of valve-opening pressure (OP) and release time (RT) on IVGP and evaluate the effects of inocula donor on IVGP of selected substrates. Settings for OP were 1, 3, or 8 psi and for RT were 250 or 500 msec. Blended inocula (strained ruminal fluid and ruminal solids blended with media) were composited from 3 steers fed high-NDF (40.3% DM; HF) or high-starch (28.3% DM; HS) diets. Data acquisition terminated early in run 4, and only IVGP for 3, 4.5, 6, 9, 12, 24, and 36 h were evaluated. Duplicate substrates and triplicate blanks were fermented for each OP and RT combination in two runs each with HF or HS inoculum. For each time, the statistical model included order of inoculation, donor (D), substrate (S), D*S, OP, and RT, with module within run as the experimental unit. Blank IVGP increased until 12–18h, then decreased linearly with a leak rate of −0.35 mL/h. Blank subtraction corrected for leakage resulting in plateau-shaped curves and differentiated lag responses for all S. Donor HF generated higher blank IVGP (4.4 mL at 9 h) than HS, which indicated more fermentable matter in HF inoculum. Blank IVGP decreased with increasing order of inoculation. Across S, IVGP differed ($p < .01$) among OP after 3 h (22.9, 0.5, and −23.7 mL/g, for 1, 3, and 8 psi, respectively). For 3 to 24 h, IVGP was higher ($p < .01$) for 500 than 250 msec RT (maximum difference of 38.1 mL/g at 9 h). Numerical derivatives of cumulative curves showed spikes when valves opened. Lower OP and shorter RT resulted in more valve openings, and also obtained lower headspace pressures. Donor HF generated lower IVGP than HS across all S, which was significant ($p < .006$) after 6 h. Up to 18 h, there was a D*S interaction ($p < .036$) with HF generating more IVGP for stover while HS was greater for corn starch. There was little difference in IVGP between HF and HS for solka floc or HMC. Results indicate that blank correction was necessary and IVGP was greater for OP of 1 psi and RT of 500 msec. Data acquisition settings may affect fermentation or create artifacts in measurements. Settings and donors should be

optimized to meet experimental objectives.

Key Words: Ankom RF, gas production, inoculum donor

1639 Effect of duration of in vitro incubation on disappearance of NDF and starch from chopped corn plants versus their resulting corn silages.

L. Nuzback*[1], B. Mahanna[1], R. A. Zinn[2], S. Dennis[1], and F. Owens[1], *[1]DuPont Pioneer, Johnston, IA, [2]University of California-Davis, El Centro.*

The corn silage fermentation process and its duration can alter the extent of in vitro digestion of NDF and starch. The objective of this study was to determine whether extending in vitro incubation time will enlarge or dispel differences between fermented and unfermented corn plants in extent of in vitro digestion. Ten corn silages were prepared from Pioneer non -BMR hybrids grown at a single location and harvested on a single date at an average of 36% DM. Disappearance of NDF and starch from the unfermented chopped corn plants and from the kernel processed corn silages produced from these plants fermented for 4 mo was measured after various in vitro incubation time intervals at a commercial laboratory. Despite differences among samples in NDF and starch content, no differences among these silages for in vitro NDF digestibility or 7 h starch digestion were detected. At the longest incubation times tested, unfermented plants and corn silages had similar digestibility. But at shorter incubation times, extent of digestion of NDF and starch for the corn silages was related curvilinearly ($P < 0.05$) to those for unfermented plants. In vitro disappearance of NDF was 9, 12, 11, 10, 9, and 3% points lower for corn silages than for chopped corn plants at in vitro incubation times of 6, 12, 24, 30, 40, and 240 h. In vitro starch disappearance was 5, 9, 12, 5, 0, and 0% points greater for corn silages than for chopped corn plants at in vitro incubation times of 2, 4, 7, 12, 24, and 72 h. The correlation between unfermented plants and their silages in both NDF and starch disappearance within an incubation time interval proved weak (R2 = 0.00 to 0.36). In vitro disappearance of starch from these corn silages was not correlated with kernel processing score. Based on the typical in vitro fermentation times used commercially, corn silage fermentation for 4 mo increased in vitro digestion of starch but decreased in vitro digestion of NDF. The difference between unfermented corn plants and corn silages at various in vitro fermentation times implies that improvements in ruminal starch digestion from corn silage allowed to ferment for several months should be greatest with shorter ruminal residence times (7 h or less). However, adverse effects on NDF digestion may partially counterbalance the energy benefit from increased ruminal starch digestibility associated with longer fermentation times.

Key Words: corn silage, NDF, starch

1640 Rumen protozoal communities are dynamic after a dietary switch from conserved forage to pasture.

M. L. Bainbridge*, L. K. Saldinger, J. W. Barlow, J. P. Alvez, J. Roman, and J. Kraft, *University of Vermont, Burlington.*

Rumen protozoa shift in response to dietary factors, however, little is known about the stabilization of rumen protozoa populations after a diet change. The objective of this study was to characterize the weekly shift in rumen protozoal communities during the transition from a conserved forage (CF) to pasture. Individual rumen digesta samples were obtained from five lactating Holstein cows on weeks −1, 1, 2, 3, 4, and 5 relative to the diet switch. DNA was extracted from rumen digesta and the V3-V4 region of the 18S rRNA gene was amplified using PCR. Sequence reads were produced with the Illumina Miseq (v.3) platform and bioinformatics were performed using the MOTHUR program (v. 1.36.1). Real-time PCR was used to assess protozoal densities (cells/mL digesta). The PROC MIXED procedure of SAS (v. 9.4) was used to analyze data using a repeated measures ANOVA. On week 5 of pasture, protozoal densities were higher than CF (4.97 vs. 3.48 cells/mL digesta, respectively; $P < 0.01$). The genera *Entodinium* ranged from 2–79% abundance, *Dasytricha* from 3–71%, *Eudiplodinium* from 1–51%, *Isotricha* from 1–35%, and *Ostracodinium* from 1–17%. The genus *Isotricha* was most abundant on week 1 after the diet switch ($P < 0.05$). The abundance of protozoa belonging to the genus *Dasytricha* was higher than the CF diet by week 5 on pasture ($P < 0.05$), while protozoa of the genus *Eudiplodinium* tended to be lower after week 5 when compared to CF. In conclusion, protozoal populations were highly dynamic across weeks and within animals.

Key Words: diversity, Illumina MiSeq, protozoa densities

1641 Effects of *Bacillus subitilis* supplementation on milk production and rumen fermentation of dairy cows.

A. Bach*[1] and N. Nakamura[2], *[1]IRTA, Caldes de Montbui, Spain, [2]Asahi Calpis Wellness Co., Ltd., Tokyo, Japan.*

The objective of this study was to assess the effect on milk performance and rumen fermentation of *Bacillus subtilis* C-3102 (Calsporin®; Asahi Calpis Wellness Co., Ltd., Japan). Three hundred and seventy-five lactating cows (132 primiparous, 243 multiparous; BW = 621 ± 76 kg; DIM = 145 ± 93, yield = 42.1 ± 8,1 kg/d) were randomly allocated to 3 treatments and fed a common TMR containing 15.4% CP, 39.7% NDF and 1.57 Mcal of NEl/kg. Treatments consisted of no supplementation (T0), 1.5 x 10^5 CFU/g (T1), and 3 x 10^5 CFU/g (T2) supplementation with *B. subitilis* C-3102. Calsporin® was supplemented individually during milking using a precision feeding system. At each milking, cows received either 100 g of barley (T0), or 100–150 g of barley containing Calsporin®

Table 1640.

	Diet						SE	*P* value

Un = unclassified; *P*-values compare the CF diet with the average of pasture weeks 4 and 5.

to supplement either 0.3 (T1) or 0.6 g/cow/day (T2) for 105 d. Cows are milked 3 times a day. Milk production was recorded daily. Thirty cows (10 from each treatment) were sampled for rumen contents at 42 and 84 d using an esophageal tube after the morning milking. Rumen pH and VFA concentrations determined. Data were analyzed using a mixed-effects model with week as a repeated measure. Cow was the experimental unit (n = 125). Primiparous cows on T2 produced more ($P <$ 0.01) milk after wk 6 of study (35.6 ± 0.82 kg/d) than primiparous cows on T1 and T0 (34.2 ± 0.82 kg/d), whereas multiparous cows on both T1 and T2 (38.5 ± 0.82 kg/d) produced ($P <$ 0.05) more milk than multiparous cows on T0 (36.1 kg/d) after 3 wk of study. Changes in rumen fermentation profile were minor. Rumen molar proportions of propionate decreased (P < 0.05) at 84 d compared with d 42 in T1 and T2 (from 26.8 to 25.2 ± 0.48%) compared with T0, which remained constant (24.8 ± 0.48%). Molar proportions of rumen butyrate decreased ($P < 0.05$) between 42 and 84 d in T0 (from 11.5 to 9.9 ± 0.43%) compared with in T1 and T2, which remained constant (10.5 ± 0.43%). The supplementation of Calsporin® seems to exert a positive effect on milking persistency of dairy cows, with a positive response already obtained 1.5 x 10^5 CFU of *B. subtilis*/g. About 3 and 6 wk of exposure to treatments are needed for a milk response to become evident in multiparous and primiparous cows, respectively.

Key Words: probiotic, rumen, yield

1642 Effect of *Enterococcus fecalis* SROD5 supplementation on microbial communities and quantities of in vitro rumen fermentation.

L. L. Mamuad, S. S. Lee*, A. A. Biswas, and C. D. Jeong, *Sunchon National University, Suncheon, Korea.*

Enterococcus fecalis is one of the beneficial microorganisms, which produces fumarate reductase that converts fumarate to succinate and reduces methane production in vitro. Hence, this study was conducted to determine the effect of *E. fecalis* SROD5 supplementation on archaeal diversity and microbial population. Fresh culture of *E. fecalis* SROD5 (7.5 × 10^8 cfu/ml) at different inclusion rates (0, 0.1%, 0.5%, and 1.0%) were investigated using in vitro rumen fermentation. Ruminal samples were collected from cannulated Holstein Friesian cow and 40:60 rice straw to concentrate ratio were used as substrate at 1 g dry matter (DM) per 100 ml buffered rumen fluid. Samples from in vitro fermentation of 12 h incubation were used for determination of microbial community and quantity. Pyrosequencing of archaeal 16S rRNA gene showed that the number of operational taxonomic units (OTU) was highest in supplementation of 0.1% *E. fecalis* SROD5 (39). Shannon-Weaver index were comparable among control and treatments while Chao 1 was higher in 0.1% and 0.5% supplementation of *E. fecalis* SROD5 with 52 and 54, respectively. Meanwhile, alignment of archaeal reads showed that almost all retrieved from in vitro rumen fermenta samples fell into the phylum *Euryarchaeota*, which predominantly affiliated with family *Methanobacteriaceae* (97% to 99%) followed by *Methanomicrobiaceae*, and *Methanosarcinaceae*. Abundance of *Methanobrevibacter* was higher in non-supplementation of *E. fecalis* SROD5 with 96.54%. Higher abundance of *Methanomicrobium* was observed in 0.1% *E. fecalis* SROD5 supplementation while higher abundance of *Methanosphaera* and unclassified *Methanobacteriaceae* as well as the presence of *Methanimicrococcus* were observed in 0.5% *E. fecalis* SROD5. Supplementation of 0.1% *E. fecalis* had the highest quantities of total bacteria (2.59 × 10^8 copies/ml), total fungi (1.03 × 10^4 copies/ml), *Fibrobacter succinogenes* (1.62 × 10^5copies/ml), and *Ruminococcus flavefaciens* (1.51 × 10^3 copies/ml) while the highest methanogen quantity was observed in non-supplementation of *E. faecium* with 2.74 × 10^1 copies/ml). Addition of *E. fecalis* SROD5 changed the archaeal communities of in vitro rumen fermenta. Supplementation of 0.1% *E. fecalis* SROD5 increased microbial

population and decreased methanogen quantity.

1643 Effects of dietary neutral detergent fiber and starch ratio on rumen epithelial cell morphological structure and gene expression in dairy cows.

L. Ma[1], M. Zhao[1], J. Xu[2], L. Zhao[1], and D. Bu[*1,3,4], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, China, [2]Kunming Institute of Botany, Chinese Academy of Sciences, Kunming, China, [3]Hunan Co-Innovation Center of Animal Production Safety, CICAPS, Changsha, China, [4]CAAS-ICRAF Joint Laboratory of Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, China.*

Dietary neutral detergent fiber (NDF):starch ratio has been considered a potential indicator to reflect carbohydrate composition in diet formulation and could affect the composition and content of VFA in rumen of dairy cow. Rumen epithelial papilla as small bumps of the rumen mucosal epithelium could broaden the surface of the rumen, which was beneficial for improving the absorption ability of nutrients, especially for VFA. This study was designed to investigate the effect of dietary NDF:starch ratio on rumen epithelial cell morphological structure and gene expression. Eight primiparous dairy cows including 4 rumen cannulated animals were assigned to 4 total mixed rations with NDF:starch ratios of 0.86, 1.18, 1.63, and 2.34 from T1 to T4 in a replicated 4 × 4 Latin square design. The duration of each period was 21 d including a 14 d adaptation period and a 7 d sampling period. Rumen epithelial papilla was collected from rumen cannulated cows. Morphological structure of rumen epithelial papilla was detected and several genes related to the absorption and metabolism of VFA and growth of rumen epithelial papilla cell were analyzed with quantitative real-time PCR, including NHE1, NHE3, NHE4, MCT1, MCT2, MCT4, Na/KATPase, HMGCS, ACSS1, ACSS2, ACSS3, HMGCL, ACAT1, IGFBP3, IGFBP5, and IGFBP6. The results showed that the thickness of stratum spinosum and basale was linearly increased with increasing of dietary NDF:starch ratio (39.58^{a}, 42.84^{a}, 43.24^{a}, and 54.22^{b} mm for T1 to T4, $P = 0.02$), which indicated that surface of the rumen wall could be broadened and the absorption capability of VFA could be improved with the increasing dietary NDF: starch ratio. Expression of HMGCS as the limited enzyme in synthesis of ketone body metabolized by VFA was linearly downregulated ($P = 0.02$), while the expression of MCT2 positively correlated with the absorption capability of VFA was linearly upregulated with the dietary NDF:starch ratio increasing ($P < 0.01$). As dietary NDF:starch ratio increased, expression of IGFBP5 related to the growth of rumen epithelial papilla was downregulated ($P < 0.01$), while IGFBP6 expression was upregulated ($P < 0.01$), which were regulated by the short-chain fatty acids (SCFA) part of VFA. Dietary NDF:starch ratio significantly improved the thickness of stratum spinosum and basale of rumen epithelial papilla and regulated genes expression of VFA absorption and metabolism and growth of rumen epithelial cell, which may be indicative of an activated response of VFA absorption improvement with dietary NDF:starch ratio increasing.

Key Words: dairy cow, NDF: starch ratio, rumen epithelial cell morphological, gene expression

1644 Rumen disappearance of capsaicin and dihydrocapsaicin in lactating dairy cows.

J. Oh[*1], D. M. Bravo[2], E. H. Wall[2], and A. N. Hristov[1], *[1]The Pennsylvania State University, University Park, [2]Pancosma, Geneva, Switzerland.*

The objective of this study was to assess rumen disappearance rate and escape of the two main active compounds of *Capsicum* oleoresin, capsaicin (CAP), and dihydrocapsaicin (DHC), in lactating dairy cows. The study involved 4 early- to late-lactation Holstein cows (24 ± 2.9 kg/d DMI; 38 ± 5.2 kg/d milk yield; 624 ± 28 kg BW) and consisted of 3, 10-d experimental periods. *Capsicum* oleoresin (CO) was administered into the rumen of the cows at 3 pulse-doses: 250, 500, and 1000 mg/cow. All cows received 250 mg CO in period 1500 mg in period 2, and 1000 mg in period 3. Chromium-EDTA was used as a rumen fluid phase passage rate marker. On day one of each experimental period, CO and Cr-EDTA solutions were administered intraruminally in each cow through the rumen cannula at the time of feeding (cows were fed once daily around 8 a.m.). Rumen fluid samples were collected at 0 (background), 0.5, 1, 2, 6, 12, and 24 h post-CO administration and analyzed for Cr, CAP, and DHC. Concentration data were fitted to a single exponential decay model using the NLIN procedure of SAS. The rate of degradation of CAP or DHC was found as: $k_{Cr} \div k_{CAP}$ or $k_{DHC} \times 100$, where k_{Cr} is the slope of decline in Cr concentration in ruminal fluid (on average 0.25 ± 0.06 h^{-1}) and k_{CAP} or k_{DHC} are slopes of decline in CAP and DHC concentrations. Rumen disappearance rates of CAP were 1.34 ± 0.711, 0.91 ± 0.248, and 1.50 ± 0.309 h^{-1} for 250, 500, and 1000 mg CO, respectively. Rumen disappearance rates of DHC were 2.22 ± 1.018, 1.82 ± 0.336, and 1.62 ± 0.372 h^{-1}, respectively. Rumen escape of CAP was estimated at 15.4, 32.6, and 17.6%, respectively, and that of DHC was 31.7, 19.3, and 16.1%, respectively. Average concentration of DHC in fecal samples was 35.6 ± 6.05 ng/g with the 1000 mg dose, whereas capsaicin was not detected in feces. CAP and DHC concentrations were 361 ± 52.6 and 203 ± 27.9 ng/mL in milk, respectively, with the 1000 mg dose, and the compounds were not detected in milk from non-treated cows. In this study, rumen escape of CAP and DHC in lactating dairy cows was

between 15.4 and 32.6%, depending on dose.

Key Words: capsaicin, dihydrocapsaicin, rumen disappearance

1645 WS Effects of capsaicin source on blood capsaicin, glucose and insulin concentrations, rumen fermentation and nitrogen balance of sheep.

J. B. Alford[1], J. G. Castro*[1], E. R. Oosthuysen[1], S. L. Rosasco[2], R. D. Richins[1], E. J. Scholljegerdes[1], D. M. Hallford[2], and C. A. Loest[1], *[1]New Mexico State University, Las Cruces, [2]Animal and Range Science Dep., New Mexico State University, Las Cruces.*

This study evaluated the bioavailability of ruminally-protected capsaicin, and potential effects on rumen microbial fermentation, diet digestibility, and N retention of sheep. Twenty-one wether lambs (36.1 ± 1.0 kg BW) were used in 2 experimental periods (19 d each) based on BW (9 and 12 lambs in period 1 and 2, respectively). From d 1 to 7 of each period, lambs were adapted to indoor individual pens, and then moved to metabolism crates from d 8 to 19. Lambs were fed twice daily alfalfa hay and 1 of 3 supplements containing no capsaicin (CON), unprotected capsaicin (DCAP), or ruminally-protected capsaicin (RPCAP). On d 14 and 19, blood samples were collected at 0, 0.5, 1, 2, 4, 8, and 12 h, and on d 19 rumen fluid samples were collected 4 h after supplement delivery. Feces and urine were collected once daily for 5 d. The experiment was a randomized complete block, and the model included treatment, h, and treatment × h. Capsaicin was not detected in serum of lambs, and no treatment × h interactions ($P \geq 0.06$) occurred for plasma glucose or insulin on d 14 or 19. Total VFA concentrations were lowest for DCAP, intermediate for RPCAP, and greatest for CON ($P = 0.05$). Acetate proportions (mol/100 mol) tended to be lower ($P = 0.06$) for DCAP than CON and RPCAP. Fecal excretions of DM, OM, NDF, and ADF were lower ($P < 0.01$), and DM, OM, NDF, and ADF digestibility (% of intake) were greater ($P < 0.01$) for lambs fed DCAP than CON and RPCAP. Nitrogen intake, fecal and urinary N, N digestibility, and N retention were not affected ($P \geq 0.15$) by treatments. Greater differences in rumen VFA concentrations between DCAP and CON than RPCAP and CON suggest that shifts in microbial fermentation were greater when capsaicin was not ruminally-protected in a prill. Undetectable capsaicin in serum of lambs receiving capsaicin, and minimal effects of RPCAP on N balance indicates the concentration of capsaicin provided may not have entered systemic circulation. This could be due to potential microbial breakdown, inability to be absorbed, or rapid post-absorptive metabolism. Further work is warranted to develop a source of absorbable capsaicin that will withstand degradation in the rumen to allow an increase in blood capsaicin to serve as a potential anti-inflammatory supplement in ruminants.

Key Words: capsaicin, ruminally-protected, sheep

Fig 1646.

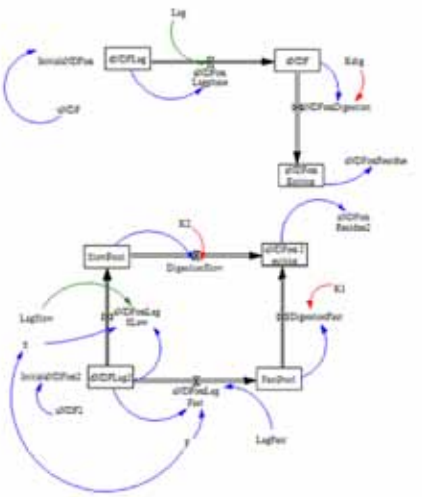

Figure 1. Multi compartment model describing in-vitro aNDFom digestion.

1646 Describing aNDFom in vitro digestion with a multi-compartment model and evaluation of predictions in the CNCPS v7.0 model.

A. M. Zontini* and M. E. Van Amburgh, *Cornell University, Ithaca, NY.*

Models such as the CNCPS rely on having accurate values for digestion rate to aid in predicting metabolizable energy and protein yield from the rumen and subsequent milk yield and total tract digestibility. In vitro aNDFom digestion displays a sigmoidal shape, which is the result of a two-step process: the lag phase, where bacteria attach to substrate and establish digestion and the digestion phase where substrate is being degraded. In previous mechanistic models, the lag phase was discrete, meaning that aNDFom digestion could occur only after the lag phase was over. In other statistical models aNDFom digestion has been described with a multi-compartment system using γ functions. Such models can describe the sigmoidal shape of aNDFom digestion but the estimated rate of digestion were probabilistic and not deterministic. The objective of this study was to develop a mechanistic model that describes the sigmoidal behavior of in vitro aNDFom digestion, using differential equations to provide deterministic values of digestion rates. The proposed are multi-compartments models (Fig. 1), one describing aNDFom in plant by-products, where the digestible aNDFom fraction (dNDF) is unique; and the other describing aNDFom digestion in forages, where dNDF is further fractionated into fast and slow digesting pools. In both feed types a fraction remains un-digested over time (uNDF). In these models, the lag phase is a rate, the life-time of the dNDF fractions is consistent with a γ distribution, and the behavior of the system is sigmoidal. The model was fitted to 36 conserved forages, 32 fresh forages; and 15 plant by-products analyzed in-vitro. The quality of fit was evaluated with overall slope (1.03), intercept (0.01), R^2 (0.98), and an

RMSE (0.02) of the regressions of observed versus predicted. Further, the relevance of the model predictions were assessed by evaluating the RMSE of CNCPS predictions of ME allowable milk and aNDFom TTD, using information from a lactating cattle study where treatment diets were formulated to quantify the effects of aNDFom source and digestibility. Parameters of aNDFom digestion were calculated for each ingredient of the diets, and used as inputs for CNCPSv7.0. The experimental design was a 3 x 3 Latin square with 21 d adjustment and 5 d sampling periods this was used to develop the RMSE calculations. The RMSE of predictions among the three treatments were 0.8 Kg for ME allowable milk and 4% for aNDFom total tract digestibility.

Key Words: aNDFom, modeling, multi compartments model

1647 WS mammalian hormones associated with stress impact microbial fermentation of rumen fluid in vitro. L. L. Rath*, K. L. Samuelson, A. L. Salazar, F. A. Lopez, E. J. Scholljegerdes, and C. A. Loest, *New Mexico State University, Las Cruces.*

Mammalian stress hormones may negatively impact bacteria found in the digestive tract, which could be harmful to animals undergoing stress such as newly received cattle. This study evaluated the effects of epinephrine, norepinephrine, and cortisol on rumen microbial fermentation and gas production in vitro. Treatments included no stress hormone (CON), epinephrine (EPI), norepinephrine (NOR), cortisol (CORT), and a combination of EPI, NOR, and CORT (ALL). Catecholamine treatments were added to fermentation flasks at 1.125 ng/mL, and the cortisol treatment was added at 1.15 ng/mL of rumen fluid. At initiation of the study, rumen fluid was collected from two ruminally-cannulated cows, homogenized with McDougal's artificial saliva, and inoculated with one of 5 treatments for 5 consecutive periods. The rumen microbial fermentation products ammonia (NH_3) and volatile fatty acids (VFA) were sampled at h 0, 2, 4, 6, 8, and 12 during each of the first 4 periods to produce a total of 120 in vitro fermentation samples. The pH was also measured at each collection time. Gas production was measured during the final period at h 0, 0.25, 0.5, 0.75, 1, 1.5, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12 from 24 fermentation flasks in which the 5 treatments were present in 4 replicates allowing for 4 blanks. Neither pH, NH_3, nor total VFA concentration were different ($P \geq 0.40$) among treatments. Molar percentages of acetate and isovalerate in rumen fluid were lower ($P < 0.01$) for EPI and NOR than CON, CORT, and ALL. Conversely, molar percentages of butyrate in rumen fluid were greater ($P = 0.03$) for EPI and NOR than CON, and intermediate for CORT and ALL. A treatment × hour interaction ($P < 0.01$) was observed for gas production from 8 h of incubation to the culmination of this experiment, indicating that microbial fermentation is altered by treatments.

Key Words: catecholamine, cortisol, fermentation

1648 RNA sequencing reveals differential expression of genes associated with an altered morphology of rumen papillae in lactating dairy cows fed diets with various forage sources. B. Wang[1], D. M. Wang[1], M. Liu[1], X. B. Wang[1], L. L. Guan[*2], and J. X. Liu[1], *[1]Institute of Dairy Science, Zhejiang University, Hangzhou, China, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Canada.*

Rumen epithelial wall plays an important role in nutrient absorption and animal health. However, whether forage quality affects rumen epithelial morphology is unclear. The current study was conducted to elucidate the effects of forage quality on rumen epithelial morphology and the potential underlying molecular mechanisms by determining the transcriptome of the rumen epithelium. To achieve these goals, eighteen mid-lactation dairy cows were fed three diets containing different forage sources, including alfalfa hay ($n = 6$, AH), corn stover ($n = 6$, CS), and rice straw ($n = 6$, RS), for 14 wk. The particle size of each diet, ruminal volatile fatty acids, and rumen epithelium thickness were determined, and RNA-sequencing was conducted. The dietary effect on gene expression was investigated by characterizing differential expressed genes through pair-wise comparisons (AH vs. CS, AH vs. RS, CS vs. RS). The concentration of volatile fatty acids in the rumen was greater in AH than in either CS or RS ($P < 0.05$). The thickness of the rumen papillae was greater in RS-fed cows than in cows fed AH or CS ($P < 0.05$), whereas the thickness of the papillary epithelium was reduced in CS-fed cows compared with those fed AH or RS ($P < 0.05$). In total, 37, 47, and 30 differentially expressed genes were identified from pair-wise comparisons between AH vs. CS, AH vs. RS, and RS vs. CS, respectively. Functional analysis revealed these genes involved in ion binding, proliferation and apoptotic processes, and regulation of cellular growth involving extracellular matrix proteins. Our results suggest that forages with different particle sizes and nutrients values affected rumen epithelium morphology by impacting ion binding, cell growth, and cell proliferation/apoptosis. Our findings provide insight into fundamental understanding on the effects of the dietary particle size and nutrient composition on rumen function that are needed for better management of dairy cow feeding.

Key Words: forage particle size, RNA sequencing, rumen epithelial morphology

1649 Effect of ruminal inoculum from bison or cattle on in vitro gas production, feed digestibility, and responses to exogenous enzyme supplementation.

Z. X. He[1,2], G. O. Ribeiro Jr.[1], V. Bremer[3], K. A. Beauchemin[1], T. A. McAllister[1], and W. Z. Yang[*1], *[1]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, Canada, [2]Key Laboratory for Agro-Ecological Processes in Subtropical Region, Hunan Research Center, The Chinese Academy of Sciences, Changsha, China, [3]Elanco Animal Health, Greenfield, IN.*

The objective of this study was to evaluate the effects of increasing the proportion of inoculum from bison vs. cattle with and without feed enzyme (FE) supplementation on in vitro fermentation of barley straw (BS), alfalfa hay (AH), and wheat dried distillers grain with solubles (DG). Two batch culture runs were conducted for each substrate examined. Barley straw and AH were ground through a 1-mm screen and DG was incubated as-is. In run 1, inocula were prepared by combining rumen fluid (vol/vol) of cattle fed a diet containing 70% BS and 30% concentrate (DM basis) and bison rumen fluid (unknown diet) at ratios of 100:0, 67:33, 33:67, and 0:100, respectively. The substrates were incubated for 96 h to determine gas production (GP) kinetics with gas pressure recording at 3, 6, 9, 12, 24, 36, 48, 72, and 96 h. Additionally, DM disappearance (DMD) was determined in run 2. Each run was a completely randomized design without or with FE addition at a rate of 2.0 μL/g substrate DM. The FE was a xylanase–glucanase commercial blend. Asymptotic GP (ml/g DM) of BS (254) and AH (263) was not affected, whereas that of DG responded quadratically (244, 240, 238, and 260; $P < 0.04$) with increasing bison inoculum. Rate of GP (%/h) also responded quadratically for BS (1.6, 1.6, 1.2, and 1.7%/h; $P < 0.01$) and AH (3.0, 3.0, 2.7, and 3.0%/h; $P < 0.03$) with increasing bison inoculum. Lag time of GP linearly ($P < 0.01$) decreased for BS (0.58, 0.93, 0.22, and 0.07 h), AH (0.63, 0.61, 0.29, and 0 h) and DG (0.21, 0.64, 0.11, and 0 h) with increasing bison inoculum. A quadratic ($P < 0.02$) response of DMD (31, 36, 35, and 34%) of BS to increasing bison inoculum was observed, whereas DMD of AH (55, 54, 51, and 51%) and DG (59, 58, 56, and 56%) linearly ($P < 0.01$) decreased. Addition of FE improved ($P < 0.05$) DMD of DG. Compared to cattle inoculum, bison inoculum did not enhance in vitro GP or DMD of the substrates examined. However, the mixture of cattle and bison rumen inocula did appear to synergistically reduce the lag time of GP and improve the DMD of BS. It suggests that the cattle rumen inoculum may lack certain enzymes that were present in the bison inoculum to digest BS, and that these enzymes were not provided by the FE examined.

Key Words: gas production, in vitro digestion, rumen inocula

1650 Ruminal fermentation from Nellore steers supplemented with additives in the rainy season.

E. E. Dalanttonia[*1], J. F. Lage[2], E. San Vito[1], P. D. S. Castagnino[3], L. Maneck Delevatti[4], R. A. Reis[5], and T. T. Berchielli[6], *[1]Universidade Estadual Paulista Júlio de Mesquita Filho-UNESP, Jaboticabal, Brazil, [2]Trouw Nutrition Brazil, Campinas, Brazil, [3]UNESP JABOTICABAL, Jaboticabal, Brazil, [4]UNESP, Jaboticabal, Brazil, [5]Sao Paulo State University, Jaboticabal, Brazil, [6]São Paulo State University-UNESP, Jaboticabal, Brazil.*

This trial aimed to evaluate the ruminal parameters (pH, ammonia-N and the VFA production) from animals fed supplements with monensin (MON), virginiamycin (VM) or both associated, in the rainy season. Twelve steers cannulated in the rumen (518.42 ± 55.40 kg) were housed in 12 paddocks (one animal on each paddock) of Brachiaria cv. 'Xaraés' and supplemented daily in 0.3% of BW. The diets were: supplement without additives (SUP), with MON (SUPM- 80 mg/kg), with VM (SUPV- 150 mg/kg) and supplement with MON and VM (SUPMV- 80 and 150 mg/kg, respectively). There were four experimental periods of 28 d (27 d for adaptation and 1 d for sampling). Animals were housed continuously in the paddocks with animals used in a trial for performance evaluating. Ruminal pH, ammonia-N, and VFA were measured on samples taken over a 12 h on Day 28 of each experimental period. Ruminal content was obtained at 0, 2, 4, 6, 8, 10, and 12 h after the period of feeding (1000 am). Data were analyzed as a completely randomly design with three replicates by treatment on each period, using the MIXED procedure of SAS. The pH, ammonia-N and VFA were analyzed as a repeated measure. The means of least squares were generated and compared ($P < 0.05$) by Tukey test. The ruminal pH from animals supplemented with additives were greater than animals supplemented without additives ($P < 0.01$), already for the concentrations of ammonia was not significant effect ($P = 0.09$). The acetate ($P < 0.01$) and propionate concentrations ($P < 0.01$) were lower in animals supplement with additives than animals supplemented without additives. However, the A:P ratio did not change ($P = 0.13$) with the inclusions of additives in supplements. The inclusion of MON, VM or both associated in supplements to fed steers on pasture in the rainy season increases the ruminal pH, decreases the acetate and propionate concentrations without affect the A:P ratio.

Key Words: monensin, pasture, propionate, ruminal pH, virginiamycin

1651 The micro gas test: A small scale in vitro system for high throughput analysis. K. Elberg[1], P. Steuer[*2], U. Habermann[2], J. Lenz[2], M. Nelles[1,3], and K. H. Südekum[4], *[1]Department of Waste Management and Material Flow, University of Rostock, Rostock, Germany, [2]Senzyme GmbH, Troisdorf, Germany, [3]German Biomass Research Center GmbH, Leibzig, Germany, [4]Institute of Animal Science, University of Bonn, Bonn, Germany.*

The evaluation of ruminal degradability of feeds and feed additives requires the knowledge of characteristic (kinetic) parameters. These parameters are mainly obtained using in vitro gas production methods. These include measurements at constant pressure (e.g., Hoheneheim gas test (HGT)), measurements at constant volume with accumulating pressure and measurements at constant volume with regular venting. To facilitate automated high throughput measurements, a small-scale system, based on pressure measurement with interval venting was developed and validated. The micro gas test [MGT] represents a cheap and versatile in vitro batch method which reduces the required inoculum volume as well as the personnel effort and space requirements significantly. The MGT is conducted in 20 mL gas chromatography vials that serve as reactors for gas production. Samples (e.g., feedstuffs) and reagents (e.g., feed additives) are accurately weighed into the vials and subsequently closed with a gas-tight sealing. The regulation of CO_2 atmospheric condition is realized through previous gas application. The ruminal fluid solution, which serves as inoculum, is prepared according to the HGT standard procedure. Incubation is performed in a heating chamber at 39°C and starts with dispensing 5 mL inoculum through a cannula into the sealed vial. Simultaneously the pressure is released through a second cannula to atmospheric pressure. For 24 and 48 h, respectively, relative pressure increase in the headspace above the sample is recorded at predefined intervals and subsequently vented. Measurements can be performed manually with manometers or automatically with adjusted autosampling systems. For the validation of the MGT a total of 14 feedstuffs, including a hay and a concentrate standard, were simultaneously incubated in the HGT and the MGT system. The same substrate-inoculum-ratio was applied for further comparison of kinetic parameters. The dried and ground (< 1 mm) feedstuffs covered a wide range of chemical compositions and digestibilities. The HGT method was prepared according to standard procedure. Compared to HGT the MGT resulted in lower ($P < 0.05$) maximum gas productions for all feedstuffs except lignocellulose. The differences were congruent to former findings on system comparisons between HGT and methods with constant volume and pressure release. However, a strong relationship between the HGT and MGT 24 h gas production could be observed. The regression analysis of mean values of both methods resulted in the equation: y = 0.87x + 1.62 with an R^2 of 0.99.

Key Words: automation, Hohenheim gas test, pressure measurement

1652 Rumen protozoal community structures are not altered in lactating dairy cows offered alternative forage crops during short-term grazing experiments. L. M. Cersosimo[*1], R. Tacoma[1], S. Greenwood[1], K. Juntwait[2], A. F. Brito[2], and J. Kraft[1], *[1]University of Vermont, Burlington, [2]University of New Hampshire, Durham.*

The objective of this study was to compare the rumen protozoal community structures and VFA in cows grazing pasture strip-tilled with alternative forage crops (AFC) or traditional grass-legume pasture mix. The study consisted of two, 21-d experiments, spring (SPR) and summer (SUM). Sixteen lactating Jersey cows (SPR: 85 ± 46 DIM; SUM: 143 ± 58 DIM) were split into two groups with eight cows assigned to the AFC (treatment, TRT) and eight cows assigned to traditional mixed grasses-legumes (control, CON). Pasture comprised 40% of the diet (DM basis), while a TMR comprised 60%. SPR AFC (2.4% of total DM) included barley, hairy vetch, rye, triticale, and wheat, and SUM AFC (10.0% of total DM) included buckwheat, oats, and chickling vetch. Milk samples were collected for four consecutive milkings (d 19–21). Individual whole rumen digesta samples (500 mL) were collected on d 20 and 21 of each experiment. Ruminal VFA samples were analyzed by GLC. Microbial DNA was extracted and the V3-V4 regions of the protozoal 18S rRNA gene were amplified via PCR. The program MOTHUR was used to perform bioinformatics analyses. A student's *t* test (JMP Pro 12) compared the LSM between groups and the PROC CORR model in SAS (v.9.4) performed Pearson correlations between rumen protozoal genera, animal performance, and VFA. Yields of milk, milk fat, and milk protein (kg/d) in SPR were: CON, 22.5; 1.08; 0.80 and TRT, 23.4; 1.15; 0.85 and in SUM: CON, 17.3; 0.74; 0.59 and TRT, 18.9; 0.92; 0.70, respectively. Total VFA (m*M*), and molar proportions of acetate (70.8%), propionate (16.0%), and butyrate (1.93%) did not differ in either experiment. The SUM TRT group had a lower ($P < 0.01$) isobutyrate proportion (0.80%) than the SUM CON group (0.98%). Abundance of protozoal taxa did not differ between groups in either experiment. The protozoal genera *Eudiplodinium* (CON: 43.0%; TRT: 49.3%) and *Entodinium* (CON: 48.1%; TRT: 37.1%) were most abundant in SPR and SUM, respectively. The protozoal genus *Diplodinium* (SPR: 6.48%; SUM: 3.28%) was positively correlated ($P < 0.001$) with milk production ($r = 0.69$), milk fat ($r = 0.64$), protein yields ($r = 0.61$), and ruminal propionate ($r = 0.38$; $P = 0.04$). The protozoal genus *Entodinium* was negatively correlated with milk yield ($r = -0.48$; $P < 0.01$). In conclusion, the rumen protozoal community structures and predominant VFA were not altered in AFC-fed cows, yet the genus *Diplodinium* was positively

correlated to animal performance and VFA.

Key Words: ciliates, *Diplodinium,* organic

1653 Metabolomics analysis reveals effect of corn silage levels on ruminal metabolic profiles in Holstein heifers.

J. Zhang, H. Shi, Z. Cao, S. Li, and Y. Wang*, *State Key Laboratory of Animal Nutrition, Beijing Engineering Technology Research Center of Raw Milk Quality and Safety Control, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

Controlling DMI could be one of the strategies to reduce feed cost and to increase efficiency in dairy heifer growth, whereas the metabolic mechanisms involved in control feeding have not been well examined. The objective of this study was to determine the effect of differing forage-to-concentrate ratios on the ruminal metabolite profiles in heifers under restricted feeding. Twenty-four Holstein heifers (8–10 mo and 253 ± 29 kg of BW) with similar body condition were randomly assigned into four groups and fed diets containing 20% (F20), 40% (F40), 60% (F60), and 80% (F80) of corn silage. All diets were isonitrogenous and isocaloric and provided equal amount of nutrients, and allowed for 800 g/d of ADG. The amount of feed offered was adjusted weekly based on BW. Total tract apparent digestibility of nutrients was determined with acid-insoluble ash as an internal digestibility marker with the TMR and fecal samples. Rumen fluid was sampled from each cow through a stomach tube 4 h after morning feeding at d 30 and analyzed using gas chromatography-time-of-flight/mass spectrometry. The digestibilities of DM (80.9% for F20, 79.4% for F40, 77.2% for F60, and 73.1% for F80, $P < 0.001$) and OM (84.3%, 82.3%, 80.1%, and 76.1%, respectively, $P < 0.001$) decreased linearly with increased corn silage. In total, 247 metabolites were identified from all four groups. The principal component analysis of the relative concentration of mutual metabolites revealed four separated metabolite profile clusters of four groups. The clusters derived from the F40, F60, and F80 partly overlapped with each other, whereas the cluster from the F20 was separated from the other three groups. When the mutual metabolites were used for pathway analysis, the impact values of the pathway were 0.32, 0.23 and 0.21 for pyruvate metabolism, citrate cycle and lysine degradation, respectively. These three pathways may play important roles in improvement of nutrition degradation and utilization. These indicated that lower forage level could promote rumen fermentation and provide more available nutrition for heifers.

Key Words: corn silage levels, heifers, metabolomics

1654 Response of rumen microbiota to diets containing different corn silage levels in Holstein heifers.

H. T. Shi[1], Z. J. Cao[1], S. K. Ji[1], H. T. Zhang[1], S. L. Li[1], and Y. J. Wang*[2], *[1]State Key Laboratory of Animal Nutrition/Beijing Engineering Technology Research Center of Raw Milk Quality and Safety Control, College of Animal Science and Technology, China Agricultural University, Beijing, China, [2]State Key Laboratory of Animal Nutrition, Beijing Engineering Technology Research Center of Raw Milk Quality and Safety Control, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

Ruminants have evolved through a close symbiotic relationship with a vast ensemble of ruminal microbiota, which give important metabolic capabilities on the host. The objective of the present study was to evaluate effects of dietary corn silage levels on the changes in the microbiota of the rumen in Holstein heifers. Twenty-four half-sib Holstein heifers (8 to 10 mo of age) were blocked by BW and age in a randomized complete block design in equal numbers and assigned randomly to one of the four diets containing corn silage levels at 20, 40, 60, or 80% of DM. All diets were provided as TMR and calculated to meet the nutrition requirement of 800 g/d of ADG. The rumen contents were collected by the oral stomach tube method. Total genomic DNA of ruminal microorganism was extracted from the whole ruminal contents containing solid and liquid fractions. The V3-V4 region of the bacteria 16S rRNA gene (primers 336F and 806R), ITS1 region of the internal transcribed spacer region of fungi (primers ITS1-F and ITS2), and the partial 18S rRNA gene of protozoa (primers P-SSU-316F and GIC758R) were amplified by PCR. Paired-end sequencing was performed to sequence all libraries on an Illumina Miseq platform according to the standard protocols. For bacteria, a total of 1,544,372 valid reads and 202,189 OTUs were obtained by pyrosequencing. At the OTU level, a significant difference was found in the bacterial communities among all the treatment groups (AMOVA, $P < 0.05$), except that between the 40% and 60% forage groups (AMOVA, $P = 0.23$). The total number of valid reads and OTUs obtained for protozoa were 1,302,936 and 15,279. At the OTU level, a significant difference was found in the protozoal communities between the 20% and 60% forage groups (AMOVA, $P < 0.05$), between the 20% and 80% forage groups (AMOVA, $P < 0.05$), and between the 40% and 80% forage groups (AMOVA, $P < 0.05$). For anaerobic fungi, a total of 1,231,562 valid reads and 33,427 OTUs were obtained. At the OTU level, no significant difference was found in the fungal communities among all the treatment groups. This study demonstrated that the bacterial and protozoa communities in the rumen of Holstein heifers were altered at the OTU level by the dietary forage levels.

Key Words: forage level, heifer, ruminal microbe

1655 Effect of acetate addition and headspace gas composition on in vitro production of volatile fatty acids and gases. L. M. Judd* and R. A. Kohn, *The University of Maryland, College Park.*

The development of in vitro methods to accurately estimate gas production and volatile fatty acid (VFA) profile in rumen fermentation would enable isolation of fermentation effects from animal interactions. This experiment compared 4 headspace gas combinations with or without addition of 50 mM sodium acetate. Gas headspace treatments were: 1) CO_2 (100%), 2) CO_2–CH_4 (50/50), 3) CO_2–H_2 (95/5), and 4) CO_2–CH_4–H_2 (47.5/47.5/5). Each treatment was replicated in 4 tubes with repeated measures of VFA and gas volume taken at 0, 4, 16, 24, and 48 h. Timothy hay (0.1 g) was added to 20-mL tubes, and 0.5 mL sodium acetate solution or buffered medium were added to each tube. Tubes were equilibrated with each gas mixture before adding 9.5 mL rumen fluid. Tubes were incubated at 39°C while shaking with 20-mL syringes attached to collect and measure produced gases. Butyrate production at 4 h was affected ($P < 0.05$) by gas composition, and was: 2.96, 3.09, 2.33, and 1.44 (mM; SE ± 0.437) for treatments 1–4. Propionate production at 48 h was affected ($P < 0.05$) by gas composition, and was: 8.71, 8.97, 10.60, and 7.12 (mM; SE ± 0.789) for treatments 1–4. Gas production at 4 h was 1.08, 2.70, 0.98, and 1.43 (ml, SE ± 0.327) for treatments 1–4. Lower starting concentration of CO_2 in headspace gas may have caused CO_2 efflux from the buffer. There was a trend ($P < 0.1$) for an effect of the gas mix at 24 h on the acetate: butyrate (A:B) ratio of produced VFA. A:B ratios of produced gases were: 2.95, 2.77, 2.87, and 2.18 (mM; SE ± 0.208) for treatments 1–4. In contrast to expectation, there was a trend ($P < 0.08$) for greater acetate production with acetate addition (10.71 mM) than without (7.11 mM, SE ± 1.413). Initial gas composition of in vitro procedures can affect gas production and VFA profiles with higher percentage of CH_4 and H_2in headspace (more reduced conditions) favoring propionate and butyrate over acetate and gas production.

Key words: fermentation, gas profile, in vitro, volatile fatty acids

1656 Predicting the time course of ruminal pH from continuous reticular pH measurements. D. J. Seymour*[1], K. M. Wood[2,3], J. P. Cant[1], and G. B. Penner[2], *[1]Department of Animal Biosciences, University of Guelph, Guelph, Canada, [2]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Canada, [3]University of Saskatchewan, Saskatoon, Canada.*

While the ability to continuously measure ruminal pH has been developed, its use is limited by its on-farm practicality. Being able to predict ruminal pH with an orally bolus-dosed reticular pH probe would add increased functionality to existing technology and aid in the diagnosis of SARA. The objective of this study was to develop a model to predict the time course of ruminal pH from continuous reticular pH measurements. pH was recorded every 5 min for 15 d in both the reticulum and rumen of 4 Hereford crossbred heifers (291 ± 8kg BW) as the proportion of concentration in the diet increased every 3 d from 50 to 60, 70, 80, and 88%. Visual inspection of pH time series data revealed that fluctuations in ruminal pH were smaller and lagged behind those of reticular pH. Fitting a polynomial distributed lag model to predict ruminal pH from reticular pH produced residuals that were serially correlated. Because residuals are not available for prediction of ruminal pH with only a reticular pH probe, a novel approach to autocorrelation correction was sought. Based on the hypothesis that over- and underprediction of ruminal pH is related to similar errors in reticular pH, a penalized cubic spline function was fit to time series of reticular pH to generate a smoothed predicted reticular pH curve with residuals. Ruminal pH was then estimated from predictions and residuals of the reticular spline function using the MIXED procedure of SAS. As an alternative, ruminal pH was predicted directly from reticular pH using an unobserved components model (UCM). The predictive ability of both methods was evaluated using 10-fold cross validation. The unobserved components model was able to fit the data better compared to the alternative model (RMSE = 0.26414 vs. 0.47120) though with a higher AICc score (−10356 vs. −21021); this can be resolved by log-transforming the data before analysis. The UCM also had a smaller average error in ruminal pH prediction compared to the alternative model (0.22 pH vs. 0.35 pH) with fewer model parameters (5 vs. 11). The low error is sufficient to predict ruminal pH from continuous reticular pH measurements, allowing for a more cost-effective diagnosis of SARA in near real-time using existing reticular pH probes.

Key Words: SARA, ruminal pH, unobserved components model

1657 Changes in milk production efficiency and ruminal bacterial community composition following near-total exchange of ruminal contents between high- and low-efficiency Holstein cows. P. J. Weimer*[1], M. S. Cox[2], T. Vieira de Paula[3], M. Lin[4], and G. Suen[2], *[1]USDA-ARS, Madison, WI, [2]University of Wisconsin-Madison, Madison, [3]Federal Univ. of Mato Grosso, Cuiabá, Brazil, [4]Yangzhou University, Yangzhou, China.*

The objectives of this study were to determine if milk production efficiency (MPE) could be altered by near-total exchange of ruminal contents between high- and low-MPE cows and to characterize ruminal bacterial community composition (BCC) before exchange and over time post-exchange. Three pairs of ruminally cannulated, third-lactation cows were selected whose MPE (energy corrected milk per unit dry matter

intake [ECM/DMI]) at similar levels of ECM differed over their first two lactations when fed the same total mixed ration. At 79–279 DIM, ~95% of ruminal contents were manually exchanged between cows within each pair. Ruminal pH, and concentrations and proportions of VFA, along with BCC (as determined by 16S rRNA gene sequencing on an Illumina MiSeq) were assessed immediately before and after the exchange, and just before feeding on days −8, −7, −5, −4, −1, 1, 2, 3, 7, 10, 14, 21, 28, 35, 42, and 56, relative to the day of exchange. Where ruminal pH or mol fraction of individual VFA differed ($p < 0.01$) between cows before exchange, they returned to the recipient cow's profile within 1 d. For all 3 low-MPE (LE) cows, MPE increased over 7 d post-exchange but declined thereafter. Two of the 3 high-MPE (HE) cows displayed sharp drops in MPE following introduction of the ruminal contents from the corresponding LE cow, but one surprisingly displayed a transient increase in MPE. For all 6 cows, both liquid- and solids-associated BCC were dissimilar between individuals within a pair before contents exchange. Immediately following exchange, BCC in all three pairs for both phases were more similar to that of the received inoculum than to pre-exchange BCC for that individual. For 5 of 6 cows, the solids-associated community returned within 5–7 d to higher similarity to the pre-exchange community of that host than to the donor community. Individual variability before the exchange was greater in liquids than in solids, as was the variability in the response of their bacterial communities to the exchange. One pair showed rapid return to pre-exchange BCC within 2 d, while the other two pairs took 7–10 d to become more similar to the pre-exchange host than the donor, and continued to change until reaching similarity to the pre-exchange community by 5–7 wk post-exchange. The data suggest a role for the ruminal bacterial community as a variable in MPE.

Key Words: milk production efficiency, ruminal contents exchange, ruminal microbiome

1658 Synergism of cattle and bison inoculum on ruminal fermentation and bacterial communities in an artificial rumen (Rusitec) fed barley straw.

D. B. Oss[1], G. O. Ribeiro Jr.[*2], M. I. Marcondes[1], W. Yang[3], K. A. Beauchemin[2], R. J. Forster[2], V. Bremer[4], and T. A. McAllister[3], *[1]Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Brazil, [2]Lethbridge Research and Development Centre, Agriculture and Agri-Food Canada, Lethbridge, Canada, [3]Lethbridge Research and Development Centre, AAFC, Lethbridge, Canada, [4]Elanco Animal Health, Greenfield, IN.*

This study evaluated the effect of increasing the proportion of bison relative to cattle inoculum on fermentation and microbial populations within an artificial rumen (Rusitec) fed barley straw. The experiment was a completely randomized design with four treatments (0, 33, 67, and 100% of bison inoculum replacing cattle inoculum) replicated in two Rusitec apparatuses with 8 fermenters each ($n = 4$/treatment). The experiment lasted 15 d with 8 d of adaptation and 7 d of sampling. Fermenters were fed a diet of 70% barley straw and 30% concentrate (DM basis). True digestibility of DM (DMD) was determined after 48 h of incubation from d 13 to 15, and daily NH_3 and VFA production were measured on d 9 to 12. Protozoa counts were determined at d 9, 11, 13, and 15 and particle-associated bacteria (PAB) from d 13 to 15. Selected bacterial populations in the PAB were measured using real-time polymerase chain reaction (qPCR). Data were analyzed using the MIXED procedure of SAS. Individual fermenter was considered the experimental unit and day of sampling as a repeated measure. Increasing the proportion of bison inoculum had a quadratic effect ($P < 0.05$) on straw, concentrate and total DMD (50.3, 52.0, 52.8, and 50.3% DMD, respectively), and on straw and total NDF disappearance (NDFD). Increasing bison inoculum linearly increased concentrate NDFD, total and concentrate N digestibility, as well as total daily VFA and acetate production. A quadratic response ($P < 0.05$) was observed for daily ammonia-N, propionate, and butyrate production. Increasing the proportion of bison inoculum linearly increased ($P < 0.05$) total protozoa numbers and had a quadratic effect ($P < 0.05$) on *Fibrobacter succinogenes*, linearly increased ($P < 0.10$) *Ruminococcus flavefaciens* and decreased ($P < 0.05$) *Ruminococcus albus* 16S rRNA copy numbers. Overall, bison inoculum more readily degraded feed protein than cattle inoculum, with a mixture of inoculums synergistically increasing the DMD and NDFD of barley straw. Direct inoculation of rumen contents across ruminant species may be a means of increasing ruminal fiber digestion.

Key Words: bison, rumen inoculum, Rusitec

1659 Effect of peNDF on milk production and composition in goats fed with NNFS replacing alfalfa hay.

D. Esparza*, R. Rodriguez, F. G. Veliz, O. Angel, T. Arbez, and P. Robles-Trillo, *Universidad Autonoma Agraria Antonio Narro, Torreon, Mexico.*

The aim of this work was to evaluate the effect of physically effective neutral detergent fiber (peNDF) in diets with non-forage fiber sources (NFFS) replacing alfalfa hay on milk production and milk composition in dairy goats. The experiment was designed as 4 x 4 Latin square with 8 Alpine goats at final stage lactation. Goats were offered 1 of 4 diets with different peNDF, 2 diets with alfalfa hay (peNDF = 17.3 and 24.1%), and 2 diets with NFFS replacing alfalfa hay (peNDF = 22.3 and 26.8%). The peNDF contents were determined from the sum of the proportion of dietary DM retained either on the 2 or on the 3 sieves of the Penn State Particle Separator multiplied by the neutral detergent fiber concentration of the diet. Each period consisted of 11-d of adaptation stage and 3-d of experimental measurements. Subsequently, diets were exchanged during the other 3 periods. During the experimental days, milk production was recorded and milk fat,

Table 1659.

Table. Milk production and composition affected by peNDF of diets with NFFS replacing alfalfa hay

	peNDF					
peNDF	17.3%	24.1%	22.3%*	26.8%*	SE	P
Milk production (l/d)	1.26[b]	1.39[a]	1.21[b]	1.25[b]	0.16	0.043
Fat (%)	3.10[b]	3.22[b]	4.05[a]	4.41[a]	0.57	0.001
SNF (%)	8.63[a]	8.48[a]	8.53[a]	8.49[a]	0.17	0.397

*Diets with NFFS replacing alfalfa hay

nonfat solids, and protein were determined using an infrared analyzer. Data were analyzed using GLM procedure of SAS. According to our results, milk production was higher in the diet that contained more alfalfa hay ($P = 0.043$) and milk fat was higher in both rations with NFFS ($P = 0.001$). There was no effect on milk nonfat solids ($P = 0.39$) and protein ($P = 0.353$). In conclusion, the substitution of NDF from alfalfa with NDF from NFFS modified the peNDF in rations without reduced milk production and milk fat in goats.

Key Words: dairy goats, milk production, peNDF

1660 Effects of conventional dietary adaptation over periods of 6, 9, 14, and 21 d on rumen morphometrics of Nellore cattle. D. D. Estevam[1], I. C. Pereira[1], A. L. Rigueiro[2], F. T. Pereira[2], C. L. Martins[1], M. D. Arrigoni[1], and D. D. Millen[*2], *[1]São Paulo State University (UNESP), Botucatu, Brazil, [2]São Paulo State University (UNESP), Dracena, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to determine the effects of adaptation periods of 6, 9, 14, and 21 d on rumen morphometrics, and cell death and proliferation of rumen epithelium of feedlot Nellore cattle. The experiment was designed as a completely randomized block, replicated 6 times, in which 96 20-mo-old yearling Nellore bulls (391.1 ± 30.9 kg) were fed in 24 pens (4 animals/pen) according to the different adaptation periods adopted: 6, 9, 14, and 21 d. Each of the adaptation diets containing 70.0%, 75.0%, and 80.5% concentrate were fed for 2-d, 3-d and 7-d to cattle adapted for 6-d, 9-d and 21-d, respectively. The adaptation diets containing 70.0%, 75.0%, and 80.5% concentrate were fed for 4-d, 5-d and 5-d, respectively, to cattle adapted for 14-d. The finishing diet contained: 71.5% cracked corn grain, 14.0% sugarcane bagasse, 10.5% peanut meal, 2.5% supplement, 1.0% urea, and 0.5% limestone (DM basis). After adaptation one animal per pen was slaughtered ($n = 24$) for rumen epithelium evaluations. The remaining 72 animals were harvested after 88-d on feeding. At harvest, a 1-cm^2 fragment of each rumen was collected from cranial sac. The number of papillae per cm^2 of rumen wall (NOP) was determined, as well as the mean papillae area (MPA). The rumen wall absorptive surface area in cm^2 (ASA) was calculated as follows: 1 + (NOP*MPA)–(NOP*0.002). The papillae area expressed as % of ASA was calculated as follows: (NOP*MPA/ASA)*100. The cell proliferation index (CPI) and cell death index (CDI), both expressed as % of cells proliferating or dying in the rumen epithelium, were determined by PCNA and TUNEL immunohistochemistry techniques, respectively. Orthogonal contrasts were used to evaluate linear, quadratic, and cubic relationship between adaptation periods and the dependent variable. As the adaptation period lasted longer, ASA in cm^2 was affected ($P = 0.03$) cubically (6-d = 37.7; 9-d = 32.5; 14-d = 40.9; 21-d = 39.6). An interaction was observed between adaptation periods and harvesting dates for papillae area ($P = 0.04$), CPI ($P = 0.003$), and CDI ($P = 0.02$), where cattle adapted in 14-d showed larger papillae area (6-d = 97.0%; 9-d = 96.0%; 14-d = 97.5%; 21-d = 96.8%), and smaller CPI (6-d = 58.0%; 9-d = 58.5%; 14-d = 44.8%; 21-d = 53.3%) and CDI (6-d = 62.8%; 9-d = 60.0%; 14-d = 50.4%; 21-d = 57.1%) at the end of adaptation period, but no differences were detected ($P > 0.10$) at the end of finishing period. Yearling Nellore bulls should be adapted in 14 d, because it promoted better rumen epithelium development by the end of adaptation period.

Key Words: adaptation, Nellore, rumen

1661 Pantothenic acid does not affect the concentration of biotin in plasma of Holstein bull calves. G. Ferreira*, C. L. Teets, A. N. Bladen, and A. Geiger, *Virginia Polytechnic Institute and State University, Blacksburg.*

Pantothenic acid interferes with biotin absorption in non-ruminant species. The objective of this study was to determine whether pantothenic acid affects the concentration of biotin in the blood of young calves. Weaned bull calves ($n = 16$) were fed ad libitum a pelleted starter including no B-vitamins and hay for 2 wk before the beginning and until the end of the experiment. Water was available ad libitum at all times. Two weeks after weaning, calves were blocked by age and randomly assigned to 4 treatments according to a randomized complete block design. Treatments consisted of administering, for 14 d, a daily gelatin capsule containing no B-vitamins (CON), 10 mg of biotin (Rovimix Biotin; BIO), 240 mg of pantothenic acid (Rovimix Calpan; PAN), and 10 mg biotin + 240 mg pantothenic acid (BIO+PAN). Expeller soybean meal was used as a carrier of the vitamins in the capsules.

Blood samples were collected by venipuncture of the jugular vein at Days 0 and 14. Concentrations of avidin-binding substances (ABS) in plasma (1:20 dilution) were determined by a single-step competitive enzyme-binding assay (Ridascreen Biotin kit; R-Biopharm GmbH, Darmstadt, Germany). Statistical analysis was performed using the MIXED procedure of SAS as for a randomized complete block design with repeated measures. The statistical model included the effects of treatment (fixed, df = 3), block (random, df = 3), treatment by block interaction (random, df = 9), time (fixed, df = 1), treatment by time interaction (fixed, df = 3), and the random residual error. The concentrations of ABS in plasma were similar for all treatments ($P > 0.24$) and did not change after dosing vitamins over time (3.47 and 3.07 ng/mL for Days 0 and 14, respectively; SEM = 0.7 ng/mL; $P > 0.63$). Plasma concentrations of ABS were substantially higher than those previously reported for lactating dairy cows (0.7–2.1 ng/mL). Based on these data, and contrary to our expectations, pantothenic acid did not affect the absorption of biotin in young calves.

Key Words: biotin, calves, pantothenic acid

1662 Short-term feeding of a tocopherol mix (α-, β-, γ-, and δ) alters the daily pattern of tocopherol isoforms present in milk and blood in lactating dairy cows.

Y. Qu*[1], T. H. Elsasser[2], J. R. Newbold[3], E. E. Connor[4], M. Garcia[1], C. M. Scholte[1], and K. M. Moyes[1], *[1]Department of Animal and Avian Sciences, University of Maryland, College Park, [2]USDA-ARS, Animal Biosciences and Biotechnology Laboratory, Beltsville, MD, [3]Cargill Innovation Center, Velddriel, Netherlands, [4]USDA-ARS, Animal Genomics and Improvement Laboratory, Beltsville, MD.*

Fed over several weeks, diets supplemented with α-tocopherol will increase α-tocopherol concentrations in blood and milk. With new attention being paid to other non-α isoforms of vitamin E, how short-term supplementation of other tocopherol isoforms affects subsequent milk and blood concentrations is poorly understood. The objective of this study was to determine the daily pattern of change in the concentrations of 4 isoforms (α-, β-, γ-, and δ) of tocopherol in blood and milk of cattle supplemented with a tocopherol mixture. Four healthy, multiparous Holstein cows (DIM: 179 ± 17 d) were fed a vegetable-derived oil (Tmix) enriched with γ- and δ-isoforms of Vitamin E (9% α-, 1% β-, 62% γ-, and 24% δ-tocopherol) for 7 consecutive days (~620 g Tmix/cow·d^{-1}). Composite milk (~25mL) and whole blood (~15mL) samples were collected daily before the morning feeding. Tocopherol isoform concentrations were determined by high pressure liquid chromatography. Data were analyzed in a complete randomized design with repeated measures. Significance was declared at $P \leq 0.05$. Gamma and α-tocopherols in blood increased by d 1 and d 2, respectively, after feeding with peak concentrations achieved by d 5 (3.6 ± 0.2 μg/mL and 14.1 ± 0.5μg/mL, respectively) when compared to d 0 (0.59 ± 0.2μg/mL and 10.0 ± 0.5μg/mL, respectively). In milk, γ- and α-tocopherol concentrations were elevated by d 2 (0.26 ± 0.04 mcg/g) and d 3 (0.72 ± 0.05mcg/g), respectively, compared to d 0 (0.06 ± 0.04mcg/g and 0.52 ± 0.05mcg/g, respectively). The data illustrate that ~5 d of Tmix feeding at the level used may be sufficient to reach a higher stabilized range of concentrations of the two measurable isoforms in milk and blood in the lactating Holstein. The data establish that this experimental design is adequate toward further refinement of experiments that will be valuable toward characterizing the kinetics and biological value of α- and γ-tocopherols. Additional sampling at the gut level may be informative in determining the fate of other isoforms.

Key Words: concentration, cow, tocopherol

1663 Effect of rumen protected vitamin B complex on metabolic parameters, milk production, and d 15 conceptus and endometrium outcomes.

M. Kaur*[1], I. Hartling[1], T. A. Burnett[1], L. Polsky[1], R. L. A. Cerri[1], and H. Leclerc[2], *[1]Applied Animal Biology, Faculty of Land and Food Systems, University of British Columbia, Vancouver, Canada, [2]Jefo Nutrition, St. Hyacinthe, Canada.*

The aim of this project was to determine the effects of a rumen-protected vitamin B complex supplementation (VIT B) compared with a control diet containing no supplement (CON) on: milk production and components, concentrations of BHBA, haptoglobin and progesterone in plasma, ovarian dynamics, and Day 15 conceptus and endometrial outcomes. Fifty-one multiparous Holstein cows from the herd at the UBC Dairy Education and Research Centre were enrolled into the study 3 wk before parturition and were randomly assigned to one of the two treatments. Blood samples (2/week), weekly milk samples, and daily feed intake were collected. Cows were enrolled onto a double-ovsynch protocol at 33 ± 3 days post-partum and inseminated by timed artificial insemination (AI). Ovarian structures were monitored and measured using *per rectum* ultra-sonography. The uterus was flushed on Day 15 post-AI for conceptus collection and endometrial samples were collected at the same time. Data were analyzed by ANOVA using the GLM procedure of SAS. Overall, 42 cows were flushed and 13 embryos were collected (recovery rate = 31%). Vitamin B supplementation had no affect on the size of the embryo ($P = 0.49$), ovulatory follicle size ($P = 0.51$), or CL size at embryo collection ($P = 0.51$). However, cows with third or higher parity had significantly larger embryos compared to second parity cows (9.39 ± 1.44 vs. 1.73 ± 1.76, $P < 0.05$). Milk production ($P = 0.90$), milk fat ($P = 0.86$), and protein ($P = 0.37$) values were also similar between the two groups. BHBA levels between the two groups were identical ($P = 0.94$). To understand the effect of vitamin B complex supplementation on fertility at a molecular levels, transcripts related to embryo development

(WNT, AXIN, FZD), immune system (CXCL, IL, MX), adhesion (MYH, MMP), and genes involved in the regulation of vitamin B molecules (FOLR1, TCII) are being analyzed from the endometrial biopsies. In conclusion, strategic dietary vitamin B supplementation during the transition and early lactation did not affect major outcomes of production and reproduction in lactating dairy cows. Benefits of vitamin B in fertility might potentially be linked to endometrial and conceptus gene expression; however, no major differences were observed in production or metabolic parameters.

Key Words: conceptus, cows, dairy, endometrium, gene expression, milk production, nutrition, reproduction, rumen protected, Vitamin B complex

RUMINANT NUTRITION: WESTERN SECTION

1664 WS Effect of crude protein supplementation on performance of cow-calf pairs and replacement heifers grazing late growing season forage.

L. Canterbury*, P. Ebert, D. G. Lust, and E. A. Bailey, *Department of Agricultural Sciences, West Texas A&M University, Canyon.*

Concurrent experiments were conducted to evaluate the effect of protein supplementation to beef cattle grazing warm-season shortgrass forage during the late growing season. Cattle in all experiments grazed adjacent shortgrass pastures dominated by Buffalograss (*Buchloe dactyloides*) and Blue Grama (*Bouteloua gracilis*). Stocking rates ($\geq$ 2.3 ha/animal) were maintained such that forage availability was not limiting throughout the experiment. Precipitation in the area during the experiment was 176% of normal. For all Exp., treatments consisted of a supplemented group (1.32 kg per head of a 39% CP range cube fed 3 times a week) and a non-supplemented control group. Supplemented animals were fed a daily average of 0.22 kg of CP. In Exp. 1, 45 multiparous cow-calf pairs (initial BW 646 ± 13 kg) were individually weighed and body condition scored every 14 d. Forage clippings were taken simultaneously with BW measurements. Cow measurements and forage clippings began July 6 and concluded September 28. Cow final BW (P = 0.24) and ADG (P = 0.38) were not affected by treatment. There was no difference (P = 0.97) in cow final BCS regardless of treatment. Calf ADG (P = 0.54) and weaning weight (P = 0.45) were not affected by treatment. In Exp. 2, 26 primiparous cows (initial BW 546 ± 12 kg) were supplemented and measurements obtained in the same manner as Exp.1. Cow final BW (P = 0.39) and final BCS (P = 0.81) did not differ between treatments. Cow ADG (P = 0.07) tended to be greater when supplemented with 0.22 kg CP per day. Calf ADG (P = 0.50) and weaning weight (P = 0.11) did not differ between treatments. In Exp. 3, 25 replacement heifers (initial BW 412 ± 9 kg) were observed for BW and forage clippings were obtained every 14 d. Heifer final BW (P = 0.17) was not different between treatments. Heifer ADG (P = 0.02) was greater for supplemented heifers. Supplementing protein to cattle grazing late season medium quality forage is advantageous for increasing ADG in replacement heifers and potentially beneficial to improve condition in lactating primiparous cows. Repeating this experiment under varied precipitation patterns, as is normal for short-grass regions, would be beneficial to further examine the impact of late growing season protein supplementation on cow-calf pair/replacement heifer performance.

Key Words: beef cows, forage quality, supplementation

1665 WS Effect of corn-based supplementation on gas emissions, performance, and energetic losses of steers grazing wheat pasture.

P. Ebert[1], E. A. Bailey*[1], A. L. Shreck[2], N. A. Cole[2], J. S. Jennings[3], *[1]Department of Agricultural Sciences, West Texas A&M University, Canyon, TX, [2]USDA-ARS Conservation and Production Research Laboratory, Bushland, TX, [3]Texas A & M AgriLife Research and Extension Center, Amarillo.*

Thirteen Angus-cross steers (initial BW = 436 + 24 kg) were used in a crossover design to evaluate the effects of corn supplementation on gas emissions, performance, and energetic losses of steers grazing wheat pasture. Steers were allowed ad libitum access to wheat pasture (1.2 steers/ha), and were individually supplemented one of two treatments daily for two 30 d periods. Treatments included either 0.2 kg of pelleted wheat middlings (CON), or a dry-rolled corn supplement fed at 0.5% of BW plus 0.2 kg of pelleted wheat middlings (SUPP). After initial 30 d period, treatments were alternated and steers were supplemented an additional 30 d. Fecal output was determined with titanium dioxide (TiO_2) as an external marker. Beginning on d 14 of each period 15 g of TiO_2 was added to each steers supplement. In vitro analysis of wheat forage was determined to estimate DM digestibility of the wheat forage for each 30 d period. Forage intake was calculated using the determined fecal output and estimated forage digestibility. Ruminal CH_4 and CO_2 fluxes were measured using a GreenFeed (C-Lock Inc., Rapid City, SD) system. Urine energy loss was assumed to be 1.4% of GE intake. Oxygen production was estimated from CO_2 production, assuming a respiratory quotient of 1.05. Forage intake as percent of BW did not differ (P = 0.15) between CON (3.22%) and SUPP (3.61%). Average daily gain for CON and the SUPP averaged 1.4 kg and 1.3 kg, respectively, and was not influenced (P = 0.54) by supplementation. There were no differences ($P \geq 0.63$) among treatments for OM digestibility (CON: 84.9%; SUPP: 84.6%) and NDF digestibility (CON: 82.5%; SUPP: 83.1%). Carbon dioxide excreted (CON: 9.8 kg/d; SUPP: 10.5 kg/d) tended to be less (P = 0.08) for CON. No differences (P = 0.43) were observed in CH_4 emissions among CON and the SUPP supplement (334 and 351 g CH_4/d,

respectively). Corn supplementation decreased ($P = 0.02$) CH_4 g/kg of DMI by 20.5%. Methane as percent of GE intake was decreased ($P = 0.02$) by 21.6% when steers consumed the SUPP compared to CON. Heat production as a percent of GE intake decreased ($P = 0.03$) when steers consumed the SUPP. Under the conditions of this experiment, cereal grain supplementation reduced CH_4 emissions.

Key Words: energetic losses, methane, wheat pasture

1666 WS Effects of rumen protected arginine supplementation to cows during early or late gestation on progeny glucose tolerance.

L. R. Owensby*[1], C. B. Gardner[1], R. C. Dunlap[2], C. A. Loest[1], S. L. Ivey[1], S. H. Cox[2], A. F. Summers[3], and E. J. Scholljegerdes[1], *[1]New Mexico State University, Las Cruces, [2]Corona Range and Livestock Research Center, Corona, NM, [3]Animal and Range Science Dep., New Mexico State University, Las Cruces.*

Our hypothesis was calves gestated by dams supplemented rumen protected arginine during early or late gestation would have improved glucose tolerance. To test this hypothesis, a two yr study was conducted. Dams were randomly assigned to one of three treatments; 1) grazing native range plus dried distillers grain (Control), or grazing native range plus dried distillers grain and Arg fed to provide 180 mg L-Arg/kg BW either during 2) early gestation (EARG) or 3) late gestation (LARG). In yr 1, 16 yearling calves (heifers $n = 8$, steers $n = 8$) and in yr 2, 24 (heifers $n = 10$, steers $n = 14$) yearling calves underwent a glucose tolerance test (GTT). On the days of the GTT, cattle were fed at 0600 h and indwelling jugular catheters were inserted at 0700 h. A 50% dextrose solution was injected at 0.5 mL/kg BW via the jugular catheter and subsequent 6 mL blood samples were collected at −5, −2, 0, 3, 6, 9, 12, 15, 20, 40, 60, 80, 100, and 120 min relative to the dextrose infusion. Glucose half-lives were estimated by regressing the logarithmically transformed glucose concentrations over time and area under the curve was determined using the trapezoidal summation method. Glucose area under the curve (AUC) did not differ ($P = 0.13$) between treatment groups; however, overall glucose concentration (conc.) tended ($P = 0.06$) to be lower for calves of arginine supplemented dams when compared with non-supplemented dams. There were no differences between treatment groups in reference to insulin AUC ($P = 0.57$), insulin half-life ($P = 0.85$), or overall insulin concentration ($P = 0.47$). In conclusion, rumen protected arginine supplementation to cows during varying times in gestation tends to affect overall glucose concentration in progeny during a glucose tolerance test; however, does not affect glucose or insulin AUC, half-life, or overall insulin concentration.

Key Words: arginine, glucose AUC, glucose half-life

1667 WS Effects of administering Ralgro to Holstein calves during the hutch period on growth performance.

K. L. McCarthy*[1], E. J. Scholljegerdes[1], J. A. Gould[2], and W. T. Nichols[3], *[1]New Mexico State University, Las Cruces, [2]Reynolds Creek Calf Ranch, Melba, ID, [3]Merck Animal Health, DeSoto, KS.*

We hypothesized that early administration of a Ralgro implant to 1 d old Holstein calves will improve growth performance. One thousand two hundred and forty-eight 1 d old Holstein steer calves (initial BW 41.2 ± 0.2 kg) were utilized in a completely randomized block designed experiment with truck load serving as the block (6 loads). On d 0, calves were individually weighed, tagged with an electronic identification tag, and vaccinated with Vision CD-T with Spur during initial processing. Calves were randomly assigned within block to receive one of two treatments: 1) growth implant containing 36 mg Zeranol ($n = 584$) or no growth implant ($n = 598$). Calves were individually housed in wood hutches and provided ad libitum access to grain starter (17.2% CP, 4% fat and NEm 0.49 Mcal/kg and NEg 0.34 Mcal/kg) and water. In addition, calves were offered two 1.9-L bottles of milk replacer two times daily (25.5% CP and 22.5% fat, DM basis). Implanted calves had greater DMI ($P < 0.01$) compared to non-implanted calves over the 92-d period. Likewise, ADG was greater ($P < 0.01$) when calves were implanted at 1 d of age versus non-implanted calves. However, due to the increase in DMI and ADG for calves receiving implants, G:F tended to differ ($P = 0.08$) between treatments. Overall, implanting calves with 36 mg of Zeranol did not appear to have any adverse effects on intake or feed efficiency in 1 d old calves during the hutch phase and improved ADG by 6%.

Key Words: calf, growth, hutch, implants, Zeranol

1668 WS Effects of protein concentration and degradability on performance and carcass characteristics of finishing heifers receiving 0 or 400 mg ractopamine hydrochloride.

K. L. Samuelson*[1], M. Hubbert[2], E. R. Oosthuysen[1], Z. Bester[1], and C. A. Loest[1], *[1]New Mexico State University, Las Cruces, [2]Clayton Livestock Research Center, NMSU, Clayton, NM.*

This study evaluated if excess protein decreases performance and carcass quality of finishing cattle fed diets with or without ractopamine hydrochloride (RH). Heifers were assigned to 48 pens in a randomized complete block design and pens of cattle were randomly assigned to 3 protein and 2 RH (0 vs. 400 mg/day) treatments. Protein treatments were steam-flaked corn-based diets containing 13.9% CP, 8.8% RDP, and 5.0% RUP (CON), 20.9% CP, 13.4% RDP, 6.1% RUP (High RDP), or 20.9% CP, 9.1% RDP, 10.4% RUP (High RUP). Cattle were weighed at initiation of RH and at shipping. No RH × CP

interactions ($P \geq 0.11$) occurred for performance or carcass traits. Excess CP did not affect ($P \geq 0.12$) final BW or ADG. Carcass-adjusted final BW and ADG tended to be greater ($P = 0.06$) for cattle receiving High RDP than High RUP and CON. Water intake, DMI, G:F, and carcass-adjusted G:F were not different ($P \geq 0.12$) among CP treatments. Hot carcass weight tended to be greater ($P = 0.06$) for cattle receiving High RDP than High RUP and CON. Dressing percentage was lower ($P < 0.01$) for cattle fed High RUP than High RDP and CON. Marbling score, 12th rib fat depth, LM area, and yield grade were not different ($P \geq 0.16$) among CP treatments. Heifers receiving High RUP tended to have lower ($P = 0.10$) KPH than CON. Percentage choice tended to be greater ($P = 0.09$) for heifers receiving High RDP vs. High RUP. Water and DMI were not different ($P \geq 0.36$) for RH vs. no RH. Cattle receiving RH had greater ($P < 0.01$) final BW, ADG, carcass-adjusted final BW, and carcass-adjusted ADG, and lower ($P < 0.01$) G:F and carcass-adjusted G:F compared with no RH. Hot carcass weights were greater ($P < 0.01$) and dressing percentage tended to be greater ($P = 0.09$) for cattle receiving RH, while marbling score was not affected ($P = 0.11$) by RH. Twelfth-rib fat depth tended to be lower ($P = 0.08$), and KPH was lower ($P = 0.02$) for RH vs. no RH. The LM area was greater ($P = 0.03$) for cattle receiving RH vs. no RH. Excess CP does not negatively impact performance or carcass traits of finishing cattle, and no interactions between CP and RH suggest that CP requirements are not affected by RH.

Key Words: cattle, protein, ractopamine hydrochloride

1669 WS Evaluation of *Eragrostis tef* (Zucc.) as a forage option for grazing beef cattle in the Southern High Plains. D. Sugg[*1,2], [1]*Texas Tech University, Lubbock,* [2]*Angelo State University, San Angelo, TX.*

To assess the potential of *Erogrostis tef* to provide a late summer supply of forage for livestock production in the Southern High Plains, four 2.66 ha paddocks equipped with subsurface drip irrigation were seeded with *Eragrostis tef* ('Tiffany' teff) at a rate of 3.72 kg/ha. Each paddock was stocked with commercial beef steers ($n = 5$; 289 ± 30.38 kg initial shrunk BW) at 51 d post-seeding resulting in an initial forage allowance of 202 kg DM/100 kg BW. Weekly samples of whole plant and canopy structure were obtained to describe DM, OM, and fiber concentrations. Appropriate sample height of canopy for the purposes of estimating selection quality was determined at the most proximal grazing site to each quadrat toss by recognition of a tiller with at least one leaf possessing the flat defoliation pattern characteristic of an ungulate bite. Biweekly samples included analysis of CP and IVTD. Leaf percentage of entire plant was quantified at 21 d intervals. Available DM and OM peaked at Day 28 and was lowest at Day 56 ($P < 0.01$). Whole plant and canopy DM ($P < 0.01$), OM ($P < 0.01$), NDF ($P < 0.01$), ADF ($P < 0.01$), and CP ($P < 0.01$) differed by day. Only in vitro true digestibility was not affected by maturation of either whole plant ($P = 0.12$) or canopy structure ($P = 0.61$). Leaf proportion of whole plant structure aligned with times of peak forage mass availability ($P < 0.01$). Teff grass stocked at a moderate rate with growing beef calves achieved adequate production with minimal inputs forage with minimal inputs to provide a quality forage base for approximately 2 mo of grazing in the Southern High Plains.

Key Words: digestibility, forage quality, grazing, teff, water

---

1670 WS Salivary cortisol concentrations affect rumen microbial fermentation and nutrient digestibility in vitro. K. L. Samuelson[*1], A. L. Salazar[1], L. L. Rath[1], J. B. Alford[1], E. R. Oosthuysen[1], S. L. Ivey[1], D. M. Hallford[2], and C. A. Loest[1], [1]*New Mexico State University, Las Cruces,* [2]*Animal and Range Science Dep., New Mexico State University, Las Cruces.*

This study investigated effects of cortisol on fermentation and digestibility of nutrients by rumen microorganisms. Four dual-flow continuous culture fermentor (2700 mL) systems were used in a 4 × 4 Latin square design with 4 periods and 4 treatments. Each experimental period consisted of 13 d, which allowed 7 d for microbial adaptation, 3 d for cortisol treatment application, and a 3 d post-treatment period. Treatments consisted of 0, 3, 6, or 9 ng/mL of cortisol mixed into artificial saliva and continuously infused at a rate of 1.55 ± 0.05 mL/min. For the 3 d treatment period and the 3 d post-treatment period samples were collected at 0, 3, 6, 9, 12, 24, 36, 48, 60, and 72 h and were analyzed VFA, and NH_3. During the 3-d sampling period effluent was composited for analysis of OM, NDF, and CP digestibility. During cortisol treatment, cortisol × h ($P \leq 0.01$) was observed for acetate and valerate, total VFA and isobutyrate tended to increase from 0 to 3 ng/mL, but were not different among 3, 6, and 9 ng/mL (quadratic, $P \geq 0.12$), butyrate tended to decrease from 0 to 3 ng/mL cortisol, and was not different among 3, 6, and 9 ng/mL (quadratic, $P = 0.07$), and isovalerate was not different among 0, 3, and 6 ng/mL, but decreased from 6 to 9 ng/mL of cortisol (quadratic, $P = 0.06$). Digestibility of OM (g/d and % of intake) tended to be lower (quadratic, $P = 0.12$), and NDF digestion (g/d and % of intake) was lower (quadratic, $P = 0.09$) for 9 ng/mL cortisol compared to 0, 3, or 6 ng/mL. Digestibility of CP (g/d and % of intake) was not different ($P \geq 0.23$) among treatments. In the period after cortisol treatment, a cortisol × h ($P = 0.03$) was observed for isobutyrate, NH_3 decreased linearly ($P = 0.04$) with increasing cortisol, valerate tended to increase linearly ($P = 0.14$) with increasing concentrations of cortisol, and isovalerate was lower for 9 ng/mL than 0, 3, and 6 ng/mL cortisol (quadratic, $P = 0.10$). Digestibility (g/d and % of intake) of OM, NDF, and CP were not different ($P \geq 0.51$) among treatments. Results indicate that cortisol may influence rumen microbial fermentation and digestion when

present in saliva at 9 ng/mL.

Key Words: cortisol, fermentation, rumen

1671 WS Shifting the paradigm of liver abscess dogma in USA feedlots. Z. Bester*[1], M. Hubbert[2], R. E. Carey[1], K. L. Samuelson[1], and C. A. Loest[1], *[1]New Mexico State University, Las Cruces, [2]Clayton Livestock Research Center, NMSU, Clayton, NM.*

Liver abscesses in feedlot cattle are a major economic, welfare, and production concern to the cattle feeding industry. Severe liver abscesses (LA) reduce ADG by as much as 0.20 kg, DMI by 5%, trimming loss by 0.43%, carcasses grading choice by 7%, and HCW by 36 kg. In processing facilities, LA introduce operational and food safety concerns. These include a reduction in processing efficiency, lost time as a result of line stoppages, and offal condemnation in addition to the consumer risk associated with LA contamination of edible meat. Tylosin phosphate, a macrolide antibiotic, has been shown to reduce LA by 75% and level of *Fusobacterium Necrophorum* in the rumen by 80 to 90%. During this initial observational study, a total of 83 feedlot pens (each individual feed yard exceeding 40,000 head capacity) within three geographical regions (Arizona, Colorado, and the Texas Panhandle) were sampled. Feedlot pen data were collected within 1 wk before harvest and cattle were traced to the packing plant. Every third rumen and its matching liver were tagged (if condemned only). Rumens were scored for consolidation, scars, moderate and acute lesions, and a sample was taken. Livers were scored based on an adaptation of the Elanco Liver Check scoring system. Holstein cattle had a greater ($P < 0.05$) percentage of LA than beef breeds (30.3 vs. 20.0%). Additionally, Holstein cattle had 11% severe LA (A+) compared with 4% for beef breeds ($P < 0.05$). No geographical difference ($P \geq 0.10$) were detected for liver abscess prevalence and averaged 23, 25, and 26% for the Texas Panhandle, Arizona, and Colorado regions, respectively. Liver abscess rate and severe LA (A^+) incidence differed between feedlots ($P < 0.05$) with within feedlot variation. A correlation was observed for LA% and days on feed ($R^2 = 0.22$; $P = 0.04$) and for LA % and breed ($R^2 = 0.29$; $P = 0.01$). No correlation was observed between LA percentage and tylosin phosphate, and between LA percentage and rumen lesions ($P \geq 0.10$). These data indicated no association between LA and rumen damage as a result of acidosis. Rumen lesions averaged 12.2%, of which 9.3% were consolidated, 2.4% scar tissue, and the remainder moderate and acute lesions. This study justifies further investigation of feedlot soil and manure as the source of LA causing pathogens to evaluate the within feedlot variation observed for in LA percentage in cattle.

Key Words: cattle, feedlot, liver abscess

SMALL RUMINANT

1672 Protein supplementation and herbage allowance for pregnant ewes grazing low-quality pasture. C. H. E. C. Poli*[1,2], B. M. Paulino[1], A. B. Moraes[1], Z. M. S. Castilhos[3], F. C. A. Silva[3], N. M. Fajardo[1], C. M. Pimentel[4], D. B. David[5], E. B. Azevedo[6], and J. J. Villalba[2], *[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [2]Utah State University, Logan, [3]Fundação Estadual de Pesquisa Agropecuária, Porto Alegre, Brazil, [4]Universidade de Brasília, Brasília, Brazil, [5]Fundação Estadual de Pesquisa Agropecuária, São Gabriel, Brazil, [6]Universidade Federal do Pampa, Itaqui, Brazil.*

Protein supplements mixed with mineral salt have been widely used in beef production in tropical countries, but few studies have been performed to test their use with sheep or pregnant animals. This study assessed the effect of protein supplementation under two herbage allowances aiming at overcoming ewe undernutrition during gestation and lactation in low-quality pastures during winter. At approximately fifty days of gestation, 36 ewes carrying singletons and of similar stage of pregnancy were chosen from a group of 50 using an ultrasound technique. Ewes were allocated into four treatments in a randomized block design with three replications, where each paddock with 3 ewes was considered the experimental unit. The treatments were arranged in 2 x 2 factorial design of two herbage allowances: 1) low (LH) 10 kg^{-1} dry matter (DM) per 100 kg liveweight (LW) and 2) high (HH) 20 d^{-1} DM per 100 LW; and two supplements: 1) protein plus a mineral salt mix (PS) and 2) mineral salt alone (S). Both supplements were offered in ad libitum amounts. Due to differences in daily nutrients requirements and pasture quality, the trial was divided into two periods: pregnancy and lactation. Animals grazed a low-quality *Brachiaria arrecta* cv. Napier (crude protein: 67 g kg^{-1}, neutral detergent fiber: 710 g kg^{-1}) pasture. Animal performance was assessed every 21 d. Other variables such as herbage structure and composition, lamb birth weight, daily supplement intake, and placenta weight were also measured. There was no effect ($P \geq 0.05$) of PS on ewe average daily gain (ADG), placenta weight, lamb birth weight or lamb ADG. Protein supplement intake was greater ($P \leq 0.05$) than mineral salt intake in both reproductive stages, being greater during lactation, but it was not enough to increase the productive performance of ewes during the last third of pregnancy or during lactation. In conclusion, regardless of herbage allowance, the use of protein supplements on low-quality pastures does not improve the nutritional status of ewes or lambs before weaning. **Key Words:** fetal development, maternal nutrition, sheep

Fig 1673.

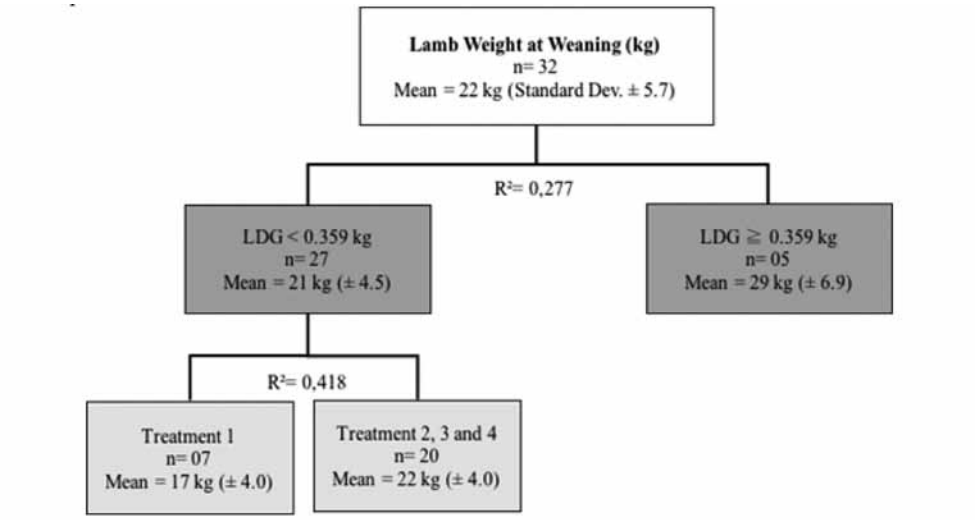

Figure 1 Decision Tree Test showing the lamb weight at weaning partitioned through R^2-values, explained by lamb daily gain (LDG) and treatments (food restriction during different ewe pregnancy periods).

1673 Food restriction in ewes during different pregnancy periods affects milk production and lamb growth. C. H. E. C. Poli[*1,2], L. A. Sphor[2], A. L. G. Monteiro[3], J. F. Tontini[2], C. Bremm[2], P. C. F. Carvalho[2], and J. J. Villalba[1]. *[1]Utah State University, Logan, [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [3]Universidade Federal do Paraná, Curitiba, Brazil.*

This study assessed the effect of food restriction during different periods of ewe pregnancy on milk production and lamb growth. Thirty-five adult pregnant ewes were assigned to four treatments (7–10 animals/treatment), which varied in the period when food restriction (removal of a supplement fed at 150 g/Kg BW/day) was applied: first third period of pregnancy (T1); second third period of pregnancy (T2); third third period of pregnancy (T3), or no supplement restriction (Control; T4). All ewes grazed together in a Bermuda grass cv. Tifton-85 pasture of low biomass (below 1000 kg DM/ha), and once a day they received the supplement [14% CP; 3.5% EE; 16% ADF], or not, according to treatment. Ewes were weighed every 14 d during pregnancy. Lamb birth weight (LBW) and placenta weight (PW) were assessed at lambing. Daily milk production (MP) and lamb daily gain (LDG) were recorded until weaning. The experiment was performed in a completely randomized design, and the data were analyzed by a Decision Tree multivariate analysis. Treatments explained 23% of MP, with greater milk production per day for T2 and T4 (3423 g ± 1047.7 g SD) than for T1 and T3 (2294 g ± 1091.1 g SD). LBW was best explained by the number of lambs per ewe (R^2 = 0.52), and PW had a positive correlation (R^2 = 0.72) with LBW, independent of the number of lambs per ewe. When the LDG was lower than 359 g, the lowest LDG and the lamb weight at weaning were observed in T1 (Fig. 1). Despite the relatively low nutrient requirements from ewes during early pregnancy, these results point to the importance of avoiding dietary restriction during this period to enhance MP and LDG. On the other hand, nutrient restriction during mid-pregnancy had no consequences on milk production or lamb growth.

Key Words: sheep nutrition, sustainability, fetal development

1674 Relationship between infrared thermography measures and feed efficiency in New Zealand sheep. S. P. Miller[*1], S. Dowling[2], J. C. Munro[3], Y. R. Montanholi[3], J. R. Webster[2], and P. L. Johnson[1], *[1]AgResearch, Mosgiel, New Zealand, [2]AgResearch, Hamilton, New Zealand, [3]Department of Plant and Animal Sciences, Faculty of Agriculture, Dalhousie University, Truro, Canada.*

A data set to investigate genetic parameters for feed efficiency in New Zealand maternal sheep is being collected. As measurement of this trait is expensive, route to market for breeders will be through genomic selection. Another potential way to enable breeders to select for this difficult to measure trait, combined with genomics will be through predictor traits. Using custom built electronic feeding stations, individual feed intake was collected on 197 ewe lambs born in September 2014 with the 6-wk feed intake trial taking place June-August 2015. Residual feed intake (RFI; MJ/day) was determined using a prediction model that included mid-point body weight ($kg^{0.75}$) and average daily gain. Infrared thermography measures were investigated as a potential indicator trait with images collected at two time points. A thermal video captured the left side of the head, and back of the ear (approximate distance of 0.5 m), using an infrared camera (ThermaCamS60, FLIR, Systems AB, Dandoryd, Sweden). Four head sub-regions were identified

and maximal and average temperature calculated for the eye, bridge of the nose, muzzle, and middle of the back of the ear. To identify potential regions of influence a sub-set of images from 30 individuals were interpreted representing the six most extreme RFI animals (three high RFI; three low RFI), and also individuals with extreme RFI values from four sires identified as the producers of the most extreme RFI progeny (two high RFI sires; two low RFI sires). The difference in RFI was significant ($P < 0.001$) between the extreme groups (-1.5 ± 0.28 MJ/day vs. $+1.6 \pm 0.29$ MJ/day). Within a time point, the average temperature measurements for the four different positions were significantly correlated (all $P < 0.01$). Between time points, back of the ear measurements showed the highest correlation ($r = 0.7$; $P < 0.001$) and the greatest mean temperature difference between groups at each measurement point. At the first time point, the estimated average ear temperature of the lowest RFI animals was 26.7 ± 0.67°C vs. 29.2 ± 0.69°C for the highest RFI animals ($P = 0.015$), with corresponding values at the second time point of 27.2 ± 0.55°C vs. 29.5 ± 0.59°C ($P = 0.011$). These results provide evidence of a relationship between thermal images and feed efficiency in maternal growing sheep that will be investigated further as a potential indicator trait for selection in industry.

Key Words: indirect, phenotyping, selection

1675 Ground redberry juniper and urea in supplements fed to Rambouillet ewe lambs on growth, blood serum, and fecal N. T. R. Whitney[*1] and J. P. Muir[2], *[1]Texas A&M AgriLife Research, San Angelo, [2]Texas A&M AgriLife Research, Stephenville.*

Effects of using ground redberry juniper and urea in dried distillers grains with solubles (DDGS)-based supplements fed to Rambouillet ewe lambs ($n = 48$; 42 kg ± 3.8) on growth, blood serum, and feces were evaluated. In a randomized design study (40 d), individually-penned lambs were fed a basal diet of ground sorghum-sudangrass hay (ad libitum) and of 1 of 8 supplements (fed separately from the hay; 6 lambs/treatment; 496 g/d; DM basis) in a 4 × 2 factorial arrangement with 4 concentrations of ground juniper (15, 30, 45, or 60% of DM) and 2 levels of urea (1 or 3% of DM); dried distillers grains with solubles was replaced as percentage of juniper increased. Lamb growth was evaluated on d 0, 5, 12, 19, 26, 33, and 40. Blood serum was evaluated on d 6 to 8, 20 to 22, and 34; feces were collected on d 34. A repeated measures analysis showed factorial by day interactions ($P < 0.001$) for hay DMI, total daily DMI, BW, ADG, and G:F, with only a few differences within day. Overall, hay and total DMI were similar among lambs ($P > 0.44$), but lambs fed 60% juniper-based supplements had the least amount of supplement intake ($P < 0.01$). Overall, lambs fed 15% juniper-based supplements had the greatest ($P < 0.04$) ADG and G:F vs. the other lambs. Percentage of urea in the supplement did not affect ($P > 0.23$) overall intake of hay or supplement, ADG, or G:F. However, lambs fed 15% juniper-based supplement tended to have greater ($P = 0.07$) final BW than lambs fed 60%, and urea used at 1% of supplement vs. 3% resulted in reduced final BW ($P = 0.03$). Fecal DM was similar ($P > 0.15$) among lambs, but fecal N was greater ($P < 0.02$) for lambs fed the 15% and 45% juniper-based supplements vs. 60% juniper-based supplement. In conclusion, when ewe lambs were fed a low-quality basal hay diet, growth performance declined when 60% juniper or 3% urea was used in supplements. This decline can be attributed to differences in supplement concentrate:forage ratio, fiber, degradable N, and plant secondary compounds, all of which can affect intake and growth. However, an economic analysis is needed to determine maximum inclusion rate of juniper and urea in rangeland supplements, especially when trying to only meet the maintenance requirement of the animal.

Key Words: juniper, lambs, supplement

1676 The relationship between body condition score and body weight, body linear measurements and real-time ultrasound body composition measurements in Alpine does before breeding and kidding. F. R. B. Ribeiro[*1], B. Barcelos[2], L. C. Nuti[1], W. B. Foxworth[1], S. K. Lewis[1], Y. Jung[1], S. Horner[1], B. L. Jackson[1], and G. R. Newton[1], *[1]Prairie View A&M University, Prairie View, TX, [2]School of Animal Science and Food Engineering, University of Sao Paulo, Pirassununga, Brazil.*

The objective of this study was to determine the relationships between body condition score (BCS) and body weight (BW), hip height (HH), wither height (WH), girth circumference (GC), and real-time ultrasound (RTU) measurements of body composition in Alpine does before breeding ($n = 66$) and before kidding ($n = 34$). Thirty-two animals were not included in the before kidding measurements due to culling or failure to give birth. The body composition traits measured by RTU were 12th–13th rib fat thickness (uBF) and rump fat thickness (uRUMP). Ultrasound measurements were taken using an Aloka 500 with a 12 cm 3.5 MHz transducer. Hair was clipped and vegetable oil was used as a coupling agent to enhance image quality. Data were analyzed using the Proc CORR and Proc REG procedures of SAS. Body condition score was highly correlated ($P < 0.01$) with uBF and uRUMP before breeding ($r = 0.45$ and 0.39, respectively) and before kidding ($r = 0.84$ and 0.74, respectively). Body weight and HH were highly correlated before breeding ($r = 0.63$; $P < 0.0001$), but not before kidding ($r = 0.27$; $P = 0.12$). Girth circumference was highly correlated to BW ($r = 0.78$; $P < 0.0001$) and correlated to HH ($R = 0.38$; $P = 0.037$) before kidding. Wither height and HH were highly correlated only when measured before kidding time ($r = 0.63$; $P < 0.001$). Prediction equations were developed to predict BCS using a stepwise procedure. Body condition score before breeding can be predicted from uBF with an R^2 of 0.21. Prediction of

BCS before kidding using uBF had an R^2 of 0.63, which was the first variable included in the model. Inclusion of three additional variables (uRUMP, HH, and WH) in the full model improved the R^2 to 0.76. Results indicate that RTU body composition traits are highly correlated with BCS in Alpine goats and that the accuracy of prediction was improved when does were close to parturition. More research is needed to refine the models and improve accuracy of prediction.

Key Words: body composition, goat, ultrasound

1677 Effects of selection for high and low juniper-consuming goats on rumen fermentation characteristics. W. C. Stewart*[1], T. R. Whitney[2], E. J. Scolljegerdes[3], D. F. Waldron[4], J. W. Walker[4], and J. M. B. Musser[5], *[1]Montana State University, Bozeman, [2]Texas A&M AgriLife Research, San Angelo, [3]New Mexico State University, Las Cruces, [4]TX A&M AgriLife, San Angelo, [5]Texas A&M, College Station.*

The objective of this study was to determine if ruminal fermentation characteristics differed in goat lines selected for high (HIGH) or low (LOW) juniper-consumption. Five Boer × Spanish-composite bucks (age = 2 yr; initial BW = 67.2 ± 4.3 kg) selected from each line were subjected to three different 25-d periods: 1) native range infested with juniper (Period 1); 2) group fed ad libitum sorghum × sudangrass hay (Period 2); 3) individually fed 3% BW of sorghum × sudangrass hay and ad libitum redberry juniper foliage offered fresh daily (Period 3). During each period, rumen fluid was evaluated for pH, VFA, ammonia N (NH_3–N), and IVDMD of juniper foliage. There was a period effect ($P < 0.02$) for all response variables. A selection line × Period interaction was observed for total VFA ($P < 0.01$) because HIGH, which exceeded LOW during Periods 1 and 3 was lower in Period 2. However, total VFA did not differ within period between HIGH and LOW. During Period 1, when goats grazed juniper infested native rangelands, rumen fluid from HIGH contained greater ($P < 0.05$) ruminal isovalerate, and tended to have greater ruminal isobutyrate ($P = 0.09$) and NH_3–N ($P = 0.07$) than LOW. When transitioned to a sorghum × sudangrass hay diet (Period 2), total ruminal VFA concentrations declined 26 and 4% for HIGH and LOW, respectively, and total VFA ($P = 0.08$) and valerate ($P = 0.09$) tended to be greater for LOW compared to HIGH. In vitro digestibility of juniper did not differ ($P = 0.48$), but declined 13 and 12% for HIGH and LOW, respectively, from Period 1 to 2. During Period 3, when transitioned to individual pens with ad libitum access to sorghum × sudan hay and juniper foliage, juniper intake did not differ ($P = 0.16$) with HIGH consuming 1.2 g/kg BW of juniper compared to 0.62 g/kg BW for LOW. Although no differences were detected ($P > 0.05$) for VFA, NH_3–N, pH, and IVDMD between HIGH and LOW goats during Period 3, total VFA from HIGH increased 48% vs. 7% in LOW from period 2 to 3. Propionate increased 16% in HIGH compared to a 5% decrease in LOW from Period 2 to Period 3. Overall, results indicate that ruminal fermentation characteristics differ between divergent goat lines selected for high and low juniper consumption when consuming diets with and without juniper.

Key Words: genetic selection, goats, juniper

1678 Ground redberry juniper and urea in DDGS-based supplements do not adversely affect ewe lamb rumen microbial communities. S. L. Ishaq*[1], C. J. Yeoman[1], and T. R. Whitney[2], *[1]Montana State University, Bozeman, [2]Texas A&M AgriLife Research, San Angelo.*

Effects of using ground redberry juniper and urea in dried distillers grains with solubles (DDGS)-based supplements fed to Rambouillet ewe lambs ($n = 48$; 42 kg ± 3.8) on ruminal parameters and microbial communities were evaluated. In a randomized design study (40 d), individually-penned lambs were fed ad libitum, a basal diet of ground sorghum-sudangrass hay and of 1 of 8 supplements (6 lambs/treatment; 496 g/d; DM basis) in a 4 × 2 factorial arrangement with 4 concentrations of ground juniper (15, 30, 45, or 60% of DM) and 2 levels of urea (1 or 3% of DM). Growth performance, serum, and fecal characteristics were reported. Ruminal fluid was collected via oral lavage at the end of the trial (d 34). Total VFA was unchanged ($P > 0.51$) with supplements. As a percentage of total VFA, propionic was similar ($P = 0.34$), acetic acid increased ($P = 0.004$) and butyric acid decreased ($P = 0.03$) as concentration of juniper increased in the supplement; urea did not have an effect ($P > 0.10$). Ammonia N was not affected ($P > 0.12$), but ruminal pH increased ($P < 0.001$) with juniper concentration; not with urea ($P > 0.89$). Treatment (individual juniper or urea concentrations, or juniper × urea) effects on operational taxonomic unit (OTU) abundance were not significant using ANOSIM ($P > 0.05$), AMOVA ($P > 0.01$), or PERMANOVA ($P > 0.05$). Treatments did not produce significantly different phylogenetic trees by structure ($P > 0.05$, unweighted UniFrac), but did produce some small, yet significant pairwise comparisons by abundance (weighted UniFrac). Samples did not significantly cluster by diet or supplements using metric multi-dimensional scaling plots. Families Prevotellaceae and BS11 gut group (Bacteroidetes) decreased with increasing concentrations of both juniper and urea, while families Acidaminococcaceae and S24–7 increased. Christensenellaceae and Lachnospiraceae increased with juniper concentration at a 1% urea. High concentrations of juniper were associated with Moraxella and Streptococcus, low concentrations of urea were associated with Fretibacterium, and high concentrations of urea were associated with Oribacterium and Pyramidobacter. In conclusion, on a low-quality basal hay diet, ewe lamb ruminal parameters can be attributed to differences in the concentrate:forage ratio, fiber, degradable N, and secondary compounds. Despite some differences in bacterial

diversity between treatments, due to changes in volatile fatty acid profile, ammonium, and pH, there was not a significant difference in OTU presence or abundance.

Key Words: bacterial diversity, lambs, supplement

1679 Fatty acid profile, sensory traits, and aromatic compounds of chops from lambs fed ground woody plants as roughage in feedlot finishing diets. K. R. Wall[*1], C. R. Kerth[1], T. R. Whitney[2], S. B. Smith[1], J. L. Glasscock[2], and J. T. Sawyer[3], [1]TX A&M University, *College Station, [2]Texas A&M AgriLife Research, San Angelo, [3]Tarleton State University, Department of Animal Science and Veterinary Technology, Stephenville, TX.*

We hypothesized that ground woody plants in feedlot diets would increase saturated fatty acids and modify sensory characteristics and volatile aroma compounds of loin chops. A completely randomized design study using Rambouillet wether lambs (n = 48) consisted of 2 feeding periods: Period 1 = fed a 70% concentrate (consisting mainly of 40% dried distillers grains with solubles, DDGS; 21.7% sorghum grain) diet from d 0 to 27 d and Period 2 = fed an 86% concentrate (consisting mainly of 40% DDGS and 37.5% sorghum grain) diet from d 28 to 57. In each feeding period, lambs were individually fed 6 diets that differed only by roughage source: cottonseed hulls (CSH; control) or ground wood consisting of either redberry (RED), blueberry (BLUE), or one-seed juniper (ONE), eastern red cedar (ERC), or mesquite (MESQ). After humanely harvesting the lambs and chilling the carcasses for at 48°C for 48 h, five chops, 2.54-cm thick, were cut starting from the posterior end of the LM; the first chop was designated the analysis of fatty acid composition, cut to straighten the LM face, vacuum-packaged separately, and stored at −80°C until analyzed. Subsequently, four, 2.54-cm-thick chops were serially cut for sensory and GC/MS/Olfactory analysis, labeled, vacuum packaged separately, and stored at −10°C until analyzed. Chops from lambs fed MESQ tended (P = 0.07) to have less total saturated fatty acids compared to chops from lambs fed either RED or ONE. No other fatty acids were affected (P > 0.10) by roughage source. Neither sensory traits nor cook loss percentage were affected (P > 0.17) by roughage source. A total of 95 aroma chemical compounds were detected by GC/MS/Olfactory methods and included alkanes, alcohols, aldehydes, acids, ketones, sulfur-compounds, and pyrazines. The CSH had greater (P < 0.05) amounts of 1-pentanol (bread or cereal aroma) compared to BLUE, ERC, or MESQ. Heptanal (medicinal aroma), pentanal (bread aroma), 1-(1H-pyrol-2yl)-ethanone, 2-heptanone (fruity aroma), and 2-pentyl furan (caramel aroma) amounts were greater (P < 0.05) in CSH than all other roughages. We conclude that woody plants can be included in feedlot rations of lambs with no adverse affects on fatty acid profile, sensory traits, or aromatic compounds.

Key Words: carcass, lamb, sensory

1680 Feeding behavior of grazing lambs in a silvopastoral system. F. de Oliveira Scarpino van Cleef[*1,2], T. Silva do Nascimento[1], L. Ariel Tosi[1], D. J. A. Santos[1], and A. C. Ruggieri[1,2], *[1]Sao Paulo State University, Jaboticabal, Brazil, [2]CNPq, Brasilia, Brazil.*

Silvopastoral systems may contribute to the reduction of the effects caused by climate change in grazing animals. The aim of this study was to evaluate the presence of trees (*Eucalyptus urophylla* × *Eucalyptus grandis*) on the behavior of grazing finishing lambs in Massai grass (*Panicum maximum* × *Panicum infestum*). Twenty-four crossbred lambs (27 ± 3.3 kg BW and approximately 90 d old) were blocked by initial BW and assigned into three experimental treatments: TA = unshaded Massai grass pasture; TB = Massai grass pasture with eucalyptus trees spaced 12 × 2m; TC = Massai grass pasture with eucalyptus trees spaced 6 × 2m. Light interception was the criteria for starting grazing period and the residual pasture height was fixed in 20 cm. Animals were observed over 9 consecutive days (3 d of occupation in each of 3 paddocks) to assess the grazing activities: feeding (FE), lying ruminating (LR), standing ruminating (SR), lying (LY), standing still (SS), searching for food (SF), and other activities (OT). Three trained observers recorded the behavioral activities, every 10 min, for 12 h (from 0700 to 1900 h). Data were submitted to analysis of variance and F test at 5% significance, using the GLM procedure of the statistical package SAS, and the treatments' means were compared using Tukey test at 5% significance. They were included in the model the treatment, block, day of occupation, day of occupation nested within the treatment, and interactions of treatment × block, and treatment × day of occupation. Animals in TA spent more time on FE (TA = 59%, TB = 53%, TC = 50%, P < 0.0001), with no differences observed between treatments with trees. Time of LR was greater for TB (TA = 25.7%, TB = 30%, and TC = 23%, P < 0.0001), and the interaction was observed between TB and day of occupation (P = 0.02), with animals spending more time on this activity at second and third occupational d. On the other hand, animals in TC stayed more time on LY (TA = 5.7%, TB = 7.7%, and TC = 11.8%,P < 0.0001), SS (TA = 2.5%, TB = 3,01%, and TC = 4,2%, P = 0.0001), and having other activities (TA = 0.7%, TB = 0.6%, and TC = 2.9%, P < 0.0001) than animals in TA and TB. The activities SR and SF did not differ among treatments (P = 0.08 and P = 0.14, respectively). Because of the greater availability of shade, the silvopastoral system improved the state of welfare of the lambs, shown by the greatest time spent on ruminating.

R^2 = coefficient of determination. C.V. (%) = coefficient of variation. IW = initial weight. FW = final weight. TG = total gain. DLG = daily liveweight gain. FCR = feed conversion ratio. Mean followed by same letters are not significantly different by F test (5%). * P< .05

1681 Intake, digestibility, and performance of hair sheep lambs fed with ammoniated cotton gin trash treated with exogenous fibrolytic enzymes. D. G. Quadros*, *Bahia State University, Barreiras, Brazil.*

This study was performed to evaluate intake, digestibility, and performance of Santa Ines lambs fed with diets containing ammoniated cotton gin trash (CGT) treated with exogenous fibrolytic enzymes (EFE). CGT was pre-treated with 6% urea (25% of moisture for 80 d) according previous studies. Treatments were 0, 2, 4, and 6% of EFE (75% cellulase and 25% hemicellulase), applied 24h before feeding. In addition, there was a control group fed with non-ammoniated and untreated CGT. The experiment was a completely randomized block design with five treatments and six replications (animals), with three males and three females per treatment, from February to May 2014 in Animal Science Center at UESB, in Vitoria da Conquista, Bahia, Brazil. Isonitrogenous and isocaloric diets were balanced according to NRC for 20 kg animals, liveweight gain of 200 g with estimated intake of 4.5% of bodyweight (61% TDN and 15% CP). Concentrate contained corn, soybean meal, and minerals, fed in a concentrate:roughage ratio of 50:50. The lambs were feedlotted for 84 d, being the first 21 d of adaptation and three periods of data collection of five consecutive days in each 16 d. For evaluating intake and digestibility, feed, orts, and feces were collected, using NDFi as an internal marker. There was no effect of EFE on intake, with the average values of 1311.4, 1189.9, 254.1, 748.9, and 810.0 g per day for DM, OM, CP, NDF, and TDN, respectively. EFE increased NFC intake ($P < 0.05$), by 17.0% units for each 1% of EFE. There were no differences on apparent digestibility of CP and EE ($P > 0.05$) with EFE application; however, digestibility of DM, OM, NDF, ADF, FC, NFC, and TDN were increased linearly ($P < 0.05$). Males (240 g) gained daily more weight than females (158.4 g) ($P < 0.05$), although there was no effect of EFE ($P > 0.05$). Despite the benefits of ammonization and EFE on digestibility and intake of CGT, there was no significant effect on performance.

Key Words: cellulase, feedlot, hemicellulase, ruminants.

1682 Effects of forage quality and breed on rumination time in goats. S. N. LeShure*, T. A. Gipson, A. L. Goetsch, R. Puchala, and T. Sahlu, *American Institute for Goat Research, Langston University, Langston, OK.*

Rumination time is one of the many key factors in determining animal wellbeing. The objective was to investigate effects of forage quality and breed on rumination time in goats. The experiment was 2 simultaneous 4 × 4 Latin squares having a 2 × 4 factorial treatment arrangement with 2 breeds (Alpine and Spanish) and 4 treatments [24 h fasting (FAST), low-quality hay (LOW; mixed grass), LOW plus concentrate (CONC; 80% corn and 20% soybean meal at 1% BW(DM)), and high-quality hay (HIGH; alfalfa)]. Twelve mature does of each breed were placed in individual metabolic crates and given free access to hay unless fasting. There were 4 periods of 72 h with 3 rotations of 8 does/day (24 h × 3 d). Does were digitally recorded for 24 h, then observations were encoded for ruminating bouts and bout duration. Data were analyzed using a mixed model consisting of DMI as a covariate, treatment, breed, and treatment x breed as fixed effects and animal within square as a random effect. Feed intake relative to $BW^{0.75}$ was 0, 17, 28, and 21 g/kg $BW^{0.75}$ for FAST, LOW, CONC, and HIGH, respectively (SEM = 1.6) and 17 and 16 g/kg $BW^{0.75}$for Alpine and Spanish, respectively (SEM = 1.4).

Total rumination duration was affected by breed ($P < 0.01$) and treatment ($P < 0.01$). Alpine goats ruminated longer ($P < 0.01$) than Spanish (310 vs. 249 min, respectively; SEM = 12.8) and rumination duration while fasting was lower ($P < 0.01$) than for other treatments (229, 313, 282, and 295 min for FAST, LOW, CONC, and HIGH, respectively; SEM = 17.6). Treatment did not affect ($P > 0.10$) the number of rumination bouts; however, Alpines had a greater ($P < 0.01$) number of bouts than Spanish (29 vs. 20 bouts, respectively; SEM = 1.9). Average bout duration was affected by both treatment ($P < 0.01$) and breed ($P < 0.01$). Average bout while fasting was shorter ($P < 0.01$) than for other treatments (10, 13, 13, and 15 min for FAST, LOW, CONC, and HIGH, respectively; SEM = 0.9). Spanish had longer ($P = 0.03$) rumination bouts than Alpine (14 vs. 11 min, respectively; SEM = 0.8). In conclusion, similar dry matter intake among non-fasting treatments may have prevented effects on rumination, although greater differences between breeds and fasting state had marked influences.

Key Words: forage quality, goats, rumination

1683 Genome-wide association analysis of residual feed intake and milk yield in dairy goats.

C. B. Wasike[1], M. Rolf[2], N. C. D. Silva[1], R. Puchala[1], T. Sahlu[1], A. L. Goetsch[1], and T. A. Gipson[*1], *[1]American Institute for Goat Research, Langston University, Langston, OK, [2]Oklahoma State University, Stillwater.*

Interest in both dairy and meat goat production in the US has been increasing, and there is tremendous opportunity for genetic progress in traits that are easy to measure (e.g., milk yield) and those that are more difficult (e.g., residual feed intake, RFI). However, there is little research or infrastructure within the goat industry for implementation of large-scale genetic evaluation. The objective of this study was to conduct a genome-wide association study (GWAS) for RFI and total milk yield in dairy goats. Forty-eight Alpine females (56.4 ± 7.15 kg BW; 423 ± 146.1 kg milk; 225 ± 20.9 d in milk; 16 primiparous) were used. Data in mid- to late lactation were used to calculate RFI. Milk yield and components were collected over a 12-wk period in mid- to late lactation and were used to calculate energy-corrected milk yield (ECMY). ECMY DMI, and BW from the same period were used to calculate RFI, which ranged from −794 to 594 g. DNA was collected via venipuncture and stored on Whatman FTA cards. Genotypes were assayed using the Illumina 52K goat SNP chip. SNPs with a minor allelic frequency < .01 were removed, resulting in 48,632 SNPs available for analysis. Missing genotypes were imputed using BEAGLE and SNP effects were estimated using GenSel on the iPlant platform. For RFI, the posterior mean of the residual variance was 47,934 and the posterior mean of genetic variance was 14,428, giving an estimated heritability of 0.23. For total milk yield, the posterior mean of the residual variance was 10,141 and the posterior mean of genetic variance was 9826, giving an estimated heritability of 0.49. The 100 SNP with the greatest effects contributed 3.1% and 3.3% of the total genetic variance for RFI and total milk yield, respectively. Although the sample size in this study is very small and the ideal usage of genomic information would be to supplement large-scale genetic evaluation programs, it illustrates the potential of utilizing genomic selection with phenotypes on large populations of dairy goats to make genetic improvement. Genetic selection for RFI and milk yield in dairy goats may be expedited by selection programs that incorporate genomic information, particularly in the absence of large, nationwide breeding value prediction programs.

Key Words: dairy goats, residual feed intake, SNP

1684 Effect of Narasin on nutrient intake and digestibility in wethers fed high-forage diets.

D. M. Polizel[*1], M. F. Westphalen[2], A. A. Miszura[1], M. H. Santos[1], R. G. Silva[1], A. V. Bertoloni[1], G. B. Oliveira[1], M. V. C. Ferraz Junior[1], M. V. Biehl[2], I. Susin[2], and A. V. Pires[1,2], *[1]FMVZ/University of Sao Paulo, Pirassununga, Brazil, [2]ESALQ/University of Sao Paulo, Piracicaba, Brazil.*

The objectives in this trial were to determine the effects of adding increased levels of narasin on nutrient intake and digestibility in wethers fed low quality forage. Five White Dorper x Santa Inês wethers (BW 68.7 ± 2.1 kg), cannulated in the rumen, were used in a 5 × 5 Latin square design. Animal were fed daily and diet was composed of coastcross bermudagrass hay (91.0% DM; 67.2% NDF; 32.1% ADF; 6.8% CP; 3.2% EE; 17.3% NFC; 5.5% ash). Narasin was offered twice a day and levels were 0 (control, N0), 8 (N8), 16 (N16), 24 (N24), or 32 (N32) mg/kg DM, corresponding to 0, 80, 160, 240, and 320 mg of Zimprova 100®. The delivery vehicle of narasin was 20 g of ground corn containing the set dosage of narasin in 1 kg of DM. Every experimental period lasted 20 d. The first 15 d were used to adapt the wethers with the experimental diets. Daily feed intake and fecal output were determined on Days 16, 17, 18, and 19 of each period. For total collection of feces, harnesses with collection bags were used to avoid contamination of feces by urine. Data were analyzed using the MIXED procedure (SAS Inst. Inc.) and the LSMEANS option was used to generate individual means. The effect of narasin levels were evaluated using linear and quadratic orthogonal contrasts. The effects were considered significant when $P < 0.10$. Increasing levels of narasin did not affect dry matter (1.1 ± 0.2 kg; $P = 0.70$), organic matter (1.0 ± 0.2 kg; $P = 0.69$), NDF (0.7 ± 0.1 kg; $P = 0.69$), and ADF (0.3 ± 0.01 kg; $P = 0.68$) intakes. Experimental diets did not affect DM (50.5 ± 2.6%; $P = 0.57$) and OM (50.9 ± 2.6%; $P = 0.63$) digestibilities. However, narasin increased linearly NDF digestibility (N0: 50.4%; N8: 53.7%; N16: 51.8%; N24: 55.0%; N32: 55.2%; $P = 0.06$). ADF digestibility tended to differ with increased levels of narasin (N0: 49.1; N8: 51.1; N16: 49.2; N24:

53.4; N32: 53.0%; $P = 0.15$). Levels of narasin improve NDF digestibility in wethers fed a low quality forage diet without affecting nutrient intake.

Key Words: intake, ionophore, narasin.

1685 Effects of different levels of zilpaterol hydrochloride on feedlot performance and carcass characteristics of hair-breed ram lambs.

J. Cayetano de Jesús[1], R. Rojo-Rubio[*2], H. Lee-Rangel[1], L. Avendaño-Reyes[3], U. Macias-Cruz[3], A. Olmedo-Juarez[4], J. Vazquez-Armijo[2], and S. Rebollar-Rebollar[2], *[1]Universidad Autonoma de San Luis Potosi, San Luis Potosi, Mexico, [2]Universidad Autonoma del Estado del Mexico, Temascaltepec, Mexico, [3]Universidad Autonoma de Baja California, Mexicali, Mexico, [4]Centro Nacional de Investigacion Disciplinaria en Parasitologia Veterinaria, INIFAP, Cuernavaca, Mexico.*

Twenty-four Dorper × Pelibuey ram lambs initially weighing 30.73 ± 1.04 kg were used in a randomized complete block experimental design to evaluate effects of different levels of zilpaterol hydrochloride (ZH; 0, 0.1, 0.2, and 0.3 mg/kg BW) on feedlot performance and carcass characteristics of ram lambs. After a 30-d feeding period, all lambs were harvested. All data collected were analyzed with analysis of variance using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). Means were separated with a PDIFF STDERR statement. Significance was declared at $P \leq 0.05$ and tendency when $0.05 < P \leq 0.10$. The doses of ZH improved ($P < 0.05$) feed intake, water consumption, ADG, and G:F. Carcass characteristics as HCW, CCW, KPH, dressing %, LM area, LM pH at 24 h, leg perimeter were not affected ($P > 0.05$) by ZH level supplementation. Inclusion of different levels of ZH in feedlot finishing diets improve feedlot performance; without affecting carcass characteristics.

Key Words: β-adrenergic agonist, carcass characteristics, feedlot sheep, growth rate

1686 Performance of lambs fed high concentrate-diets containing monensin or narasin.

D. M. Polizel[*1], M. F. Westphalen[2], R. G. Silva[1], A. A. Miszura[1], M. H. Santos[1], M. V. C. Ferraz Junior[1], M. V. Biehl[2], A. V. Pires[1], and I. Susin[2], *[1]FMVZ/University of Sao Paulo, Pirassununga, Brazil, [2]ESALQ/University of Sao Paulo, Piracicaba, Brazil.*

The objective in this trial was to determine the effect of ionophore inclusion (monensin or doses of narasin) on performance of lambs fed high-concentrate diet. Forty-five (30 males and 15 females) Dorper x Santa Inês lambs were assigned to a randomized complete block design, defined by age (90.5 ± 0.8 d old), sex, and initial BW (25.3 ± 0.5 kg). Lambs were housed in "tie stalls" and fed a TMR composed of 90% concentrate. Diets were isonitrogenous (15.5% CP, DM basis) and treatments were Control (without ionophore), monensin (25 mg/kg DM), and three doses of narasin (5, 10 or 15 mg/kg DM), corresponding to the experimental diets C, M, N5, N10, and N15, respectively. Feed ingredients (ground corn, ground hay, soybean meal, limestone, mineral salt, urea, and ammonium chloride) and ionophores were mixed using a horizontal mixer. The experiment lasted 56 d and lambs were weighted after a fasting period of 14 h on Days 0, 14, 28, 42, and 56. Average daily gain (ADG), dry matter intake (DMI), and feed efficiency (FE) were determined in each period. Data were analyzed using the MIXED procedure (SAS Inst. Inc.). There were two contrasts previously defined (I: control vs. ionophores; II: monensin vs. narasin). The effects of levels of narasin (control, N5, N10, and N15) were evaluated using linear and quadratic orthogonal contrasts. The effects were considered significant when $P < 0.10$. Inclusion of ionophores did not affect BW 14d after start receiving the experimental diets. However, on d 28 animals fed the diets containing narasin (5, 10, or 15 mg/kg) were heavier ($P = 0.01$) than those fed monensin (C: 32.7; M: 31.3; N5: 32.2; N10: 33.2; N15: 33.2 kg). On d 42 there was an increased linear effect ($P = 0.04$) for levels of narasin and animals fed monensin were lighter than animals fed narasin (C: 36.8; M: 36.1; N5: 36.1; N10: 38.0; N15: 37.8 kg; $P = 0.07$). There was an increased linear effect ($P = 0.02$) on final BW (d56) and animals fed narasin were heavier than those fed monensin (C: 40.9; M: 40.2; N5: 40.5; N10: 42.4; N15: 42.5 kg; $P = 0.02$). There was no effect ($P = 0.40$) on DMI (1.09 ± 0.04 kg/d). Narasin increased ($P = 0.04$) feed efficiency (C: 0.25; M: 0.25; N5: 0.25 N10: 0.26; N15: 0.27). Narasin improved lamb performance compared to a monensin dosage of 25 mg/kg.

Key Words: feed efficiency, ionophore, narasin.

1687 Effects of high concentrations of crude glycerin on blood parameters of energy metabolism in finishing lambs.

E. H. C. B. van Cleef[*1,2], M. T. C. Almeida[1,2], H. L. Perez[1,2], V. B. Carvalho[1], J. R. Paschoaloto[1], E. S. Castro Filho[1], and J. M. B. Ezequiel[1], *[1]São Paulo State University, Jaboticabal, Brazil, [2]FAPESP, São Paulo, Brazil.*

Forty crossbred (Santa Ines × Dorper) ram lambs (21.7 ± 2.7 kg BW, 90 d old) were used to evaluate the effects of high concentrations of crude glycerin on some blood parameters of energy metabolism. Lambs were assigned to a complete randomized block design (initial BW) and fed four isonitrogenous (18.4% CP) and isocaloric (2.7 Kcal ME/kg) experimental diets containing corn silage (40%), and concentrate (60%) composed of soybean hulls, soybean meal, mineral premix, and crude glycerin replacing 0 (G0), 10 (G10), 20 (G20), or 30% (G30) corn cracked grain, on a DM basis. Crude glycerin totally replaced corn grain in G30 and it was composed of 83% glycerol, 95% DM, 6% salt, and less than

0.01% methanol. The feedlot period lasted 66 d (21 d adaptation [three step-up diets] and 45 d finishing period). Animals were fed twice daily (0700 and 1900 h). Blood samples were collected from the jugular by venipuncture on the d 0 and d 45 of finishing period (day effect), before morning feeding and 4 h after feeding (prandial effect). Serum total cholesterol (TC), serum triglycerides (TG), blood glucose (BG), serum HDL-cholesterol (HDL), serum LDL-cholesterol (LDL), and serum VLDL-cholesterol (VLDL) were evaluated. Data were analyzed using a linear mixed model with Kenward-Rogers adjustment for calculation of degrees of freedom. Whenever the F-test was significant, contrast analyses were performed and differences of least squares means were determined using the pairwise Tukey–Kramer multiple test. Crude glycerin did not change BG concentrations, but a day effect was observed ($P < 0.001$) for this variable. A linear decrease in TC was observed with increasing concentrations of crude glycerin in the diets ($P = 0.02$). A prandial effect was observed for TG ($P = 0.001$) and for VLDL ($P < 0.0001$), while HDL concentrations linearly decreased ($P < 0.001$), and showed a day effect ($P < 0.001$) and a prandial effect ($P = 0.02$). The concentration of LDL linearly decreased with crude glycerin inclusion, and showed a significant day effect ($P < 0.001$). The average values (mg/dL) observed for treatments G0, G10, G20, and G30 were, respectively: TC = 41.0, 41.2, 36.4, 36.1; TG = 12.5, 13.2, 12.1, 15.3; BG = 83.6, 85.7, 82.1, 87.2; HDL = 13.3, 12.7, 11.4, 10.7; LDL = 25.2, 22.9, 23.8, 22.3; VLDL = 2.5, 2.6, 2.4, 3.1. Feeding crossbred finishing lambs up to 30% crude glycerin can decrease the concentration of some blood parameters of energy metabolism, such as total cholesterol, HDL and LDL.

Key Words: blood, glycerol, sheep

1688 Effect of diets rich in starch or digestible fiber on glucose metabolism of ewes and goats in mid-lactation. M. F. Lunesu*[1], G. C. Bomboi[2], M. Decandia[3], G. Molle[3], G. Gaspa[1], A. S. Atzori[1], L. S. Knupp[4], and A. Cannas[1], *[1]Dipartimento di Agraria, University of Sassari, Sassari, Italy, [2]Dipartimento di Medicina Veterinaria, University of Sassari, Sassari, Italy, [3]Dipartimento per la Ricerca nelle Produzioni Animali, Agris Sardegna, Sassari, Italy, [4]Departamento de Zootecnia, Universidade Federal de Vicosa, Vicosa, Brazil.*

This study evaluated if dietary carbohydrate type (starch vs. fiber) can modulate glucose metabolism in ewes and goats in mid-lactation. At c.a. 95 d in milk (DIM), 20 ewes and 20 goats were subdivided into two groups. The first one (10 sheep and 10 goats) received a high-starch diet (HS; 24.1% starch, 36.4% NDF, 15.4% CP, DM basis) and the other (10 sheep and 10 goats) a highly-digestible fiber diet (HF; 10.5% starch, 46.8% NDF, 15.4% CP, DM basis), obtained by replacing corn and barley meal with soybean hulls. At 153 DIM, glucose tolerance tests (GTT) were performed on 10 sheep and 10 goats selected from each group. Diet was withdrawn in the afternoon of the day before the test. One mL of a 50% glucose solution per kg of BW was injected into the jugular vein of each animal. Blood samples were collected 15 min before and at 5, 10, 15, 30, 45, and 90 min after glucose injection. At 165 DIM, all the animals were subjected to blood postprandial sampling at 30, 60, 120, 180, and 240 min post feeding. Blood glucose was assayed by an enzymatic-colorimetric method. Blood glucose concentration data were analyzed by the PROC MIXED of SAS with repeated measurements. For GTT the incremental area under the curve (AUC), the fractional turnover rate (k), and the half-life were calculated and data were analyzed with a two-factor (diet within species and species) ANOVA. The −15-min glucose concentration was higher in sheep than goats (73.5 vs. 53.6 mg/dl; $P < 0.005$) but was not affected by diet. During the GTT, the mean blood glucose concentration was greater in sheep than goats (228.1 vs. 209.2 mg/dl; $P < 0.05$) and in HS goats than HF goats (217.9 vs. 198.6 mg/dl $P < 0.01$), whereas it did not differ between HS sheep and HF sheep. The values of AUC, k and half-life were not affected by species or diet. Regarding the postprandial sampling, mean blood glucose concentration was higher in sheep than goats (60.3 vs. 50.3 mg/dl; $P < 0.001$) and in HS goats than HF goats (52.2 vs. 48.1 mg/dl; $P < 0.001$), whereas it did not differ between HS sheep and HF sheep. In conclusion, it seems that the source of carbohydrates modulated blood glucose metabolism in goats but not in sheep.

Key Words: fiber, glycemia, goats, sheep, starch

1689 Reproductive parameters of Dorper ewes in south Texas. E. C. Taylor*[1], J. A. Reyes[1], M. R. Garcia[1], and R. Stanko[2], *[1]Texas A&M University-Kingsville, Kingsville, [2]Texas A&M University-Kingsville, Texas A&M AgriLife Research, Kingsville.*

The overall objectives of two studies were to determine reproductive characteristics of Dorper ewes in south Texas and their potential use in accelerated mating. The initial study characterized month of puberty and subsequent anestrus in 16 spring-born, pre-pubertal ewe lambs (34.9 ± 0.43 kg). Lambs were monitored over a 13-mo period (September to October). Lambs were housed together and fed commercial pellets (2% BW, DM basis) and ad libitum hay. The second study determined the effect of a 9-d controlled vaginal insert (CIDR; 0.3 g progesterone) administered on d 0 of a 30-d anestrus breeding season (June). Thirteen non-lactating, postpartum (90 ± 4.5 d) ewes of second parity were randomly allocated into one of two treatment groups. All ewes were bled weekly for serum progesterone analysis to confirm anestrous, ovulation, and pregnancy. Ewes were continuously exposed to a fertile ram during the 30-d anestrous breeding season. Six ewes received a CIDR on d 0 to 9 (CT) and were housed separately and away from seven control ewes (CON). Two additional ewes were

housed in isolation and served as anestrous sentinels. Rams were alternated between CT and CON on d 16. Cumulative percentage of spring-born ewe lambs attaining puberty by September and December was 25% and 100%, respectively. Lambs had a mean BW of 39.1 ± 0.72 kg at 100% pubertal. During January, 62.5% of ewe lambs became anestrous and all were in anestrous by the seventh day of March. Resumption of estrous cycles began in May (6.25%) and continued through September (100%). Postpartum, CT ewes had a reduced ($P <$ 0.02) ram introduction to lambing interval (152.8 ± 3.2 d) as compared to CON ewes (165.7 ± 3.0 d). Ram introduction to lambing interval for CT ewes which conceived first service was further reduced as compared to CON ewes conceiving at first service (149.3 ± 1.3 d vs. 160.7 ± 1.5 d; $P < 0.01$). However, CT and CON ewes had similar conception rate (83.3% vs. 87.7%), days to conception (5.0 ± 4.5 vs. 14.7 ± 4.1), and lambs per ewe (1.4 ± 0.3 vs. 2.0 ± 0.3). We conclude that Dorper ewe lambs are sexually mature during the first fall-breeding season and enter anestrus as yearlings (March to May). Ram exposure alone is as effective as progesterone co-treatment to induce breeding of 90-d, postpartum Dorper ewes during the late anestrus season.

Key Words: anestrus, CIDR, Dorper

1690 Comparison of linear model and artificial neural network using antler beam diameter and beam length of white-tailed deer (*Odocoileus virginianus*).

S. O. Peters[*1], M. Sinecen[2], G. R. Gallagher[3], L. A. Pebworth[3], J. S. Hatfield[3], and K. Kizilkaya[2], *[1]Department of Animal Science, Berry College, Mount Berry, GA, [2]Adnan Menderes University, Aydin, Turkey, [3]Berry College, Mount Berry, GA.*

A thirty-one-year (1977–2008) record of field-dressed weight (FDW), antler diameter (AD), and beam length (BL) of male white-tailed deer (WTD) harvested at Berry College Wildlife Management Area (WMA), Mount Berry, Georgia, was analyzed using linear model and Artificial Neural Network (ANN). A total of 3564 male WTD were harvested at the WMA during the period under study. Of the total deer harvested, 63.95% were 1.5 yr old and 22.42%, 8.64%, 3.87%, and 0.67% for 2.5, 3.5, 4.5, and 5.5 yr old, respectively. The mean FDW of deer was 32.33 kg. Linear model and ANN were used to predict antler diameter and beam length of WTD. Linear model used to analyze AD and BL of deer includes the factors of year and month of harvest, and the covariates of age and FDW. For ANN, the two-layer feed-forward perceptron, also called single hidden layer feed-forward neural network was used to estimate AD and BL of deer. In the training phase of ANN, year, month of harvest, age, and FDW were linearly combined with a vector of weights. The resulting linear score was then transformed using an activation function to produce the output of the single hidden neuron. The estimates of correlation coefficients between FDW and AD, FDW and BL, and AD and BL were 0.75, 0.77, and 0.85 ($P < 0.01$), respectively. The estimates of regression coefficients indicated that FDW of the deer affected ($P < 0.05$) AD (0.92 ± .03) and BL (0.74 ± .02). Correlation coefficients between observed and predicted values of AD and BL from linear model are 0.81 and 0.83. However, ANN results in higher correlation coefficients (0.94 and 0.86) between observed and predicted values of AD and BL than linear model. This result demonstrates the utility of ANN in multidimensional data analysis.

Key Words: linear model, neural network, white-tailed deer

1691 Induction of sexual activity in Dorper ewes: Effect of two intramuscular doses of progesterone vs. progesterone vaginal sponges + eCG.

J. Z. Ordonez[*1], O. Ángel-García[1], E. Carrillo[2], J. Luna-Orozco[3], C. A. Meza-Herrera[4], R. Rodriguez[1], and F. G. Véliz-Deras[1], *[1]Universidad Autónoma Agraria Antonio Narro, Torreón, Mexico, [2]Instituto Tecnologico de Torreon, Torreón, Mexico, [3]Centro de Bachillerato Tecnologico Agropecuario N. 1, Torreón, Mexico, [4]Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Mexico.*

The use of intravaginal sponges is a high-cost treatment which requires trained personnel while can generate reproductive problems in the animals. Therefore, the use of intramuscular (im) progesterone (P4) could be an alternative to avoid such a scenario. The reproductive outcomes of Dorper anestrus ewes using different im doses of P4 regarding the use of P4-intravaginal sponges + eCG, was evaluated. The study was carried-out in northern Mexico during the anestrus season (26°N, February). Anestrus ewes (n = 52, 3–5 yr old) similar body weight (BW) and body condition score (BCS) were subjected to two transrectal ultrasound screenings on Days 14 and 7 prior to the onset of the experimental treatments to confirm the absence of functional corpora lutea. Thereafter, ewes were randomly distributed to three experimental groups: 1) IMG1 (n = 21; 41.7 ± 4.0 kg BW, 2.1 ± 0.2 BCS) receiving 30 mg-im of P4 on Days 5 and 2 prior to eCG administration, 2) IMG2 (n = 17; 41 ± 7 kg BW, 2.0 ± 0.6 BCS) receiving 20 mg-im of P4 on Days 5 and 2 prior to eCG application, and 3) IVS (n = 14; 41.5 ± 3.0 kg BW, 2.0 ± 0.2 BCS), receiving an intravaginal sponge Chronogest® during 6 d and removed 24 h prior to eCG application (d 0). The three groups received a single dose of 300 IU eCG im on d 0. Estrus activity was recorded after exposure to one sexually active male during 15 min twice per day (0800 and 1800 h) × 5 d. On Day 10, the percentage of ovulations across treatments was determined by detecting the presence of corpora lutea throughout ultrasonographic scanning (USS). Then, on Day 45, another transrectal-USS was performed to determine pregnancy rate. Estrus activity,

ovarian activity and pregnancy were evaluated among treatments thru X^2considering the daily and cumulative proportions of these variables (MYSTAT 12 X2 program). The percentage of estrus were different ($P < 0.05$) between all the groups (43% IMG1, 35% IMG2, and 100% IVS). The largest ovulation percentage and gestation rate ($P < 0.05$) were observed in IVS group (93% and 79%, respectively), and similar ($P > 0.05$) for both IMG groups (62% IMG1 and 59% IMG2 for ovulation percentage, and 24% for gestation rate in both groups). Results demonstrated a better reproductive performance of previously anestrus Dorper ewes treated with intravaginal P4-sponges + eCG with respect to those receiving the im administration of P4. In conclusion, the synchronization protocol using two injections of progesterone had less sexual response compared to the use of vaginal sponges.

Key Words: anestrus, ewes, progesterone

1692 Effect of supplementation with antioxidants in goats and their newborns evaluated during the transition period.

B. Barcelos*[1], F. R. B. Ribeiro[2], S. K. Lewis[2], W. B. Foxworth[2], L. C. Nuti[2], G. R. Newton[2], V. F. P. Rícspoli[3], L. B. Correa[1], and A. Saran Netto[1], *[1]School of Animal Science and Food Engineering, University of Sao Paulo, Pirassununga, Brazil, [2]Prairie View A&M University, Prairie View, TX, [3]School of Veterinary Medicine and Animal Science, University of Sao Paulo, Sao Paulo, Brazil.*

The objective of this study was to evaluate hematological parameters of dam and newborn goats of the does that were supplemented with Selenium and Vitamin E. Also, the amount of Selenium and Vitamin E of the serum and milk was measured for evaluation of amount that was transferred from dam to newborns. Fifteen Saanen does that were supplemented starting on the fourth month of pregnancy until the end of the experiment and twenty-one kids from these does were used. The does and the newborns were divided into three groups based on the dam treatments: Control and Control milk (base diet with 50% forage and 50% concentrate); Se and Se milk (2.5 mg of Se/Kg Dm added to the diet) and Sev and Sev milk (2.5 mg of Se/Kg DM and 1000 IU/day of Vitamin E/kg DM), for does and kids, respectively. The kids started receiving ad libitum access to feed from 7 d postpartum. The experiment continued for 56 d. Blood samples were collected from dam before the supplementation, during the partum and 2, 7, 14, and 28 d postpartum. Milk was collected during partum and 28 d postpartum. Blood samples were collected from newborns before ingesting of colostrum and 2, 7, 14, and 28 d postpartum. Blood samples were analyzed for Selenium, Vitamim E, Erythrocyte (red blood cell- RBC- 10^6/mm^3), Hemoglobin (Hb-g/dL), Hematocrit (Hct-%), Mean Corpuscular Volume (MCV-μ^3), Mean Corpuscular Hemoglobin (MCH-pg), Mean Corpuscular Hemoglobin Concentration (MCHC-%), Red Cell Distribution Width (RDW-%). Milk samples were analyzed for Selenium and Vitamin E. Kids were weighed at birth and 7, 14, 21, and 28 after birth. The experimental design was a complete randomized design with repeated measures, with replications. Data were analyzed by analysis of variance and the means were compared by Tukey test ($P \leq 0.05$). There was no significant effect of treatment ($P > 0.05$) for all hematological parameters, Vitamin E for dam and newborns nor for weight of the kids. For Se the results showed significant increase ($P < 0.05$) of the transfer from dam to the kids with values of 0.20, 0.17, and 0.08 mg/kg of dam serum; 0.49, 0.25, and 0.062 mg/kg of dam milk and 0.15, 0.18, and 0.057 mg/kg of kids serum of treatments Sev, Se, and control, respectively

Key Words: birth, nutrition, selenium, vitamin E

1693 Effects of feeding varying levels of deoiled distillers dried grains with solubles on fatty acid composition of subcutaneous adipose tissue in meat goats.

K. C. Camareno*[1], A. T. Sukumaran[1], J. Scott[2], N. Gurung[2], T. T. N. Dinh[1], and D. D. Burnett[1], *[1]Mississippi State University, Department of Animal and Dairy Sciences, Mississippi State, [2]Tuskegee University, Tuskegee, AL.*

Deoiled distillers dried grains with solubles (D-DDGS), a by-product of the fuel ethanol industry, have increasingly been used as ingredients in livestock feed. These D-DDGSs have a reduced fat content and increased protein content making them attractive ingredients, however, feeding D-DDGS can affect carcass composition. The objective of this study was to investigate the effect of D-DDGS on fatty acid (FA) composition of subcutaneous (s.c.) adipose tissues in goats. Four experimental diets containing 50% Bermuda grass hay plus 50% concentrate mix containing 0 (CON), 10, 20, or 30% D-DDGS (D-DDGS10, D-DDGS20, or D-DDGS30, respectively) in the diet were randomly assigned to twenty-four castrated male Kiko goats ($n = 6$ per treatment). The goats were slaughtered at 84 d and s.c. fat was collected from directly over the sternum of the carcass, and were then pulverized, and stored at −80°C. The fat samples were directly derivatized for fatty acid identification and quantification on a gas chromatography system (Agilent Technologies, Santa Clara, CA) using internal standard calibration. Fatty acid methyl ester concentrations were used to calculate fatty acid concentrations and percentages. Statistical analysis was performed using the GLIMMIX procedure of SAS 9.4 (SAS Institute Inc., Cary, NC.) and statistical significance was determined at $P \leq 0.05$. D-DDGS did not affect total FA content ($P \leq 0.395$) of adipose tissues, however, their inclusion changed concentrations and percentages of important FA ($P < 0.038$). Concentrations of 18:1 t, 18:2 n6c, 20:1 n9c, and polyunsaturated (PUFA) of s.c. fat from D-DDGS30 goat were 16.26, 16.29, 9.35, and 19.74 mg/g, respectively, which were greater than those from D-DDGS10 and CON

goats ($P < 0.026$). Because of the similar total FA content, the percentages of 18:1 t, 18:2 n6c, 20:1 n9c, and PUFA (2.12, 2.11, 1.25, and 2.56%, respectively) were also greater in s.c. fat of D-DDGS30 goats than those of D-DDGS10 and CON goats. Although concentration of 20:4 n6c was similar among CON and D-DDGS treatments ($P = 0.408$), its percentage was greater in s.c. fat of D-DDGS30 goats than that of CON goats ($P = 0.018$). These data indicate that feeding D-DDGS30 increased the percentages of unsaturated fatty acids in the s.c. depot of the meat goats in the current study and may be used to alter carcass fat composition.

Key Words: adipose tissue, distillers, goat

1694 Dietary effects of grass hay and alfalfa hay on the digestive microbiome of the alpaca. C. Carroll*, K. D. Olsen, J. M. Chaston, and T. F. Robinson, *Brigham Young University, Provo, UT.*

The purpose of this study is to identify the effects of a grass hay diet (GH) and an alfalfa hay diet (AH) on the digestive microbiome of the alpaca. Ten adult male alpacas were randomly selected for the study and divided into two groups; each group was fed a different diet (GH or AH) for thirty days. Both groups were fed once daily ad libitum. At the end of the feeding period, digesta samples were taken from the first stomach compartment (C1), duodenum, jejunum, ileum, cecum, and large intestine of each alpaca. Bacterial DNA was isolated from each sample and sequenced to identify operational taxonomic units, or bacterial taxa. All data were analyzed using QIIME software. Comparisons of the microbial composition of samples from grass-fed and alfalfa-fed alpacas at each digestive tract sample site showed that the microbiome at any single body site differed with diet ($P < 0.05$). Among the differences noted in the microbiomes of alpacas fed AH include a shift toward a higher proportion of phylum *Euryarchaeota* and a lower proportion of phylum *Actinobacteria* in the duodenum, ileum, and jejunum; and a higher proportion of phylum *Euryarchaeota* with a lower proportion of phylum *Bacteroidetes* in the cecum and large intestine. Analyses of the microbial composition of each body site revealed the presence of three different microbiomes per diet treatment group ($P < 0.05$); that of C1, the small intestine (duodenum, jejunum, and ileum), and the distal intestine (cecum and large intestine). The predominant phyla were *Firmicutes* (all sites), *Bacteroidetes* (C1, cecum, and large intestine), *Actinobacteria* (duodenum, jejunum, and ileum), and *Euryarchaeota* (duodenum, jejunum, and ileum). These data demonstrate that, in alpacas, forage type does affect the predominant microbes and though taxa are similar between tract sites, there are shifts in the populations.

Key Words: alpaca, forage, microbiome

1695 Sunflower and palm cake as supplemental fatty acid sources to feedlot lambs. J. G. de Souza[*1,2], P. G. Cirqueira[2], J. P. I. S. Monnerat[3], and C. V. D. M. Ribeiro[2], *[1]Penn State University, University Park, [2]Federal University of Bahia, Salvador, Brazil, [3]Federal University of Pernambuco Rural, Recife, Brazil.*

The sunflower cake and palm cake are two by-products of the biodiesel industry with different profiles of fatty acids (FA). The sunflower cake has 60% of unsaturated FA and the palm cake is rich in medium-chain fatty acids (MCFA). Feeding both sources to ruminants may increase FA digestibility and improve energy intake. Therefore, the objective of this study was to evaluate the interaction of the dietary supplementation of sunflower cake and palm cake on DMI and blood parameters of feedlot lambs. Twenty non-castrated lambs [23.81 ± 4.3 kg] were individually penned and used in a completely randomized design. The animals were fed 40% Tifton hay plus 60% concentrate, with 5% of supplemental FA (% DM). The treatment diets consisted of the contribution of each fat source to the total FA supplementation, as follows: 1) 100% of supplemental FA from sunflower cake; 2) 66% from sunflower cake and 33% from palm cake; 3) 33% from sunflower cake and 66% from palm cake; and 4) 100% of supplemental FA from palm cake. The collection period started on the 35th d of the feedlot period and lasted for 5 d, when the DMI was determined. Blood parameters were taken on the 36th d at 0, 3, 6, and 9 h after the morning feeding. Data were compared by orthogonal polynomial contrasts to determine linear and quadratic effects of the substitution of sunflower cake by palm cake, and significance was declared at 5%. No effect was observed for the daily average serum concentrations of AST (199.80, 197.51, 196.78, 185.56 UI/L), ALT (36.07, 45.21, 41.96, 38.09 UI/L), urea (39.31, 43.55, 48.96, 47.11 mg/dL), triglycerides (18.35, 18.53, 16.16, 17.05 mg/L), and NEFA (1.01, 1.15, 1.17, 1.31 mmol/L) as sunflower cake was substituted by palm cake. A treatment by time interaction ($P < 0.05$) was observed only for triglycerides and NEFA. There was a linear effect ($P < 0.05$) for DMI (1.266, 1.017, 1.177, 0.902 kg/d) and ether extract intake (0.09, 0.05, 0.05, 0.03 kg/d) as sunflower cake was substituted by palm cake. In conclusion, replacement of sunflower cake by palm cake decrease DMI without affecting blood metabolites.

Key Words: blood parameters, sheep, supplemental fatty acids

1696 Ground chevon as influenced by different concentrations of rosemary extracts. M. Y. Muñoz[1], J. H. Lee[2], C. D. Santos[1], X. Ma[2], A. Discua[*2], and B. Kouakou[2], *[1]Universidad Nacional de Agricultura, Catacamas, Honduras, [2]Fort Valley State University, Fort Valley, GA.*

Rosemary extracts (RE), containing high concentrations of polyphenol compounds that have antioxidant and antimicrobial properties, which could increase the shelf-life of fresh meat. Numerous studies have been conducted to enhance the quality of fresh meat from ruminants by feeding dietary supplements containing high amounts of polyphenol compounds. However, limited information is available on the effectiveness of RE on shelf-life of ground chevon (goat meat). The aim of this study was to determine the effect of different concentrations of RE on the physicochemical and microbial properties of ground chevon stored under retail display conditions. Ground chevon was prepared with shoulder and leg cuts from Kiko crossbred (8 mo old, BW = 39.7 ± 2.55 kg) male goats, treated with four different concentrations of RE (0, 0.02, 0.1, or 0.25%). Each batch of RE treated ground chevon (3/RE; 8.0 kg/batch) was placed on high barrier polypropylene trays and sealed with lidding films (30 trays/batch), and stored in a display case at 4°C over a 15-d period. Six packages (250 g/package) from each RE treatment (30 packages/RE) were analyzed for color properties (CIE L*a*b* values), lipid stabilities (thiobarbituric acid-reactive substances, TBARS), and bacterial counts (total aerobic bacteria, coliforms, *Escherichia coli*, yeasts, and molds) after 1, 4, 8, 12, 15 d of storage. All data were analyzed as a randomized block design, blocked by batch, with a 4 × 5 factorial treatment arrangement using the MIXED procedure of SAS. Ground chevon that contained 0.1 or 0.25% RE had higher ($P < 0.01$) CIE L*(lightness) values than that contained 0% RE. The CIE a* (redness) and b* (yellowness) values of ground chevon significantly decreased after 12-d of storage. Ground chevon containing 0.1 or 0.25% RE had lower ($P < 0.01$) total aerobic bacteria than that containing 0.02 or 0% RE. Furthermore, total aerobic bacteria counts increased ($P < 0.01$; 2.32 to 4.39 ± 0.073 log CFU/g) with storage time in ground chevon containing all different concentrations of RE. This trend was also found in the yeast and mold counts in the ground chevon. The TBARS values varied for all RE treated groups and remained lower than 1.0 mg MAD/kg over the storage period. The results indicated that higher concentrations of rosemary extracts in ground chevon might inhibit the growth of aerobic bacteria. However, the lipid stability of ground chevon was not enhanced by the inclusion of rosemary extracts.

Key Words: ground chevon, rosemary extracts, shelf-life

1697 Post-estrus GnRH administration does not improve fertility in Alpine goats in northern Mexico. Z. Santos[*1], C. A. Meza-Herrera[2], J. M. Guillen[1], F. Arellano[1], R. Rodriguez[1], and F. G. Véliz-Deras[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreon, Mexico, [2]Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Mexico.*

The aim of this study was to evaluate the possible effect of GnRH administration during the implantation process in Alpine goats in northern Mexico (26° 23 'N). The study included sexually active bucks ($n = 4$) and multiparous anestrus Alpine goats ($n = 26$). Early in May, goats with homogeneous body condition score (3.0 ± 0.11) were treated with 20 mg of progesterone i.m (d0) and 24 h later (d1) received 100 IU of eCG. Thereafter, on d-13 post-estrus, goats were randomly distributed into the following experimental groups: 1) the GG group ($n = 14$) received 4 mg of GnRH i.m. (synthetic analog) and 2) the GC ($n = 12$) served as a control, receiving saline. Estrus activity was confirmed every 12 h for 5 min using an aproned male from d 0 to d 15. Once in standing estrus, goats were bred by a sexually active male. Then, on d45, a transrectal ultrasonographic scanning (USS; HS-2000, Honda Electronics Co, LTD) was performed to determine pregnancy rate. The response variables estrus response (ER), ovulation (OR) and pregnancy (PR) rates were analyzed by X^2 and estrus latency (EL) with a t-student test (SYSTAT 12, Evanston, IL, USA). None of the response variables EL, ER, OR, and PR differed ($P > 0.05$) between experimental groups. Administration of GnRH on d-13 post-estrus did not improved fertility in Alpine goats from northern Mexico.

Key Words: GnRH, progesterone, synchronization

Table 1699.

Table 1. Reproductive performance of anovulatory goats exposed to males previously treated with estrogenized females either changed every 12 h (GR) or not-changed (GN) and males with control saline-treated females (GC) under the anestrus season (Feb-Mar) and natural photoperiod at 26°N

	GR	GN	GC
Goats (n)	(24)	(24)	(24)

1698 Quality of chevon chops as influenced by different packaging atmospheres. C. D. Santos[1], J. H. Lee[2], M. Y. Muñoz[1], A. Discua[2], X. Ma[2], D. Kafle[*2], and B. Kouakou[2], *[1]Universidad Nacional de Agricultura, Catacamas, Honduras, [2]Fort Valley State University, Fort Valley, GA.*

Vacuum and modified atmosphere packaging (MAP) techniques are used to extend the display life of fresh meat. The aim of this work was to evaluate the microbial and physicochemical properties of goat meat (chevon) cuts packaged under different atmospheres. Chevon chops from Kiko crossbred (8 mo. old, BW = 39.7 ± 2.55 kg) male goats were packaged under high carbon dioxide (CO_2; 80%), nitrogen (N_2; 80%), vacuum (VAC), or ambient air (AIR) atmospheres (30 packages/atmosphere) using an MAP tray sealer. All treated packages were stored at 4°C under 1700 lux of fluorescent lighting for 15 d. Six packages (4 chops/package) from each packaging treatment (6 packages/d) were analyzed for color properties (CIE L*a*b* values), lipid stabilities (thiobarbituric acid-reactive substances, TBARS), and bacterial counts (total aerobic bacteria, coliforms, *Escherichia coli*, yeasts, and molds) after 1, 4, 8, 12, 15-d of storage. All data were analyzed as a completely randomized design with a 4 × 5 factorial treatment arrangement using MIXED procedure of SAS. Chevon chops from high N_2 packages had higher ($P < 0.01$) CIE a*(redness) and lower b* (yellowness) values than those from VAC packages. The CIE a* and b* values of chevon chops significantly decreased with storage time; however, the CIE L* (lightness) values increased ($P < 0.01$) with storage time with some variations. No significant differences were found in the bacterial counts in chevon cuts from vacuum and high-CO_2 and-N_2 packages. Coliforms (1.26 to 5.11 ± 0.158 log CFU/g), *E. coli* (1.26 to 5.11 ± 0.073 log CFU/g) yeasts (1.02 to 3.06 ± 0.085 log CFU/g) and molds (1.72 to 5.55 ± 0.135 log CFU/g), and total aerobic bacterial (2.08 to 5.42 ± 0.243 log CFU/g) counts increased ($P < 0.01$) with storage time in chevon chops from all packaging treatments. The TBARS values of chevon chops varied for all packaging treatments and increased ($P < 0.01$) as the storage time progressed (0.13 to 0.31 ± 0.026 mg MAD/kg). The results indicated that high nitrogen atmosphere packaging might improve the color property of fresh chevon cuts. However, neither vacuum nor modified atmosphere packaging methods might significantly inhibit the lipid oxidation and microbial growth in fresh chevon cuts during 15 d storage.

Key Words: chevon chops, packaging atmospheres, shelf-life

1699 Reproductive performance of anovulatory goats stimulated by bucks previously exposed to estrogenized does. J. M. Guillen[*1], C. A. Meza-Herrera[2], Z. Santos[1], and F. G. Véliz-Deras[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreon, Mexico, [2]Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Mexico.*

The aim of this study was to evaluate the effectiveness to induce estrus response of cross-mix dairy anovulatory goats by the stimulus of either sexually active bucks or estrogenized does. Bucks (n = 12) were randomly allotted to three experimental groups (n = 4 per group): A) (GR) males in contact with 2 estrogenized females (EF) for 12 h, and then changed for 2 different EF for 12 h: B) (GN), males were exposed to 2 EF for 12 h, separated 1 h and returning the same goats for 12 h, C) (GC) males were exposed 12 h to 2 anestrous does treated with saline, separated 1 h and returning the same goats for 12 h. While the EF received 2 mg of estradiol cyprionate × 3 d, control females received 1 mL of saline × 3 d. On May 15, 72 cross-mix dairy multiparous females were distributed in 3 homogeneous groups (24 goats each) according to body condition (3.0 ± 0.11 units), and exposed to the previously treated males (GR, GN, GC). Females goats were checked every 12 h × 5 min with a male; on estrus manifestation, females were bred. On Day 45, a transrectal ultrasound scanning was performed to determine pregnancy rate. The estrus response, ovulation, and pregnancy rates were analyzed by X^2while estrus latency considered a t-student test (SYSTAT 12, Evanston, IL, USA). The reproductive response of treated goats is presented in Table 1. Results demonstrate that induction of males with estrogenized females is an effective method to induce out-of-season reproductive function in northern Mexico.

Key Words: buck effect, estrogenized goats, estrus induction

1700 Effect of dried distillers grains on diet digestibility, body weight gain, and carcass composition of lambs. J. R. Bárcena-Gama[*1], K. R. Curzaynz-Leyva[1], C. Sánchez del Real[2], J. C. Escobar-España[1], M. I. Rivas-Martínez[1], E. A. Santillán-Gómez[1], and S. S. Gonzalez-Muñoz[3], *[1]Colegio de Postgraduados, Montecillo Texcoco, Mexico, [2]Universidad Autónoma Chapingo, Chapingo Texcoco, Mexico, [3]Colegio de Postgraduados, Montecillo Estado de Mexico, Mexico.*

Dried corn distillers grains with solubles (DDGS) can partially replace grains and forages in diets for ruminants. Therefore, the objective of this study was to evaluate the effect of diets with or without DDGS on DM, NDF and ADF digestibility, DM intake, ADG, and carcass composition of lambs. The experimental design was completely randomized with four treatments: 1) control, 0.0% DDGS, 2) 15% DDGS, 3) 30% DDGS, and 4) 45% DDGS. Thirty-two Criollo lambs (28.56 ± 2.19 kg initial BW) housed in individual metabolic cages were used in this experiment during 60 d (n = 8). Data were analyzed with PROC MIXED of SAS and treatments means were compared using Tukey test ($P < 0.05$). As compared to control, DDGS increased DM intake (1.7 kg vs. 1.4 kg control), ADG only for lambs fed 15% DDGS (288 g d^{-1} vs. 238 g d^{-1}control), and decreased DM digestibility (7.0%) in lambs fed 45% DDGS ($P < 0.05$). Lambs fed diets with DDGS showed higher weight (8.0%) and yield (2.0%) of hot and cold carcass, but rib eye area was lower for lambs fed 15% DDGS ($P < 0.05$), and no differences were found for back fat ($P > 0.05$). Therefore, the inclusion of DDGS in diets for lambs increased DM intake and improved carcass weight and yield, without affecting back fat.

Key Words: DDGS, lambs, performance.

1701 Effect of high concentrations of crude glycerin on feed intake and growth of feedlot ram lambs. M. Almeida[*1,2], J. M. Bertocco Ezequiel[3], J. R. Paschoaloto[3], H. L. Perez[1,2], V. B. Carvalho[3], E. S. Castro Filho[3], and E. H. C. B. Van Cleef[2,3], *[1]São Paulo State University, Jaboticabal, Brazil, [2]FAPESP, São Paulo, Brazil, [3]Unesp, São Paulo State University, Department of Animal Science, Jaboticabal, Brazil.*

The objective of this study was to evaluate the effects of high concentrations of crude glycerin (CG) on feed intake and growth of finishing lambs. Forty crossbred (Santa Ines × Dorper) ram lambs (21.7 ± 2.7 kg BW and approximately 90 d old) were assigned to a complete randomized block design and fed four isonitrogenous (18.4% CP) and isocaloric (2.7 Kcal ME/kg) experimental diets containing 0, 10, 20, or 30% of CG (83% glycerol), on a dry matter basis. In the diet containing 30% CG, the by-product totally replaced corn grain. The experimental diets were formulated with 30% corn silage and 70% concentrate (corn grain [except the diet with 30% CG], soybean hulls, soybean meal, urea, minerals, and crude glycerin [except the control treatment]). Lambs were housed in a naturally ventilated barn with individual pens, and fed ad libitum twice daily. Animals were weighed at 14-d intervals and were harvested when they reached approximately 35 kg BW. Feed intake and growth were evaluated during the initial (d 0 to d 14), intermediate (d 14 to d 28), and cumulative feedlot period. Data were analyzed using a MIXED procedure, with treatment included as fixed effect and block as random effect. The increasing inclusion of CG in the diets linearly increased days on feed ($P = 0.02$). Dry matter intake (DMI) during the initial feedlot period was decreased with CG inclusion (Linear, $P = 0.03$), while during the intermediate feedlot period, a tendency was observed for DMI to reduce when animals were fed CG (Linear $P = 0.09$). Regarding the cumulative feedlot period, a quadratic effect was observed on DMI ($P = 0.04$), with greater intakes for animals fed treatment containing 10% CG. There was a tendency for reduced average daily gain (ADG) in animals fed CG during initial feedlot period (Linear, $P = 0.08$). The CG also decreased ADG during intermediate feedlot period ($P = 0.02$), and during the cumulative finishing period (Linear, $P = 0.003$). When all treatments with CG were compared with controls, there was a tendency for reduced ADG during intermediate and cumulative periods ($P = 0.07$, $P = 0.09$, respectively). There was also a tendency for reduced cumulative feed efficiency (Linear, $P = 0.07$), when CG was added to the diets. In conclusion, adding up to 10% of CG in diets for crossbred finishing lambs improves feed intake and animal growth.

Key Words: by-product, glycerol, sheep

1702 Conditions to evaluate differences among individual sheep and goats in resilience to restricted drinking water availability. U. L. Mengistu[1,2], R. Puchala[1], T. Sahlu[1], T. A. Gipson[1], L. J. Dawson[1,3], and A. L. Goetsch[*1], *[1]American Institute for Goat Research, Langston University, Langston, OK, [2]School of Animal and Range Sciences, Haramaya University, Dire Dawa, Ethiopia, [3]Center of Veterinary Health Sciences, Oklahoma State University, Stillwater.*

Thirty-six yearling Boer goat (BOE), Katahdin sheep (KAT), and Spanish goat wethers (SPA) were used to study appropriate conditions to evaluate resilience to restricted drinking water availability. Moderate quality grass hay was consumed ad libitum with concentrate (80% corn, 20% soybean meal) supplemented at 0.5% BW. Baseline conditions were determined in the last 2 wk of a 3-wk period (i.e., 100% level). Thereafter, water availability was decreased by 10% every 1 (1X) or 2 wk (2X) to 40% of baseline intake (i.e., 90, 80, 70, 60, 50, and 40% levels), but also with 2 wk at 40% for the 1X restriction

treatment. There was an interaction (P < 0.001) between animal type and restriction level in hay DMI, with values of 346, 360, 358, 276, 286, 235, and 176 g/d for BOE, 656, 592, 592, 469, 522, 407, and 307 g/d for KAT, and 392, 390, 368, 273, 298, 298, and 219 g/d for SPA at levels of 100, 90, 80, 70, 60, 50, and 40%, respectively (SE = 29.1). Moreover, hay DMI by 2X wethers was much lower in wk 2 vs. 1 at the 40% level (week × level interaction, P = 0.008; 409, 369, 345, 377, 336, and 276 g/d in wk 1 and 428, 398, 312, 352, 310, and 203 g/d in wk 2 at 90, 80, 70, 60, 50, and 40% levels, respectively; SE = 23.4). Restriction level affected (P < 0.001) plasma cortisol concentration in 2X wethers on the last day at each level (12.4, 14.0, 23.3, 26.4, and 32.6 nmol/l for 100, 70, 60, 50, and 40% levels, respectively; SE = 3.62). Plasma vasopressin concentration in 2X wethers at the end of each week at 60, 50, and 40% levels was affected by an interaction (P = 0.006) between week and restriction level (3.98, 5.61, and 7.84 in wk 1 and 6.40, 7.22, and 7.06 pmol/l in wk 2, respectively; SE = 0.564). In conclusion, there was some indication that DMI by KAT was more subject to adverse effects of very low water availability but not mild restriction compared with goats. Based on vasopressin concentration, a length of at least 2 wk rather than 1 with a set level(s) of restricted water availability seems desirable, which might also increase meaningfulness of measures such as BW. Results for DMI and cortisol concentration suggest appropriateness of a maximum restriction level of 50%.

Key Words: goats, sheep, water

1703 High concentrations of crude glycerin change ruminal in vitro greenhouse gas emissions in feedlot sheep.

M. Almeida[*1,2], J. M. Bertocco Ezequiel[3], J. R. Paschoaloto[3], H. L. Perez[1,2], V. B. Carvalho[3], E. S. Castro Filho[3], and E. H. C. B. Van Cleef[2,3], *[1]São Paulo State University, Jaboticabal, Brazil, [2]FAPESP, São Paulo, Brazil, [3]Unesp, São Paulo State University, Department of Animal Science, Jaboticabal, Brazil.*

The objective of this study was to evaluate the effects of high concentrations of crude glycerin (CG) on in vitro greenhouse gas emissions in feedlot sheep. Eight crossbred (Santa Ines × Dorper) ruminally cannulated male sheep (64.5 ± 8.5 kg BW) were distributed in a replicated 4 × 4 Latin square design. Treatments consisted of isonitrogenous (18.4% CP) and isocaloric (2.7 Kcal ME/kg) diets containing 0, 10, 20, or 30% CG, on diets' dry matter basis. In the diet with 30% CG, corn grain was totally replaced. The experimental diets contained 30% corn silage and 70% concentrate (corn grain [except the diet with 30% CG], soybean hulls, soybean meal, urea, minerals, and crude glycerin [except the control treatment]). The animals were housed in semi-covered individual pens and fed ad libitum twice daily. After 21-d adaptation period, rumen content was sampled to serve as inoculum for in vitro incubations. Approximately 200 mg (DM basis) of each diet and buffered rumen fluid (20 mL McDougall's buffer and 10 mL rumen fluid) were placed into 60-mL penicillin glass bottles, purged with helium gas and sealed. The gas production (mL/g DM and mL/g DM disappeared), terminal pH, and DM disappearance were evaluated after 24-h incubation at 39°C. DM disappearance was obtained filtering and drying incubation residues. Gas production was estimated using a digital pressure meter and a transducer, while CH_4 and CO_2concentrations were obtained using gas chromatography. Data were analyzed using MIXED procedure, with fixed effects of diet and period, and random effects of sheep (diet). Orthogonal contrasts were used to determine the linear and quadratic effects of CG. Total gas production was linearly increased with inclusion of CG to the diets ($P = 0.04$), while CO_2 production tended to decrease ($P = 0.10$), decreasing proportion of CH_4 in total gas. DM disappearance was not affected by treatments (average = 46.7%), and when this parameter was taken into account in the gas production calculation, the same effect was observed for total gas production ($P = 0.04$), and CO_2 production linearly decreased ($P = 0.03$). The increasing inclusion of CG in the diets linearly increased terminal pH ($P = 0.02$). In conclusion, high concentrations of crude glycerin have no effect on diets' DM disappearance, but increase in vitro total gas production, decreasing proportion of CH_4 and increasing terminal pH.

Key Words: by-product, glycerol, methane

1704 Factors influencing estimates of energy used for activity by grazing meat goats.

M. E. Brassard[1,2], R. Puchala[*2], T. A. Gipson[2], T. Sahlu[2], and A. L. Goetsch[2], *[1]Universite Laval, Quebec City, Canada, [2]American Institute for Goat Research, Langston University, Langston, OK.*

Ten yearling Boer goat wethers (45.4 ± 0.92 kg) consuming fresh Sudangrass ad libitum while grazing (GRA) a 0.8-ha pasture or individually confined (CON) were used in a crossover experiment with 3-wk periods to evaluate factors influencing estimates of energy used for activity (AEC) when grazing. Fresh forage offered to CON wethers was 15.9 and 13.4% CP and 65.0 and 67.4% NDF in periods 1 and 2, respectively. Based on forage and fecal AIA, forage DE concentration for CON averaged 67.9 and 56.5% in periods 1 and 2, respectively. From these values and fecal DM, least squares means of ME intake were 405 and 484 kJ/kg $BW^{0.75}$ for CON and GRA, respectively (SE = 15.4). Heat energy (HE) determined from heart rate (HR) measured over 1 d and the ratio of HE to HR estimated earlier was less (P < 0.001) for CON than for GRA (482 and 642 kJ/kg $BW^{0.75}$; SE = 17.2). To estimate the AEC from total HE and the partitioning of its sources, a ME requirement for maintenance of 427 kJ/kg $BW^{0.75}$) was assumed; HE expended for tissue energy gain was determined from recovered energy (RE) when greater than 0 and an efficiency of ME use for gain of 0.40 ± 0.009 ([0.0423 × forage ME in MJ/kg DM] + 0.006); and, when RE was less than 0,

the efficiency of use for maintenance of energy from forage and mobilized tissue was 0.68 ± 0.004 ([0.019 × forage ME in MJ/kg DM] + 0.503). The resultant AEC was 39 and 213 kJ/kg $BW^{0.75}$ for CON and GRA, respectively (SE = 21.9). Assuming that mobilized tissue energy was used for maintenance more efficiently (i.e., 0.80) than forage ME yielded slightly greater AEC of 57 and 241 kJ/kg $BW^{0.75}$ for CON and GRA, respectively (SE = 23.9). The former AEC value for GRA and that determined from the difference between GRA and CON HE were much greater than AEC based on time spent in different activities (i.e., lying, standing, grazing, and walking) multiplied by corresponding HE and assuming that AEC resulted from HE when standing, grazing, and walking (217 ± 19.7, 165 ± 19.3, and 46 ± 4.85 kJ/kg $BW^{0.75}$, respectively). In conclusion, determining the AEC of meat goats while grazing by subtraction of other sources of HE is influenced by specific assumptions of energy requirements and efficiencies of use for different physiological functions.

Key Words: activity, energy, goats, grazing

1705 The response to artificial infection with *Haemonchus contortus* and growth performance of sheep and goat progeny of selected parents in a central performance test.

Y. Tsukahara*, T. A. Gipson, S. P. Hart, L. J. Dawson, Z. Wang, R. Puchala, T. Sahlu, and A. L. Goetsch, *American Institute for Goat Research, Langston University, Langston, OK.*

Fifteen Katahdin (KS-A; 4.0 mo old, 38 kg), 5 Katahdin (KS-B; 3.0 mo, 20 kg), 16 Dorper (DS; 3.4 mo, 25 kg), and 17 St. Croix sheep (CS; 4.2 mo, 18 kg) and 20 Kiko (KG; 3.9 mo, 19 kg), 16 Boer (BG; 4.4 mo, 16 kg), and 18 Spanish goat (SG; 4.3 mo, 18 kg) males from 5 commercial farms in KS, MO, and AR and Langston University (LU) were used to investigate growth performance and response to artificial infection with *Haemonchus contortus* in year 3 of a central test at LU. Animals tested were progeny of dams (based on on-farm data) and sires classified as Resistant and Moderate in year 2. The test entailed an adjustment period of 2 wk followed by 8 wk of data collection. Animal groups were housed separately in adjacent pens with automated feeders allowing free-choice access to a 15% CP diet. During adaptation, anthelmintic treatment resulted in low fecal egg count (FEC; < 600 eggs/g), after which 10,000 larvae were administered orally. Packed cell volume (PCV) was measured weekly and FEC was determined 5 times in wk 5-9. The cubic clustering criterion of SAS® categorized resistance classes. The GLM procedure included animal group and resistance classification, initial BW, PCV, and FEC were covariates, and the logarithmic transformation ln(x+100) was used for mean FEC. Animal group affected (P < 0.01) ADG (308, 264, 321, 254, 139, 243, and 147 g; SEM = 14.6), DMI (2.34, 1.65, 1.65, 1.32, 0.79, 1.28, and 0.94 kg/d; SEM = 0.069), and PCV (25.4, 24.3, 28.6, 29.3, 25.8, 22.9, and 25.7% for KS-A, KS-B, DS, CS, KG, BG, and SG, respectively; SEM = 0.65). The resistant males had highest (P = 0.04) ADG (256, 237, and 225 g for Resistant, Moderate, and Susceptible, respectively; SEM = 8.8). There was an animal group × resistance classification interaction (P = 0.04) on FEC (270, 2346, and 4633 with KS-A, 1088, 5272, and 8263 with KS-B, 442, 1140, and 2370 with DS, 209, 870, and 2368 with CS, 248, 994, and 2431 with KG, 1182, 2164, and 4523 with BG, and 215, 1203, and 3132 eggs/g (untransformed) with SG for Resistant, Moderate, and Susceptible classes, respectively; SEM = 295.0). The correlation coefficient between sire and progeny FEC was 0.27 (P = 0.004) and that of PCV was 0.44 (P < 0.001). In conclusion, selection for resistance did not adversely affect performance of males, and there were moderate relationships between indices of parasite infection of sires and progeny.

Key Words: goats, internal parasitism, sheep

1706 Species and breed differences of small ruminants in response to experimental infection with *Haemonchus contortus* and growth performance in a centralized performance test.

Y. Tsukahara*, T. A. Gipson, S. P. Hart, L. J. Dawson, Z. Wang, R. Puchala, T. Sahlu, and A. L. Goetsch, *American Institute for Goat Research, Langston University, Langston, OK.*

The response to experimental infection with *Haemonchus contortus* and growth performance of small ruminant males were compared in a central performance test at Langston University (LU). Seventy-five Boer (3.8 mo of initial age, 19 kg), 51 Kiko (3.7 mo, 19 kg), and 50 Spanish goats (3.9 mo, 18 kg) and 43 Dorper (3.9 mo, 29 kg), 75 Katahdin (3.7 mo, 28 kg), and 42 St. Croix sheep (4.2 mo, 20 kg) from 8 commercial farms in AR, KS, MO, and OK and LU were housed separately in adjacent pens with automated feeders allowing free-choice access to a 15% CP (DM) and 50% concentrate pelletized diet. The test entailed an adjustment period of 2 wk followed by 8 wk of data collection. Body weight was determined weekly. During adaptation, anthelmintic treatment resulted in low fecal egg count (initial FEC = 64 eggs/g; SEM = 7.0), after which a dose of 10,000 larvae was administered orally. After the infection, packed cell volume (PCV) was measured weekly and FEC was determined 5 times in wk 5-9. Data were analyzed using the GLM procedure of SAS® with fixed effects of species and breed within species. Initial BW, PCV, and FEC were covariates and the logarithmic transformation was used for individual mean FEC. Species differed in ADG (P < 0.01; 176 and 305 g; SEM = 4.1), DMI (P < 0.01; 1.14 and 1.81 kg/d; SEM = 0.032), FEC (P = 0.02; 1897 and 1488 eggs/g in untransformed scale; SEM = 135.1), and PCV (P < 0.01; 26.7 and 29.1% for goat and sheep; SEM = 0.20). Dorper and Katahdin had greatest (P < 0.01) ADG (231, 154, 144, 329, 316, and 270 g; SEM = 6.8) and DMI (1.37, 0.94, 1.11, 1.98, 1.94, and 1.51 kg/d

for Boer, Kiko, Spanish, Dorper, Katahdin, and St. Croix, respectively; SEM = 0.054). St. Croix had the lowest ($P < 0.05$) FEC (1701, 2548, 1442, 1957, 1587, and 921 eggs/g; SEM = 233.9) and highest ($P < 0.01$) PCV (25.8, 27.8, 26.5, 29.0, 27.7, and 30.7% for Boer, Kiko, Spanish, Dorper, Katahdin, and St. Croix, respectively; SEM = 0.34). In conclusion, there was considerable variability between species, among breeds, and within breeds in resistance to internal parasite based on FEC and PCV after an artificial challenge with *H. contortus* larvae in a standardized environment.

Key Words: goat, internal parasite, sheep

1707 Effects of adding water to total mixed ration on water consumption, nutrient digestibility, wool cortisol, and blood indices in Corriedale ewes under hot and humid conditions.

J. Ghassemi Nejad[1], K. Sung[1], B. Lee[2], J. Peng[2], J. Kim[2], S. Oh[2], B. Chemere[2], and B. Kim[*1], *[1]Department of Animal Life System, College of Animal Life Science, Kangwon National University, Chuncheon, South Korea, [2]Kangwon National University, Chuncheon, Korea.*

The objective of this study was to determine the effect of adding water to total mixed ration (TMR) on water consumption, nutrient digestibility, wool cortisol, and blood indices in Corriedale ewes under hot and humid conditions. Nine Corriedale ewes (ave. BW = 41 ± 3.5 kg) were individually fed diets based on maintenance requirements in metabolic crates. Sheep were assigned to three treatment groups according to a 3 × 3 Latin square design for 3 periods of 21 days duration each (9 sheep per treatment). Treatments were TMR moisture for 40%, 50%, and 60%. No differences were found in body weight gain among all treatment groups ($P > 0.05$). Nitrogen balance including digestible N, retained N, and urinary and fecal N showed no change among the treatment groups ($P > 0.05$). Water consumption was the lowest in 50% TMR moisture group than the other groups ($P < 0.05$). Other than ether extract which was higher in 60% TMR moisture group ($P < 0.05$) the differences among nutrient digestibilities including CP, crude fiber, OM, DM, NDF, ADF, and NFC were not significant ($P > 0.05$). No significant difference was observed for serum protein, BUN, glucose, and TG among the treatment groups ($P > 0.05$). Wool and blood cortisol were not different among the treatment groups ($P > 0.05$). Blood hematology including RBC, WBC, hemoglobin, hematocrit, basophils, and eosinophils were not different among the treatment groups ($P > 0.05$). It is concluded that the increase of TMR moisture at 40%, 50% and 60% had no effects on water consumption, N balance parameters, and nutrient digestibilities except for the ether extract under hot and humid environmental conditions. Additionally there were no effects on stress conditions (chronically known as wool cortisol levels), as well as blood cortisol levels, and immune functions of ewes.

Key Words: blood parameters, Corriedale ewes, digestibility, stress, TMR moisture, wool cortisol

---

1708 Effects of pasture access regimen on grazing behavior and energy utilization by Alpine goats.

A. Keli[1,2], L. P. S. Ribeiro[*2,3], T. A. Gipson[2], R. Puchala[2], and A. L. Goetsch[2], *[1]Department of Animal Production, National School of Agriculture, Meknes, Morocco, [2]American Institute for Goat Research, Langston University, Langston, OK, [3]Department of Animal Science, Federal University of Bahia, Areia, Brazil.*

Twenty-eight Alpine goats (initially 53.2 ± 1.80 kg BW and 26 ± 2.5 days in milk; 11 primiparous) were used to evaluate effects of different pasture access regimens on grazing behavior and energy utilization in a 16-wk experiment with 4-wk periods. Treatments were access to grass and(or) legume pasture from 0800 h, after the morning milking at 0700 h, to 1600 h (SET); continually other than during milking (CG); from the time of no moisture on leaf surfaces until milking at 1600 h (ND-M); and from the time of no leaf surface moisture until sunset (ND-D). The SET, CG, and ND-M goats were supplemented with 1.5% BW (DM) of concentrate immediately after the afternoon milking, whereas ND-D goats were supplemented at sunset. The ND-M and ND-D goats were fed alfalfa hay when length of pasture access was less than 6 h, with the level based on length of pasture access. Digestibility of OM determined each period from fecal DM and AIA in feedstuffs and feces was 77.0, 79.1, 81.3, and 77.8%, respectively (SE = 1.46), and ADG was similar among treatments (−12, −15, 2, and −6 g for CG, ND-D, ND-M, and SET, respectively; SE = 10.9). Neither fecal egg count nor FAMACHA score was affected by treatment ($P > 0.05$). Based on data from GPS collars and leg activity monitors, treatment affected ($P < 0.05$) time spent grazing (7.43, 6.93, 5.86, and 6.18 h, respectively; SE = 0.343), resting while lying (8.48, 8.82, 10.63, and 9.11 h, respectively; SE = 0.480) and standing (6.33, 7.29, 6.85, and 7.82 h, respectively; SE = 0.338), and walking (1.75, 0.95, 0.66, and 0.90 h for CG, ND-D, ND-M, and SET, respectively; SE = 0.093). Intake of ME was similar among regimens ($P > 0.05$; 26.73, 24.54, 26.25, and 22.37 MJ/d, respectively; SE = 1.522), although heat energy determined from heart rate and heat energy per heart beat was greatest for CG ($P < 0.05$; 14.41, 13.11, 12.90, and 13.03 MJ/d for CG, ND-D, ND-M, and SET, respectively; SE = 0.392). Milk energy yield was similar among treatments (5.41, 5.06, 5.34, and 5.55 MJ/d, respectively; SE = 0.35), but milk energy:ME intake was greatest ($P < 0.05$) for SET (0.228, 0.219, 0.220, and 0.275 for CG, ND-D, ND-M, and SET, respectively; SE = 0.0104). In conclusion, restricting time of pasture access from the morning to afternoon milking appeared to favorably affect efficiency of energy utilization for lactation, not relating to

Table 1709.

Table 1. Equations used to predict energy requirements for maintenance and gain in indigenous goats.

1709 Energy and protein requirements of indigenous goats. A. K. Almeida*[1], K. T. Resende[1], I. A. M. A. Teixeira[1], S. D. A. Ribeiro[2], M. T. Rodrigues[3], and J. A. Garcia[3], *[1]UNESP, Univ. Estadual Paulista, Department of Animal Science, Jaboticabal, Brazil, [2]Capritec, Espirito Santo do Pinhal, Brazil, [3]Universidade Federal de Vicosa, Vicosa, Brazil.*

The objective of this study was to estimate energy requirements of indigenous goats weighing from 5 to 25 kg of body weight (BW). Goats were weaned at 79 ± 4.4 days after the beginning of experiment. Milk and solid diet intake were recorded daily. Total ration had 11.0 MJ/kg ME and 144 g/kg CP (DM basis). To determine energy maintenance requirements, 33 goats weighing 4.90 ± 0.302 kg of initial BW were used. Ten goats were slaughtered to estimate body energy and protein at the beginning of the experiment, then retained energy. The remaining goats were randomly assigned to two DM intake levels: ad libitum and restricted-fed (1.20X maintenance). Heat production was calculated as the difference between ME intake and retained energy (RE, kJ/kgEBW$^{0.75}$). Net energy requirement for maintenance (NE_m) was estimated as β_0 of relationship between HP and MEI (Table 1, Eq.[1]). Metabolizable energy required for maintenance (ME_m) was calculated iteratively, when HP = MEI. Efficiency of energy utilization for maintenance (k_m) was calculated as NE_m/ME_m. A linear regression of retained CP on CP intake (g CP/kg EBW$^{0.75}$) was used to calculate net protein requirements for maintenance (NP_m). The intercept of regression (Table 1, Eq.[2]) was assumed to be the endogenous and metabolic losses of N×6.25, which represented the NP_m. Net energy and protein requirement for gain (NE_g and NP_g, respectively) were obtained using 26 goats fed ad libitum randomly slaughtered at 5.40 ± 0.484 kg BW (n = 10), 15.8 ± 0.655 kg BW (n = 10), and 26.3 ± 1.27 kg BW (n = 6). The first derivative of allometric equation (used to calculate energy and protein contents in the EBW; Table 1, Eq. [3] and [4]) with respect to EBW yielded estimates of the NE_g and NP_g. A Monte Carlo-based method was used to simulate variation of NE_g and NP_g. Estimated NE_m was 344.1 ± 14.6 kJ/kgEBW$^{0.75}$, resulting in 568.4 kJ/kgEBW$^{0.75}$ ME_m, thus k_m was 0.605. The NP_m was 1.091 ± 0.435 g CP/kgEBW$^{0.75}$·at NI = 0. The CP intake required for maintenance, at which retained CP = 0, was 3.87 g CP/kgEBW$^{0.75}$. The growth phase, NE_g ranged from 8.59 ± 0.555 to 8.75 ± 0.821 MJ/kg and NP_g increased increased from 186.6 ± 5.25 to 230.8 ± 10.4 g CP/kg of empty weight gain in indigenous goats weighing from 5 to 25 kg BW. It is expected that indigenous goats are later maturing animals. That would explain the lack of significant increase in NE_g as BW increased. We thank FAPESP for financial support (grant No. 2014/14939-0, 2014/14734-9, 2015/26000-5).

Key Words: comparative slaughter, gain, maintenance.

1710 Nutrient content of crop residues selected by grazing goats. J. Mendoza*[1], L. Gaytan[1], M. Mellado[2], O. Angel[1], and I. Chavarria[1], *[1]Autonomous Agrarian University Antonio Narro, Torreon, Coahuila, Mexico, [2]Autonomous Agrarian University Antonio Narro, Saltillo, Coahuila, Mexico.*

In Mexico, the majority of goats are exploited extensively, so their diet depends on native vegetation on rangelands, and occasionally crop residues. There is no information on the nutritional quality of different crop residues used by goats. Therefore, the objective of this study was to determine the nutrient content of two crop residues: alfalfa roots (goats grazed in a plowed crop of alfalfa) and oats (straw), selected by mixed breed goats (crossbred dairy goats) grazing in these crop fields. The collection of forage selected by goats was carried out by 10 multiparous goats, which carried a plastic

rope (1.5 m long and 0.5 cm in diameter) tied around their neck. Forage was collected directly from their oral cavity by separating the jaws with the hands, without impeding their grazing activity. Goats were restrained momentarily by holding them with the rope attached to their neck. This procedure was repeated about every 10 min for 3 hours a day, collecting approximately 300 g of forage (green matter) during 5 days (collections were made by one person per goat). A portion of this material was washed immediately with distilled water and was used for the determination of minerals. The data analysis was performed using analysis of variance (ANOVA) using the PROC GLM procedure of SAS. Ash content of goat diets grazing the alfalfa residue was higher ($P < 0.01$) (14.6 ± 1.7 vs. 11.0 ± 0.8) than goats grazing oat residues. NDF was higher ($P < 0.05$) in the alfalfa forage (predominantly roots) selected by goats (57.0 ± 1.9 vs. 53.6 ± 3.9) compared with diets of goats grazing oat residues. The protein content was higher ($P < 0.05$) in forage selected by goats on the oat residues (9.4 ± 1.0) compared to alfalfa residues (8.0 ± 1.2). The Ca, Cu, Mn, and Fe concentrations were higher ($P < 0.01$) in the goat diets grazing on alfalfa residues compared to oat residues. It was concluded that goats grazing on oat residues select diets higher in nutrients compared to diets selected on plowed alfalfa (high root consumption). However, goats ingesting alfalfa residues, mainly roots, had access to higher levels of minerals.

Key Words: alfalfa, NDF, nutritional quality, oats, protein

1711 Genomic evaluation and population structure of eleven Russian sheep breeds. T. E. Deniskova[1], A. V. Dotsev[1], K. Wimmers[2], H. Reyer[2], V. R. Kharzinova*[1], E. A. Gladyr[1], G. Brem[1,3], and N. A. Zinovieva[3], *[1]L.K. Ernst Institute of Animal Husbandry, Moscow, Russian Federation, [2]Genome Biology, Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [3]Institute of Animal Breeding and Genetics, VMU, Vienna, Austria.*

Availability of high-density SNP arrays created an opportunity to understand current genetic structure and differentiation of sheep breeds and to find ways for their improving via whole genome analysis. A wide range of sheep breeds including wool, meat, milk types, and dual- and multi-purpose breeds was established in Russia. Although the breeds have unique gene pool and are a part of national heritage, they have not been genotyped yet and there is no information of their polymorphism at genome level. In this regard, our aim was to evaluate genetic diversity and population structure of some Russian sheep breeds. We used OvineSNP50K BeadChip to genotype 141 sheep of 11 breeds including Romanov (ROM, n = 22), Baikal fine-fleeced (ZBL, n = 12), Tuvan short fat tailed (TUV, n = 16), Kuibyshev (KUI, n = 11), Soviet Merino (SVM, n = 10), Kuchugur (KCH, n = 12), Karakul (KAR, n = 16), North Caucasian merino (NCM, n = 11), Russian long haired (RLH, n = 11), Stavropol (STA, n = 10), and Manych merino (MAN, n = 10). Quality control (QC) of SNPs and summary statistics were performed in PLINK v1.07. R v3.2.3 was used to create input files and visualize the data. After QC overall 48,842 SNPs (90%) were involved in the further analysis, 47,980 (or 98.3% from detected) were polymorphic. The highest polymorphism level among the breeds was identified in ZBL (97.4%), whereas KCH, RLH, STA were characterized by 93.4, 93.7, and 93.8% of polymorphic loci, respectively. Observed heterozygosity was 0.370 ranging from 0.361 in ROM to 0.398 in ZBL. All breeds were characterized by heterozygote excess ranging from 0.84 in ROM to 9.78% in KCH. The minor allele frequency was 0.305 overall for all breeds. The MDS analysis showed pattern corresponding breeds productivity type. Merino breeds (STA, SVM, MAN, ZBL) with close NCM group and semi-fine fleeced clade of RLH and KUI clustered separately from KAR and TUV with coarse wool. Multi-purpose KCH occupied an equidistant position. The most remote group was ROM, probably, due to their unique genetic traits such as extremely high prolificacy and adaptability to any conditions of keeping and feeding. Our study represents the initial phase of large-scale SNP genotyping of Russian sheep breeds. The research was conducted under financial support of Russian Scientific Foundation (project N° 14-36-00039).

Key Words: genetic diversity, sheep breeds, whole-genome studies

1712 Plate waste and artificial rearing of orphaned lambs versus ewe reared lambs. A. DiPastina* and D. J. R. Cherney*, Cornell University, Ithaca, NY.*

In this study, our objective was to determine the possible use of breakfast plate waste from a university dining hall as a supplement to lamb creep feed other than as compost and to evaluate gain of artificially versus ewe reared lambs. Twelve ewes bearing twins were selected. Twins were given 177 mL of ewe's colostrum each on day 0 immediately after birth and again 4 hours later, and then were randomly assigned to groups. Groups consisted of 12 lambs reared with their dams (NR), 12 artificially reared on milk replacer (AR). Half of each set of lambs were fed a standard creep feed (SC). The other lambs were fed a creep feed containing about 15% plate waste, which replaced some of corn and soybean meal of the standard creep (PW). Both creep feeds contained the same amount of crude protein, neutral detergent fiber, and total digestible nutrients (20.8 ± 3.11%, 23.9 ± 6.22%, and 79 ± 2.12% TDN, respectively). A 2 x 2 factorial was used to compare rearing methods and creep feed treatments for all 24 lambs. The AR lambs were housed in 0.9 x 0.9 meter pens in pairs. The NR lambs were housed with their dams in 1.5 x 1.5 m pens with access to a 0.6 x 1.5 m creep area. Lambs

were weighed daily from days 0 to 30. Lambs weighed 3.76 ± 0.712 kg at birth. Creep feed was offered starting at 10 d of age. Creep feed was weighed 3x daily, and more added if necessary. Creep feed intake did not differ between AR and NR lambs, but AR lambs grew at a greater rate (0.28 kg/d) versus NR lambs (0.27 kg/d; $P < 0.05$). Lambs offered SC consumed more (20.24 ± 11.17 g/d) than lambs offered PW feed (8.83 ± 8.21 g/d; $P < 0.05$). Artificially grown lambs fed SC grew faster ($P < 0.01$) but consumed less milk replacer per day (1.75 ± 0.75 L/day) than PW fed lambs (2.93 ± 1.14 L/day). Lambs fed PW consumed feed at a more accelerated rate past 20 d than what lambs consumed on SC, suggesting possible acceptability issues that decreased over time with the PW. Results indicate that AR lambs can have growth rates greater than or similar to NR lambs, but intensive management is required. In addition, PW produced acceptable growth rates in lambs pre-weaning, but PW use needs continued research to assess issues such as acceptability.

Key Words: orphan lambs, plate waste

1713 Effects of corn silage levels on methane emissions and blood metabolite concentrations of drying-off Xinong Saanen dairy goats. P. Wang*[1], Y. Xue[2], G. Ma[1], and J. Luo[1], *[1]Alltech-NWAFU Animal Science Research Alliance, College of Animal Science and Technology, Northwest A&F University, Yangling, China, [2]Alltech, Lexington, KY.*

The objective of this study was to determine the effects of increasing corn silage level in drying-off Xinong Saanen dairy goats on methane emissions and blood metabolites concentrations. Twenty-one drying-off Xinong Saanen dairy goats (3.36 ± 0.95 yr old; BW = 64 ± 9.19 kg) were randomly allocated to 3 treatments with 7 goats per treatment (one goat of MS treatment got fever and excluded) and were fed 3 levels of corn silage with 2 7-d periods: 0.33 kg/d for LS, 0.47 kg/d for MS, 0.55 kg/d for HS (DM basis), respectively. Goats were fed twice daily by pens. Concentrate, corn silage, and alfalfa hay were provided separately. Concentrates were offered at 0.58 kg/goat daily, and alfalfa hay was ad libitum. Methane emissions were measured on 2 7-d periods using 3 polymethyl methacrylate chambers (length × width × height = 1.2 m × 0.6 m × 1.0 m; bottom is open). One of 7 goats for each treatment was placed in the chamber for 30 min (1200 h-1230 h) during gas sampling day, and temperature was recorded simultaneously. Daily methane emission rates were estimated based on the emission rate of 1200 h-1230 h and the percentage of 1200 h-1230 h methane production in daily methane production. Blood serum samples were collected once on the last day of the experiment to analyze concentrations of blood urea nitrogen (BUN), glucose (GLU), total protein (TP), β-hydroxybutyrate (BOHA), NEFA, and triglyceride (TG). Data were analyzed by GLM and treatment means were compared by LSD test ($P \leq 0.05$). Methane emission rate ranged from 9.90-11.89 g/d, 452.37-508.51 mg/d per kg metabolic body weight (MBW), 7.55-8.52 g/kg DMI. Increasing corn silage intake showed the potential to reduce methane emission rate (9.90 ± 4.00 g/d for HS, 10.58 ± 1.84 g/d for MS, and 11.89 ± 2.03 g/d for LS), although no significant differences were found. The relatively higher methane emission of LS was in accordance with higher hay intakes (0.50 ± 0.06 kg/goat for LS vs. 0.19 ± 0.09 kg/goat for HS, 0.20 ± 0.09 kg/goat for MS). Serum concentrations of BUN, GLU, TP, BOHA, and NEFA were not affected by corn silage intake, whereas serum TG concentration increased with increasing corn silage level ($P < 0.05$). These results indicated that increasing corn silage level potentially reduced methane emissions with accordingly decreased hay intakes.

Key Words: corn silage, dairy goat, methane

1714 Inclusion of a by-product of *Myrtus communis* in the diet of lactating sheep: Performance and health. A. Nudda*[1], G. Battacone[1], P. Nicolussi[2], F. Correddu[1], G. Pulina[1], and P. Bonelli[2], *[1]Dipartimento di Agraria, University of Sassari, Sassari, Italy, [2]Istituto Zooprofilatico Sperimentale della Sardegna, Sassari, Italy.*

By-product resulting from myrtle liqueur preparation of *Myrtus communis* berries could represent a suitable source of polyphenolic compounds. The present study aimed to investigate the effect of dietary supplementation of exhausted berries of *Myrtus communis* (EBM) on milk production and composition, blood metabolic profile and the efficiency of nitrogen utilization in lactating dairy ewes. Thirty Sarda dairy ewes were randomly assigned to 3 dietary treatments consisting of a control diet (CON), a diet supplemented with 50 g/d per head of EMB (EMB50), or a diet supplemented with 100 g/d per head of EMB (EMB100). The study lasted 13 wk, with a 2 wk adaptation period and an 11 wk experimental period. Milk yield was measured and milk samples were collected weekly and analyzed for fat, protein, and milk urea content (MU). Blood samples were collected on d 0, 15, 30, 45, and 60 of the experiment and analyzed for hematological parameters, albumin, alkaline phosphatase (ALP), bilirubin, creatinine, gamma glutamyltransferase (GGT), aspartate aminotransferase (AST), alanine aminotransferase (ALT), protein, blood urea (BU), and serum protein fractions. The urinary N excretion was estimated. Dietary treatments did not affect milk yield and composition, except for MU, which decreased as the dose of EMB in the diet increased (41.5, 37.6, 32.4, respectively; $P < 0.05$). Diet influenced blood urea content (BU), which decreased with the inclusion of EMB in the diet (72.4, 61.3, 59.0, respectively; $P < 0.05$). The urinary N excretion was reduced by the EMB supplementation (19.9, 17.8, 14.9, respectively; $P < 0.05$). The reduction in MU, BU, and estimated urinary excretion suggests that the use of EMB might reduce N emissions. The results on milk production

and composition and hematological parameters suggests that EMB can be included in the diet of dairy ewes without adverse effects on performance and health status.

Key Words: blood parameters, by-product, lactating sheep

1715 Genetic parameter estimates for productivity of the Katahdin and Hampshire ewe and its components. J. G. Pérez-Álvarez, F. A. Rodríguez-Almeida*, and J. Domínguez-Viveros, *Universidad Autónoma de Chihuahua, Chihuahua, Mexico.*

Productivity of the ewe is one of the most important economic traits in lamb production, and predicted as a biological index could facilitate selection decisions for genetic improvement if not negatively related to any of its components. In order to estimate genetic parameters for total weight of lamb weaned at 75 d per lambing ewe (TWW) and its components [average weaning weight (AWW), number of lambs born (NLB), and number of lambs weaned (NLW)] in two distinct breeds, 4439 and 1076 records from 3166 Katahdin (KT) and 646 Hampshire (HS) ewes with progeny from 556 and 72 sires in 91 and 10 flocks in México, respectively, were analyzed. Because NLB and NLW were about the same in HS, NLW was not analyzed for this breed. Weaning weights were adjusted to a female equivalent base for each breed by type of birth and region, prior to the calculation of TWW and AWW. Heritability and genetic correlations were estimated by bi- and tri-variate analyses with the MTDFREML software. The models included the fixed effects of contemporary group-season-year-flock and the linear and quadratic covariate age of the ewe at lambing, and the direct additive genetic and permanent environment random effects of the ewe. For TWW and AWW, also the random effect of sire of mating was included, as well as the fixed effects of NLB and NLW for AWW. Parameter estimates were very similar for both breeds. Heritability estimates for TWW, AWW, NLB, and NLW ranged from 0.13 to 0.18, 0.15 to 0.18, 0.10 to 0.16, and 0.14 to 0.16, respectively. The average estimates of r_g of the component traits with TWW in KT and HS were 0.87 and 0.67 for AWW, 0.83 and 0.70 for NLB, and 0.98 for NLW, and between components in KT were 0.98 for NLW and NLB, 0.35 (tri-) and 0.65 (bi-variate) for AWW and NLW, and around 0 for AWW and NLB in both breeds. Variance for sire of mating random effects as proportion of phenotypic variance were consistently moderate (0.16 and 0.25 for TWW and AWW, respectively) only for the HS breed. In conclusion, a moderate genetic response to selection is expected for the KT and HS ewe productivity without adverse effects in any of its component traits.

Key Words: ewe productivity, genetic correlation, heritability

1716 Effects of protected methionine supplementation during dry period of seasonally synchronized goats on blood parameters and the subsequent lactation. *F*. Piccioli-Cappelli[1], A. Minuti*, M. Maiocchi, M. Mezzetti, and E. Trevisi, *Università Cattolica del Sacro Cuore, Piacenza, Italy.*

At the end of pregnancy, goats experience a marked body fat mobilization and inflammatory events that may increase the risks of ketosis and oxidative stress and impair health. It is recognized that methionine (Met), often deficient in the diet of ruminants, acts as a donor of thiol groups, which are essential in alleviating the negative effects of stress and inflammation. The aim was to study the effects of feeding protected Met (Timet®, Vetagro, RE, Italy) during the dry period to double its content in metabolizable protein. Fourteen Saanen goats were divided into 2 groups of 7 goats each. During the last month of pregnancy the control (CTRL) group received 320 g of soya meal (Met = 0.2% DM) and the treatment (TRAT) group received 300 g of a protein supplement containing Timet® (Met = 0.4% DM). Both groups were fed hay ad libitum and the supplement resulted in a diet with the same energy content (1.4 Mcal/kg DM) and protein (CP 14.2% DM). Blood samples were collected every 7 d and milk samples on 7th and 14th d of lactation. Data were analyzed using Proc. Mixed of SAS. Before kidding, at blood level TRAT compared with CTRL goats had lower concentrations of urea, NEFA (0.22 vs. 0.37 mmol/L, $P < 0.10$), indicating a lower mobilization of body reserves and lower BHB (0.34 vs. 0.48 mmol/L, $P < 0.07$), indicating lower ketogenesis. Altogether these data indicate a higher availability of glucose in TRAT goats. TRAT compared to CTRL goats had a better liver metabolism (i.e., higher concentrations of albumin 35.4 vs. 33.9 g/L, $P < 0.10$), and this could result in a more favorable condition concerning both inflammatory status (lower levels of haptoglobin, 0.13 vs. 0.41 g/L) and oxidative stress (lower levels of reactive oxygen metabolites, 16.7 vs. 19.0 mg H_2O_2/dL) resulted numerically, although not statistically, different. During the first two weeks of lactation these responses likely allowed the TRAT group to yield more milk (2.83 vs. 2.18 kg/d, $P < 0.12$) and lactose (137 vs. 98 g/d, $P < 0.05$); moreover, milk from TRAT treated goats had a significantly lower somatic cells count (2.72 vs. 3.13 logN/mL, $P < 0.05$). Thus, the data indicate that supplementation of Met in late gestation can help goats to mitigate the frequent adverse metabolic and inflammatory conditions that characterize this physiological phase, and to improve the beginning of the lactation cycle.

Key Words: goat, inflammation, metionine, pregnancy

1717 Responses of hair sheep breeds to high heat load index conditions. D. Tadesse*, R. Puchala, T. A. Gipson, Y. Tsukahara, and A. L. Goetsch, *American Institute for Goat Research, Langston University, Langston, OK.*

Fourteen Dorper (D; 59 ± 3.2 kg), 13 Katahdin (K; 58 ± 2.5 kg), and 8 St. Croix (SC; 50 ± 3.0 kg) female sheep (> 1.5 yr) were used to evaluate responses to high heat load index (HLI) conditions. After 4 wk of thermoneutral conditions (70 HLI), in sequential 2-wk periods daytime HLI was regulated near 85, 90, and 95 and that at night was 70, 77, and 81, respectively. Data were analyzed with a mixed model containing breed, week within period, measurement time (0700, 1300, and 1700 h), three-way interactions, and baseline covariates. Rectal temperature (RT) at 1300 and 1700 h was lowest for SC (38.36, 38.87, and 38.96 for D, 38.31, 38.85, and 38.87 for K, and 38.29, 38.64, and 38.66 °C for SC at 0700, 1300, and 1700 h, respectively; SE = 0.046). A similar interaction ($P = 0.052$) occurred for panting score (PS, 0-4.5; 0.10, 0.64, and 0.54 for D, 0.09, 0.70, and 0.58 for K, 0.02, 0.42, and 0.40 for SC at 0700, 1300, and 1700 h, respectively; SE = 0.064). Breed differences in PS resulted from highest HLI in period 3 (0.07, 0.17, and 1.03 for D, 0.08, 0.15, and 1.14 for K, 0.04, 0.06, and 0.73 for SC in period 1, 2, and 3, respectively; SE = 0.080). Period, week, and time interacted ($P < 0.001$) in respiration rate (RR) (period 1: 41, 102, and 97 in wk 1, 50, 124, and 115 in wk 2; period 2: 56, 158, and 124 in wk 1, 65, 160, and 134 in wk 2; period 3: 76, 219, and 161 in wk 1, 130, 164, and 148 in wk 2 at 0700, 1300, and 1700 h, respectively; SE = 6.6). There was a corresponding interaction ($P < 0.001$) in RR:RT as an index of energy expended to minimize RT (period 1: 0.40, 1.00, and 0.96 in wk 1, 0.05, 1.22, and 1.14 in wk 2; period 2: 0.57, 1.55, and 1.22 in wk 1, 0.66, 1.58, and 1.31 in wk 2; period 3: 0.75, 2.14, and 1.58 in wk 1, 1.28, 1.61, and 1.44 in wk 2 at 0700, 1300, and 1700 h, respectively; SE = 0.064). In conclusion, some measures suggest higher tolerance of high HLI by SC than D or K. There appeared to be considerable adaptation in RR from wk 1 to 2 of period 3 to minimize RT in the early afternoon, which was at least partially facilitated by higher RR in the early morning before HLI increased.

Key Words: hair sheep, heat, temperature

1718 In vitro efficacy of three novel compounds on development and survival of gastrointestinal nematode larvae in feces of sheep. J. E. Miller*[1], V. Kelly[2], and J. M. Burke[3], *[1]Louisiana State University, Baton Rouge, [2]Louisiana State University School of Veterinary Medicine, Baton Rouge, [3]USDA-ARS, Booneville, AR.*

Gastrointestinal nematode (GIN) parasites are a major constraint to profitable sheep production. The long-term use of anthelmintics has resulted in GIN populations developing resistance to those available. The objective of this study was to determine the efficacy of three novel compounds on development and survival of GIN larvae in feces of sheep. Feces were collected directly from the rectum of 10 lambs and combined to make one large sample. This sample was homogenized by thorough mixing by hand and five 2-g subsamples were randomly selected for determination of fecal egg count (FEC) using the McMaster technique. Fifty 5-g subsamples were then randomly selected and individual fecal cultures were made by mixing with an equivalent volume of vermiculite and adding water to make a soft crumbly culture composition. Three novel synthetic compounds (Bedoukian Research, Inc.) similar to natural flavor/fragrance application compounds were diluted 1:10, 1:1,000, and 1:10,000. Five mL of water (control) and each dilution of the compounds were thoroughly mixed with a culture, making 5 replicates/dilution. Cultures were incubated at 27°C for 2 wk, after which, they were processed by a baermann procedure to recover infective larvae (L3). The number of L3 were counted to estimate L3/g of feces. The mean FEC (3530 ± 231) indicated that the GIN eggs were evenly distributed in the homogenized fecal mass, so all subsamples were considered to have equivalent FEC. The control larval recovery was 814 L3/g, and recovery for all the dilutions of the 3 compounds was < 10 L3/g. This indicated very high efficacy of L3 reduction (over 98.7%, $P < 0.05$). These novel compounds may be a viable treatment to aid in the control of GIN infection by reducing development and survival of larvae in feces, thus reducing pasture infectivity.

Key Words: control, nematodes, sheep

1719 Recovery of fibroblast cells up to 65 d of postmortem storage of sheep ear skin at 4°C. M. Singh* and X. Ma, *Fort Valley State University, Fort Valley, GA.*

Animal cloning technology has renewed interest in tissue storage, since these tissues can be used to reintroduce lost genetics back into the breeding pool in animal agriculture, preserve genetic diversity, and revive endangered species. Several studies have demonstrated that cell survival decreases with increasing postmortem tissue storage. However, the limits of time interval within which live cells can be recovered

from animal tissues postmortem have not been adequately studied. The objective of this study was to evaluate the time limits of cell survival in sheep skin tissues stored at 4°C after the death of the animal. Outgrowth of cells around small tissue explants in cultures was used as a measure of cell recovery. Ear skin was procured from the university slaughter house from six random but healthy animals and stored at 4°C in the lab. We cultured 2–3 mm^2explants (n = 60) after 0, 10, 20, 27, 30, 35, 38, 41, 45, 50, 55, 60, 65, and 70 d of tissue storage. DMEM media supplemented with 10% FBS and 50 units/mL of penicillin and 50 µg/mL of streptomycin was used. Twelve dishes (60 mm) for each time point were used. After 10 d of culture in a CO_2incubator, outgrowth of fibroblast-like cells around the explants was scored. Out of 481 explants that adhered to dish surface, 374 exhibited outgrowth. Our results showed outgrowth of cells up to 65 d of postmortem storage. In general, the number of outgrowing cells decreased with increasing postmortem storage time. To test the differences between cell cultures obtained from postmortem fresh and stored tissues, we established secondary cultures from primary cells of 0-dpm and 65-dpm time points from selected cell lines and studied their growth profile (p5 level) which showed similar morphology and growth curves. The karyotype analysis of 65 dpm tissue derived cells revealed a normal female karyotype without any genetic aberrations. Both cultures have been passaged up to 33 times which exhibit similar morphology; however, they grew very slowly. These results suggest that live cells can be recovered from skin tissues of sheep and perhaps other animals for more than 2 mo after their death with comparable growth profiles.

Key Words: cell culture, fibroblast cells, postmortem tissue storage, sheep, skin

1720 Morphometric measurements and body weight affected by breed, age, and sex in the Sindh goat breed populations of Pakistan. M. Moaeen-ud-Din[*1], G. Bilal[1], J. M. Reecy[2], M. S. Khan[3], and S. Razzaq[1], *[1]PMAS-Arid Agriculture University, Rawalpindi, Pakistan, [2]Iowa State University, Ames, [3]University of Agriculture, Faisalabad, Pakistan.*

Sindh province is harbor of maximum goat breeds in Pakistan. However, there is scarcity of information regarding the indigenous goat breeds of Sindh province on morphometric measurements and weight. Therefore, the current study was designed to study the effects of age, sex, and breed on body weight and body measurements of ten goat breeds in their respective breeding tracts. A survey was performed in breeding tracts of ten goat breeds of Sindh viz. Kamori, Tapri, Bugi-Turi, Pateri, Kachan, Jattan, Lohri, Chappar, Barri, and Thari. During the current study HyderAbad, Matiyari, Hala, Methi, Umer kot, Tharparkar, Thatha, Badin, Dadu, and Mirpur Khas districts of Sindh province were visited. Data were collected and arranged according to age class (class 1: 1–6 mo, class 2: 7–12months, class 3: 13–18 mo, class 4: 19–24 mo, class 5: 25–36 mo, class 6; 37–48 mo, class 7: 49–60 mo, class 8: > 60 mo), sex, and breed. Data were analyzed using Mixed Procedure by REML methodology in SAS (Version 9.2) to investigate the effect of breed, age, and sex on body weight and body measurements. Overall breeds did differ for live body weight, heart girth, length, height, and chest length ($P < 0.05$). However, there was no difference among breeds in term of pubic bone length ($P < 0.05$). Kamori had mean body weight of 67.58 ± 1.41 kg, followed by Pateri (50.01 ± 1.50kg), Bugi-Turi (44.13 ± 1.33kg), Barri (43.50 ± 1.60kg), Kachan (42.50 ± 1.60kg), Tapri (39.33 ± 1.55kg), Jattan (38.63 ± 1.51kg), Chappar (38.03 ± 1.49kg), Lohri (35.41 ± 1.60kg), and Thari (33.94 ± 1.45kg). There was significant difference among age class for all the body measurement and body weight ($P < 0.05$) except for pubic bone length. Overall male goats showed higher body weight and height. The present study revealed variations in body measurements and body weight across age, sex, and breed in Sindh for the first time. As goats are mainly raised for meat production in the area, Kamori goat showed highest body weight followed by Pateri, Bugi-Turi, Barri, Kachan, Tapri, Jattan, Chappar, Lohri, and Thari. Moreover, if breeds are to selected for mutton based on body weight, then Kamori are followed by Pateri, Bugi-Turi, Barri, Kachan, Tapri, Jattan, Chappar, Lohri, and Thari. This could be useful information if a selection program is to be launched in the future to improve meat production in the province.

Key Words: AJK, goat breeds, body measurements, body weight

1721 Effects of supplementing olive pomace as a feed additive on weight gain in *Capris aegagrus hircus*. P. Urso*, M. M. Beverly, S. F. Kelley, M. J. Anderson, J. L. Leatherwood, K. J. Stutts, and S. Nair, *Sam Houston State University, Huntsville, TX.*

In the livestock industry, feed is one of the highest variables affecting the cost of production. A producer's goal is to find the least costly feedstuff that is effective in meeting nutrient requirements of livestock, particularly during winter months. Olive pomace is a by-product of the olive oil industry and could be considered as a potential livestock feedstuff to be used as an energy supplement due to its high fat content (15%). The objective of our study was to determine if olive pomace could be used as an acceptable low cost feedstuff to maintain weight during the colder winter months. To accomplish this 28 Spanish influence goats were fed (2% of body weight, BW) varying amounts of fermented pomace with a protein pellet to meet maintenance requirements. The four test groups (n = 7) consisted of a 3:1, 1:1, and 1:3 olive pomace to concentrate ratio (O:C) as well as a control containing no pomace. All groups received molasses at 0.5% BW

to improve the palatability of the feed and to further homogenize the ration to discourage selective eating of the mixture. Does were fed in herring bone style runs every morning for 49 d. The average daily gain (ADG) for the 1:3, 1:1, 3:1, and control groups were 0.0370, 0.0166, 0.0119, and 0.0262 kg/day, respectively, with no difference detected between groups ($P > 0.88$). The similar ADG across groups suggests that pomace can be an effective feed additive to reduce feed costs. A difference ($P < 0.01$) in consumption rates was detected between treatments with the 3:1 group consuming more feed with an average of 0.785 kg/day compared to the control at 0.694 kg/day. Additionally, olive pomace may be considered as a cost effective supplement to reduce costs for maintenance rations. Using ANOVA, cost efficiency of the test groups were compared. Rations costs were calculated at $0.153/g for the 3:1 ration compared to $0.6386/kg for the pelleted control ration. On average, this difference in input cost can reduce a producer's cost of feed by $13.53/hd over a 49 d maintenance feeding period ($P < 0.01$) by feeding olive pomace. While further research is needed to determine the optimum levels of olive pomace feeding, it remains a viable alterative to high cost feedstuffs.

Key Words: goats, olive, pomace

1722 Genetic and non-genetic effects on performance traits in a U.S. population of dairy sheep.

T. W. Murphy*[1], M. Baldin[2], Y. M. Berger[3], R. L. Burgett[4], P. W. Holman[3], and D. L. Thomas[1], *[1]University of Wisconsin-Madison, Department of Animal Sciences, Madison, [2]Pennsylvania State University, Department of Animal Science, University Park, [3]University of Wisconsin-Madison, Spooner Agricultural Research Station, Spooner, [4]National Sheep Improvement Program, Ames, IA.*

There are relatively few dairy sheep operations in the U.S., but the industry is growing. Genetic improvement in dairy flocks has come through "breeding-up" ewes of common meat and wool breeds to European dairy breeds with imported rams and semen. This process has led to a crossbred domestic dairy sheep population consisting of East Friesian (EF), Lacaune (LA), and non-dairy (Meat) breeds. The objectives of this research were to: 1) determine the non-genetic factors affecting ewe performance, 2) estimate genetic parameters of and among traits, and 3) evaluate the genetic trends in traits of economic importance. Data were obtained from flock records collected at the Spooner Ag Research Station, University of Wisconsin-Madison from 1995–2015. There were 5438 records on number of lambs born per ewe lambing (NLB) and 4763 records on 180-d adjusted milk (MY), fat (FY), and protein (PY) yield, and percentage fat (%F) and protein (%P). There were 1969 and 1688 ewes with NLB and lactation records, respectively. The two multiple trait repeatability models jointly analyzed NLB, MY, FY, and PY or NLB, MY, %F, and %P. The significant fixed effects were trait dependent but included a proportion of EF and LA breeding, EFxLA and LAxMeat specific retained heterosis coefficients, age of ewe at lambing, and production year. The estimated heritabilities were 0.08 ± 0.02, 0.30 ± 0.04, 0.26 ± 0.04, 0.29 ± 0.04, 0.53 ± 0.04, and 0.61 ± 0.04 for NLB, MY, FY, PY, %F, and %P, respectively. NLB had a negative genetic correlation with %F (−0.25 ± 0.12). However, all other estimates of genetic correlations between NLB and lactation traits were low. The yield traits had high genetic correlations with each other (0.90 ± 0.02 between MY and FY, 0.96 ± 0.01 between MY and PY, and 0.93 ± 0.01 between FY and PY). There were unfavorable genetic correlations of −0.29 ± 0.08 between MY and %F and −0.35 ± 0.08 between MY and %P. The genetic correlation between %F and %P was high (0.60 ± 0.05). The regression of MY predicted breeding value on ewe year of birth revealed an average genetic improvement of 2.60 ± 0.12 kg yr^{-1} from 1995 to 2014 in this population. Due to the current restrictions and difficulties surrounding importation of foreign germplasm, a national dairy sheep genetic evaluation program is key to the continued improvement of U.S. flocks.

Key Words: crossbreeding, dairy sheep, genetic parameters

1723 Effects of high concentrations of crude glycerin on feed intake and ruminal parameters of sheep.

E. H. C. B. van Cleef*[1,2], M. T. C. Almeida[1,2], E. S. Castro Filho[1], I. Monsignati[1], H. L. Perez[1,2], and J. M. B. Ezequiel[1], *[1]São Paulo State University, Jaboticabal, Brazil, [2]FAPESP, São Paulo, Brazil.*

Eight ruminally-cannulated crossbred (Santa Ines × Dorper) male sheep (64.5 ± 8.5 kg) were used to evaluate the effects of high concentrations of crude glycerin on dry matter intake, and ruminal parameters. Animals were assigned to a replicated 4 × 4 Latin square design and, in pairs, were fed one of the four experimental diets. Isonitrogenous (18.4% CP) and isoenergetic (2.7 Mcal ME/kg DM) diets were composed of corn silage, soybean hulls, soybean meal, mineral premix, and crude glycerin replacing 0 (G0), 10 (G10), 20 (G20), or 30% (G30) corn cracked grain (DM basis), in a roughage:concentrate ratio of 40:60. Crude glycerin totally replaced corn grain in G30, and contained 83% glycerol, 95% DM, 6% salt, and less than 0.01% methanol. Each experimental period lasted 21 d (14 d adaptation and 7 d data collection). Animals were fed twice daily (0700 and 1900 h), and feed delivered and refused were weighed every morning to assess DMI. Ruminal pH, ammonia nitrogen (NH_3–N), and short-chain fatty acids (SCFA; acetate [C2], propionate [C3], butyrate, isobutyrate, valerate, and isovalerate) were evaluated at 0, 2, 4, 8, 10, and 12 h after feeding. No interaction time of observation × treatments was observed. The DM intake tended to show a quadratic effect ($P = 0.09$), with greater values observed for

G10 and G20 (1375 and 1336 g/d, respectively). Ruminal pH tended to linearly increase ($P = 0.07$), with values from 6.0 (G0) to 6.2 (G30). A tendency for a quadratic effect of ruminal concentrations of NH_3–N ($P = 0.06$) was observed, with lesser values for treatments with intermediate levels of crude glycerin (9.6 and 10.2 mg/dL, respectively for G10 and G20). Crude glycerin inclusion linearly decreased total SCFA ($P < 0.0001$), acetic acid ($P < 0.0001$), butyric acid ($P = 0.0004$), isobutyric acid ($P = 0.0007$), isovaleric acid ($P = 0.003$), and C2:C3 ratio ($P < 0.0001$). The production of propionic and valeric acids were not influenced by treatments (average = 8.7 and 0.5 mg/dL); however, the proportion of propionate linearly increased from 21 to 34% of total SCFA produced. The inclusion of up to 30% crude glycerin in diets for crossbred sheep promotes quadratic effect on DM intake and ruminal concentrations of NH_3–N, changes SCFA profiles and increases ruminal pH.

Key Words: glycerol, rumen, sheep

1724 Serum anti-mullerian hormone as an indicator of fertility in Katahdin ewes. M. Acharya*[1], J. M. Burke[2], E. Smyth[2], L. Ngere[2,3], and R. W. Rorie[1], [1]*Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville,* [2]*USDA-ARS, Booneville, AR,* [3]*Oak Ridge Institute for Science and Education, Oak Ridge, TN.*

Individual ewes vary in reproductive performance parameters, such as age at first lambing, twinning rate, and ability to breed during off-season. Previous studies indicate that anti-mullerian hormone (AMH) in circulation reflects the total pool of follicles within the ovaries, and is positively correlated with fertility. In this study, retrospective analysis was used to determine if AMH could serve as an indicator of ewe fecundity. Serum samples were collected from 152 Katahdin ewes ranging from 0.5 to 7 yr of age, their pregnancy and lambing rate recorded, and estimated breeding values obtained from the National Sheep Improvement Program. Anti-mullerian hormone was analyzed using an equine and ovine AMH enzyme-linked immunosorbent assay (ELISA) kit. Continuous variables were analyzed by ANOVA and categorical data by chi-squared, using JMP® (SAS institute) software. Serum AMH ranged from 0.04 to 0.39 ng/mL, with mean of 0.17 ng/mL. Mean serum AMH was similar ($P = 0.37$) across all ewe age groups (< 1, 1 to 2, 2 to 3, and > 4 yr). The distribution of AMH concentrations was divided into quartiles (AMH Q1 through Q4, with the Q1 lowest and Q4 the highest). There was no relationship (fall; $P = 0.65$; summer; $P = 0.11$) between AMH quartile and mean number of lambs born (NLB) from fall and summer breeding. No correlation ($P = 0.39$) was found between individual estimated breeding value for NLB and serum AMH concentration. A significant correlation ($P < 0.01$; $r = 0.411$) existed between mean NLB per individual ewe during summer (0.79) and fall (1.44). Overall pregnancy rate was higher ($P < 0.01$) for fall (79%) than summer (48%) breeding. It was noted that 25/68 (36.8%) of ewes < 2 yr of age fell into the lowest AMH quartile (Q1) as compared with 13/84 (15.5%) for older ewes. Similarity of AMH among different ewe age groups and a lower percentage of older ewes in AMH Q1 could reflect particular selection criteria.

Key Words: anti-mullerian hormone, ewes, reproductive performance

1725 Fatty acid composition of different fat depots from hair and wool x hair crossbred lambs supplemented with highly digestible fiber containing agro-byproducts on pasture. C. Tripp*[1], J. H. Lee[1], S. Wildeus[2], A. Discua[1], and D. Kafle[1], [1]*Fort Valley State University, Fort Valley, GA,* [2]*Virginia State University, Petersburg.*

Agro-byproducts such as soy hull and corn gluten have been recognized as economical sources of feeds for small ruminants because they can provide supplemental nutrients for small ruminants with highly digestible fiber. However, their effect on the fatty acid profile of different fat depots in lambs has not been completely studied. This study was conducted to determine the fatty acid composition of different fat depots from grazing lambs supplemented with highly digestible fiber containing agro-byproducts. Thirty-six 7.5-mo-old purebred hair (Barbados Blackbelly and St. Croix) and crossbred wool (Dorset) x hair lambs grazed predominantly Jesup tall fescue pasture. Lambs were randomly assigned to a pasture-only, or a soy hull (SH) or corn gluten feed (CGF) supplemented group balanced by breed type. Supplement was provided at 2% of BW daily at individual feeding stations. After 77 d of grazing, lambs were slaughtered using standard procedures. Intramuscular, subcutaneous, and kidney fats were obtained from each carcass. Total lipids from each fat depot sample were extracted by the chloroform-methanol method. Extracted lipids were prepared for the fatty acid methyl esters (FAME) and then analyzed by a gas chromatography. All data were analyzed as a completely randomized design with a 2 × 3 factorial treatment arrangement: breed type (pure- or cross-bred) and diet (pasture-only, pasture plus SH or CGF) as main effects. The fatty acid profiles of different fat depots from lambs were significantly influenced by supplementation. Compared with lambs supplemented with SH or CGF, pasture-only fed lambs had higher concentrations of γ-linolenic (C18:3n6; 0.50 or 0.52 vs. 0.64%), arachidonic (C20:4n6; 2.10 or 2.06 vs. 3.31%), eicosapentaenoic (C20:5n3; 0.46 or 0.36 vs. 1.06%), and docosahexaenoic (C22:6n3; 0.55 or 0.52 vs. 1.27%) acids, but lower ($P < 0.05$) concentrations of palmitic (C16:0; 17.0 or 18.1 vs. 15.9%) and oleic (C18:1n9; 33.8 or 32.8 vs. 29.1%) acids in intramuscular fat; higher ($P < 0.05$) concentrations of myristoleic (C14:1n5), palmitoleic

(C16:1n7), α-linolenic (C18:3n3; 1.80 or 1.24 vs. 2.84%), and C18:3n6 (0.83 or 0.65 vs. 2.66%) acids, but a lower ($P < 0.01$) concentration of C18:1n9 in subcutaneous fat; and a higher ($P < 0.01$) concentration of C14:1n5, but a lower concentration of C18:1n9 in kidney fat. The results indicate that fresh lamb from pasture only fed-lambs might have healthier fatty acid profiles compared with that from lambs supplemented with soy hull or corn gluten feed.

Key Words: agro-byproduct, fatty acid, lamb

SMALL RUMINANT SYMPOSIUM: ENHANCING SMALL RUMINANT PROFITABILITY

1726 Profitability of small ruminant production systems.

G. W. Williams* and D. P. Anderson, *Texas A&M University, College Station.*

The prolonged decline in U.S. sheep numbers is well documented. Well known reasons for the decline include dwindling U.S. demand for lamb, relative prices for competing meats, the rise of man-made fibers competing with wool, discontinuation of the U.S. Wool Incentive payment program, grazing allotment policies for public lands, and restrictions on predator control. Another critically important force behind falling U.S. sheep numbers has been rising costs resulting in unprofitable conditions, forcing producers to reduce the size of their flocks or exit the industry. Using extension sheep production budgets, this study examines and compares sheep production costs across various states representing conventional sheep production based on an average flock size with costs and returns on a per ewe basis. The weighted total variable cost was $124.44 per ewe in 2015 and ranged from $148 per ewe in Kentucky to $118 per ewe in Wyoming. Receipts were the highest in the Eastern region at $179 per ewe and were the lowest in Texas at $98 per ewe. Net returns ranged from a-$41 to $21 per ewe in Texas and Kentucky, respectively. Costs between regions reflected significant differences in production systems. For example, feed made up just over 50% of total variable costs in Texas and 22% of total variable costs in Wyoming. Hired labor made up 37% of total variable costs in Wyoming or $44 per ewe. Predator control costs were $10.50 per ewe in Texas but only $1-$2 in the other regions. The results highlight the variable nature of the cost of sheep production and the range of production systems across the country. Policy changes that affect hired labor costs, for example, affect Wyoming and Western region production more than smaller flocks in the East with little, if any, hired labor. New technologies or predator control systems would be likely to see the greatest returns in Texas and the Southwest or in the Mountain West. Changes in public land grazing policies would have the biggest effect in the West. Positive returns in Kentucky indicate opportunities for industry expansion in the Eastern half of the U.S.

Key Words: cost of production, net returns, production systems, sheep

1727 Contribution of hair sheep to small ruminant profitability.

J. Morgan*, *Round Mountain Consulting Service, Fayetteville, AR.*

Hair sheep numbers in the United States have increased dramatically in the past twenty years as documented by breed registry data. Characteristics promoted by hair sheep producers include: moderate or small framed, easy care, parasite resistant, twinning, productivity in extensive systems, aseasonal breeders, and adapted to heat and humidity. These descriptors suggest that hair sheep have the potential to add to the profitability of small ruminant production in the USA. Two hair sheep breeds rank among the top six breeds for numbers of sheep registered in the USA from 2002 to 2015 (Table 1 for 2003–2015). The increase in hair sheep registrations occurred while the vast majority of wool sheep registries experienced declines of 25–75% in their registration numbers from 1990 to 2015. Research results from three research stations will be discussed since they document productivity of hair sheep and hair sheep crosses. These stations include USDA ARS Meat Animal Research Center in Nebraska, USDA ARS Small Farm Research Center in Arkansas, and Texas A&M Agrilife Research Center in San Angelo, Texas. Data from these stations and other university studies find that the weights of weaned and finished hair sheep lambs are well suited to markets and regions of the country that reward the non-traditional or light lamb market. In the Nebraska and Arkansas production systems, hair sheep genetics produced 150–200% lamb crops in forage-based systems compared to annual NASS reports of 110% for the United States. In west Texas, research results indicate that lamb markets differentially impact hair sheep (Dorper) and wool sheep (Rambouillet) producers based on corn prices and weather (Sheep and Goat Research Journal, In Press). During drought years, Dorpers wean significantly more lambs. When corn prices are high, Dorpers bring premium prices for the light lamb, non-traditional markets. When corn prices are low, wool feeder lambs bring premium prices. A significant percentage of the hair sheep operations, using breed association membership, are located in regions of the country where sheep numbers have traditionally been low, especially the Southeastern region. It is suggested that lack of shearers, decreased quality and quantify of wool, resistance to parasites (documented by Virginia Tech, LSU, USDA Booneville, among others) and adapted to heat and humidity help with popularity of these breeds in this region.

Key Words: breed registry, hair, sheep

1728 Contribution of newer goat breeds to small ruminant profitability. R. Browning, Jr.*[1] and M. L. Leite-Browning[2], [1]*Tennessee State University, Nashville,* [2]*Alabama A&M University, Huntsville.*

Profitability in commercial meat goat enterprises is affected by animal productivity, market value, and input costs. Productivity indicators include doe reproductive output, kid growth rate, carcass merit, and hardiness. Breed choice(s) can affect these profit factors and set the path to profit or loss. Meat goat breed options are scant compared to other ruminant livestock sectors in the US. The South African Boer goat was a highly visible new breed introduced in the 1990s to enhance meat production of the US herd base of primarily Spanish-type goats. This model has been repeated worldwide. New Zealand Kiko goats were also imported by US interests in the 1990s. New breeds are usually introduced with a focus on improving growth and end-products (e.g., meat, milk, fiber) while overlooking fitness traits (health and reproduction) that may be greater profit drivers, especially if doelings are retained for future breeding. Successful new breed introductions require some level of adaptation to destination environments, particularly in low-input systems. Loss of native or naturalized local genotypes possessing desirable fitness levels while pursuing improved growth or end-product traits is a global concern. This was true after large-scale crossbreeding of naturalized Spanish goats with imported Boer commenced. Research indicated that Boer germplasm generated an insignificant to negative impact on doe fitness compared to the Spanish maternal base. Reductions in doe reproductive output, wellness, and stayability point to lowered expected enterprise profitability. Health and stayability problems increase input costs. Economic analysis demonstrated lower annual net return for Boer does (-$52.25) compared to Spanish does ($7.18) in a low-input setting. Some relative increases in weight were evident using Boer at various research stations, but improvements in carcass merit were not so obvious. One carcass trait noticeably improved by the Boer influence was conformation score. Improved conformation score can increase market value. Across performance traits, other data suggests that Kiko goats may be a favored import over Boer for increasing commercial herd profitability. The newest breed garnering attention among US producers is the South African Savanna. Like Boer and Kiko in the 1990s, current industry use of Savanna is preceding objective characterization. The newer breeds have increased industry popularity, but not necessarily profitability. Proper selection and use of new and established breeds in meat goat mating systems is important for profitability in a low-input commercial setting. Managing around poor meat goat breed choices is probably not profitable or sustainable.

Key Words: breed, meat goat, profitability

1729 Contribution of forage production systems to small ruminant profitability. R. Ehrhardt*, *Michigan State University, East Lansing.*

Improving forage utilization is a key consideration in increasing production efficiency and decreasing the cost of production in a small ruminant farming systems. In much of North America, winter dormancy and to a lesser extent, slow growth in mid-summer, creates barriers in both forage availability and quality in perennial-based grazing/forage production systems for small ruminants. To better understand how to optimize forage systems for sheep production in the upper Midwest USA, a series of grazing studies were conducted with sheep over a 3 yr period to examine forage utilization, animal performance, and cost of production on annual, short-term perennial, and perennial pastures. These pastures were evaluated as part of a 3 yr pasture rotation system and compared to a perennial only system. This rotation was established in year 1 by converting perennial pastures to annual crops between after attaining approximately 60% of historical seasonal biomass production (mid-June conversion). Annual crops evaluated included warm season grasses, brassicas, and their mixtures. In year 2 a short-term perennial pasture consisting of red clover, ryegrass, and chicory was established in early spring into the annual forage residue from year 1. In late summer of year 3, a perennial pasture was reestablished. The perennial pasture used as a base of comparison consisted of a mixture of alfalfa, endophyte free tall fescue and orchard grass. Animal performance on these pastures and within these systems was measured by the growth performance of lambs post-weaning expressed on a lamb (g/day) and land basis (kg/hectare). Individual lamb gains on brassica (310 g/d) and short-term perennial (278 g/d) pastures approached that of the same genotype fed a concentrate diet fed in confinement (330 g/d). On a land basis, seasonal gains on short-term perennial pasture excelled (1430–1640 kg/ha) over other pastures. The cost of lamb gain was calculated for each pasture ranking lowest to highest were short term perennial < perennial < brassica monocultures < brassica/warm season mixes < warm season monocultures. In summary, complimentary pasture rotation systems offer value to small ruminant production by reducing the cost of gain, allowing opportunities for finishing on pasture, improving parasite management, improving soil health, and overall system productivity and profitability.

Key Words: sheep, goats, forages, grazing

SWINE SPECIES

1730 Probiotic treatment using *Bacillus subtilis* PB6 improves the growth performance, intestinal morphology, enzyme activities and barrier function in low birth weight piglets. L. Hu, L. Che**, X. Peng, Q. Xu, Z. Fang, S. Xu, Y. Lin, and D. Wu, *Institute of Animal Nutrition, Sichuan Agricultural University, Chengdu, China.*

This study aimed to investigate the effects of *Bacillus subtilis* PB6 supplementation in milk formula on growth performance, intestinal development, and immune function in low birth weight (LBW) piglets. Piglets with a birth weight near the mean litter birth weight (SD 0.5) were identified as normal birth weight (NBW), whereas those with at least 1.5 SD lower birth weight were defined as LBW. Fourteen pairs of NBW and LBW piglets (7 d old) were randomly assigned to receive the formula milk or formula milk with *Bacillus subtilis* PB6 for a period of 21 d. At Day 28, blood samples, intestinal tissues, and digesta were collected at necropsy and analyzed for morphology, digestive enzyme activities, immune cells, gene, and protein expressions as well as microbial population. Data were analyzed by SPSS software using the MIXED procedure. Regardless of the diet, LBW decreased the average daily dry matter intake (−31%, $P <$ 0.001) and the average daily growth (−28%, $P < 0.001$). Moreover, LBW decreased plasma concentration of immunoglobulin A (−17%, $P < 0.001$), interleukin-1β (−12%, $P =$ 0.006), the count (−33%, $P = 0.021$) and percentage (−13%, $P = 0.025$) of blood lymphocytes compared to NBW piglets. LBW decreased the villous height (−8%, $P = 0.039$) and enzyme activity of maltase (−24%, $P = 0.011$), as well as the mRNA abundances of *Toll-like receptor 9* (−34%, $P = 0.020$) and *Toll-interacting protein* (−21%, $P = 0.001$) in ileum. Regardless of body weight, the supplementation of *Bacillus subtilis* PB6 markedly decreased the feed:gain ratio (−10%, $P = 0.034$), which could be related to the better intestinal morphology, increased enzyme activities of maltase (+19%, $P = 0.082$) and sucrase (+23%, $P = 0.095$) in jejunum. Moreover, the protein abundances of *Zonula occludens-1* and *Claudin-1* (+33~54%, $P < 0.05$) in ileum, as well as the copy number of *Bacillus* ($P = 0.01$) in colonic digesta were increased in piglets supplemented with *Bacillus subtilis* PB6 relative to piglets with control diet. Our results indicated that LBW impaired the growth and intestinal development as well as immunity of piglets, however, dietary supplementation of *Bacillus subtilis* PB6 improved the growth performance with better intestinal development and barrier function in both NBW and LBW piglets.

Key Words: immunity, low birth weight, probiotic

1731 Dietary nucleotides supplementation improves the intestinal development and immune function of low birth weight piglets. L. Hu, L. Che**, X. Peng, Q. Xu, Z. Fang, S. Xu, Y. Lin, and D. Wu*, Institute of Animal Nutrition, Sichuan Agricultural University, Chengdu, China.*

This study aimed to determine whether dietary nucleotides supplementation could improve growth performance, intestinal development, and immune function of low birth weight (LBW) piglets. Piglets with a birth weight near the mean litter birth weight (SD 0.5) were identified as normal birth weight (NBW), whereas those with at least 1.5 SD lower birth weight were defined as LBW. Fourteen pairs of NBW and LBW piglets (7 d old) were randomly assigned to receive a liquid milk-based control diet (CON diet) or diet supplemented with nucleotides (NT diet) for a period of 21 d. NT diet was formulated by adding 0.74% nucleotides in CON diet, the pattern of nucleotides (5'-AMP, CMP, GMP, IMP, UMP) was similar as that in sow milk. Data were analyzed by SPSS software using the MIXED procedure. Compared with NBW piglets, LBW piglets had significantly lower average daily dry matter intake ($P = 0.001$) and average daily gain ($P < 0.001$). Moreover, LBW decreased the villous height ($P = 0.008$) and villi: crypt ratio ($P = 0.014$) in duodenum, as well as maltase ($P = 0.033$) activity in jejunum. In addition, LBW decreased the serum concentrations of immunoglobulin A ($P < 0.001$), interleukin-1β ($P = 0.017$) and interleukin-10 ($P = 0.008$), as well as the percentage of peripheral lymphocytes ($P = 0.015$). Meanwhile, the downregulation of innate immunity-related genes such as *Toll-interacting protein* (TOLLIP) ($P = 0.012$) and *Toll-like receptor* (TLR) 2 ($P = 0.073$) was observed in the ileum of LBW relative to NBW piglets. Regardless of birth weight, however, feeding NT diet decreased ($P = 0.001$) the feed:gain ratio, increased villous height in duodenum ($P = 0.036$), activities of lactase ($P = 0.019$) and maltase ($P = 0.055$) in jejunum, also increased count of peripheral leukocytes ($P = 0.039$), serum concentrations of immunoglobulin A ($P = 0.001$), and interleukin-1β ($P = 0.019$) as well as gene expressions of *TLR-9*, *TLR-4*, and *TOLLIP* (all $P < 0.05$) in ileum. In addition, the protein expressions of *Claudin-1* and *Zonula occludens-1* ($P < 0.05$) in ileum were markedly increased by feeding NT diet relative to CON diet. Our results indicated that LBW impaired the growth performance, intestinal and immune function, but dietary supplementation of nucleotides improved the growth performance, digestive capability, and immunity.

Key Words: immunity, low birth weight, nucleotides

1732 Effect of supplemented mineral phosphorus and fermentable substrates on gut microbiota composition and metabolites, phytate hydrolysis, and health status of growing pigs. C. M. E. Heyer*, S. Schmucker, E. Weiss, M. Eklund, T. Aumiller, E. Graeter, T. Hofmann, M. Rodehutscord, L. E. Hoelzle, J. Seifert, V. Stefanski, and R. Mosenthin, *University of Hohenheim, Institute of Animal Science, Stuttgart, Germany.*

The present study examined the impact of diets with varying CaP levels and fermentable substrates on intestinal CaP concentration, phytate (*myo*-inositol hexakisphosphate, $InsP_6$) hydrolysis, the intestinal microbiota, and the immune system in pigs. In 2 consecutive experiments, 31 growing pigs (55 ± 4kg) were allotted to a 2 × 2 factorial arrangement with 4 treatment groups, and were fed either a corn-soybean meal or a corn-pea based diet with differences in digestibility, each with 2 different CaP levels (low vs. high, supplemented with monocalcium phosphate). After 3 wks of adaptation to the diets, all pigs were immunized twice with keyhole limpet hemocyanin (KLH) (wk 4 and 6) and blood samples were taken 2 wks after the second immunization. In wk 8, the amount of anti-KLH IgG and anti-KLH IgM were analyzed in blood samples. After slaughtering in wk 9, jejunal and cecal digesta were analyzed for Ca, P, and inositol phosphate isomers, determination of 16S rRNA gene copy numbers by qPCR and bacterial metabolite analyses. Pigs fed the low-CaP diets showed lower plasma anti-KLH IgG concentrations ($P < 0.05$). The low-CaP level promoted jejunal *Bifidobacterium* spp. ($P < 0.01$). For the pea diets, jejunal *Lactobacillus* spp. were lower ($P < 0.05$). In the cecum, *Eubacterium rectale* and *Roseburia* spp. ($P < 0.05$) were lower for the low-CaP diets. For the pea diets, the caecal *Eubacterium rectale* and *Bifidobacterium* spp. ($P < 0.05$) were lower. In the cecum, total SCFA, acetate, and propionate ($P < 0.01$) were lower for the low-CaP diets. Acetate and butyrate ($P < 0.05$) in caecal digesta were lower for the pea diets. The P net absorption in the jejunum and cecum was lower ($P < 0.01$) for the low-CaP diets. In addition, the $InsP_6$ hydrolysis in digesta samples was not affected by the dietary treatment, nevertheless the $InsP_6$ concentration in the jejunum was lower for the pea ($P < 0.05$) and low-CaP diets ($P < 0.05$). In conclusion, the present study demonstrated that CaP and fermentable substrates modulate the adaptive immune response and the intestinal microbiota, and sufficiently high amounts of CaP may be required to support the adaptive immune response, beneficial saccharolytic bacteria and SCFA production. It needs to be further elucidated whether variations in P digestion and/or absorption might explain the complex relationship between P, the immune system, and the microbial ecosystem.

Key Words: immune system, intestinal microbiota, phosphorus, pig

1733 Sexual development and boar taint in male pigs selected for divergent residual feed intake. A. Prunier*[1], S. Parois[1], N. Le Floc'h[1], and H. Gilbert[2], *[1]PEGASE, Agrocampus Ouest, INRA, Saint-Gilles, France, [2]GenPhyse, Université de Toulouse, INRA, INPT, INPT-ENV, Castanet-Tolosan, France.*

Improving feed efficiency and rearing entire male pigs are relevant strategies to reduce feed cost and environmental waste in pig production. The major constraint for rearing entire male pigs being boar taint, an experiment was performed to determine the consequences of a divergent selection on residual feed intake (RFI: low RFI = LRFI; high RFI = HRFI) on pubertal development, and boar taint. Forty-one purebred French Large White male pigs in the course of a divergent selection experiment for RFI (10th generation of selection, $n = 20$ or 21 per line) were recruited. Blood samples were drawn at 125, 140, 154, and 168 ± 1 d of age (mean ± SD) for plasma estradiol (E2) and testosterone (T) determination by EIA. At slaughter at 177 ± 4 d of age (108 ± 14 kg liveweight), a backfat sample was collected in the neck for androstenone and skatole determination by HPLC and genital tract was removed for testes and Cowper gland weighing after tissue trimming. All data were analyzed by ANOVA using R, including line as a fixed effect. Plasma E2 and T were log transformed for normalization and analyzed using a repeated in time model with nlme. Fat androstenone and skatole were analyzed using a generalized mixed model with lme4. Other data were analyzed using lm. Growth rate, age, and liveweight did not differ between lines ($P > 0.1$). Testes weight was similar in both lines (LRFI: 527 ± 23 g; HRFI: 471 ± 33 g, $P > 0.1$) whereas Cowper glands were heavier in LRFI pigs (176 ± 10 g vs. 100 ± 8 g). Fat androstenone (1.97 ± 0.31 vs. 0.56 ± 0.08 μg/g pure fat) and skatole (0.14 ± 0.02 vs. 0.05 ± 0.01 μg/g pure fat) were also higher in LRFI pigs ($P < 0.001$). The interaction age x line for E2 and T was not significant ($P > 0.1$). Across ages, plasma T (5.0 ± 0.9 vs. 2.7 ± 0.7 ng/mL plasma) and E (25.5 ± 2.9 vs. 11.4 ± 1.0 pg/mL plasma) were also higher in LRFI than in HRFI pigs ($P < 0.001$). In both lines, both hormones increased with age ($P < 0.001$). Overall, these data suggest a lower testicular activity in the HRFI than in the LRFI line which is positive for meat quality but may be detrimental to the reproductive function in the HRFI line.

Key Words: androstenone, boar, estradiol, feed efficiency, testosterone

1734 Effects of dietary live yeast supplementation on growth and immunological parameters of weaned piglets challenged with *Escherichia coli* K88.

Q. Xu and L. Che*, C. Wu, X. Peng, C. Yan, L. Hu, L. Qin, R. Wang, Y. Lin, Z. Fang, and D. Wu, *Institute of Animal Nutrition, Sichuan Agricultural University, Chengdu, China.*

This study aimed to investigate the effects of dietary live yeast (*Saccharomyces cerevisiae*, Phileo Lesaffre Animal Care, France) supplementation on growth performance and immunological parameters of piglets challenged with enterotoxigenic *Escherichia coli* K88. A total of 180 weaned piglets (6.39 ± 0.05 kg) were randomly allocated into 5 treatments with 6 pens and 6 piglets (3 barrows and 3 gilts) per pen, receiving the control (CON) diet, diets supplemented with antibiotics plus ZnO (ABT-ZnO:2250 mg/kg of ZnO, 20 mg/kg Colistin and 75 mg/kg Aureomycin), live yeast at 1 (LY1), 2.5 (LY2.5), or 5 g/kg (LY5) for a period of 2 wk. On Day 8, six piglets from CON group received sterilized Luria Broth as control ($n = 6$), while another 30 piglets from CON ($n = 6$), antibiotic plus ZnO ($n = 6$), LY1($n = 6$), LY2.5 ($n = 6$), and LY5 ($n = 6$) groups, were orally challenged with Luria Broth containing $1x10^{11}$ cfu of *E. Coli* K88. Body weights and pen feed disappearance were recorded weekly to determine ADG, ADFI, and F:G. On d 10, blood, ileum, and mesenteric lymph node (MLN) tissue samples were collected at necropsy and analyzed for immunological parameters. Data were analyzed by SPSS software using the GLM procedure. Pigs fed ABT-ZnO diet had higher ($P < 0.05$) ADG and ADFI than pigs fed CON, LY1, and LY5 diets during the first week, while ADFI and F:G were similar between pigs fed ABT-ZnO and LY2.5 diets. Moreover, the ADG of pigs fed LY1 diet was similar to pigs fed ABT-ZnO diet during the second week. Compared with the pigs fed ABT-ZnO diet and non-challenged pigs, pigs fed LY2.5 and LY5 diets had higher ($P < 0.05$) plasma concentration of immunoglobulin G. Relative to the non-challenged pigs, moreover, the plasma concentration of Pig Major Acute Phase Protein (PMAPP) was increased ($P < 0.05$) in the challenged pigs fed CON diet, but PMAPP had not been markedly affected in the pigs previously fed ABT-ZnO and LY5 diets. Relative to the non-challenged pigs, *E. coli* K88 challenge up-regulated ($P < 0.05$) the mRNA abundances of toll-like receptor 4 (TLR-4), toll-like receptor 9 (TLR-9), myeloid differentiation factor 88 (MyD88), tumor necrosis factor receptor-associated factor 6 (TRAF-6), and interleukin-6 (IL-6) in ileum, however, those genes were downregulated by feeding LY5 diet. In conclusion, pigs fed live yeast diet had similar ADFI and F:G as pigs fed ABT-ZnO diet during the first week, the higher inclusion of live yeast could improve immunological parameters of piglets challenged with *E. coli* K88.

Key Words: immunity, intestine, live yeast

1735 Assessment of the age of lesions on the pig carcass at the abattoir through spectrophotometric color assessment and gene expression analysis.

M. Vitali*[1], S. Conte[2], M. Lessard[3], G. Martelli[1], F. Guay[4], and L. Faucitano[5], *[1]University of Bologna, Bologna, Italy, [2]Agriculture and Agri-Food Canada, Lennoxville, Canada, [3]Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, Canada, [4]Universite Laval, Quebec City, Canada, [5]Agriculture and Agri-Food Canada, Sherbrooke, Canada.*

The presence of skin lesions downgrades carcass value and indicates poor animal welfare preslaughter. The aim of this study was to assess the age of lesions on the carcass at slaughter through spectrophotometric color assessment and gene expression of the following genes involved in tissue inflammation and repair: CCL2, IL6, ITGA3, MMP1, and SERPINE1. A total of 96 barrows (100 ± 10kg), allotted into 8 pens of 12 pigs each, were used. Over a three day period, each pig was mixed four times: in the finishing pen 2 d before slaughter, at loading, and in the lairage pen at the abattoir. Fighting- and mounting-type lesions were selected through visual assessment and video validation. Twenty lesions and control skins (with no lesions) per age group (total of 80 lesions and control skins) were selected, with each group consisting of 1, 4, 24, and 48 h old lesions. Data and skin samples were collected at the abattoir. For gene expression analysis, a skin biopsy of 4 mm was taken on each lesion and control skin at bleeding. After extraction, RNA was analyzed by qPCR to evaluate gene expression involved in tissue inflammation and repair. In the cooler, the color of each lesions and control skin was assessed through Minolta spectrophotometer. Delta values for each lesion were calculated between color and gene expression values obtained from the lesioned and control skin. Statistical analyses were performed using the mixing procedure of SAS, with log transformation applied to gene expression data. The time of infliction had an effect on Minolta L* and a* values ($P < 0.01$ for both), with 1 h old lesions being darker (higher-DL* value) than 4 and 24–48 h old ones ($P < 0.05$) and redder (higher Da* value; $P < 0.01$) than 24–48 h old lesions. The different lesions age resulted in a different expression of CCL2 and IL6 cytokines ($P < 0.001$), and other genes involved in tissue repair and remodeling (MMP1, ITGA3, SERPINE1) whose genetic expression was greater ($P < 0.01$) in 1 h old lesions compared with 24–48 h old ones. Furthermore, when compared with 4 h old lesions, 1 h old lesions presented a greater expression of CCL2 and ITGA3 ($P < 0.01$), and MMP1 ($P < 0.05$). To conclude, the spectrophotometric color assessment and the analysis of inflammatory and tissue repair gene expression in the carcass lesions at slaughter may be reliable methods to discriminate between fresh and older lesions at the abattoir.

Key Words: age, pigs, skin lesions

1736 Blood plasma replacement by hydrolyzed yeast in weaned piglets' diets. J. A. Rivera*[1], L. F. Araújo[2], R. L. D. C. Barbalho[3], M. A. Bonato[3], L. A. Vitagliano[4], G. D. Santos[3], and M. L. Cuadros[5], *[1]Faculdade de Medicina Veterinária e Zootecnia–VNP/FMVZ/USP, Pirassununga, Brazil, [2]University of Sao Paulo, Pirassununga, Brazil, [3]ICC Brazil, Sao Paulo, Brazil, [4]Universidade de São Paulo, Pirassununga, Brazil, [5]Veterinary Medical, Universidad Peruana Cayetano Heredia, Lima, Peru.*

The aim of this study was to evaluate partial levels or complete substitution of blood plasma by hydrolyzed yeast as a source of nucleotides in piglets' diets. For this, 1600 weaned piglets (± 21 d of age) Agroceres PIC® distributed in a randomized block design with 4 treatments and 10 replicates of 40 animals each. The nursery phase was divided in four: pre-initial I: 22 to 28 d; pre-initial II: 29 to 35 d; initial I: 36 to 47 d; and initial II: 48 to 63 d. The treatments consisted of different inclusions of plasma and hydrolyzed yeast (*Saccharomyces cerevisiae*) [HY] (Hilyses®-from ICC Brazil Company): 1- Control–conventional diet provided at the farm, with normal levels of plasma (6, 4, 2, and 0%- in the respective phases); 2- Diet with plasma reduction (3, 2, 1, 0) + HY (4, 3, 2, and 0%); 3- Diet with plasma reduction (1.5, 1, 0.5 and 0%) + HY (6, 4.5, 3, and 0%); 4- Diet without plasma + HY (8, 6, 4, and 0%). The piglets begin receiving the experimental diets after weaning until the end of this phase (± 66 d). The feed intake (FI) and body weight were measured at the end of each phase. Based on this, FI (g/d), body weight gain (BWG, g/d) and feed conversion ratio (FCR, g/g) were calculated. Mortality were daily observed and noted. Data obtained were analyzed with GLM (SAS) procedure and means were compared by Tukey test ($P = 0.05$). In phase pre-initial 1 the control treatment (no replacement) resulted in better ($P < 0.05$) FI and BWG, when compared to other treatments. However, during phase pre-initial 2, treatments with the larger proportion of HY (3 and 4) showed an increase ($P < 0.05$) in FI (26.3 and 13.7%, respectively); in phase initial 1, improved ($P < 0.05$) BWG (30.8%, for both treatments) and FCR (−17.4 and −17.3%, respectively). Considering the total period, the treatment 3 improved numerically (not statistically) FI (4.1%), BWG (8%), FCR (−2.3%), and mortality (−83.3%). The analysis of the data allow us to conclude that, in commercial farm conditions, the replacement of blood plasma by hydrolyzed yeast as a source of nucleotides is a viable alternative, and may even improve FI, BWG, FCR, and mortality.

Key Words: nucleotides, nursery, nutrition, *Saccharomyces cerevisiae*

1737 Effects of dietary energy on muscle growth of low birth weight neonatal pigs. Y. Chen*, S. R. McCauley, K. R. Oliver, R. P. Rhoads, and S. W. El-Kadi, *Virginia Tech, Blacksburg.*

Increasing the efficiency of nutrient utilization in farm animals remains one of the most important means to increasing profitability. It is well documented that increasing energy intake increases insulin-like growth factor I (IGF-I) concentration in animals. In addition, our previous data suggest that IGF-I signaling is compromised in muscle of low birth weight (LBWT) compared to normal birth weight (NBWT) neonatal pigs. We hypothesized that LBWT pigs have a higher energy requirement compared to their NBWT siblings. Twelve pairs of 7-d old, sex matched LBWT (1.73 ± 0.24 kg) and NBWT (2.42 ± 0.29 kg) pigs from the same litters were used. Pigs were fed either a low (LE) or high energy (HE) isonitrogenous diets, that contained 80 or 100% of NRC metabolizable energy requirement for 14 d. Body composition was determined by dual energy X-ray absorptiometry before and 13 d after initiation of feeding. On the last day of the study, pigs were euthanized to collect blood, and weigh and sample muscles. Plasma IGF-I concentration was measured using a commercial ELISA kit, and muscle mRNA expression by real-time PCR. Body weight was lower for LBWT than NBWT pigs throughout the study ($P \leq 0.05$). Lean and fat deposition increased with feeding in both LBWT and NBWT pigs, but was lower in LBWT compared with their NBWT littermates ($P \leq 0.05$). Longissimus dorsi (LD), gastrocnemius, semitendinosus and soleus muscle weights were lower in LBWT compared to NBWT pigs ($P \leq 0.05$). However, there was no effect of diet energy content on body composition and muscle weights. Plasma IGF-I concentration in LBWT pigs was lower than NBWT when pigs were fed LE diet, but increased to similar level as the NBWT group when pigs were fed the HE diet ($P \leq 0.05$). Gene expression of IGF-I, IGF-I receptor, and IGF binding protein 3 and 5 were lower in the LD muscle of LBWT compared with NBWT pigs fed the LE diet, while the mRNA abundance of these proteins was similar in LBWT and NBWT pigs fed the HE diet ($P \leq 0.05$). These results suggest that although increasing dietary energy content increased plasma IGF-I concentration and muscle mRNA expression of IGF-I and IGF binding protein 3 and 5 in LBWT pigs, the increase in growth was only modest indicating that other macronutrients may be limiting growth.

Key Words: dietary energy, LBWT, muscle growth

1738 Prediction of the concentration of androstenone in backfat from boar carcasses using indicators of sexual development. A. Prunier*[1], S. Parois[1], A. Faouën[1], and C. Larzul[2], *[1]PEGASE, Agrocampus Ouest, INRA, Saint-Gilles, France, [2]GenPhyse, Université de Toulouse, INRA, INPT, INPT-ENV, Castanet-Tolosan, France.*

Predicting fat androstenone concentration using a rapid and cheap method applied to live pigs is needed for efficient genetic selection against boar taint. Piétrain x (Large White x Landrace) boars were slaughtered either at 119 ± 4 kg live weight and 168 ± 1 d of age (S1, n = 48) or at 116 ± 4 kg and 174 ± 1 d of age (S2, n = 42). Blood and saliva samples were collected on D 0 (S1: 29 d, S2: 35 d before slaughter) and D 27 (S1: 2 d, S2: 8 d before slaughter) to measure plasma concentrations of estradiol and testosterone and salivary concentration of estrone by EIA. A backfat sample was collected on live pigs by biopsy on D 27 and on carcasses at slaughter to measure concentration of androstenone by HPLC. Testes and Cowper glands were weighed at slaughter after tissue trimming. Data were analyzed using the R MASS package. When necessary, variables were log or square root transformed for normalization. Predictive models of fat androstenone at slaughter were established with the modlin function. Plasma estradiol and fat androstenone on D 27, taken separately, were good predictors of fat androstenone at slaughter (mean R^2 between measured and predicted values was 0.48 and 0.43, respectively for each predictor) in S1 pigs. The quality of the prediction decreased between S1 and S2 pigs despite inclusion of salivary estrone in the equation with estradiol. To conclude, plasma estradiol can be considered as a good predictor of fat androstenone at slaughter if the delay between blood collection and slaughter is short.

Key Words: estradiol, estrone, genital tract

1739 Effects of dietary ramie (*Bochmeria nivea*) powder at different levels on carcass traits, muscle fiber characteristics, and muscular free amino acid profile of Chinese indigenous finishing pigs. Y. Tang*, *Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha, China.*

The experiment was conducted to investigate the effects of containing different levels of ramie powder in finishing pig diets on carcass traits, muscle fiber characteristics, and muscular free amino acid (FAA) profile. A total of 150 Xiangcun Black pigs, a Chinese local breed, with initial body weight (70.71 ± 1.21 kg) were used in a 50-d feeding study. Pigs were randomly allotted to 1 of 5 isonitrogenous and isoenergetic diets (corn-soybean meal-based) containing 0, 3, 6, 9, or 12% ramie. There are 6 replicate pens per treatment with 5 pigs per pen. On d 50, a subsample of 40 pigs (8 pigs per treatment) was harvested and carcass traits were calculated. Measurements of diameter and density of myofibers in longissimus dorsi muscle (LM) were taken. Muscle samples including LM and biceps femoris muscle (BM) were analyzed for myosin heavy chain (MyHC) mRNA expression level and FAA profile. The data were analyzed by SPSS 18.0 software with ANOVA analysis. Polynomial contrasts were performed to determine linear and quadratic effects. The level of P < 0.05 was the criterion for statistical significance. Overall, increasing dietary ramie reduced (linear, P < 0.05; 34.09 to 25.02 mm) the backfat thickness and increased (linear, P < 0.05; 23.46 to 32.38 cm2) the loin-eye area of the finishing pigs. A quadratic effect of MyHC IIb mRNA expression level in the LM was also observed as the dietary ramie added (P < 0.05), and the lowest value (0.77) was noted in 9% ramie group, along with the increased (P < 0.05) density of myofibers with a quadratic effect, but diameter of myofibers in the LM was linearly reduced (P < 0.05, 74.06 to 67.07 μm). Inclusion of ramie powder in the diet could up-regulate MyHC I mRNA expression level in the BM (quadratic, P < 0.05), with the highest point (1.77) in 9% ramie group. In addition, increasing dietary ramie linearly lowered (P < 0.05) the contents of essential amino acid (EAA) and total amino acid (TAA) in the LM, while linearly heightened (P < 0.05) both contents in the BM. In conclusion, these results suggested that ramie is an effective and unconventional feed crop to improve carcass traits and muscle fiber characteristics, and the underlying mechanism may be partly due to the alteration in MyHC gene expression levels and muscular FAA profile induced by dietary ramie.

Key Words: carcass trait, finishing pig, free amino acid, myofiber, ramie

1740 Effects of different sources and routes of administration of copper and vitamins A and D on gut volatile fatty acids and gene expression involved in regulation of innate and acquired immunity in piglets. L. Lo Verso*[1], J. J. Matte[1], G. Talbot[1], J. Lapointe[1], N. Bissonnette[1], F. Guay[2], N. Gagnon[1], B. Ouattara[1], and M. Lessard[1], *[1]Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, Canada, [2]Universite Laval, Quebec City, Canada.*

Placental and colostral transfers of copper and vitamins A and D are limited in pig species (Matte et al., 2014, JAS 92-Suppl. 2:153). Because these micronutrients can influence intestinal microbiota and development of immunocompetence, the aim of the study was to evaluate the influence of different neonatal supplementation strategies on volatile fatty acid (VFA) concentration, pH, and modulation of cytokine gene expression in piglets' gut. Within each litter from 5 sows, 10 newborn piglets were allocated to one of the following combinations of sources and routes of micronutrient administrations: oral vitamin D3, retinol-acetate and $CuSO_4$ (T1); oral

25-OH-D3, β-carotene and Cu-yeast (T2); exposure to UVB light (20 min every second day), oral retinol-palmitate and Cu-gluconate (T3); intramuscular vitamin D3 and retinol-propionate and oral Cu-acetate (T4); oral saline (CTL). Oral or intramuscular provisions corresponded to 12 mg of copper and 70 and 12 MIU of vitamins A and D, respectively. This design was repeated with 5 other sows fed daily supplements of 25-OH-D3 (4 MIU), β-carotene (24 MIU), and Cu-yeast (45 mg) from 90 d of gestation to 21 d of lactation. At 23 d of age, 2 d after weaning, 5 repetitions of a combination of sow and piglet factorial treatments were sacrificed: caecal pH was recorded and digesta samples from cecum and mid-colon were taken to measure VFA concentrations. Mesenteric lymph nodes and jejunal and ileal mucosal samples were collected for measurement of cytokine gene expression by quantitative real-time PCR. Supplementation to sows significantly reduced caecal pH ($P < 0.01$) and increased both caecal ($P < 0.05$) and colonic ($P < 0.01$) VFA concentrations. Within piglet treatments, caecal VFA concentration was higher in T3 than in T4 ($P < 0.05$), but no difference was detected among other groups. For cytokine gene expression, jejunal IL-10 expression was reduced in T2 compared to T1, T3, or T4 groups ($P < 0.05$), while supplementation to sows increased gene expression of IL-22 ($P < 0.01$), IL-1β ($P < 0.05$), and IL-8 ($P < 0.05$) in the mesenteric lymph nodes. These results indicated that sow supplementation in combination with exposure to UVB light and oral supplementation of vitamins D and A and copper was an efficient administration method to modulate intestinal production of VFA by microbiota and cytokine gene expression compared to CTL. These results are in line with data indicating that copper and vitamins A and D statuses of neonatal piglets are increased by oral supplementation or UVB light (results not shown).

Key Words: copper, gut, piglets, retinol, vitamin D

1741 Comparison of transport characteristics of ferrous sulfate and iron glycine chelate across IPEC-J2 cell monolayers. *S. Fang*, College of Animal Science, Zhejiang University, HangZhou, China.*

The study was conducted to compare the transport characteristics of ferrous sulfate ($FeSO_4$) and iron glycine chelate (Fe-Gly) across porcine jejunal cell line (IPEC-J2) monolayers. IPEC-J2 cells were seeded onto the 6-well transwell collagen-coated PTFE filters and evaluated for study use on the 19–22th days. The trans-epithelial electrical resistance (TEER) value of 7510.92 ± 1586.44Ω·cm^2 was observed, a transportation percentage (0.92%) of fluorescein sodium could meet the requirements of tightness. The AKP activity in the apical side (AP) had significant higher than the basolateral side (BL) ($p < 0.01$), which means the IPEC-J2 cells has well polarity. These cell monolayers were used for the transport studies. For transport study, sample solutions containing different iron concentrations (5, 10, and 20 μmol/L) were added to AP and a buffer was added to BL. Different times (0–120 min) and temperatures (37°C, 4°C) were designed to study the effects on transportation in the same iron concentration (10 μmol/L). Samples were removed from the buffer and the iron concentrations were analyzed by atomic absorption spectrophotometer. Triplicate wells were used for each treatment. The results showed that transports of Fe-Gly and $FeSO_4$ across IPEC-J2 cell monolayers are linear increased as time went on ($R^2 = 0.9518$, $R^2 = 0.9428$, respectively). Iron transport amount of Fe-Gly and $FeSO_4$ under 37°C are significant higher than those under 4°C ($P < 0.05$), so did the apparent permeability coefficient (*Papp*). These results suggest that the absorption of Fe-Gly and $FeSO_4$ in IPEC-J2 cells may through active transport. However, no concentration-dependent iron transport was found, at concentration of 5 and 10μmol/L, iron transport in Fe-Gly treatment was higher than $FeSO_4$, at concentration of 20μmol/L, transport amount of both iron sources significantly reduced ($P < 0.05$), iron transport amount in Fe-Gly treatment was significant lower than $FeSO_4$ ($P < 0.05$). Distinct absorption mechanism may account for the transport difference between these two iron sources at different concentrations.

Key Words: IPEC-J2; absorption; ferrous sulfate; iron glycine chelate; active transport

1742 Studing of population structure of European wild boar (*Sus scrofa*) and its subspecies, inhabiting Russia. A. A. Traspov[1], O. V. Kostyunina[1], I. A. Domsky[2], A. V. Ekonomov[2], A. A. Sermyagin[*1], and N. A. Zinovieva[1], *[1]L.K.Ernst Institute of Animal Husbandry, Moscow, Russian Federation, [2]Institute of Hunting and Fur-farming named after professor B.M. Zhitkov, Kirov, Russian Federation.*

Genetic studies help to shed a light on the topic but it embraces various aspects including economic, social, and technical issues. Genetic structure of wild boars from Russia can represent flexible territorial clusterization on large geographical areas. In this study, we performed whole-genome SNP analysis of wild boars inhabiting the Russian Federation. Forty animals represent 11 regional subpopulations of the wild boars. They were genotyped using Porcine 60K BeadChip (Illumina Inc., USA). All populations belong to European part of Russia, including Arkhangelsk, Chelyabinsk, Kirov, Krasnodar, Kurgan, Novgorod, Smolensk, Tumen, Udmurtia, Vladimir, and Volgograd regions. We used PLINK v1.09 to obtain Multi-Dimensions Scaling matrix (MDS) and pairwise clustering based on IBS distances. Neighbor Joining tree provided by MEGA v.7 software, based on Tamura-Nei model. In addition, we evaluated population structure of wild boars using ADMIXTURE 1.20 package and calculated pairwise differences and F-statistics between subpopulations. Visualization of data was performed by R. Analysis of spatial distribution showed that at least four groups of animals, which belong

to Arkhangelsk, Kirov, Novgorod, and Vladimir subpopulations, performed separated clustering. Another seven subpopulations have formed a huge single group. We could observe the exchange of single animals between Smolensk and Arkhangelsk subpopulations. The same result was shown by NJ-tree dendrogram and IBS-clustering matrix—most part of animals formed main core with minor branches. Analysis of admixture was performed for the number of clusters (K) from 2 to 7. Analysis of population structure performed for the clusters number K = 2 and 3 according to obtained lowest values of CV errors (0.76395 and 1.42878, respectively) and showed high divergence of the Arkhangelsk subpopulation among all other subpopulations. The presence of clusters may probably indicate the existence of wild boar subspecies. There are no Asian subspecies of wild boar in the European territory of Russia, so we can presume that Arkhangelsk wild boar subpopulation belongs to European-Caucasian subspecies of wild boar. This is the first large-scale analysis of the Russian wild boars performed on whole-genome level. Studies will be continued with involving wild boars inhabiting the whole area of distribution of this species in Russia.

Key Words: phylogenetic, population studies, wild boar

1743 Supplementation with a blend of capsicum and artificial sweetener improves performance of growing and finishing pigs. C. Ionescu*, C. Soulet, C. Bruneau, and E. H. Wall, *Pancosma, Geneva, Switzerland.*

Supplementation of piglets with the artificial sweetener SUCRAM® increases intestinal expression of sodium-glucose co-transporter-1, glucose uptake, and mucosal growth. Both SUCRAM® and capsicum oleoresin improve efficiency of growth in pigs; however, responses to the two additives fed in combination have not been described. The objective of this experiment was to determine the effects of such a blend on feed intake and performance of growing and finishing pigs exposed to a dietary energy challenge. Pigs (PIC380 x Large White/Landrace; n = 252 barrows & 252 gilts) were housed in 24 pens under 12-h artificial lighting, were blocked by BW and gender, and were randomly assigned to two treatments (n = 21 pigs per pen; 12 pens per treatment) during grower and finishing phases (Grower 1: 25–50 kg; Grower 2: 50–75 kg; Grower 3: 75–100 kg; Finsher: 100–129 kg). Dietary treatments were: 1) Low-NE which was a standard diet formulated to meet NRC recommendations, with wheat millrun added to decrease net energy by 100 kcal NE/kg; and 2) Low-NE + supplementation with a blend of capsicum oleoresin and SUCRAM® (CAPS-SUC; 75 g/ton; TakTik® X-Hit; Pancosma, Geneva, Switzerland). Diets were fed ad libitum as mash feed and disappearance of feed was measured by a robotic recording system. Pigs and remaining feed were weighed at the end of each feeding phase to calculate daily gain and daily feed intake, respectively. Mortality, pulls, and health records were monitored; growth performance, days to market weight, and carcass characteristics were measured. Inclusion of CAPS-SUC in the Low-NE diet increased daily gain in both the Grower 1 (949 vs. 974 g/d; $P < 0.05$) and Finisher phases (921 vs. 938 g/d; $P < 0.05$). This appeared to be partly driven by feed intake, which was numerically increased with CAPS-SUC when all phases were considered (2.70 vs. 2.85 g/d; $P < 0.20$). Feed ÷ gain was not affected by treatment across all phases (2.98 vs. 2.97; $P > 0.80$). Removals and deaths were not affected by treatment ($P > 0.50$). Carcass weight was increased (101.7 vs. 102.5 kg; $P \leq 0.05$) and days to slaughter were decreased (18.2 vs. 16.7; $P \leq 0.10$) with CAPS-SUC. Feed costs were not affected by treatment ($0.72 vs. $0.73/kg; $P > 0.20$). The results of this study indicate that CAPS-SUC can improve performance of growing and finishing pigs when a dietary challenge is introduced.

Key Words: feed additive, phytonutrient, Sucram

1744 Effects of different sources and routes of administration of copper and vitamins A and D on piglets gut microbiota. G. Talbot[1], M. Lessard[*1], E. Yergeau[2], N. Gagnon[1], L. Lo Verso[1], J. Lapointe[1], N. Bissonnette[1], D. Bueno Dalto[1], B. Ouattara[1], F. Guay[3], and J. J. Matte[1], *[1]Agriculture and Agri-Food Canada, Sherbrooke Research and Development Centre, Sherbrooke, Canada, [2]Université du Québec, Centre INRS-Institut Armand-Frappier, Laval, Canada, [3]Universite Laval, Quebec City, Canada.*

Placental and colostral transfers of copper and vitamins A and D micronutrients from dams to neonates are limited in pig species (Matte et al., 2014, JAS 92-Suppl. 2:153). The aim of the study was to evaluate the influence of different perinatal micronutrient supplementation strategies on piglets' gut microbiota. Within each litter from 5 sows, 10 newborn piglets were allocated to one of the following combinations of sources and routes of micronutrient administrations: oral vitamin D3, retinol-acetate and $CuSO_4$ (T1); oral 25-OH-vitamin D3, β-carotene and Cu-yeast (T2); exposure to UVB light (20 min every second day), oral retinol-palmitate and Cu-gluconate (T3); intramuscular vitamin D3 and retinol-propionate and oral Cu-acetate (T4); oral saline (CTL). Oral or intramuscular provisions corresponded to 12 mg of copper and 70 and 12 MIU of vitamins A and D, respectively. This design was repeated with 5 other sows fed daily extra supplements of 25-OH-vitamin D3 (4 MIU), β-carotene (24 MIU) and Cu-yeast (45 mg) from 90 d of gestation to 21 d of lactation. At 21 d of age, feces were collected and piglets were weaned. At 23 d of age, 5 repetitions of a combination of sow and piglet factorial treatments were sacrificed and feces and content from mid-jejunum, ileum, mid-colon, and rectum were collected to characterize gut microbiota. Bacterial communities were analyzed by sequencing the V3-V4 regions of

16S rRNA genes on an Illumina MiSeq. Bioinformatic analyses were performed on our internal data analysis pipeline and statistics were performed in R. The analysis of bacterial community composition at the class level revealed that sow supplementation significantly increased the relative abundance of *Bacilli* in feces at d 21 ($P = 0.04$) but not at d 23. Gut microbiota diversity significantly differed ($P = 0.03$) according to supplemental treatments provided to piglets. However there was no piglet treatment effect on gut microbiota based on PCoA analyses. The Shannon diversity of jejunal and ileal microbiota was significantly ($P < 0.05$) decreased when supplementation was given to sows. Sow supplementation also significantly increased *Bacilli* in both jejunum and ileum ($P < 0.001$, both). The study demonstrated that piglet gut microbiota can be modulated by daily extra supplementation of vitamins A and D and organic copper to sows during late pregnancy and lactation periods. Further studies are thus warranted to study mechanisms of action explaining the impact of such maternal micronutrient supplementation on bacterial colonization in piglets gut.

Key Words: copper, gut microbiota, piglets, retinol, vitamin D

1745 Diurnal heat stress reduces nursery-grower pig performance and intestinal integrity.

N. K. Gabler*[1], G. R. Murugesan[2], S. Schaumberger[3], U. Hofstetter[3], and G. Schatzmayr[4], [1]*Department of Animal Science, Iowa State University, Ames,* [2]*BIOMIN America Inc., San Antonio, TX,* [3]*BIOMIN Holding GmbH, Getzersdorf, Austria,* [4]*BIOMIN Research Center, Tulln, Austria.*

Heat stress negatively affects performance and intestinal integrity of livestock. Our objective was to characterize the effects of diurnal heat stress on nursery-grower pig performance and intestinal integrity. Forty-eight individually penned crossbred gilts (21 ± 2.0 kg BW) were randomly assigned across two environmental treatments (thermal neutral (TN) or diurnal heat stress (HS), $n = 24$/trt) at the Iowa State University Swine Nutrition Farm. All pigs were allowed ad libitum access to water and a corn-soybean diet that met or exceeded NRC (2012) requirements. After a thermal neutral acclimation period, 24 pigs (HS) were exposed to 3 d of diurnal heat stress with 6 h in HS conditions (38°C; 40–60% humidity) and 18 h in thermal neutral conditions (32°C; 40–60% humidity). The remaining 24 TN pigs were maintained for these 3 d under thermal neutral conditions (28°C; 40–60% humidity). Pig rectal temperature (Tr), respiration rates (RR), BW changes, and feed disappearance were recorded over the environmental treatment. Blood samples were collected at the end of the 3 d environmental treatment and metabolites, endotoxin, cytokines, and acute phase proteins were evaluated. All pigs were sacrificed after the 3 d environmental treatment and ex vivo ileum integrity was assessed in Ussing chambers by measuring transepithelial resistance (TER), FITC-dextran (FD4), and FITC-LPS permeability. As expected, HS pig Tr were increased on average 2°C over the 3 d period ($P < 0.05$) and RR increased from 50 to 150 breathes per min (TN verses HS, respectively, $P < 0.01$). Compared to TN, HS pigs had a 30% reduction in ADFI and a 76% reduction in ADG over the 3 d environmental treatment ($P < 0.05$). Gain to feed was also reduced due to HS compared to TN (0.16 verses 0.55, $P = 0.016$). Ileum TER was significantly decreased ($P = 0.04$), FTIC-LPS ($P < 0.01$) and FD4 ($P = 0.015$) permeability increased due to HS compared to TN pigs. Serum endotoxin was significantly elevated due to HS ($P = 0.031$) and there was a reduction in LPS-binding protein ($P = 0.06$) and tumor necrosis factor α ($P = 0.04$) in HS compared to TN pigs. Overall, HS reduced blood insulin concentrations by 50% ($P = 0.02$), but did not affect blood glucose concentrations ($P = 0.47$). Altogether, short exposure to diurnal heat stress significantly reduced pig performance and intestinal integrity compared to those exposed to thermal neutral conditions.

Key Words: heat stress, intestine, pig

1746 Effect of diet composition on piglet growth and digestibility responses to a high dietary canola content.

G. A. Mejicanos*, *University of Manitoba, Winnipeg, Canada.*

Soybean meal (SBM) and canola meal (CM) are the most extensively used protein supplements in the feed industry, whereas corn and wheat are the main sources of energy in swine diets in North America. Although recent studies show that piglets can handle relatively high levels of CM, it is unclear whether this ability depends on the cereal base the diet. Thus, the aim of the study was to determine whether the composition of the main feed ingredients in the basal diet influences pig response to high dietary CM inclusion as indicated by growth performance and apparent total tract digestibility (ATTD) measurements. Ninety-six pigs [(Yorkshire-Landrace) x Duroc)] with an initial BW of 6.63 + 0.028 kg (barrows) and 6.78 + 0.036 kg (gilts) were used in this 28-d feeding study. There were 8 replicate pens per treatment each with 3 pigs. Pigs were randomly allotted to one of four dietary treatment: 1) Corn-SBM; a corn-SBM based diet, 2) Corn+20%CM; a corn-SBM diet with SBM partially replaced by 20% CM, 3) Wheat-SBM; a wheat-SBM based diet, and 4) Wheat+20% CM, a wheat-SBM diet with SBM partially replaced by 20% of CM. A two phase feeding program was used (phase 1, 1 to 14 d post-weaning and phase 2, 15 to 28 d post-weaning). Average daily gain (ADG), average daily feed intake (ADFI), and feed efficiency (G:F) were recorded weekly. Freshly voided fecal samples were collected on d 21 and 27 to determine ATTD of CP and energy. Data were analyzed as a randomized complete block design using MIXED procedure of SAS. No significant differences were observed in ADFI, ADG, and FBW among treatments ($P > 0.10$). Pigs

fed on the wheat + 20% CM diet had higher G:F ratio compared with those fed on the corn-SBM diet (0.95 vs. 0.79, $P < 0.01$) during phase 1. However, the corn-SBM diet had higher ATTD of CP and energy compared with piglets fed the corn+20% CM, wheat-SBM, and wheat+20% CM diets (96.6 vs. 89.0, 90.9, and 87.2%; and, 95.3 vs. 89.6, 90.8, and 86.9%, $P < 0.01$) during phase 2. In conclusion, results indicated that the composition of the main feed ingredients in the basal diet influences feed efficiency, likewise protein and energy digestibility when CM is included at 20% level without affecting voluntary feed intake and ADG.

Key Words: canola meal, diet composition, digestibility

TEACHING UNDERGRADUATE AND GRADUATE EDUCATION

1747 Increase in demand for hands-on instruction in animal science curriculum.

R. Woiwode*, *Colorado State University, Fort Collins.*

In animal science programs across the United States, the fraction of undergraduate students that have livestock experience before entering college is diminishing. Students in many programs clamor for hands-on experiences with animals and livestock, as it is relevant to their program of study, and may provide a competitive advantage in applying to a veterinary program. An experimental course was proposed for two primary purposes; first to address the specific demand encountered in the Department of Animal Sciences at Colorado State University, and second to provide greater pre-employment training and experience in course development and instruction for a doctoral student wishing to pursue an academic path. With guidance from the department head, a course description, outline, and schedule were constructed and presented to the departmental curriculum committee. Upon receiving authorization for the course to be listed on an experimental basis, registration was made available to the first ten students to enroll. The three credit course consisted of two lectures per week and one lab. Students were guided through an introduction to classical behaviorism and ethology, moving on to species specific behaviors of the major livestock species. Information was presented first in lecture, and reinforced through lab exercises. In labs, students were introduced to concepts through expert demonstration of animal handling or management techniques, and then practiced the skill with close supervision. Students had several opportunities to increase their proficiency with specific skills before they were given a practical assessment. Students were assessed on their assimilation of lecture material through traditional written exams, as well as in class and take home quizzes. Evaluation of the course was conducted with questions ranked in a 5-point Likert scale to assess student perceptions and effectiveness of the course to achieve university learning goals. Students felt this course was an important part of their academic experience, and indicated that the exposure to the livestock species and various sectors of the livestock industry they were exposed to in this course was an invaluable experience. Finally, students felt that the size of the class provided optimum opportunity for students to receive instruction, practice, and demonstrate proficiencies.

Key Words: hands-on instruction, livestock experience, livestock handling, proficiency

1748 Adding a student-generated summary of main points to a lecture as a learning tool in an advanced nutrition course.

S. L. Hansen*, *Iowa State University, Ames.*

Learning-centered classrooms encourage students to focus on the thinking required to master a concept. Previous work has suggested that increasing the number of focused engagement activities such as Turn To Your Partner (TTYP) within a class period enhances student retention of information in an advanced animal science course. The TTYP activity allows at least 3 opportunities to think about the learning, as the student generates his/her own answer, discusses it with a partner, and participates in whole class discussion. Starting each class period with a defined set of learning outcomes provides focus to the lecture and provides an outline from which students can study. Similarly, a structured ending to a class period that includes a review of the most salient points from a lecture could be beneficial to student learning. Students in a senior level animal nutrition course ($n = 34$ students) were asked to generate overall summary statements at the end of lecture ($n = 23$ lectures in the semester). During the last 5 min of class, students were asked to compile summary points from the lecture using the TTYP format. Students were given approximately 2 min to generate a list of 3 to 5 primary summary points from the day's lecture material or discussion. They were then allowed to work with a partner for another minute, and then brought back to group discussion. Students were held accountable for their learning by being called on at random to share what they and their partner had identified as a critical summary point for the day's material. This continued until all points were exhausted. Critical opportunities for student development included the opportunity for the instructor to correct misconceptions, and for students to develop better note taking and summarizing skills. Students gave feedback halfway through the semester and 80% specifically mentioned that summary point generation was a factor in class that positively affected their learning. Twenty-three students completed the final anonymous course evaluation, and 87% replied to the question "what helped your learning most in this class"? Of those replies, 100% indicated the TTYP and summary exercise were beneficial in their learning. Including

a summary exercise at the end of each class was a positive addition to an advanced nutrition course and contributed to the success of students.

Key Words: learning, summary points, undergraduate

1749 Teaching animal welfare via competitive judging contests. C. B. Shivley*[1], F. B. Garry[2], and T. Grandin[1], [1]*Colorado State University, Fort Collins,* [2]*Colorado State University, College of Veterinary Medicine and Biomedical Sciences, Fort Collins.*

The scientific study of animal welfare involves complex assessments of an animal's physical health, emotional state, and the naturalness of its environment. As the public becomes more aware of animal welfare, the demand for students knowledgeable about animal welfare science is increasing, yet many universities provide little training in this field. The Animal Welfare Judging and Assessment Contest (AWJAC) was created in 2002 at Michigan State University with support from Purdue University to teach students how to assess and critique the welfare of animals used for food production, research, companionship, and other human purposes. Each year at the annual competition, computer-based scenarios on four pre-determined animal species are presented to the students with information on performance, health, physiology, handling, and behavior of the animals. The students evaluate the scenarios to determine which facility has the best welfare, and defend their decision through oral reasons presented to judges. The competition now has undergraduate, graduate, and veterinary divisions. The 2015 competition was held at Ohio State University with 25 teams and 105 individuals competing. A course was created at Colorado State University (CSU) in 2012 to prepare students for the competition, and can serve as an example of how to teach students about animal welfare assessment. The course teaches students about general animal welfare principles, provides in depth training on the four featured species through guest lecturers, field trips, and review of the scientific literature, and develops public speaking skills. The CSU teams have continued to be successful at the contest, and in 2015 CSU won first place in the graduate division, as well as numerous individual awards. The contest combined with the course provides learning opportunities about the growing field of animal welfare science.

Key Words: animal welfare, judging teams, welfare assessment

1750 Integrated program for reducing bovine respiratory disease complex (BRDC) in cattle, coordinated agricultural project (CAP): Translation of multi-omics research results into teaching programs. M. G. Thomas*[1], R. M. Enns[1], R. Hagevoort[2], J. S. Neibergs[3], A. L. Van Eenennaam[4], H. L. Neibergs[5], and J. E. Womack[6], [1]*Department of Animal Sciences, Colorado State University, Fort Collins,* [2]*New Mexico State University, Dairy Extension, Clovis,* [3]*Washington State University, Pullman,* [4]*University of California, Davis,* [5]*Department of Animal Sciences, Washington State University, Pullman,* [6]*Texas A&M University, College Station.*

Bovine respiratory disease complex is a common cause of morbidity and mortality in cattle, especially young animals exposed to stress. This disease is considered a complex because of numerous pathogens, environmental and management factors of the beef and dairy industries. Susceptibility to BRDC is also considered a complex trait as it is very polygenic. The general research objective of this CAP is to use genomic approaches to identify chromosome regions associated with susceptibility to BRDC. The genomic approaches described in the research publications from this CAP involve multiple types of data and results, such as genome-wide association and SNP-chip data, DNA and RNA sequencing, quantitative genetics and many physiological measures of the immune system. The results will be translated to beef and dairy industries via selective breeding tools and methods for disease prevention and management. These types of tools are known as genome-assisted EPD and PTA. A translational effort of research findings, which also includes cattle health and behavior results, is encompassed in multiple teaching and extension efforts described on this website: http://www.brdcomplex.org/. Examples of the genomic translational educational effort include the Herd Health and Breeding and Genetics modules within the U.S. Dairy Education and Training Consortium (USDETC) and two online graduate courses titled: I) Applied Disease Management for BRD and II) Genetics and Genomics of BRD in Cattle. Within these activities, students learn about the various types of omics data and how these data are used in the calculations of genome-assisted estimated breeding values. This CAP is now in its latter years of funding, and the research team is

successfully publishing results. Therefore, quality multi-omics information is available to teach students about various types of omics data and how these data can be used in genetic improvement programs for traits that are currently difficult to measure in beef and dairy production systems. In summary, the education component of the BRDC-CAP (USDA-AFRI 2011–68004–30367) involves cross-disciplinary learning opportunities that coincide with the multi-omics research of susceptibility to BRDC.

Key Words: cattle, genomics, respiratory disease, teaching

1751 A novel approach to adviser training for relational skills. *A. L. Robinson* and H. D. Tyler, Iowa State University, Ames.*

The Iowa State University College of Agriculture and Life Sciences Dean's Task Force on First Year Student Success recommended that workshops should be developed to enhance relational skills of academic advisers. The topic of the first workshop developed was "Student Issues: Recognition and Referral". In contrast to other workshops covering similar topics, this workshop incorporated undergraduate students that had overcome a variety of barriers to their success. We maintained a small interactive workshop approach, limiting adviser enrollment to 12 advisers per workshop and incorporating an equal (or greater) number of students. During the 3-hour workshop, participants discussed common barriers to assisting students during a brief presentation on common student issues, effective communication skills for advisers, and campus and community resources available for referral. In addition, students assisted in role-playing exercises designed to simulate adviser meetings with a student in crisis, and the session ended with a panel discussion allowing advisers to ask questions directly to any of the students or the session leaders. Over 50 advisers from across campus have attended these workshops, and the session was also replicated at a regional meeting of the National Academy of Academic Advising. Advisers attending these workshops provided feedback through a survey at the end of the session rating six different aspects of the workshop on a 1–10 scale. Ratings for each aspect of the program ranged from 8.5 to 9.2, with advisers rating the student panel and student role-playing as the most impactful aspects of the workshop at 9.2/10 and 8.8/10, respectively. These data suggest that relational workshops for advisers are more impactful when a student perspective is included. Adviser comments reflected that many advisers lack confidence in their ability to respond appropriately to a student in crisis, and that their confidence increased as a result of participating in this workshop. In summary, adviser participation in relational workshops that include student participants enhances adviser confidence in their ability to recognize student issues and respond appropriately and effectively; these skills ultimately should improve student retention and success.

Key Words: academic advising, student success

1752 The effect of a real-world learning project on students' knowledge retention: A comparative study. L. M. White*, *New Mexico State University, Las Cruces.*

To be successful in many undergraduate disciplines, students must retain base knowledge from lower level courses and apply that knowledge in upper level courses. Students may benefit and realize the importance of mastering basic concepts from the opportunity to utilize base knowledge in a real-world setting. Objectives of this project were to compare students ability to retain information after completing a real-world learning project (RWLP) to base knowledge retained from exams students took during the semester, and finally to determine student's perception of the RWLP. Incoming freshmen (n = 52, 79% female, 96% animal science majors) enrolled in an introductory equine science course worked independently to create a RWLP, specifically an educational bulletin (EB) for eight main topics studied during the course. The main topics were identified by the instructors as the most important topics to learn in an introductory horse science class, and included: identification, behavior, health, nutrition, activities, hoof care, parasite/disease, and reproduction. Students completed two assessments after the course was completed, the regular course exam quiz (REQ) which contained questions (n = 16; 2 questions from each main topic) the students had previously completed on exams and the educational bulletin quiz (EBQ) which contained questions (n = 16; 2 questions from each main topic) that were generated by the instructors from each student's EB. Students also completed a 3-question survey (Likert scale 1–5) regarding the influence of the EB on their understanding of the material, retention of material presented in class, and overall impression of the EB. Student scores on the REQ and EBQ were correlated (r = 0.54 and r = 0.39, respectively) to final course grade, but not to gender ($-0.05 < r < 0.05$). Students performed better ($P < 0.0001$) on questions from the EBQ compared to questions from the REQ. Students indicated they enjoyed completing the EB and perceived that they better understood basic information and expected to better retain the material as a direct result (4.5 ± 0.1, 4.72 ± 0.1, and 4.5 ± 0.4 on a 5 point scale, respectively). Students benefited from completing the EB project by better retaining key concepts taught during an introductory equine science course and the project was highly thought of by students. Disciplines that require students to retain key concepts from lower level courses for later use in upper level courses could benefit from a RWLP like the EB.

Key Words: base knowledge retention, real-world learning project, undergraduate learning

1753 Utilization of concept mapping as a tool to qualitatively assess knowledge of college seniors in a companion animal management course.

C. L. Morris*, *Iowa State University, Ames.*

Concept mapping is a visual technique to facilitate integration of new information with previously learned material. This study was designed to evaluate the effectiveness of concept mapping as a novel method to qualitatively assess student critical thinking and understanding in a discussion-based senior level companion animal management course. Students over 3 semesters (n = 106) provided feedback after completing 9 total concept maps (3 per semester) following 3 main informational course units (n = 318 maps). A novel quantitative rubric was established, consisting of 3 categories each having 4 point levels, including Organization and Presentation, Content and Concepts, Knowledge of Concept Relationships, and Understanding Through Connections. Students completed the initial portion of maps before unit introduction and they were collected and held by the instructor (not graded) until the conclusion of the unit when they were returned to students for completion in a different color ink. Students were asked 4 anonymous questions about the maps using a standard 1–5 Likert type scale (1 = Strongly Agree and 5 = Strongly Disagree): 1) Concept maps made me think about information I already knew; 2) Concept maps helped me learn new material; 3) I liked Concept maps as an evaluation tool; 4) Concept maps were effective forms of assessment for this course. Additionally, students could submit comments regarding concept maps. A total of 87 of 106 students provided written feedback. Question score means were 1.27, 1.68, 1.45, and 1.55 for the four questions, respectively, and 94% of respondent comments were positive. Five students indicated they did not like the mapping activity and preferred essays or traditional exams. Sixty-seven percent of comments indicated maps improved learning because students were able to focus on how material specifically related to them and their existing knowledge base rather than worrying about stress of memorizing facts for exams. The words "less stressful" specifically appeared in 60% of written comments. This highlights the value of using concept mapping to develop critical thinking skills in a discussion-based class where traditional exams may not be effective. High rate of return of student feedback and consistency of positive responses from students underscore the value of this technique for qualitative assessment of knowledge and learning in a senior-level discussion-based companion animal course.

Key Words: companion animal, concept mapping, teaching

1754 Spanish for animal health and care: Toward a certificate program in field-specific Spanish.

S. Zeller*[1], M. Velazquez-Castillo[2], and I. N. Roman-Muniz[3], *[1]INTO Colorado State University, Colorado State University, Fort Collins, [2]Department of Foreign Languages and Literatures, Colorado State University, Fort Collins, [3]Department of Animal Sciences, Colorado State University, Fort Collins.*

There is increasing awareness of the need for basic field-specific communication skills in Spanish on the part of animal science and veterinary professionals working with livestock operations. Between 80% and 90% of the workforce in such establishments is comprised of Spanish-speaking immigrants with low English proficiency and minimal formal education. Until now, the ways in which this language barrier has been approached have not been informed by the growing body of research on Languages for Specific Purposes (LSP). The objective of this presentation is to detail the interdisciplinary approach to the curriculum development and implementation of a basic "Spanish for Animal Health and Care" class leading to a certificate program designed to cater to the specific language needs of future animal scientists and veterinarians. The curriculum is based on a needs analysis, which includes non-structured interviews of Spanish-speaking workers on livestock farms and livestock farm professionals, the recording of a livestock workers' safety meeting, as well as the creation of a specialized, domain-specific corpus. All course materials consist of module-specific packages of video and audio recordings, interactive hands-on materials, a library of relevant images, and a corpus of authentic texts, from which targeted vocabulary and grammatical forms are derived. The curriculum is divided into 3 performance-based units: describing and comparing animals' physical and behavioral traits, mock-trainings of new hires wherein students describe the 'why' of farm procedures, and a mock-veterinary consultation which includes descriptions of abnormal animal behavior/physicality and recommendations for care. Formal mid-term assessments demonstrate increased development of functional language proficiency by indicating ascension on the American Council on the Teaching of Foreign Languages (ACTFL) proficiency scale from novice-mid toward novice-high. Communicative tasks that form the performance-based assessments require elaborated, context-specific sentence-length discourse, which is imperative for novice-high proficiency on the ACTFL scale. Informal student evaluations report gratitude and excitement about working toward field-specific functional proficiency in Spanish, which may factor into the current class average of 87.48%. Additionally, a survey completed by 257 students in CSU's professional veterinary program revealed that 93.5% of students are interested in learning basic Spanish language skills specific to their future professional needs. 92.8% of those surveyed and 100% of students currently taking the beginner

Spanish course report that they would like to pursue a certificate program in Spanish for Animal Health and Care.

Key Words: curriculum development, languages for specific purposes, Spanish language proficiency

1755 Characterization of students' educational background and subsequent use of relevant teaching methods enhances student engagement and success in introductory animal science course. J. Adcock*[1], Q. S. Baptiste[1], and M. Knights[2], [1]*Berea College, Berea, KY,* [2]*West Virginia University, Morgantown.*

One of the most challenging dilemmas a teacher faces when designing lessons for their class is the variation of prior knowledge of their students. This is especially true in introductory Animal Science courses, where students from a variety of backgrounds and knowledge levels are placed in the same course. Some of these students probably grew up around livestock or taken Animal Science courses in high school, while others may have never had these opportunities. In an effort to reach as many students as possible, teachers must either choose to cover the basics or start at the level of the majority of the class. The first option is best for those who do not have prior knowledge, but does not permit others to advance their education. The second allows advancement for some, but leaves others behind. Thus, a survey was conducted to characterize the educational background of potential Animal Science students and to determine adoptable teaching methods that were currently being used by agriculture educators in West Virginia and Kentucky high schools. Data revealed an even divide of the sexes (Male: 56.52 vs. Female: 43.48%) among participating students with 56.52 and 26.09% of whom live in rural non-farm and farm area, respectively. Most students enrolled in Animal Science class to be in Future Farmers of America (30.43%), to pursue agriculture/animal science career (34.78%), or were just interested in animal systems (26.09%). Weighted averages of students surveyed scaled responses (0 = least to 5 = most) indicated that the majority of students claimed they had the least amount of knowledge about abstract knowledge based topics of the digestive systems (3.77), nutrition (3.77), and genetics (3.83). Indeed, the surveyed teachers' responses also indicate that the most challenging topics to teach were nutrition and genetics. Teaching strategies that were reportedly most effective included, hands-on learning, project-based experiences, active learning experiences, and varying the speaker, technology, and interactions within the learning environment. Subsequent use of the foregoing information to modify an introductory Animal Science class with students of widely diverse educational background and experiences at Berea College resulted in increased (50%) student engagement and a significant increase (16.67%) in overall student satisfaction with the course as compared to when it was taught 2 yr prior. Conclusively, the characterization of students' educational background and subsequent use of relevant teaching methods can enhance teaching effectiveness.

Key Words: educational background, teaching effectiveness, teaching methods

1756 Impact of a global food security assignment on agricultural sciences students' education and career interests. K. Matthews* and O. Bolden-Tiller, *Tuskegee University, Tuskegee, AL*

As we approach 2050, the challenge of producing enough wholesome, nutritious food for the world population is of increasing concern. Although the solution has yet to be identified, it is clear that to address this issue a well-trained workforce that understands the issue of global food security and its causes is required. Therefore, this study sought to assess the impact of a global food security assignment on freshman animal science students' understanding of global food security and their desire to pursue careers that address this issue. To address this objective, 48 students majoring in animal science at Tuskegee University completed a Likert scale survey (1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = Agree and 5 = Strongly Agree) following the completion of a global food security writing assignment. The results of the survey indicated that after completing the global food security assignment, students had an increased understanding of global food security (4.3/5.0) as well as its causes (4.6/5). Before the global food security assignment, students indicated that they had not considered pursuing a career to assist with global food security (2.4/5.0); however, after the assignment, the students were more likely (3.5/5.0) to pursue a career that addresses global food security. These findings indicate that once students are educated about agro-issues, such as global food security, they are more likely to pursue educational and career opportunities that allow them to address said issues.

Key Words: food security, students, survey

1757 Student perspectives on agricultural study abroad programs. M. M. Beverly*, S. F. Kelley, P. Urso, M. J. Anderson, J. L. Leatherwood, and K. J. Stutts, *Sam Houston State University, Huntsville, TX.*

The globalization of the US economy and agriculture products warrants agricultural programs to enrich the learning environment beyond agricultural systems in the United States, but to embrace international systems and markets, as well. International agriculture classes combined with study abroad programs have a positive effect toward students' understanding of global agriculture systems with a broadened cultural awareness. It is the study abroad experience that allows students to immerse themselves in cultural differences and obtain an understanding of different agricultural systems and policies governing food production in other countries. In the

summer of 2015, sixteen students from Sam Houston State University (62% female, 38% male, 20–24 yr of age) participated in pre-/post-surveys regarding a study abroad trip to France and Italy. In the pre-survey, 21% of the students predicted that the international experience would enhance their self-confidence/problem solving skills and on their return these characteristics increased to 40%. Students' predicted an increased knowledge in international animal regulations and practices and the post-survey verified that prediction by being 50% more confident in European Union (EU) animal agriculture practices, 62% more confident in EU animal welfare policies, and 62.5% more likely to have knowledge surrounding EU agriculture and animal organizations. When asked to if the study abroad experience increased their desire to travel abroad, 93% responded "very much". Only 2% would consider changing their academic major due to their study abroad experience. Students' responded overwhelmingly (100%) that they would recommend the program to a friend. Comments of students were: life changing, traveling with fellow students added to the experience, meeting people with the same passion for agriculture, and amazing, once in a lifetime trip. While there are many obstacles within study abroad trips, the expansion of knowledge for students is beneficial.

Key Words: international, study abroad, travel course

1758 Curriculum development for animal disaster planning.
K. Franks, S. F. Kelley*, and M. M. Beverly, *Sam Houston State University, Huntsville, TX.*

Disaster preparedness is mandated by the federal government in the United States. Until the passing of the Pet Evacuation and Transportation Standards (PETS) Act in 2006, animals were not addressed in disaster planning except in the scope of livestock disease outbreaks and the need to protect our food supply. Disasters can be defined as "sudden-onset occasions that seriously disrupt social routines…" Hurricanes, tornadoes, wildfires, droughts, floods, severe blizzards, chemical spills, industrial explosions, and other incidents are types of potential disasters. Disasters can cause anxiety, depression, stress, and fear as well as financial strains and physical injuries for both human and animal. The cattle industry has a more than $88 billion dollar a year impact, while the horse industry produces more than $39 million a year direct impact on the U.S. economy. Companion animals are a vital part of our economy as well, with owners spending in excess of $50 million a year on pets and their care. Society acknowledges the importance of the human-animal bond and its impact on mental health while studies have also shown the same effect on the mental health of animals during times of stress and separation from their owners. The Federal Emergency Management Agency (FEMA), a division of the Department of Homeland Security, provides information to understand disaster preparedness and implementation, while developing curriculum to enrich agricultural program curriculum and education students on disaster planning and preparedness. Sam Houston State University has developed a course to address the need of the gap in education when dealing with these issues. The course focuses on risk assessment, to allow the student to learn the importance of focusing resources in strategic need areas and learn where mitigation efforts would be most beneficial. Topics also include: planning for mass die off and/or mass euthanasia, mass evacuation events, and a how-to plan for the evacuation and housing of companion animals, horses, and other types of livestock. This course provides a strong foundation on how to be prepared for man-made and natural disasters.

Key Words: agriculture, disaster planning, preparedness

1759 Application of a survey instrument for assessing student demographics and interests in an animal and dairy sciences career planning course.
M. C. Nicodemus*, *Mississippi State University, Mississippi State.*

Recent changes to the Mississippi State University Animal and Dairy Sciences (ADS) curriculum was designed to address the needs of today's students preparing to enter into the animal industry. The new curriculum includes the addition of a sophomore/junior level 1 h lecture course, ADS 2111 ADS Career Planning, focused on developing life skills needed for preparing for an animal science career. The course includes resume building and skill development in interviewing along with skills in job searches and preparation needed for building a strong background to impress potential employers. The course includes speakers and industry interaction along with career research activities and group discussions. To better develop and expand the new course, a survey instrument was applied to determine student demographics and interests. Students enrolled in both the spring and fall 2015 ADS 2111 ADS Career Planning course (n = 58) were asked to take a researcher-developed survey consisting of 10 questions compiled of both open-ended and forced choice questions. The majority of students taking the course were ADS majors (98%), and of those, over half (58%) were expecting to go to veterinary college, while 27% had expectations of attending graduate school. These ongoing degrees require a GPA of 3.0 or higher in which only 17% of the students in the course had a GPA below these requirements. As for practical industry experience, 88% of the students have performed an animal science internship or will be carrying out one in the coming semester. Over half of the students (54%) planned to focus their career in companion animals, including equine. ADS 1113 Animal Science was reported by 43% as being the most useful course taken at this point in their academic career. As for future courses, 39% reported the course they looked forward to most taking was the internship course,

ADS 4420 ADS Internship. As for the student's assessment of the ADS 2111 ADS Career Planning course and what activities they felt were the most useful, almost half (48%) reported the development of a resume and cover letter was the most useful in their academic career with 71% admitting they had not done a cover letter before the course. In conclusion, through the survey insight was given on what would be beneficial to adding to the course and what topics in the course are worthy of expanding according to the students' interests and background.

Key Words: assessment, career planning, demographics,

1760 Evaluation of learning outcomes in a dairy science section of a science, technology, engineering, and math retention program. K. A. Dolecheck* and J. M. Bewley, *University of Kentucky, Lexington.*

The mission of the University of Kentucky's STEMCats program is to 1) increase retention of STEM students, 2) increase awareness of non-traditional STEM careers, 3) create an opportunity for early exposure to research, 4) diversify the student population in STEM majors, and 5) increase faculty development. Freshmen students accepted into the program spend their second semester of the year-long program working with a research lab to gain hands-on experience. The objective of this study was to evaluate learning outcomes of students participating in the first dairy section of the program. Nine students with no previous research experience were enrolled in the Spring 2016 STEMCats dairy section. At the beginning of the semester, each student completed a nine-question survey that asked them to rank their understanding of different research aspects on a 1 (low) to 5 (high) Likert scale. The survey was re-administered either five (n = 5) or six (n = 4) weeks later. Based on a paired sample t test, understanding increased between the first and second survey in the areas of "how to design a research study" (mean ± SD increase = 1.4 ± 1.2 points; $P < 0.01$), "understanding of statistical analysis" (mean ± SD increase = 1.1 ± 0.8 points; $P < 0.01$), "how to create a research poster or presentation" (mean ± SD increase = 1.6 ± 1.3 points; $P < 0.01$), "how to find research papers" (mean ± SD increase = 0.9 ± 0.9 points; $P = 0.02$), and "how to analyze other's research" (mean ± SD increase = 1.4 ± 1.5 points; $P = 0.02$). Understanding did not increase in the areas of "how to create and support/refute a hypothesis" (mean ± SD increase = 0.7 ± 1.3 points; $P = 0.17$), "how to conduct a research study" (mean ± SD increase = 1.1 ± 1.5 points; $P = 0.05$), "how to write a research abstract" (mean ± SD increase = 1.1 ± 1.7 points; $P = 0.08$), and "how to explain research to others" (mean ± SD increase = 1.1 ± 1.7 points; $P = 0.08$). Students in the STEMCats dairy section will re-take the survey again at the end of the semester to re-evaluate learning outcomes. These results can be used to analyze and adjust teaching methods for future lab sections and can serve as an example to other universities considering similar programs.

Key Words: STEM, undergraduate education, undergraduate research

1761 Student assessment of curriculum efficacy in a beef systems management course. C. E. Andresen*, E. L. Lundy, D. D. Loy, and P. J. Gunn, *Department of Animal Science, Iowa State University, Ames.*

In 2013, a modified Delphi process was utilized to conduct a needs assessment and guide curriculum reconfiguration of the senior-level beef systems management course at Iowa State University. Stakeholders-guided assessment of course objectives was accomplished through a series of surveys designed to identify subject-matter areas in which beef students need to be proficient. The result was a list of 25 subject-matter areas that were emphasized when redesigning course curriculum. In no particular order, subject areas included: history of beef production, current events, advocacy, allied industry relationships, technology utilization, business planning, record keeping, economics/risk management, employee management, management of input costs, marketing, break-evens, health, nutrition, grading systems, calculating production costs, facility design, beef quality assurance, implants and feed additives, EPDs, grazing management, reproduction, beef interactions with environment, alternative business schemes, and use of beef-based software. The objective of this study was to evaluate how students' perceived importance and knowledge of these stakeholder-derived subject-matter areas changed as a result of the course. The subject-matter areas were presented to students in an anonymous survey at the beginning and end of the course for 4 consecutive semesters. Students were asked to rank the subject-matter areas in order of perceived importance (1–25; 1 = most important, 25 = least important) and indicate their perceived knowledge of each outcome (1–4; 1 = no knowledge, 4 = expert). Data were analyzed using the MIXED procedures of SAS. In both pre- and post-course surveys, students identified business planning as the most important subject and history of beef production as the least important subject in the course. Compared to pre-course surveys, end-of-course surveys ranked beef production history ($P = 0.01$) and current events ($P = 0.04$) lower. No differences were noted between pre- and post-course survey rankings of the other 23 subject-matter areas. As a result of the course, students' perceived knowledge was increased in 22 of 25 subject-matter areas ($P < 0.01$). Although numeric increases in knowledge were noted for history of beef production, allied industry relationships, and record keeping, students did not perceive a significant change in knowledge base for these areas ($P \geq 0.07$). Thus, a renewed emphasis will be placed on these areas in future semesters. These data indicate that the curriculum revision of the senior-level beef management course at

Iowa State University has been successful in educating students on stakeholder-guided course outcomes.

Key Words: beef, curriculum revision, survey

TEACHING UNDERGRADUATE AND GRADUATE EDUCATION SYMPOSIUM: ANIMAL SCIENCE EDUCATION IN THE CURRENT ENVIRONMENT

1762 Introduction to learning theories and implications for classroom design. M. Clement*, *Berry College, Mount Berry, GA.*

Today's students may be underprepared for both graduate and undergraduate coursework, yet they seek to become professionals in their fields. Frustration on the part of all who teach in higher education has led to the question, "How do we teach today's students such that they master the content?" The answers to this question come from three areas: looking at traditional course design, backward by design, and transparent teaching. Additionally, the steps of lesson design and engagement techniques are important. Traditionally, professors planned a course by choosing a classic text, planning lectures, and hoping for the best. Traditional teaching can work, when the lessons are planned with visuals, informal assessments, and explicit teaching. Backward by design, also called understanding by design (Grant Wiggins and Jay McTighe's work), implies that an instructor look at the biggest, most important outcomes of a course, and then plan ways to get students to achieve those outcomes. Transparent teaching, as defined by Mary-Ann Winklemes, includes task, purpose, and criteria. Explicit explanations, crystal-clear aligned assessments, and a rationale of what is taught can improve student achievement. When much content must be mastered by students in order for them to progress to graduate school, or to begin their professional lives, explicit direct instruction can be powerful. Well-crafted, well-taught lessons achieve that end. Strategies for a single lesson include a focus, presentation of material, application/practice of material, and review/assessment. The knowledge base of learning continues to expand rapidly, and research-based methods of teaching do exist. The work of Brown, Roediger, and McDaniel has challenged traditional thought on how students learn, and influenced how professors can teach such that today's students can learn. All of these strategies can be used at all levels of teaching in animal science, to prepare the next generation of professionals in the field.

Key Words: college students, learning theory, teaching strategy

1763 Beyond veterinary school: Helping animal science students explore other career opportunities. J. A. Sterle*[1], H. D. Tyler[1], and J. Daniel[2], *[1]Iowa State University, Ames, [2]Department of Animal Science, Berry College, Mt. Berry, GA,*

A large percentage of students entering undergraduate animal science programs have a desire to become a veterinarian. For example, at Berry College, a private school in northwest Georgia with an animal science program, 81 ± 0.6% of the incoming freshmen (n = 194) for the last 2 yr have indicated a desire to become a veterinarian. Animal science is an appropriate undergraduate major for students interested in veterinary science, and animal science programs should help those students to successfully obtain those goals, however many students come from a background with little experience or knowledge of opportunities for a career working with animals other than veterinary medicine. At Berry College, 69 ± 1.5% of the incoming freshmen for the last 2 yr reported coming from an urban or suburban area, and only 14 ± 1.9% reported living on a farm. While more freshmen report being from a farm at Iowa State University (29.15% in 2014 and 42% in 2015), the trend is still similar. These urban and non-farm students have a desire to work with animals, but limited knowledge of the opportunities available as indicated by the fact that 25 ± 2.9% of the incoming freshmen at Berry College indicated having no experience working with their primary animal of interest. To help students further define where their passion may lie, steps have been implemented in the Department of Animal Science at Iowa State University to inform incoming and freshmen students about the diversity of careers in animal science. During campus visits with high school students and families, the vast array of opportunities surrounding careers in Animal Science are discussed briefly. More discussion follows during Freshmen Orientation, and also during ANS 110: Orientation in Animal Science. Freshmen and transfer students enrolled in ANS 110 were asked to indicate their interest in various careers at the beginning and again at the end of the semester. At the beginning of the semester, 62% (315 responding) indicated that veterinary school was their primary interest. The last week of class, only 43% (296 responding) responded that this was still at the top of their interests. Even more interesting was the increased interest in graduate school (8% in September vs. 17% in November). Identifying interests earlier in their collegiate career will allow students to take advantage of internships and other experiences more closely related to their interest.

Key Words: prevet, teaching, undergraduate

1764 A different approach in pedagogical model: Flipped classrooms. M. G. Maquivar[*1] and A. Ahmadzadeh[2], [1]*Department of Animal Sciences, Washington State University, Pullman,* [2]*University of Idaho, Moscow.*

New data indicate that undergraduate students are currently different from those 15 yr ago, their needs are different and they are more immersed in technological tools. As technology advances educators should learn more how to use these resources and pedagogical methodologies to enhance and promote active learning. Flipped classroom is a new pedagogical method developed to use different resources to create an environment where students take responsibility for their own learning. The end goal of this approach is to personalize learning and promote a more solid learning meeting the educational expectations of the new generation of undergraduate students. The concept of blended learning within flipped classrooms involves student participation through online or outside-classroom delivery of content and instruction that allows students to have some control over their time, effort, location and pace of delivery while using the traditional method of face-to-face classroom participation. The role of instructors in the classroom changes with the flipped classroom methodology, the faculty member is no longer the sole source of knowledge and information, instead, the instructor is a facilitator for students that allows students to take responsibility for much of their learning and knowledge attainment. The flipped classroom allows increasing interaction and personalized content time between students and faculty, promotes critical thinking, increase constructivist learning, engaged students in the course, and provides and incentives students to prepare for class. The adoption of this pedagogical approach is slow and the courses have to be well designed and carefully planned to avoid student frustration and dissatisfaction with the course, however, there is no doubt that flipped classroom and/or blended learning approaches addresses students learning needs.

Key Words: flipped classroom, personalized learning

1765 Teaching evaluations and other alternatives to assess good teaching and learning. K. G. Odde*, *Kansas State University, Manhattan.*

Animal Science departments have long strived for excellence in teaching. Quality teaching programs have been difficult to maintain because of reduced state funding, changing demographics of students, loss of livestock units that support teaching, and greater emphasis on extramurally funded research. Building and sustaining a culture whereby teaching receives respect similar to other mission areas is critical. Trends in higher education are toward "the research institution", since research is thought to drive more funding into the institution. However, the rapid increases in tuition rates in most institutions has made attracting students a high priority. Critical to building outstanding teaching programs is properly assessing teaching quality. The literature results on student evaluation of teaching as a tool for effectively evaluating and improving teaching are mixed. Some studies indicate that student evaluations can be useful and that results are positively correlated with learning, while others raise concerns about gender bias in student evaluations. Student evaluation of teaching is a useful tool, but has limitations. Peer evaluation of teaching can also be an effective tool in improving teaching quality.

Key Words: assessing teaching and learning, teaching evaluations

TOXIC PLANTS SYMPOSIUM

1766 Is there a difference between exposures to one or two plant toxins? K. D. Welch*, *USDA, ARS, Poisonous Plant Research Laboratory, Logan, UT.*

The majority of the plants in a given rangeland provide valuable forage for livestock species. However, plants that can poison livestock are very much a part of our rangelands. In this regard, most rangelands contain more than one poisonous plant. Frequently, much is known regarding the toxicity of individual plants and their effects on livestock. However, little is known regarding the effect of co-exposure to multiple toxic plants or even the effect of multiple toxins from an individual plant. Mixture toxicology, or the study of the co-exposure to multiple toxins, can result in additive, synergistic, or antagonistic effects. This presentation will highlight some of the recent research from the Poisonous Plant Research Lab wherein the effect of co-administering multiple plant toxins from the same plant and the effect of co-administration of different poisonous plants has been evaluated. A better understanding of the effect of co-exposure to multiple poisonous plants, and the mixture toxicology involved, will be useful in developing more beneficial management recommendations

for ranchers.

Key Words: cattle, death camas, larkspur, methyllycaconitine, mixture toxicology, multiple toxins, poisonous plants, sheep, zygacine

1767 Resistance to toxic plants: The right animal at the right time in the right pasture. B. T. Green[*1], K. D. Welch[1], J. W. Keele[2], T. G. McDaneld[2], and J. A. Pfister[3], *[1]USDA, ARS, Poisonous Plant Research Laboratory, Logan, UT, [2]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [3]USDA ARS Poisonous Plant Research Laboratory, Logan, UT*

Neurotoxic poisonous plants negatively impact livestock on many western rangelands, which results in annual economic losses of millions of dollars from animal deaths, increased management and treatment costs, and if animals are deferred from grazing, the underutilization of otherwise highly nutritious pastures and rangelands. One potential solution to the problem of toxic plants is to identify and select animals that are "resistant" to neurotoxic plants. Research at the Poisonous Plant Research Laboratory (PPRL) has focused on the physiological effects of two plant species, larkspur (*Delphinium* spp.) and lupine (*Lupinus* spp.). There are significant differences in the susceptibility of cattle breeds to larkspur and lupine. For example, when Angus and Hereford cattle were orally dosed with 8 mg/kg d-(methylsuccinimido) anthranoyllycoctonine (MSAL)-type alkaloids in the form of dried ground larkspur, Angus were significantly more resistant to the larkspur-induced fatigue ($P < 0.0001$, Two-tailed *t* test, 33 Angus versus 48 Line 1 Herefords). Breed differences have also been observed for lupine which causes birth defects in cattle by the inhibition of fetal movement. For example, when six pregnant Angus and five pregnant Holstein heifers were orally dosed with 1.1 g/kg dried ground *Lupinus leucophyllus* and fetal activity monitored via transrectal ultrasonography, there were significantly more fetal movements in Holstein heifers at eight and 12 h after oral dosing than the Angus heifers ($P = 0.0430$ and 0.0001 for eight and twelve hours after oral dosing, respectively, linear mixed model analysis). These results provide the basis for phenotypes, which can then be used in the development of a genetic test to facilitate selection of resistant animals, which can then be used to manage the risk of toxic plants.

Key Words: cattle, d-(methylsuccinimido) anthranoyllycoctonine, larkspur, lupine,

1768 Using divergent selection and genomics to uncover genetic variation underlying larkspur tolerance and susceptibility in cattle. J. W. Keele[*1], T. G. McDaneld[1], L. A. Kuehn[1], W. M. Snelling[1], R. G. Tait, Jr.[1], K. D. Welch[2], and B. T. Green[2], *[1]USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE, [2]USDA, ARS, Poisonous Plant Research Laboratory, Logan, UT.*

In the Rocky Mountain region of western US, selection for larkspur tolerance would reduce mortality of cattle from larkspur poisoning and increase opportunity to utilize pastures at peak nutrient availability resulting in increased sustainability of beef production. Previous research indicated that there are breed differences for tolerance to toxic larkspur. Our objective was to estimate heritability for larkspur tolerance within breed and evaluate the potential for increasing larkspur tolerance through artificial selection. Larkspur challenge was administered to 141 yearling steers (32 Angus, 13 Brahman, 49 Line 1 Hereford, 33 Holstein, and 14 Jersey) with a standardized dose of dried ground larkspur suspended in water and gavaged directly into the rumen. Larkspur tolerance was measured at 24 h after dosing as the length of time (up to 40 min maximum) in which the animal could sustain walking at 6.44 km/h while being led behind a tractor on a circular track. High-density SNP arrays (770,000 or 30,000 SNP) were used to genotype each steer and genotypes were used to compute the genomic relationship matrix which is a precursor to estimating heritability. Larkspur tolerance heritability estimates were similar whether estimated with REML (0.36 ± 0.30; $P = 0.10$) or Bayesian Monte Carlo Markov chain (MCMC) (0.42 ± 0.23; MCMC posterior distribution 2.5, 25, 50, 75, and 97.5th percentiles were 0.035, 0.24, 0.40, 0.59, and 0.90). To evaluate the potential for using our larkspur challenge data to calculate EBV of an untested population, we computed genomic relationship coefficients between 190 previously genotyped (but untested for larkspur tolerance and comprising the same 5 breeds in this study) cattle and the 141 steers tested for larkspur tolerance. Because of uncertainty in the heritability estimate, EBV were computed for each iteration of the MCMC to average over all possible values for heritability and weight by the appropriate posterior density. The most extreme EBV were for target animals with the strongest genetic ties to tested animals. Simulations indicated that divergent selection of parents can more than double the power for estimating heritability. Our results indicate that selection for larkspur tolerance should be effective. The rate of selection response will critically depend on challenging and testing animals with strong genetic ties to candidates for selection. Genetic ties can either be estimated from SNP genotypes or computed from common ancestry. USDA is an equal opportunity provider and employer.

Key Words: cattle, larkspur, plant toxins

1769 The relationship between swainsonine-containing plants and endophytic fungi. D. Cook*, D. R. Gardner, and J. A. Pfister, *USDA, ARS, Poisonous Plant Research Laboratory, Logan, UT.*

Swainsonine, an indolizidine alkaloid with significant physiological activity, is an α-mannosidase and mannosidase II inhibitor that alters glycoprotein processing and causes lysosomal storage disease. Swainsonine is present in a number of plant families worldwide including the Convolvulaceae, Fabaceae, and Malvaceae and causes severe toxicosis in livestock grazing these plants. The three families of swainsonine containing plants are represented by six genera of plants: *Ipomoea*, *Turbina*, *Astragalus*, *Oxytropis*, *Swainsona*, and *Sida*. Two families of fungal endophytes, Pleosporaceae and Chaetothyriaceae, that produce swainsonine have been isolated from the Fabaceae and Convolvulaceae swainsonine-containing plants, respectively. Data will be presented in regard to these plant endophyte relationships. Additionally data will be presented characterizing this interaction and the influence of environment and genotype in determining swainsonine concentrations in planta. Furthermore we will present data further exploring the diversity of plants containing swainsonine and their associated endophytes.

Key Words: locoweed, morning glory, swainsonine,

1770 Alleviation and mitigation of fescue toxicosis. G. E. Aiken*, *USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY.*

Tall fescue (*Lolium arundinaceum* L.) is a cool-season perennial grass that is utilized as a forage on approximately 16 million hectares of the USA, primarily in the transition zone between the temperate northeast and subtropical southeast. A fungal endophyte (*Epicloë coenophialia*) that infects most plants of the most widely grown cultivar, Kentucky 31 produces alkaloids that impart the plant with tolerances to environmental stresses, but also produces ergot alkaloids that causes a toxicosis. The signs of "fescue toxicosis" include maintaining rough hair coats during the summer, elevated body temperature, labored respiration, and decreased prolactin concentrations. Ergot alkaloids bind α adrenergic receptors in peripheral vasculature of ruminants that disrupts thermoregulation and makes them vulnerable to severe heat stress at onset of moderate air temperatures. Calf weight gain can be very low on toxic tall fescue, which has limited the use of fescue for stocker production. Although the grass is primarily used for cow-calf production, calving percentages, milk yields, and weaning weights can be reduced on toxic endophyte-infected tall fescue. Non-toxic endophyte tall fescues have been commercially released that demonstrate to alleviate fescue toxicosis. Other technologies, such as chemical seedhead suppression, feeding soy hulls, and overseeding with red clover also have shown to mitigate fescue toxicosis. Evaluations of the efficacy of these new technologies in enhancing cattle performance and well-being on toxic endophyte-infected tall fescue will be presented and discussed.

Key Words: endophytes, *Epicloë coenophialia*, fescue toxicosis, *Lolium arundinaceum*, tall fescue

1771 Effects of high selenium forages on reproduction in sheep. Z. Davis*, *ARS USDA, Logan, UT.*

High Se-containing forages grow on seleniferous soils in many parts of world and can cause acute or chronic selenosis in livestock. Anecdotal reports of decreased reproductive rates in livestock grazing seleniferous forages have been reported and it has been speculated that reproductive failure is one of the initial changes of Se poisoning. However, there is very limited if any information in the literature on the effects on selenium on reproduction in livestock. The objective of this research was to determine the effect of high Se forages on reproduction in ewes and rams. Ewes were randomly divided into three groups (n = 10) and fed a control alfalfa pellet (< 0.3 ppm Se) or a high Se-containing alfalfa pellet that contained either 10 or 30 ppm Se for 12 wk. Feeding of the pellets began 6 wk before exposing the ewes to rams. Each ewe was exposed to two rams twice each day for two complete reproductive cycles. After the first cycle, significantly (P < 0.05) more ewes were pregnant in the control group (10/10) than in the 10 ppm Se (6/10) and 30 ppm Se (6/10) groups. After a second cycle 9/10 and 6/10 were pregnant in the 10 and 30 ppm Se groups, respectively. In a second study rams were randomly divided into two groups (n = 10) were they were fed either a control alfalfa pellet (containing < 0.3 ppm Se) or a high Se-containing alfalfa pellet (~25 ppm Se) for twelve weeks during which time semen samples were collected weekly. After twelve weeks of being fed high Se pellets, one testicle from each ram was surgically removed, the rams were then fed a control alfalfa pellet diet (containing < 0.3 ppm Se) and allowed to recover for 8 wk at which time the second testicle was surgically removed for histological analysis. Rams fed the high Se-containing alfalfa pellet had a decrease in sperm motility and an increase in the percentage of abnormal sperm. These negative effects were reversed after the rams were fed the regular alfalfa pellets for 8 wk. None of the sheep in either study demonstrated any clinical signs of Se poisoning during the study. In summary, high selenium feeds negatively affect reproduction in both ewes and rams.

Key Words: reproduction, selenium, sheep
